Background and Aims: Miami Declaration, agreed at the G8 Environment Ministers meeting in 1997, called for cooperative actions by major industrialized governments to protect children's health. Their meeting held in Italy in 2009 agreed to collaborate on studies related to impacts of environmental chemicals and heavy metals on children's health.
Methods: In FY 2010, the Ministry of the Environment started Japan Environment and Children's Study (JECS), a birth cohort study involving 100,000 children and their parents, biological sampling and medical questionnaire from the pregnancy until the child becomes 13 years old. Large-scale birth cohorts of 100,000 children exist in Denmark and Norway, and planned in the United States. In order to strengthen coordination among these studies, the Ministry organized an international workshop in February 2011.
Results: text Experts from JECS, similar cohorts in the United States, Denmark and Korea, International Child Cancer Cohort Consortium (I4C), WHO and UNEP discussed international coordination in birth cohorts. In JECS, recruitment started in January 2011, and the methods for outcome measurements are being finalized soon. Analysis of human and environmental samples will start in a few years. Participants agreed that harmonization efforts should start at this stage when large-scale national birth cohorts are starting in several countries.
Conclusions: Working groups for harmonizing outcome and exposure measurements should be established under the auspices of intergovernmental organizations. I4C is a good example for such efforts.

CANCER PROMOTION EFFECT AFTER THE CHERNOBYL ACCIDENT IN FINLAND?

Päivi Kurttio [1]*, Karri Seppä [2], Kari Pasanen [3,4], Toni Patama [2], Keith Baverstock [4], Anssi Auvinen [1,5], Eero Pukkala [2,5], Sirpa Heinävaara [1], Hannu Arvela [1], Timo Hakulinen [2]

*Päivi Kurttio, STUK, Laippatie 4, P.O.Box 14, FI-00881 Helsinki, Finland, paivi.kurttio@stuk.fi

Background and Aims: 25 years after the accident at Chernobyl nuclear power plant people are still concerned about potential adverse health effects related to exposure to radiation. In order to test a hypothesis on cancer promotion we studied whether total cancer incidence due to the Chernobyl fallout was increased within the first eleven years after the accident.
Methods: A registry based cohort was constructed from the Finnish population with a stable residence in the first post-Chernobyl year. Exposure assessment was based on measurements of dose-rate made between May 1986 and August 1987 performed during a mobile survey with a route of 19,000 km. The analysis comprises overall cancer incidence in four exposure areas. Person-years and number of cases were stratified by sex; age group; house type; and socioeconomic status in 1985. A pre-Chernobyl period of 1981-85 was used as a baseline which reflects the underlying differences in cancer incidence between the exposure areas and represents the aggregate effect of confounding factors. Incidence rate ratios between the exposure areas in 1981-1985, 1988-1992 and 1993-1997 were estimated using the Poisson regression.
Results: In 1981-1985, the total cancer incidence rates were lower in the highest exposure area than in the other three areas where the incidences were close to each other. In 1988-1992 and in 1993-1997, the incidence rate ratios did not differ statistically significantly from those in the pre-Chernobyl period. **Conclusions:** The results do not support the promotion effect of cancers due to low doses from the Chernobyl fallout in Finland.

PRENATAL MATERNAL AND NEONATAL URINARY BISPHENOL A AND NEURODEVELOPMENT IN THE FIRST TWO YEARS FROM THE MOCEH STUDY

Background and Aims: The exposure of pregnant women to bisphenol A may result in fetal or neonatal mortality, birth defects, or reduced birth weight and growth in their offspring (The US NTP). To investigate the effect of the prenatal maternal and the neonatal urinary BPA concentration on children's neurodevelopment at 6, 12, and 24 months
Methods: Six hundred sixty three pairs (mother and infant) in the Mothers and Children's Environmental Health (MOCEH) study, a multicenter prospective cohort study since 2006, were analyzed 6 through 24 months old of child. Korean version of the Bayley Scales of Infant Development-Revised (BSID-II) was used to assess cognitive and psychomotor development at 6, 12, and 24 months of age. Prenatal urinary BPA were measured at 20 weeks, 35-40 weeks of gestational age and neonatal urinary BPA was measured at neonatal unit. The multivariate linear regression and mixed effect model adjusted for several confounding variables were used to show the association between urinary BPA level and baby's neurodevelopment.
Results: Geometric means (geometric standard deviation) of maternal (20 weeks and 35-40 weeks of gestational age) and neonatal urinary BPA concentration were 0.56 (4.47), 0.82 (5.24), 3.30 (4.27) • g/L, respectively. The neonatal urinary BPA concentration was not significantly correlated with maternal urinary BPA concentration. Prenatal maternal urinary BPA concentration at 35-40 weeks of gestational age positively associated with mental development index at 24 months of age in male compared to the mental development index at 6 months (• =2.07, p=0.004). The neonatal urinary BPA concentration was not associated with children's neurodevelopment index at 6, 12, and 24 months.
Conclusions: Prenatal maternal urinary BPA concentrations were positively associated with neurodevelopment in children at 2 years old.

DOES COMMUNITY VULNERABILITY AMPLIFY THE RELATIONSHIP BETWEEN TRAFFIC EXPOSURE AND ADVERSE BIRTH OUTCOMES? A UNIVERSITY-REGULATORY RESEARCH COLLABORATIVE ON ENVIRONMENTAL HEALTH INEQUALITIES

Rachel Morello-Frosch, **Bill Jesdale,** UC Berkeley, *School of Public Health and Department of Environmental Science Policy and Management*
Paul English, *California Environmental Health Tracking Program*
Manuel Pastor, *University of Southern California, Program on Regional and Environmental Equity*
James Sadd, *Occidental College, Department of Environmental Science*
Debbie Lowe Liang, *USEPA*
Eric Hall, *USEPA*
Matthew Lakin, *USEPA*

Background: Studies within the United States and elsewhere have identified a relationship between air pollution, preterm birth, and low birth weight Spatial variation in air pollutant concentrations in urban areas have been attributed to traffic emissions, and documented for several pollutants, including nitrogen dioxide, ultrafine particles, and particulates. Epidemiological studies have linked residential proximity to traffic, such as distance to major roadways or traffic density near specific locations with adverse perinatal outcomes, including increased risk of preterm birth, small size for gestational age, and low birth weight. However, there remains a paucity of research on traffic density and birth outcomes, and few studies have examined effect modification by area-level SES measures.
Methods: We build on existing work by examining links between traffic density and risk of preterm birth and effects on average birth weight in a large sample of singleton births (~1.5 million) in California between 2001-2005. We also assessed the potentially synergistic and confounding effects of area-level SES measures. Distance weighted traffic volume measures were geocoded to the mother's address at the time of birth.
Results: Results indicate a decrease in average birth weight with increasing traffic burden [-10.4 (95% CI: -7.1, -13.6)] in the highest versus lowest quintile of traffic density] and a higher risk of preterm birth with higher traffic density [1.04 (95% CI: 1.01, 1.07) highest versus lowest quintile of traffic density]. Effect estimates remained robust after controlling for maternal and neighborhood level SES variables. Although we did not observe effect modification by neighborhood-level SES, we did observe stronger effects for birth weight in areas characterized by higher levels of racial residential segregation.
Conclusion: Results suggest that studies applying source-specific measures of ambient pollution, such as traffic density, can elucidate policy-relevant opportunities for reducing community exposure to multiple pollutants.

TIME SERIES ANALYSES OF DAILY MORTALITY ON DAILY PM2.5, PM10 AND BLACK SMOKE LEVELS IN THE NETHERLANDS; IS DISTINGUISHING BETWEEN DIFFERENT PM MEASURES POSSIBLE ?

Paul Fischer, *National Institute for Public Health and the Environment (RIVM), Centre for Environmental Health (MGO) , P.O. Box 1, 3720 BA Bilthoven, Netherlands,*
Marten Marra, *National Institute for Public Health and the Environment (RIVM), Centre for Environmental Health (MGO) , Bilthoven, Netherlands*
Caroline Ameling, *National Institute for Public Health and the Environment (RIVM), Centre for Environmental Health (MGO) , Bilthoven, Netherlands*
Nicole Janssen, *National Institute for Public Health and the Environment (RIVM), Centre for Environmental Health (MGO) , Bilthoven, Netherlands*

Background and aims: Information on the relationship between PM2.5 levels and mortality in Europe is sparse because of the limited PM2.5 measurement data that were available until recently. In the Netherlands, daily PM2.5 data have been measured at 15 sites of the National Monitoring Network since 2008. We have analyzed PM2.5 data for 2008 and 2009 in combination with daily mortality data on total and cause-specific mortality. We have compared the results of these analyses with results for PM10 and Black Smoke over the same period.
Methods: We analysed the data using Poisson regression in generalized additive models (GAM) with R. Associations between mortality and PM were adjusted using splines for long term and seasonal trend, influenza incidence, mean temperature, relative humidity, barometric pressure, as well as indicators for day of the week and for holidays. Results were presented as Excess Risk per 10 $\mu g/m^3$ increase in daily PM concentrations. Analyses were performed for 4 different time lags. In addition distributed lag models will be analyzed.
Results: PM levels all were statistically significant associated with daily mortality. The Excess Risk for daily PM2.5 (lag 1) and daily total mortality was 0.8% (0.3% - 1.2%). Results for different measures, different lags and cause-specific mortality will be presented. Correlations between particles measures was high (> 0.79). Because of this high correlation, no distinction could be made between the relative importance of the different PM measures. Initial results of distributed lag models indicate that single lag models may underestimate the true mortality impact of PM air pollution.
Conclusion: Newly available PM2.5 data in the Netherlands show statistically significant associations with daily mortality. This is in line with data from the US and other parts of the world. Due to the high mutual correlation between the three PM measures, no distinction could be made between the relative importance of the different measures.

DELTA-AMINOLEVULINIC ACID DEHYDRATASE (ALAD) POLYMORPHISM IN LEAD EXPOSED BANGLADESHI CHILDREN AND ITS EFFECT ON URINARY AMINOLEVULINIC ACIC (ALA)

Saira Tasmin[1], Hana Furusawa[1], Yosuke Inoue[1], M. H Faruquee[2], Nicole Pei-Hsiuan Cho[1], Chiho Watanabe[1]

[1] *Department of Human Ecology, The University of Tokyo, Tokyo, Japan*

[2] *Department of Public Health, The State University of Bangladesh, Dhaka, Bangladesh*

Background and objective

Lead has long been recognized as a harmful environmental pollutant. Developing countries like Bangladesh still have higher risk of lead exposure. Previous research suggests that delta-aminolevulinic acid dehydratase (ALAD) genotype can modify lead toxicity and individual susceptibility. As children are more susceptible to lead induced toxicity, the study was to investigate the frequencies of ALAD polymorphism among environmentally lead exposed children in Bangladesh and to determine whether ALAD genotype influenced urinary excretion of aminolevulinic acid (ALA).

Methods

Subjects were elementary school children from a semi-urban industrialized area in Bangladesh. A total of 134 children were studied. Blood and urine were collected to determine the ALAD genotypes, blood lead level (BPb) and urinary aminolevulinic acid (U-ALA).

Results

The mean BPb was found 9.7 µg/dl with 34% participants exceeding 10µg/dl, the CDC recommended level of public health action. In total, the gene distribution for ALAD1-1 was 71%, ALAD1-2 was 26% and ALAD2-2 was 3%. In this study, U-ALA concentration was lower in ALAD2 carriers than ALAD1 carriers at the same exposure level for boys ($p = 0.01$). But for girls, U-ALA did not differ significantly by genotype ($p = 0.61$).

Conclusion

This study provides the information about the frequency of ALAD polymorphism in Bangladeshi children for the first time, associated with U- ALA. ALAD2 showed protective effects in terms of U-ALA among the boys exposed to environmental lead.

LIVING NEAR AGRICULTURAL PESTICIDE APPLICATIONS AND THE RISK OF ADVERSE REPRODUCTIVE OUTCOMES: A REVIEW OF THE LITERATURE

Adeleh Shirangi, *The University of Western Australia, Australia*
Mark Nieuwenhuijsen, *Center for Research in Environmental Epidemiology (CREAL), SPAIN*
Danielle Vienneau *, Imperial College London, UK*
C.D'Arcy J Holman, *The University of Western Australia, Australia*

Background and Aims: Over the last decade, there has been growing concern about the possible health effects, including a number of adverse reproductive outcomes, from pesticides exposure of people living near agricultural fields. This systematic review evaluates the current epidemiological evidence on the association between living near agricultural pesticide applications and adverse reproductive outcomes, including congenital malformations, stillbirth, intrauterine growth retardation (IUGR), low birthweight, preterm birth and spontaneous abortions.
Methods: We identified and reviewed 25 studies from a systematic search of the main scientific databases and other sources published in 1950 to 2007. Study methods and main results were summarised and tabulated according to the year of study, design and type of adverse reproductive outcome. The levels of evidence for reproductive toxicity in humans contributed by each study were assessed and the main limitations associated with these studies discussed.
Results: Overall, there was evidence of a relationship between living near agricultural fields and adverse reproductive outcomes, but the strength of evidence varied between outcomes. The evidence suggested an association for the congenital malformations, but due to methodological limitations, such as poor exposure measurement and potentially inadequate control of confounding, a firm conclusion remains beyond reach. For the other outcomes (stillbirth, IUGR, low birthweight, preterm birth and spontaneous abortion) the evidence for any associations was equivocal at best, but some leads warrant further investigation.
Conclusion: Residential proximity to agricultural pesticide applications may be an important source of ambient environmental exposure, but due to the underlying methodological difficulties the evidence for its relationship with adverse reproductive outcomes is generally weak and varied between outcomes. Improved exposure assessment methods are needed to obtain a more reliable assessment of any risks.

Shirangi A, Nieuwenhuijsen M, Vienneau, D. Holman CDJ. Living near agricultural pesticides applications and the risk of adverse reproductive outcomes: A review of the literature. *Paediatric and Prenatal Epidemiology*. 2011; 25(2):172-91

COMMUTERS' HEALTH RISK TO ULTRAFINE PARTICLES IN JAKARTA

Budi Haryanto, *University of Indonesia, Indonesia*
Julian D. Marshall, *University of Minnesota, USA*
Dane Westerdahl, *Cornell University, USA*
Scott Fruin, *University of Southern California, USA*

Background and Aims: Latest developments in epidemiological studies indicated that particles might be responsible for increases in the symptom of cardiovascular and respiratory diseases and several adverse health outcomes, including mortality, reduction of lung function, exacerbation of asthma, and an increase in emergency room visits. Public concern over air quality is enhanced by its effect on children, especially on associations with incidence and prevalence of asthma. In Jakarta, emissions of particles are expected to increase, especially its contribution from transportation. Both urban population size and the fraction of the population that owns a private vehicle are increasing. Objective of the study to determine the numbers of ultrafine particulate matter (particles with an aerodynamic diameter of 0.1 □m or less, or $PM_{0.1}$) inhaled by elementary school children, commute workers with private car and commute workers with public transport.
Methods: A *cross-sectional study design* is implemented for assessing ultrafine particulate matter concentrations inhaled by targeted population groups in Jakarta involving ten elementary school children, ten commuters with private car and ten commuters with public transports.
Results: Concentration of ultrafine particulate matter (average) of elementary school children at home, on the road and at school is 29,254/cm^3, 147,897/cm^3 and 61,033/cm^3 respectively. For those commuters with private car at home, on the road and at office is 29,213/cm^3, 310,179/cm^3 and 42,496/cm^3 respectively. For those commuters with public transport, the concentration average of at home, on the road and at office is found higher: 35,332/cm^3, 453,547/cm^3, and 69,867/cm^3 respectively.
Conclusions: School children and commuters with both private car and public transport are at high-risk to have respiratory diseases, reduction of lung function, exacerbation of asthma, and even death especially when they are on the road.
Recommendations: It is suggested that commuters should reduce their length of time during trip on the road and avoid traffic jam during on the road. Providing adequate ventilation and air circulation at home as well as in the office are needed for healthier breathing. Improving management of transportation to reduce traffic jams is also strongly recommended to local government.

H.-Erich Wichmann, *Helmholtz Zentrum München - German Research Center for Environment and Health, Institute of Epidemiology, Neuherberg, Germany - Ludwig-Maximilians-University of Munich, Institute of Medical Informations, Biometrics and Epidemiology, Chair of Epidemiology, Munich, Germany*

Objective and aim: We assess whether long-term exposure to traffic-related air pollution is associated with all-cause, cause-specific and lung cancer mortality during a period of declining concentration of particulate matter.
Methods: A cohort of approximately 4800 women (age 55 years) from the Rhine-Ruhr area, Germany, was followed for up to 18 years. Exposure to traffic-related air pollution was defined by distance of residential address to nearest major roads calculated from GIS. Furthermore, one year average PM_{10} and NO_2 concentrations were available (calculated from air-monitoring station data in close vicinity to residents of the subjects). Ninety-two per cent of all subjects lived in the same community during follow up.

Results: Sixteen per cent of the women died during the follow-up period.
(1) Distance to roads: Living closer than 50 m (vs. more than 50 m) from a busy road showed an elevated total mortality adjusted for smoking and educational level: RR=1.47 (1.16 – 1.85). For cardiopulmonary mortality the elevation was even higher: RR=1.68 (1.17- 2.41).
(2) PM10: An increment of 7 µg/m3 PM10 (interquartile range) increased all-cause mortality after adjustment for smoking and educational level (HR 1.19, 95% CI (1.07-1.31)), cardiopulmonary mortality (HR 1.47, 95% CI (1.25-1.73)), and lung cancer mortality (HR 1.59, 95% CI (1.06-2.39)
(3) NO2: An increase in exposure to NO2 by 16 µg/m3 (interquartile range) was associated with an increased hazard ratio for total (HR 1.18, 95% CI (1.07-1.30), cardiopulmonary (HR 1.91, 95% CI (1.60-2.28), and respiratory mortality (HR 2.03, 95% CI (1.26 – 3.27) after adjustment for smoking and educational level,
4) Trend: Cardiopulmonary mortality related to PM was reduced for the extended follow-up with lower PM10 concentration, but not with NO2 for which the concentrations were reduced only minor.
Conclusions: Long-term exposure to traffic-related air pollution increases all-cause, cardiopulmonary and lung cancer mortality in region with high traffic load in Germany.

THE MULTIFACTORIAL ORIGEN OF VASCULAR DISRUPTION DEFECTS IN CALI, COLOMBIA: A CASE CONTROL STUDY

Yoseth Ariza-Araujo, *Grupo Epidemiología y Salud Poblacional, Escuela de Salud Pública, Universidad del Valle. Cali, Colombia.*
Harry Pachajoa, *Grupo Malformaciones Congénitas y Dismorfología (MACOS), Facultad de Salud, Universidad Icesi. Cali, Colombia*
Milton Suárez, *Grupo de Nutrición, Facultad de Salud Universidad del Valle. Cali, Colombia*
Cristina Araújo, *Grupo de Nutrición, Facultad de Salud Universidad del Valle. Cali, Colombia*
Carolina Isaza, *Grupo Malformaciones Congénitas y Dismorfología (MACOS), Universidad del Valle. Cali, Colombia*
Fabián Méndez, *Grupo Epidemiología y Salud Poblacional, Escuela de Salud Pública, Universidad del Valle. Cali, Colombia*

Background: Vascular disruption defects(VDD) refer to birth defects caused by alteration of blood flow and decreased availability of O2 in a tissue/organ during a critical period of fetal formation. Surveillance of birth defects in Cali-Colombia is developed under the ECLAMC. An analysis of the spatial and temporal distribution reported a cluster of VDD in the poorest area of the city.
Objective: To evaluate socioeconomic, behavioral and environmental factors potentially associated to VDD in Cali
Methods: A case-control study was carried out between 2007 and 2009. Cases were newborns with VDD(mainly gastroschisis, limb reduction) and normal cariotyping. Controls were normal newborns from the same hospital with conception date +/- two weeks of cases. A questionnaire was applied to collect information about: socioeconomic condition(race, education, income level), behavioral (smoking, alcohol, marihuana and cocaine), environmental exposures(activities with high risk)and diet(folic acid, Zn, Fe). Heavy metals(Cd,Pb,Zn) were determined on hair samples of a subgroup of participants(n=50)
Results: We included 45 VDD cases and 135 controls. Women of racial minorities(black and indigenous) had an increased risk of VDD(OR:2.34;CI95=0.93-5.74). Also, mothers exposed to secondhand smoke during the first trimester had an increased risk OR:3.02(CI95%=1.34-6.8). Although, in univariate analysis, increased levels of cadmium were not related to VDD(OR:1.18;CI95%=0.24–4.74), after adjusting for low levels of Zn the risk increased to 5.22(CI95%=0.41 - 66.19). In addition, exposure to Misoprostol®, a method used for abortion, was associated with VDD(OR:14.14;CI95%:1.29–703.14)
Conclusions: Our results suggest multiple exposures potentially associated to VDD, and increased susceptibility and vulnerability. Environmental and behavioral factors, including the use of recreational drugs, smoking, and periconceptional exposure to sub therapeutic doses of abortion drugs may interact in the etiology of VDD.

THE IMPACT OF ENVIRONMENTAL FACTORS ON MALARIA IN REPUBLIC OF KOREA

Young-Min Kim, *Sungkyunkwan University School of Medicine, Republic of Korea*
Jae-Won Park, Gachon University of Medicine and Science, Republic of Korea
Hae-Kwan Jung, *Sungkyunkwan University School of Medicine, Republic of Korea*

Background and Aims: After reemerging in 1993, *Plasmodium vivax* malaria has been occurred continuously in the Republic of Korea (ROK). Early after reemergence *P. vivax* malaria mainly occurred in the areas adjacent to the Demilitarized Zone (DMZ) and most patients were soldiers. However, since 2003, the number of civilian patients has been more than soldiers. We aimed to investigate the relationship between malaria and environmental factors, such as climatic factors and land use.
Methods: Malaria data were obtained from Korean Center for Disease Control including incidence date and residence information. Among them we selected civilian and domestic cases excluding soldiers and veterans for the year of 2001-2008. Weather information, such as temperature and rainfall, and land use information were matched with the malaria cases by 47 administrative areas. We fitted to intrinsic autoregressive model to investigate the effect of climatic factors and land use on the increase in malaria adjusting neighboring effect with random effect.
Results: Total civilian cases during the study period were 6,928 showing the most value, 1,295, in 2007. Among environmental factors, temperature for warmer season (May to September), rice paddy area, and river area showed positive correlation with malaria. Gangwha county, located in adjacent to DMZ and seashore, showed the highest log relative risk after adjustment for potential confounding variables. The distances from DMZ presented deterministic to malaria incidence, which implies that malaria situation in ROK has been directly influenced by infected mosquitoes originating from the Democratic People's Republic of Korea (DPRK).
Conclusions: Climate change, such as increase in temperature, can be responsible for elevated malaria transmission risk in ROK in the future. To control malaria in ROK, Climatic factors, land use, and their combined effect should be considered and further study considering human activity is necessary.

THE EFFECTS OF A HEALTHY DIET PROGRAM ON NUTRITION AND DIET KNOWLEDGE, ATTITUDE AND BEHAVIOR OF PUPILS IN THE ELEMENTARY SCHOOL IN TAIWAN

Fu-Hui Lee, *Central Taiwan University of Science and Technology, Taichung city, Taiwan*
Li-Feng Lin, *Central Taiwan University of Science and Technology, Taichung city, Taiwan*
Tzu-I Chiu, *Central Taiwan University of Science and Technology, Taichung city, Taiwan*

Background and Aims: In recent years, there has been a growing importance of issue concerned with childhood weight control in Taiwan. This study was designed to obtain preliminary estimates of the effectiveness of a healthy diet teaching program about nutrition and diet compared with one control group.
Methods: A quasi-experimental research design was conducted in this study. The research target contained 65 students as the experimental group from the fifth grade students of one rural elementary school in central Taiwan and 35 students as the control group from the fifth grade students of another rural elementary school in the same district. Students of the experimental group received a healthy diet teaching courses including food combining, diet, nutrition and healthy eating in two units and the control group did not receive these instructions during the experimental period. Both groups were pre-tested before the intervention and post-tested one month later and the obtained data was statistically analyzed by using paired t-test and t-test. In order to evaluate the effectiveness of the program, a questionnaire including the Scale of Healthy Diet Knowledge (Kuder-Richardson reliability = 0.67), Attitude (Cronbach's α= 0.84), and Behavior (Cronbach's α= 0.74) was designed.
Results: The results on the experimental group showed that the knowledge and behavior scores of the posttest were significantly higher than the pretest, while the control group demonstrated no significant difference between the pretest and the posttest. For healthy diet knowledge on the posttest, the experimental group exhibited a significant increase than did the control group, with no significant difference between the two groups on the pretest.
Conclusions: The results indicated that the healthy diet program had positive effects on students in elementary school. Base on the findings of the study, several recommendations for health promoting school were proposed.

Association between Daily Mean Air Temperature and Mortality of Respiratory Diseases in Beijing, China: a Case-Crossover Study

Hui Tao ,Department of Occupational & Environmental Health, Peking University School of Public Health, Beijing,China
Meimei Xu,*Department of Occupational & Environmental Health, Peking University School of Public Health, Beijing,China*
Yanhui Shen , C*enter of Disease Control in Haidian District, Beijing,China*
Xiaochuan Pan,*Department of Occupational & Environmental Health, Peking University School of Public Health, Beijing,,China*

Background and Aims: To explore the association between daily mean temperature and respiratory disease death (ICD10:J00-J99) in Beijing.

Methods: Data of daily death for the respiratory diseases (ICD: J00 -J99) in Haidian District in Beijing in Jan.1, 2004- Dec. 31, 2008 were collected from the local CDC. The corresponding meteorological and air pollution data were collected from the local EPB. The temperature-stratified case-crossover design and Logistic regression model were used for the data analysis. We considered lagged exposures, confounding by air pollution and other meteorological factors.

Results : After adjusting the influence of air pollutants (e.g. SO_2, NO2, PM10) and other meteorological factors (relative humidity, wind speed and atmospheric pressure), for 1□ increase in the daily mean air temperature, the corresponding increase of daily death for the respiratory diseases was 7.3% (OR=1.073, 95% CI: 1.002-1.149) within the range (15-25□) and 25.7% (OR=1.257, 95%CI: 1.115-1.416) over 25□ respectively. No significant associations were observed statistically within the temperature below 15□.

Conclusions: The increase of daily mean air temperature may be a risk factor for the daily respiratory disease death when the temperature is higher than 15□, and the adverse effect of the temperature increase is greater over 25□ than the range 15-25□.

Background and Aims: Epidemiological studies demonstrated that fine particulate air pollution (PM) can trigger adverse health outcomes. Recently, we demonstrated that chronic exposure to air pollution is associated with increased risk of chronic rejection and mortality after lung transplantation. In the present study, we investigated whether short-term elevations in ambient PM_{10} increased the risk of acute rejection after lung transplantation.
Methods: All transbronchial biopsies from a routine follow-up of 355 transplanted patients at the University Hospital Leuven were included. Acute perivascular and peribronchial rejection was scored and % BAL neutrophils and serum CRP were assessed. We used land use data to calculate the background level of PM_{10} for each participant's home address using a kriging interpolation method. We estimated % BAL neutrophils, serum CRP and the risk of acute rejection in relation with outdoor PM_{10} concentrations on the day of tissue sampling and up to five days before. The model was adjusted for covariates such as age, sex, post-operative day (POD) and daily temperature..
Results: The odds of acute rejection increased by 30% (95% CI: 4-61%) for each 10 µg/m³ increment in ambient PM_{10} concentration three days before the day of biopsy (lag day 3). Log-transformed neutrophils and serum CRP were significantly related to PM_{10} as well. For each 10 µg/m³ increment in ambient PM_{10} concentration on lag day 2, % BAL neutrophils increased by a factor 1.09 (95%CI 1.01-1.18) and serum CRP increased by a factor 1.10 (95%CI 1.02-1.18).
Conclusions: We showed that short-term variation in ambient air pollution acts as a trigger of acute rejection after lung transplantation, probably mediated by a pro-inflammatory response.

ASSESSMENT OF THE TEMPORAL STABILITY OF LAND USE REGRESSION MODELS FOR TRAFFIC-RELATED AIR POLLUTION

Rongrong Wang, *The University of British Columbia, Canada*
Sarah Henderson, *British Columbia Centre for Disease Control, Canada*
Ryan Allen, *Simon Fraser University, Burnaby, Canada*
Michael Brauer, *The University of British Columbia, Canada*

Background and Aims: Land-use regression (LUR) models have been used to estimate exposure to traffic-related air pollution in epidemiologic studies, based on the assumption that the spatial patterns of pollution are stable over time. Under this assumption, a LUR model developed from a particular time point can be applied to other time points. However, this assumption of temporal model stability has not been adequately examined, and has specific relevance to cohort studies where models are developed in specific years and then applied to cohorts over periods of ~10 years.
Methods: A LUR model for annual average NO_2 in Metro Vancouver was developed in 2003, based on measurements at 116 locations (Henderson et al 2007). In 2010, we repeated measurements at the same locations and developed a new model using updated data for the same predictor variables. The temporal stability of LUR models over a 7-year period was evaluated by comparing model predictions and measured spatial contrasts between the two time periods.
Results: Annual average NO_2 concentrations decreased from 2003 to 2010 at 78% of the 73 measurement sites that were identical for the two periods. The correlation between measurements at these sites was 0.78 with a mean (sd) decrease of 1.3 (1.7) $\mu g/m^3$. LUR models from 2003 and 2010 explained 52% and 66% of the observed spatial variation, respectively. The 2003 model explained 52% of variability in 2010 measurements (forecast), as much as it did in the 2003 (concurrent) measurements. The 2010 LUR model explained 51% of the variability in the 2003 measurements (back-cast), less than it did in the 2010 measurements; however, the back-cast explains nearly the same amount of variability in the 2003 measurements as did the original (2003) model.
Conclusions: These results support the validity of applying LUR models to cohort studies over periods as long as 7 years.

STUDY ON SYNTHESIS OF SILVER NANOPARTICLE DECORATED ZSM-5/MCM-41 MULTIPOROUS COMPOSITE AND ITS ANTI-BACTERIA

Le Thi Hoai Nam*, *Vietnam Academy of Science and Technology, Vietnam*
Nguyen Thi Thanh Loan, *Vietnam Academy of Science and Technology, Vietnam*
Tran Quang Vinh, *Vietnam Academy of Science and Technology, Vietnam*
Le Thi Kim Lan, *Vietnam Academy of Science and Technology, Vietnam*

Background and Aims: Silver itself is known as one of the most interesting antibacterial materials. It is generally believed Ag+ can bind to bacterial cell wall membrane (slightly negative), damage it and so alter its functionality. In this report we investigate the preparation of ZSM-5/MCM-41 multiporous composite containing silver (Ag-MC-Z5) and the influence of silver concentration on disinfection capability of Ag-MC-Z5 nano-antibacterial material.
Methods: Silver nanoparticle decorated ZSM-5/MCM-41 multiporous composite has been prepared by using ion-exchange method with change of Ag concentration: 0.1; 0.3; 0.5; 0.7; 0.9 wt%. Formation of Ag nanoparticles, size and shape of Ag-MC-Z5 nano-antibacterial material were determined by X-Ray diffraction (XRD), scanning electron microscopy (SEM) and transmission electron microscopy (TEM). The antibacterial activity of silver nanoparticles against E. coli was investigated as a model for Gram-negative bacteria.
Results: The results showed the presence of spherical nanosized Ag particles about 3 nm – 4 nm. By the initial Ag concentration of nanosized materials were at least 0.5 wt%, it is noted that growth inhibition rates against E. coli was 100 % as the initial concentration of E. coli was 1.5×10^5 CFU/ml and contact time was 10 minutes.
Conclusions: Ag-MC-Z5 nano-antibacterial material has been successfully prepared. E. coli antibacterial activity of Ag-MC-Z5 nano-antibacterial material was better than that of the other materials containing silver such as silver - charcoal, Ag-TiO_2.

Keywords: ZSM-5/MCM-41 multiporous composite, silver, nano-antibacterial material, E. Coli, ion-exchange.

TAP WATER CONSUMPTION, EXPOSURE TO TRIHALOMETHANES DURING PREGNANCY AND WEIGHT GAIN IN THE FIRST SIX MONTHS OF LIFE

Jordi Sunyer, *Centre for Research in Environmental Epidemiology (CREAL), CIBER Epidemiología y Salud Pública (CIBERESP), Spain*

Background and Aims: There is some evidence that *in utero* exposure to trihalomethanes (THMs) – the most prevalent disinfection-by-product – is negatively associated with birthweight. How postnatal growth could be modified had not been studied in human. In rats, impaired postnatal growth was reported in offspring of dams exposed to chloroform. We studied the relationship between tap water consumption and exposure to THMs during pregnancy with weight gain between birth and six months in the INMA (Spain) and RHEA (Greece) mother-child cohorts.
Methods: INMA in Gipuzkoa (N=449), Sabadell (N=533) and Valencia (N=645) and RHEA in Crete (N=939) included 2,566 mother-child pairs. Weight gain was calculated as the weight difference between birth and six months. THMs levels were evaluated through *ad hoc* sampling campaigns and regulatory data, modelled and combined with personal water uses to estimate personal exposure during pregnancy. Regression models took into account confounders such as gender, birthweight, parity, maternal weight, smoking, education.
Results: Median [Interquartile Range] THMs levels (microg/l) were 16 [12-20] in Gipuzkoa, 117 [102-127] in Sabadell, 5 [4-69] in Valencia and 1.0 [0.3-4.1] in Crete. Respectively, 90%, 20%, 32% and 17% of the mothers consumed tap water during pregnancy. Six months weight gain ranged from 4.15kg in girls from Gipuzkoa to 4.90kg in boys from Crete. In a pooled analysis, infants of mothers who declared to consume tap water during pregnancy tended to have a lower weight gain (-69g; p=0.06), particularly in Sabadell (-160g, p=0.03), but no dose-response relationship with amount of consumed tap water was observed. No significant relationship was found in any cohort with chloroform or brominated THMs through ingestion, bathing or showering.
Conclusions: Characteristics were heterogeneous between the cohorts, for both outcomes and exposures. Overall, results do not suggest that tap water and more specifically THMs exposures are associated with early postnatal weight growth.

DOSE EFFECTIVENESS OF CALCIUM SUPPLEMENTATION ON REDUCING CHILDREN'S BLOOD LEAD LEVELS IN INDONESIA

Budi Haryanto, *University of Indonesia, Indonesia*

Background and Aims: Population exposures to lead are mainly related to: vehicle exhaust, in areas where leaded-gasoline is still being used; paint and lead solder in canned food; drinking water pipes; and from certain culturally-based exposures, such as use of lead-glazed ceramics or traditional medication. It is well documented that excess exposure to lead causes health problems in children including neurobehavioral deficits. The objective of this study was to examine the effectiveness of daily calcium supplementation doses on reducing blood lead levels (BLLs) among elementary school children in Bandung, Indonesia.
Methods: A community trial study design was used for this study. Forty elementary schools were randomly selected, 400 children enrolled, and a total of 298 children completed follow-up of 3 months period. Schools were divided randomly into two groups of calcium-supplement intervention groups (250 mg and 500 mg). Capillary blood samples were analyzed for lead levels before and after three months of calcium supplementation. Paired-t test, and multivariate risk factors models using Generalized Estimating Equations (GEE) were performed.
Results: The percent reduction in BLLs was 49.8% for group of 250 mg Ca and 74.5% for group of 500 mg Ca. This study found no different association between groups. The reduction in BLLs was associated with calcium supplement, nutritional status, and time of trip to school.
Conclusion: Calcium supplement dose of 250 mg per day was effective to reduce children blood lead levels up to 50%.
Recommendation: These findings suggest that calcium supplementation dose of 250 mg provides a protective effect against lead exposure among school-aged children.

Introduction: Pandemic influenza A (H1N1) has a significant public health impact. This study aimed to examine the effect of socio-ecological factors on the transmission of H1N1 in Brisbane, Australia.
Methods: We obtained data from Queensland Health on numbers of notified daily H1N1 in Brisbane by statistical local areas (SLA) in 2009. Data on weather, socio-economic index were obtained from the Australian Bureau of Meteorology, the Australian Bureau of Statistics, respectively. A Bayesian spatial conditional autoregressive (CAR) model was used to quantify the relationship between variation of influenza and independent factors and to determine its spatiotemporal patterns.
Results: Our results show that average increase in weekly H1N1 cases were 45.04% (95% credible interval (CrI): 42.63 – 45.01%) and 23.20% (95% CrI: 16.10 – 32.58%), for a 1^{o}C decrease in average weekly maximum temperature at a lag of 1 week and a 10mm decrease in average weekly rainfall at a lag of 1 week, respectively. An interactive effect between temperature and rainfall on H1N1 incidence was found (changes: 0.71%; 95% CrI: 0.48 – 0.98%). Auto-regression term was significantly associated with H1N1 transmission (changes: 2.5%; 95% CrI: 1.39 – 3.72). No significant association between socio-economic indexes for areas (SEIFA) and H1N1 was observed at SLA level.
Conclusion: Our results demonstrate that average weekly temperature and rainfall were substantially associated with H1N1 incidence at a SLA level. The ecological factors seemed to have played an important role in H1N1 transmission cycles in Brisbane, Australia.

ISEE Symposium

Prenatal exposure to POPs and age of puberty

INFLUENCE OF PERFLUORINATED COMPOUNDS (PFCS) EXPOSURE ON DEVELOPMENT AND HORMONES OF CHILDREN FROM THE DUISBURG BIRTH COHORT STUDY

Michael Wilhelm [1], Monika Kasper-Sonnenberg[1], Hermann Fromme[3], Wolfgang Völkel[3], Jürgen Wittsiepe[1], Claudia Cramer[2], Ulrich Ranft[2]
[1]Department of Hygiene, Social and Environmental Medicine, Ruhr-University Bochum, Bochum, Germany.
[2]IUF Leibniz Research Institute for Environmental Medicine Düsseldorf, Germany
[3]Department of Chemical Safety and Toxicology, Bavarian Health and Food Safety Authority, Munich, Germany, Bavarian Health and Food Safety Authority, Oberschleissheim, Germany

Among the Duisburg Birth Cohort Study which was initiated 2000-02 (Wilhelm et al., 2008, Mutat. Res. 659, 83-92) we studied associations between prenatal and postnatal PFOS and PFOA exposure and infants development and hormones. 149 mother-newborn pairs were included in the PFC study. Blood PFC levels were measured in pregnant women, in newborns, and in children at ages 6-8 years. Outcome measurements were birth weight, neurodevelopment (Bayley scales motor and mental development of infants) at 12 and 24 months, assessment of the gender role behavior in young children (Pre-School Activities Inventory (PSAI) at 6-8 years. Estradiol, testosterone, thyroid hormones (TSH, T3, T4, fT3, fT4), were measured in cord serum and at ages 6-8 and 8-10 years, dihydroxyepiandrosteronesulphate (DHEA-S) was analyzed at ages 8-10 years. Median PFOA and PFOS concentrations in serum samples were as follows: pregnant women 2.7 (PFOA) and 8.9 (PFOS) µg/l, cord serum 2.0 (PFOA) and 2.9 (PFOS) µg/l, at age 6-8 yrs 4.6 (PFOA) and 3.6 (PFOS) µg/l. The prenatal PFOS/PFOA concentrations are correlated with the concentrations at 6-8 yrs after birth. Multivariate regression analysis revealed no significant associations between the birth outcomes and thyroid hormones of the newborns and the prenatal PFOA/PFOS exposures. Prenatal PFOS exposure was negatively associated with the mental development at 12 months of infants. This effect was more pronounced in German children (mean decrease 1.7%; 95% CI 0.2% - 3.1% per doubling of exposure). We also found associations between the prenatal PFOA/PFOS concentrations, and the gender role behaviour at 6-8 yrs, the sexual hormones and the DHEA-S levels at age of 8-10 years. Conclusion: PFOS influences early mental development at a low level of effect. This effect disappears when the children are getting older. PFOA and PFOS seem to be involved in adrenal maturation and pubertal development.

BPA IS RELATED TO ABNORMAL LIVER FUNCTION : THE KOREAN ELDERLY ENVIRONMENTAL PANEL STUDY (KEEPS)

Hyunseung Park, *Department of Preventive medicine, Seoul National University College of Medicine, Korea*
Youn-Hee Lim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, Korea*
Sanghyuk Bae, *Institute of Environmental Medicine, Seoul National University Medical Research Center, Korea*
Jin Hee Kim, *Institute of Environmental Medicine, Seoul National University Medical Research Center, Korea*
Soo-Hun Cho, *Department of Preventive medicine, Seoul National University College of Medicine, Korea*
Yun-Chul Hong, *Department of Preventive medicine, Seoul National University College of Medicine, Korea*

Background and Aims : Bisphenol A(4,40-isopropylidenediphenol, BPA) is known to have adverse effect on various organs. Liver has been reported to be affected in previous animal studies, however there were few human studies and the mechanism is not clear. Our study tried to evaluate the relationship between BPA level and liver function in human using repeated measurement data.
Methods : From 2008 to 2009, a total of 556 elderly participants dwelling in Seoul were evaluated repetitively. At the first visit, demographic data, environmental exposure and habitual histories were gathered through a systemized questionnaire. Blood and urine samples were gathered at the same time and stored for analysis. Generalized linear mixed models were performed adjusting for age, sex, body mass index, drinking, smoking, exercise frequency and cholesterol level.
Results : Mean urinary BPA level were 1.03 μg/g creatinine. Higher urinary BPA levels were associated with elevated liver enzyme levels in a fully adjusted model (ALT, gamma-GTP were significant at $P<0.01$, AST showed marginal significance). Because BPA levels were significantly associated with BMI, we evaluated the BPA-liver relationship with or without controlling for BMI. The association of BPA with abnormal liver function remained significant regardless of controlling for BMI.
Conclusions : Our results suggest that BPA has adverse effect on liver in human. BPA may affect liver function independently from the pathway of obesity.

AMBIENT POLLUTION AND BIRTH OUTCOMES

Rajen Naidoo, *Department of Occupational and Environmental Health, University of KwaZulu-Natal, South Africa*
Anil Chuturgoon, *Department of Medical Biochemistry, University of KwaZulu-Natal, South Africa*
Poovendhree Reddy, *Department of Community Health Studies, Durban University of Technology, South Africa*
Kareshma Asharam, *Department of Occupational and Environmental Health, University of KwaZulu-Natal, South Africa*
Dhaneshree Naidoo, *Department of Medical Biochemistry, University of KwaZulu-Natal, South Africa*
Alisa Phulukdaree, *Department of Medical Biochemistry, University of KwaZulu-Natal, South Africa*
Devapregasan Moodley, *Department of Medical Biochemistry, University of KwaZulu-Natal, South Africa*

Background and Aims: Environmental and personal factors acting during pregnancy may result in adverse birth outcomes, and consequently ill-health in the growing infant. This pilot tested methods for sample selection, field instruments, biological testing and exposure assessment for a future birth cohort study investigating the association of respiratory health and ambient pollution.
Methods: Pregnant women selected from public sector antenatal clinics in the industrially polluted south Durban (n=50) and the less industrialised, north Durban (n=50) were interviewed about their health status, obstetric history, exposure, smoking and nutritional history. Maternal tests for oxidative stress, allergy, atopy and genetic polymorphisms, together with cord blood for heavy metals and neonatal genetic testing, were conducted. Birth outcomes were assessed at the time of delivery. We describe the early analysis of data from this study.
Results: Mean age among participants did not differ from the south (25.1 years) compared to the north (25.7 years). There was minimal evidence of chronic diseases, with prevalences of TB, asthma, chronic bronchitis, emphysema, hypertension and diabetes less than 1%. There were two stillbirths and 8.7% low birthweight (<2.5kg) newborns, Unadjusted risks for low birthweight were increased for those living among higher industrial pollution (RR=3.5, 95% CI: 0.9 - 14.47) and those exposed to motor vehicle fuel or exhaust emissions (RR=3.8, 95%CI: 1.16-12.1). Biochemical evidence of oxidative stress did not vary between north and south (Malondialdehyde was 0.06µM and 0.07µM between north and south respectively, while mitochondrial depolarisation was 43.9% and 44.5% respectively). These markers were not associated with low birthweight. HIV status was not associated with low birthweight.
Conclusions: This pilot study successfully tested methodological challenges in preparation for a birth cohort study investigating ambient pollution and respiratory outcomes. Although not a primary focus of the pilot, preliminary data analysis suggests environmental exposure related risks for low birthweight outcomes.

OCCUPATIONAL EXPOSURES AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN A HIGH TUBERCULOSIS PREVALENCE POPULATION

Rajen Naidoo, *Department of Occupational and Environmental Health, University of KwaZulu-Natal, South Africa*
Nadira Govender, *Department of Occupational and Environmental Health, University of KwaZulu-Natal, South Africa*
Umesh Lalloo, *Department of Pulmonology and Critical Care, University of KwaZulu-Natal, South Africa*

Background and Aims: Occupational exposures are associated with chronic obstructive pulmonary disease (COPD). These associations have not been investigated against the background of tuberculosis, a risk factor for COPD. This study investigated the relationship between occupational exposures and COPD in a population with a high prevalence of TB.
Methods: Pulmonologist diagnosed cases (n=110) were selected from specialist respiratory clinics at public sector hospitals, and frequency sex and age matched controls (n=102) were selected from other chronic disease clinics at the same institutions. Occupational exposure histories, smoking and other risk factors for COPD were obtained through interviews. Exposure variables included exposure to dusts and chemicals, gases and fumes (CGF). The ALOHA Job Exposure Matrix (JEM) were used to complement the self-reporting variables in the analyses. Odds ratios (OR) were calculated from logistic regression models, adjusting for smoking and past history of tuberculosis. Population attributable risk % (PAR%) was also calculated.
Results: The adjusted OR's for risk of COPD from self-reported high dust exposure-years and high chemical, gases and fume (CGF) exposure-years were 5.9 (95% CI 2.6-13.2) and 3.6 (95% CI: 1.6-7.9) respectively. The adjusted OR's from the JEM derived high cumulative exposure ranged from 1.1 (95% CI 0.6-2.4) to 2.1 (95% CI 1.1-4.2). Among smokers, there was an increased risk for COPD among those exposed to dust (OR=3.1; 95% CI: 0.4-23.9) and CGF (OR=2.3; 95% CI: 0.4-14.4). TB was a risk factor for the development of COPD (OR ranging from 7.7-8.1). The PAR% for COPD from the JEM high cumulative exposure variables ranged from 2.2% for mineral dust to 14.6% for CGF.
Conclusions: Lifetime occupational exposures contribute to the risk of COPD, adjusted for smoking. These risks are present in populations with a high burden of tuberculosis which is generally considered an important causative factor.

CHILD EXPOSURE TO ENVIRONMENTAL TOBACCO SMOKE DURING PRENATAL PERIOD

Kinga Polanska, *Nofer Institute of Occupational Medicine, Poland*
Wojciech Hanke, *Nofer Institute of Occupational Medicine, Poland*
Wojciech Sobala, *Nofer Institute of Occupational Medicine, Poland*
Danuta Ligocka, *Nofer Institute of Occupational Medicine, Poland*

Background and Aims: Worldwide, it is estimated that 250 million women smoke cigarettes every day. Despite the adverse health consequences of tobacco smoking and exposure during pregnancy, the percentage of pregnant women who smoke remains extremely high. The aim of the study was to evaluate the prenatal child exposure to environmental tobacco smoke.

Methods: The study population consisted of 1093 pregnant women from different regions of Poland among whom detail questionnaires were conducted three times during pregnancy period. From all women included into the study the saliva sample was collected to verify smoking status in pregnancy. The cotinine level in saliva was analyzed using high performance liquid chromatography coupled with tandem mass spectrometry/positive electrospray ionisation (LC-ESI^+MS/MS) and isotope dilution method.

Results: The percentage of pregnant women who smoked cigarettes decreased from 17.6% at the beginning of pregnancy to 14.1% at 12 weeks of pregnancy and 10.9% at 32 weeks of pregnancy. The highest percentages of smokers were noted among single women with lower educational level and unemployed. The sensitivity of questionnaire was 73% and cotinine as the biomarker of exposure 93%. About 70% of pregnant women were exposed to environmental tobacco smoke.

Conclusions: All effort should be taken to eliminate the pregnant women exposure to active and passive smoking.

ENVIRONMENTAL TOBACCO SMOKE EXPOSURE - PREGNANCY OUTCOMES AND CHILDREN'S HEALTH

Kinga Polanska, *Nofer Institute of Occupational Medicine, Poland*
Wojciech Hanke, *Nofer Institute of Occupational Medicine, Poland*
Wojciech Sobala, *Nofer Institute of Occupational Medicine, Poland*
Danuta Ligocka, *Nofer Institute of Occupational Medicine, Poland*

Background and Aim: Environmental tobacco smoke exposure (ETS) is associated with poor pregnancy outcomes including increases risk of spontaneous abortion, stilbirth, preterm delivery, low birth weight and sudden infant death syndrome. ETS exposure after birth can increase the risk of sudden infant death syndrome, respiratory infections, asthma, middle ear diseases and it can cause neurodevelopmental and behavioral problems in children. The aim of the study was to analyze the influence of environmental tobacco smoke exposure on pregnancy outcome and children's health.

Methods: The study population consisted of pregnant women (N=640) and their children (N=190) followed up to two years of life. Pregnant women were interviewed three times during pregnancy. From all women included into the study the saliva sample was collected three times to verified smoking status. Assessment of child ETS exposure within two years after birth was based on questionnaires conducted with mothers, confirmed by biochemical verification of cotinine level in child urine. Cotinine level in biological samples was analyzed using high performance liquid chromatography coupled with tandem mass spectrometry/positive electrospray ionisation (LC-ESI$^+$MS/MS) and isotope dilution method. Pregnancy outcome including: birth weight, length, head and chest circumference was noted by neonatologist. The children's health focused on anthropometry indicators and the incidences of upper and lower respiratory tract infections, allergy and asthma was performed by pediatricians during the first and second year of life.

Results: Multivariative analysis (including gender, gestational age and parental educational status) indicated that the newborn of smoking mothers had significantly lower birth weight (coef. - 307g, $p<0.001$), length (coef. – 1.4cm, $p=0.02$), head (coef. – 0.7cm, $p=0.002$) and chest circumference (coef. – 0.8cm, $p=0.003$). There were no statistically significant associations between ETS exposure and anthropometric measurements within first two years of life. Such exposure increases the risk of respiratory diseases but the results were not statistically significant.

Conclusions: All effort should be taken to eliminate the child ETS exposure both durirg prenatal and postnatal period.

DENTAL HEALTH FOLLOWING CHILDHOOD EXPOSURE TO IONIZING RADIATION

Angela Chetrit, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Yuval Vered, Dept. Community Dentistry, Hebrew University-Hadassah School of Dental Medicine, Jerusalem, Israel
Tova Amitai, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Harold D Sgan-Cohen, Dept. Community Dentistry, Hebrew University-Hadassah School of Dental Medicine, Jerusalem, Israel
Hadas Even-Nir, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Siegal Sadetzki, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel -Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

Background and aims: Exposure to high doses of ionizing radiation (4-30Gy) in childhood may cause dental abnormalities including root and crown defects, caries and decreased parotid secretions. Data on the effects of lower dose radiation to teeth is sparse. This study aimed to examine the long-term effects of radiation given as treatment for tinea capitis (TC) in childhood on dental health.
Methods: The target population included a subsample of 426 irradiated and 401 non-irradiated subjects from the TC cohort (estimated dose to teeth 0.2-0.4Gy). For each of the 253 irradiated and 162 non-irradiated who agreed to participate, a personal interview and a dental examination were performed. The questionnaire covered socio-demographic parameters, smoking, history of diseases and an oral hygiene habits section. The DMFT (decayed (D), missing (M), and filled (F)) index for permanent teeth was used to determine caries experience. Ordered multivariate logistic regression model was used to assess factors (gender, age, education, income, religiosity, smoking, diabetes, oral hygiene habits, dental visit and radiation status) associated with increasing DMFT values.
Results: Rates of 14.6% and 7.4% for complete missing teeth were found among irradiated and non-irradiated individuals, respectively (p=0.02). Irradiated subjects had significantly higher DMFT mean values compared to the non-irradiated (18.6$\pm$7.5 vs. 16.4$\pm$7.2, p=0.003, respectively). Controlling for the above mentioned covariates, irradiation was associated with a 60% increased risk for high DMFT (95%CI 1.08–2.33). Female gender, primary school education, current smoking and poor oral hygiene were found to be independently associated with high DMFT.
Conclusion: Our data suggest that childhood exposure to relatively low doses of ionizing radiation play a role in late outcomes of dental health. This should be taken into account when discussing the increasing use of diagnostic modalities in medicine in general as well as in dental procedures.

ASSOCIATION BETWEEN SLEEP DISTURBANCE, MELATONIN AND FEMALE BREAST CANCER

I-Lan Liu, *Department of Public Health, National Defense Medical Center, Taiwan*
Chi-Hong Chu, *Department of General Surgeon, Tri-Service General Hospital, National Defense Medical Center, Taiwan*
Chiou-Jong Chen, *Institute of Occupational Safety and Health, Council of Labor Affairs, Executive Yuan, Taiwan*
Chih-Hung Ku, *Department of Public Health, National Defense Medical Center, Taiwan*

Background and Aims: According to a 2007 Taiwan Annual Mortality Report, female breast cancer was the fourth of the top 10 cancer mortality. Ever since the industrial revolution, there has been a steady increase of working hours among female workers. Moreover, it can be argued that part of the breast cancer causing risk could be due to the suppression of melatonin in electric lighting post industrialization era. The aims of this study are to assess the association between melatonin level, sleep disturbance and female breast cancer.
Methods: This case-control study design was conducted from Sep. 2008 to Feb. 2009 in a medical center in Taipei, Taiwan. The study has been approved by the Institutional Review Board of the medical center. A self-report questionnaire was used to collect the demographic data, environmental factors, occupational exposure, family history, etc. Simultaneously, blood and urine samples were collected from volunteers during the OPD. Multiple linear regression and multiple logistic regression were used to assess the association of interests and potential confounders.
Results: There were 140 breast cancer cases and 983 controls in total. After the adjustment for confounders, we found that sleep disturbance were associated with female breast cancer (OR Ž 2.71 ž 95%CI: 1.56- 4.72). The cases' melatonin concentration of urine was lower than controls, which was significant difference after the match on age.
Conclusions: According to the result, we confirmed in the preliminary result that sleep disturbance and low melatonin concentration were some of the risk factors for breast cancer.

INCREASING RISK OF CARDIOVASCULAR DISEASE IN NON-REGULAR SHIFT WORK OF OCCUPATIONAL WORKERS WITH OBSTRUCTIVE SLEEP APNEA

Tzu-Chieh Chou, *China Medical University, Taiwan.*
Heng-Chun Chen, *China Medical University, Taiwan.*
Tung-Sheng Shih, *China Medical University, Taiwan.*
Saou-Hsing Liou, *NHRI, Taiwan.*
Hua Ting, *Chung Shan Medical University, Taiwan.*
Yu-Jung Cheng, *China Medical University, Taiwan.*
Yung-Chienm Teng, *China Medical University, Taiwan.*

Background and Aims: Workers with non-regular shift work could lead the high risk of obstructive sleep apnea (OSA) occurred. OSA was one of the independent risk factor for cardiovascular disease (CVD). However, limited studies have been postulated the relations between OSA and CVD among occupational workers. The objectives of this study were to estimate the severity of OSA and risk of CVD, and to build the potential mechanistic relations of biomarkers including oxidative stress and inflammatory markers with OSA and CVD.

Methods: We recruited 189 non-regular shift workers who examined by polysomnography (PSG) to gain the the apnea-hypopnea index (AHI) and divided into normal (AHI<5) and OSA (AHI Ž 5) groups. Blood and urine samples were collected to analyses the biomarkers of inflammation and oxidative stress such as TNF-• , interleukin-10, MDA, and 8-OHdG. High-sensitivity C-Reactive Protein (hs-CRP) and homocystein were also analyzed to be the CVD risk biomarkers of early response. Ten years CVD risk was calculated by the index from Framingham Heart Study.

Results: The results show that group of OSA in CVD risk is 9.4%, which is significant higher than normal group (7.9%, p=0.048). Significant increase of OSA group compared with normal group was also shown in hs-CRP (p=0.019). Moreover, the same patterns were showed in TNF-• and MDA, indicating the workers with OSA could have more inflammation and oxidative stress level than normal group.

Conclusion: Non-regular shift workers with OSA could lead the raising CVD risk and the oxidative stress and inflammation might be the potential mechanism.

Background and Aims: There are emerging concerns about potential effects on child health and development of early-life environmental exposure to substances such as brominated flame retardants (BFRs), perfluorinated compounds (PFCs), phthalates and phenols (including bisphenol A – BPA). A number of pregnancy and birth cohort studies are now measuring such exposures. Early collaboration between these ongoing studies will improve potential for future comparison and combined studies. Our aim is therefore to provide an overview of planned, ongoing and published biomarker measurements of emerging contaminants in European birth cohorts.
Methods: The ENRIECO inventory of birth cohorts in Europe (www.birthcohortsenrieco.net) was used to identify measurements of BFRs, PFCs, phthalates, phenols, and other compounds of emerging concern. Furthermore, publications were searched to obtain information on measured concentrations of these chemicals.
Results: Very few European cohorts have already carried out measurements of emerging contaminants; only 7 have published exposure levels. Measurements of BFRs are ongoing or planned in 11 European birth cohorts; measurements of PFCs in 10, of phthalates in 13 and of BPA in 7. Only 2 cohorts are also measuring other exposures such as parabens, triclosan and benzophenone. Biological matrices and timing of the measurements vary considerably between cohorts. BFRs have been determined mostly in blood, breast milk, and placenta, whereas PFCs have been measured mostly in blood (plasma and serum). Urine has been the most used biological matrix to measure phthalates and phenols. Most measurements are conducted prenatally or at birth and generally the measurements involve few subjects in each cohort (a few hundred maximum).
Conclusions: Although there is currently not enough data in the cohorts to combine data, many measurements are ongoing and within a few years there will be possibilities for comparison studies. Cohorts should work together to develop conversion models and inter-laboratory comparisons that will allow future combined studies.

METALS EXPOSURE IN PREGNANT WOMEN IN WESTERN AUSTRALIA

Anna C. Callan, *Centre for Ecosystem Management, Edith Cowan University, Perth, Australia*
Malarvili Ramalingam, *Centre for Ecosystem Management, Edith Cowan University, Perth, Australia*
Andrea L. Hinwood, *Centre for Ecosystem Management, Edith Cowan University, Perth, Australia*
Karyn Concanen, *Centre for Ecosystem Management, Edith Cowan University, Perth, Australia*
Mary Boyce, *Centre for Ecosystem Management, Edith Cowan University, Perth, Australia*
Jane Heyworth, *School of Population Health, University of Western Australia, Perth, Australia*
Jon Øyvind Odland, *University of Tromsø, Norway*

Background and Aims: The Australian Maternal Exposure to Toxic Substances (AMETS) study was initiated to measure the exposure of pregnant women in Western Australia to a range of persistent toxic substances in the environment. Sample collection for this study is continuing until April 2011, however preliminary results for metals in blood and urine are now available.
Methods: Pregnant women from across Western Australia have been recruited via local hospitals and the community. To date 157 women have provided blood and urine samples for the study, of which 80 blood and 120 urine samples have been analysed for metals. Participants have also completed a questionnaire and diet diary and provided samples of their household drinking water, soil and dust.
Results: Metals concentrations were low in biological samples with the exception of cadmium and uranium which were elevated with respect to the international literature (B-Cd mean 0.90µg/L, range 0.12-2.77µg/L; B-U mean 0.08µg/L, range <0.01-0.22µg/L; U-Cd mean 0.92µg/L, range 0.2-2.8µg/L; U-U mean 0.01µg/L, range <0.01-0.17µg/L). Copper concentrations were variable (B-Cu mean 1447µg/L, range 0.27-2410µg/L; U-Cu 11.8µg/L, range 1.4-55.3µg/L). Thirty percent of participants (aged 19-44 years), had urine cadmium concentrations of >1µg/L and almost 50% of participants had creatinine adjusted concentrations of >1µg/g (median 0.29µg/g, range 0.29-4.65µg/g). Concentrations of metals in soil, dust and drinking water samples were generally low.
Conclusions: Elevated biological cadmium and uranium concentrations were found in pregnant women in Western Australia. These concentrations were at levels which have the potential to increase the risks of health effects, such as decrements in bone density, in the women in later life. Environmental concentrations appeared to explain little of the variance in biological concentrations, as did the other variables collected. These results for Australia confirm those conducted in other locations where diet is the likely main source of metals exposure.

LAND USE REGRESSION MODELS OF PM_{10} AND NO_2 CONCENTRATIONS IN TAIPEI

Background and Aims: This study developed land use regression models to assess long-term exposure to ambient particulate matters of PM_{10} and NO_2, in order to minimize the exposure misclassification and achieve better individual exposure assessment for the Taiwan cohorts of the ESCAPE study.

Methods: We used a population density based sampling strategy to select 40 locations as our NO_2 measurement sampling sites in Taipei, while PM_{10} measurements were conducted at 20 sites among them, and one additional background site for annual average adjustment. PM_{10} and NO_2 concentrations were monitored simultaneously by using Harvard Impactors and Ogawa passive samplers respectively for 2-week period in three seasons during 2009 and 2010. With collected land-use datasets, containing land-cover and traffic related data, we conducted the GIS analyses to obtain a series of potential predictor variables in concentric circle buffers with several radii ranging from 25 to 5000m of each monitoring site. Based on stochastic modeling techniques, we combined the average concentrations and values of predictor variables in stepwise procedure to develop the final LUR models for PM_{10} and NO_2.

Results: The adjusted annual concentrations were 48.6±5.9 • g/m^3 for PM_{10} and 26.0±6.5 ppb for NO_2. There were 3 predictors for the final model of PM_{10} (adjusted R^2=0.78), including major road length within 25m, industry areas within 1000m, and high density residential areas within 100m. And there were 4 predictors for the NO_2 model (adjusted R^2=0.66), including low density residential areas within 500m, major road length within 25m, urban green areas within 300m, semi-natural and forested areas within 500m.

Conclusions: Our study indicates that exposure to PM_{10} and NO_2 for subjects in Taiwan cohorts of the ESCAPE study can be well estimated by LUR models with 3-4 predictors.

SPATIOTEMPORAL CLUSTERING ANALYSIS OF DENGUE INCIDENCE IN BANGLADESH

Shahera Banu, *School of Public Health, Queensland University of Technology, Australia*
Shilu Tong, *School of Public Health, Queensland University of Technology, Australia*
Wenbiao Hu, *School of Population Health, University of Queensland, Australia*
Cameron Hurst, *School of Public Health, Queensland University of Technology,Australia*
Yuming Guo, *School of Public Health, Queensland University of Technology, Australia*
Mohammad Zahirul Islam, *International Centre for Diarrhoeal Diseases Research, Bangladesh (ICDDR,B), Bangladesh.*

Background and Aims: There has been little research into the spatial distribution and clustering of dengue in Bangladesh, where dengue is endemic and occurring every year since 2000. This study examined the spatial distribution of dengue at district level and identified the district with a high relative risk of dengue in Bangladesh, using geographical information system techniques.

Methods: Data on monthly confirmed dengue cases in each district from January 2000 to December 2009 were provided by the Directorate General of Health services, Dhaka, Bangladesh. Relevant population data and electronic boundaries of each district were obtained from Bangladesh Bureau of Statistics. We identified the spatiotemporal clusters of dengue across districts using SaTScan software. The output from SaTScan was merged into the attribute table to map the spatiotemporal clusters using MapInfo professional.

Results: The results indicate that the Dhaka district had the highest risk of dengue incidence from January 2000 to December 2004 (RR = 80.39). During January 2000 Khulna district and 14 other districts of the southern part of Bangladesh were identified as secondary clusters.

Conclusions: There was a notable spatial difference in relative risk of dengue cases at the district level in Bangladesh. Some districts had significant clusters of high risk for dengue. The socio-environmental determinants of the geographical difference of dengue incidence should be addressed in future research.

OCCURRENCE AND POTENTIAL DETERMINANTS OF VISUALLY INDUCED SYMPTOMS IN SPECTATORS OF THREE DIMENSIONAL (3D) STEREOSCOPIC MOVIES

Angelo G Solimini, *Sapienza University of Rome, Italy*
Domitilla Di Thiene, *Sapienza University of Rome, Italy*
Alice Mannocci, *Sapienza University of Rome, Italy*
Giuseppe La Torre, *Sapienza University of Rome, Italy*

Background and aims. The increasing popularity of commercial movies showing three dimensional (3D) computer generated images has raised concern about image safety and possible adverse side effects on viewers. We aim to quantify the occurrence and potential determinants of visually induced symptoms in spectators of 3D movies.
Methods. Self administered questionnaires were distributed to individuals who saw a 3D movie in a cinema in the past 6 months. The questionnaire contains 20 items related to socio-demographic, individual and movie vision characteristics and visually induced symptoms (internal consistency of symptom section, Chronbach alpha=0.69). We asked to report symptoms at 3 different times: during, right after and after 2 hours from movie vision.
Results. We enrolled 177 adults (age range: 18-64 years). At least 1 symptom was reported by 61% of participants. Symptoms were reported by 54.5% individuals during the movie vision, by 35.7% right after and by11% after 2 hours from the vision. The most frequent symptoms were tired eyes (reported by 35.1% during; 13.6% right after; 3.2% after 2 hours), dizziness (14.3%, 9.1%, 0.6%) and headache (12.3%, 2.3%, 5.2%). Significant associations during the movie vision were: Tired eyes – freq. car sickness OR 2.19; 95%IC 1.06-4.52; Tired eyes – daily computer use OR 2.14 (95%IC 1.04-4.39); Dizziness-frequent headache OR 3.05 (95%IC 1.13-8.24); Dizziness- frequent car sickness OR 3.33 (95%IC 1.29-8.6). After the movie vision: Nausea– lateral and close to the screen viewing position OR 5.31 (95%IC 1.16-24.2)
Conclusions. Visually induced symptoms can result from the vision of 3D movies in cinemas. The high occurrence of symptoms, although of mild intensity and rapid disappearance, and the resulting associations with some individual and vision characteristics suggest to get additional insights on individual susceptibility factors.

CONTRIBUTION OF RADON PROGENY TO TOTAL LUNG DOSE AND ITS RELATION WITH LUNG CANCER MORTALITY AMONG FRENCH URANIUM MINERS

Eric Blanchardon, *Institute of Radiological Protection and Nuclear Safety, DRPH, SDI, Fontenay-aux-Roses, France*
Rodrigue S. Allodji, *Institute of Radiological Protection and Nuclear Safety, DRPH, SRBE, Fontenay-aux-Roses, France*
James Marsh, *Health Protection Agency, Chilton, Didcot, UK*
Sylvaine Caër-Lorho, *Institute of Radiological Protection and Nuclear Safety, DRPH, SRBE, Fontenay-aux-Roses, France*
Alain Acker, *AREVA NC, Paris, France*
Dominique Laurier, *Institute of Radiological Protection and Nuclear Safety, DRPH, SRBE, Fontenay-aux-Roses, France*

Background and aims: Uranium miners are exposed to radon gas and its short-lived progeny (RnP), long-lived radionuclides and external gamma rays. While the lung cancer risk related to radon exposure has been widely studied, the effect of the other ionizing radiations is not well known. The aim was to assess the risk of lung cancer death associated with lung doses due to these multiple types of radiation exposure in the French cohort of uranium miners.
Methods: The cohort included 3,271 exposed miners followed from 1956 through 1999. Annual exposures were assessed individually. Lung doses were calculated according to the Human Respiratory Tract Model (Publication 66 of the International Commission on Radiological Protection). Exposure-risk relations were estimated by a linear excess relative risk (ERR) model and Poisson regression was used to fit the model.
Results: Mean alpha and non-alpha absorbed doses were equal to 78 and 56 milliGray (mGy), respectively. RnP accounted for 97% of the alpha absorbed dose. A significant ERR of lung cancer death was associated with the total absorbed lung dose (ERR/Gy [95%CI] = 2.9 [0.8-7.5]), the alpha absorbed dose (4.58 [1.3-10.9]) and RnP (4.6 [1.3-11.2]). Assuming a value of 20 for the relative biological effectiveness of alpha particles in lung cancer induction, the ERR/Gy-equivalent for the total-weighted lung dose was 0.2[0.1-0.5], similar to that for the alpha-weighted and RnP-weighted lung dose.
Conclusions: These first results about lung doses from the European Alpha-Risk project, with regard to the lung dose distribution, support the major role of RnP in the risk of lung cancer death.

PERSONAL EXPOSUREAND RISK ASSESSMENT OFVOLATILE ORGANIC COMPOUNDS OF ELEMENTARY CHILDREN

Lee, CC[1]; Peng, CY[1]

[1]Graduate Institute of Occupational Safety and Health, Kaohsiung Medical University, Taiwan

Background and aims: Volatile organic compounds (VOCs) are important due to frequent presence in the environment and associated adverse health risks. VOCs are largely originated from mobile and industrial sources in ambient air. Although, several studies foundan association between long-term VOC exposure to traffic-related and/or industrial-relatedemissions and possible health effects. A few studies investigated VOC exposure in children. In this study, we assessed personal exposure to VOCs in children with different districts in terms of traffic intensity and industrial factory density, and in different seasons (fall and spring). **Methods:** Passive samplers were used to collect long term and wide range of ambient VOCs. Children wore passive samplers for 7 days. Sample extracts were analyzed by gas chromatography / mass spectrometer (GC/MS).**Results:**TVOC concentrations of spring and fall are 9.13~156.34ppb and 27.96~123.45 ppb at the industrial-area school, 9.97~86.99 ppb and 25.29~139.58 ppb at the traffic-area school, and 0.39~121.14 ppb and 12.84~151.06 ppb at the background school, respectively. Concentration magnitudes in descending order are industrial-areaschool, traffic-areaschool and background school.Concentrations are higher in fall than those in spring.Among VOCs, benzene, toluene, m-xylene, p-xylene and o-xylene are abundant VOCs. BTEX and TVOC indoor concentrations weresignificantlyhigher in the traffic andindustrial areas. **Conclusion:**Traffic and industrial school areas have a high concentration of VOC.The dataobtained in this studycan be used to estimate and represent children's VOC exposure in Kaohsiung city.Further study is neededto measure the impact of VOC on the health of the children in Kaohsiung city.

Key words：Volatile organic compounds (VOC), Passive sampler,Air pollution

RISK FROM OCCUPATIONAL AND ENVIRONMENTAL RADON AND ROLE OF SMOKING

Ladislav Tomasek, *National Radiation Protection Institute, Czech Republic*

Background and Aims: Because of the predominant role of cigarette smoking as a cause of lung cancer, an understanding of the joint effect of smoking and radon exposure is needed for the appropriate assessment of the risk from radon.
Methods: The present study is based on two Czech cohorts of U miners (N=10 900) and on another cohort of people exposed to high levels of radon in houses (N=11 900). Results are based on recent data by 2010 which include 1107 and 240 cases of lung cancer in the occupational and residential studies, respectively. Individual smoking data were collected for most of subjects (68% and 75%, respectively). The relative risk is evaluated in dependence on cumulated exposure with effect modification by time since exposure and smoking.
Results: It is shown that the excess relative risk per unit exposure from earlier periods of exposure (20 years and more) is about 1/3 in comparison to recent exposures (5-19 years), whereas the relative effect from exposures before 35 years is only about 1/10. Smoking specific estimates of excess relative risk per unit exposure were 3-5 times higher among never smokers in both studies. In addition, the interaction of radon and smoking is evaluated by geometric mixture models and is found to be between additive and multiplicative model. When smoking specific equivalent doses to the lungs and modifying effect of time since exposure are used, the combined effect of radon and smoking is close to the additive model.
Conclusions: The study confirms the additive role of smoking and radon, particularly when temporal factors and smoking specific estimates of radiation doses are used in the model. The work was conducted under project NS 10596 of the Czech Ministry of Health.

THE OPPOSING EFFECTS OF CLIMATE CHANGE AND SOCIO-ECONOMIC DEVELOPMENT ON THE GLOBAL DISTRIBUTION OF MALARIA

Andreas Béguin, *Umeå University, Sweden*
Simon Hales, *University of Otago, New Zealand*
Joacim Rocklöv, *Umeå University, Sweden*
Christofer Åström, *Umeå University, Sweden*
Valérie Louis, *University Hospital Heidelberg, Germany*
Rainer Sauerborn, *University Hospital Heidelberg, Germany*

Background and Aims: The current global geographic distribution of malaria results from a complex interaction between climatic and non climatic factors. Over the past century, socio-economic development and public health measures have contributed to a marked contraction in the distribution of malaria. Previous assessments of the potential impact of global changes on malaria have not quantified the effects of non climate factors.
Methods: In this paper, we describe an empirical logistic regression model of the past, present and potential future distribution of malaria which incorporates both the effects of climate change and of socio-economic development. In our approach, we use a WHO estimate of malarious regions, present climate data published by the University of East Anglia, and socioeconomic and climatic projections based on the latest IPCC report.
Results: A logistic regression model using temperature, precipitation and gross domestic product per capita (GDPpc) identifies the recent global geographic distribution of malaria with high accuracy (sensitivity 85% and specificity 95%). Empirically, climate factors have a substantial effect on malaria transmission in countries where GDPpc is currently less than US$20 000. Using projections of future climate, GDPpc and population consistent with the IPCC A1B scenario, we estimate the potential future population living in areas where malaria can be transmitted in 2030 and 2050. In 2050, the projected population at risk is approximately 5.2 billion when considering climatic effects only, 1.95 billion when considering the combined effects of GDP and climate, and 1.74 billion when considering GDP effects only.
Conclusions: Under the A1B scenario, we project that climate change has much weaker effects on malaria than GDPpc increase. This outcome is, however, dependent on optimistic estimates of continued socioeconomic development. Even then, climate change has important effects on the projected distribution of malaria, leading to an increase of over 200 million in the projected population at risk.

ASSOCIATION BETWEEN PESTICIDES EXPOSURE AND ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

Mei-Lien Chen, *Institute of Environmental and Occupational Health Sciences, College of Medicine, National Yang-Ming University, Taipei,Taiwan*
I-Fang Mao, *Department of Occupational Safety and Health, Chung Shan Medical University, Taichung, Taiwan*
Chun-Cheng Feng, *Institute of Environmental and Occupational Health Sciences, College of Medicine, National Yang-Ming University, Taipei, Taiwan*
Chung-Kai Wu, *Institute of Environmental and Occupational Health Sciences, College of Medicine, National Yang-Ming University, Taipei, Taiwan*
Ying-Sheue Chen, *Division of Child and Adolescent Psychiatry, Department of Psychiatry, Taipei Veterans General Hospital, Taipei,Taiwan*

Background and Aims: Pesticides are used intensively in Taiwan. Residual pesticides in fruits and vegetables are commonly reported. The risk of fetus and young children exposed to pesticides is with great concern. The objectives of the study are to establish the baseline data of exposure for young children and to explore the association between pesticides exposure and attention-deficit/ hyperactivity disorder (ADHD).
Methods: There were 153 pre-school normal children (control group) and 67 doctor-diagnosed ADHD children (case group) recruited in this study. Their urine samples were collected and structured questionnaires were completed by the parents. We analyzed the parent pesticides included organochlorines, carbamates, pyrethrins, and organophosphates and the metabolites of organophosphates - six kinds of dialkyl phosphates (DAP). After pretreatment of samples, the specimens were analyzed by using GC/mass spectrometry.
Results: The detectable pesticides included diazinon, transfluthrin, chlorpyrifos, p,p'–DDT, bioallethrin, and pretilachlor. Among them, transfluthrin and bioallethrin were the highest in terms of both detection rate and mean concentration. DDT was the least detected one. More than 25% of urine samples were detected more than two kinds of pesticides. We found one of the DAP metabolites was detected in 98% of samples, and diethylthiophosphate and dimethylphosphate had the highest detection rates (64% and 62%, respectively). Children with higher urinary dialkylphosphate concentrations, especially diethylphosphate, diethyldithiophosphate and dimethyl alkylphosphate concentrations, were more likely to be diagnosed as having ADHD; the OR were 2.587, 8.014 and 2.372, after adjusting for confounding factors during pregnancy.
Conclusions: Our results suggest that Taipei children were commonly exposed to pesticides and the association between organophosphate pesticides and ADHD was statistically significant.

CHLORPYRIFOS DEGRADATION RATE FROM DIRECT PHOTOCHEMISTRY

Ohad Zivan, *Faculty of civil and environmental engineering, Technion, Israel*
Yael Dubowsky, *Faculty of civil and environmental engineering, Technion*, *Israel*.

Background: Most of the available knowledge regarding the environmental fate of pesticides focuses on their degradation in bulk water or soil. Recently, it became clear that the degradation rate and environmental fate of pesticides are affected by photooxidation reactions when pesticides are in contact with the atmosphere. Furthermore, previous studies have mainly focused on the reactivity of the parent compound only and not of its derivatives, even though degradation products may continue to pose environmental concern.
Aims: This research provides a quantitative investigation of the photo-oxidation of thin film chlorpyrifos, an organophosphate pesticide widely used in agriculture and urban environments. This includes determination of reaction rates, quantum yields and products identification.
Methods: Chlorpyrifos degradation was studied under solar radiation in ambient and synthetic atmosphere. Actinic flux and absorbance spectra of absorbed chlorpyrifos were also measured in order to calculate the quantum yield for chlorpyrifos direct photochemistry. Photo-oxidation experiments were conducted with both analytical and technical grade chlorpyrifos, as well as with its derivative: chlorpyrifos-oxon.
Results: The photo-degradation of absorbed analytical chlorpyrifos is very fast, with half-life of 1.3 hours and quantum yield of • =0.017. While the apparent photo-degradation rate of technical chlorpyrifos is faster (0.7 hours), its quantum yield is almost the same (• =0.015). The derivative chlorpyrifos-oxon is less sensitive to photo-oxidation (• =0.001), and is therefore more likely to remain longer on open atmospheric surfaces. These results imply that chlorpyrifos-oxon is more likely to be found on aerosols from treated fields. Indeed, air sampling near chlorpyrifos treated field was found to contain chlorpyrifos-oxon. 3,5,6-trichloro-2-pyridinol, which is a major product of chlorpyrifos in bulk processes, was not detected in the laboratory film samples or in the air samples.
Conclusions: The present research provides new kinetic constants and shows that surface degradation processes should be considered in understanding environmental fate of pesticides.

The study of exposure assessment using biomarkers collected from children living in an industrial complex area in Korea

Jong-Tae Lee, *Korea University, Korea.*
Jina Heo, *Korea University, Korea.*
Hyo-Mi Kim, *Korea University, Korea.*
Seung-Do Yu, *National Institute of Environmental Research, Korea*

Background and Aims: Ulsan is one of the industrial cities where a big petrochemical complex is located. Since 2003, the study named "A Prospective Cohort Study of Environmental Pollutants: A study in an industrial complex area" has been conducted to investigate health effects associated with chronic exposure to environmental pollutants in Ulsan. Children are particularly vulnerable to adverse health effects associated with heavy metal exposure(Gunnar et al 2007). So one of the goals of the research was to investigate an association between biomarkers collected from children and area where they live.

Methods: The study participants were children aged 7-13 who lived in Ulsan. Informed consent was obtained from each participant. A questionnaire survey was conducted and bio-samples such as blood and urine were collected. A total of 734 participants had been recruited for two years(2009-2010). Area was divided into 3 groups depending on their proximity to the industrial complex. Data was analyzed using logistic regression analyses.

Results: The mean levels of blood lead and cadmium in the urine were 1.67㎍/ℓ and 0.72㎍/g creatinine, respectively. We observed a significant decrease in cadmium levels with increasing age. The lead levels in children living in study areas were lower than those in children living in comparison area but the difference was not statistically significant. On the other hand, the cadmium levels in children living in study areas were significantly higher than those in children living in comparison area after adjusting for age, income, sex, the use of odorant at home.

Conclusions: Our observation supports the hypothesis that environmental exposure levels of children are correlated with their environmental quality where they live.

RISK OF PREGNANCY LOSS ACCORDING TO URINARY PHTHALATE LEVELS AROUND THE TIME OF CONCEPTION

Gunnar Toft, *Aarhus University Hospital, Department of Occupational Medicine, Denmark, guntof@rm.dk*
Bo A.G. Jönsson, *Lund University Hospital, Sweden*
Christian H. Lindh, *Lund University Hospital, Sweden*
Tina Kold Jensen, *University of Southern Denmark, Denmark*
Niels H. Hjollund, *Herning Regional Hospital, Denmark*
Anne Vested, *Aarhus University Hospital, Denmark*
Jens Peter Bonde, *Copenhagen University Hospital Bispebjerg, Denmark*

Background and aims: Animal studies indicate that some phthalate metabolites may harm female reproductive function. The main objectives was to investigate associations between exposure to phthalate metabolites and the risk of pregnancy loss.
Methods: In a previously established cohort of first pregnancy planners we analyzed four primary and two oxidized secondary phthalate metabolites in urine samples collected at day 10 after the first day of the last menstrual period before conception occurred (n=128) and during the previous cycle (if any, n=111). Subclinical embryonal loss was identified by repeated urinary hCG measurements and information on clinical spontaneous abortions was obtained by telephone interview by the mother.
Results: An increased risk of pregnancy loss (n=48, Hazard Ratio (HR) 2.11; 95% confidence interval (CI) 1.07-4.16) was found among women with urinary concentration of mono-ethylhexyl phthalate (MEPH) in the upper tertile in the conception sample compared with women in the lowest tertile. The risk of subclinical embryonal loss (n=32) was 16.54 (CI 2.22-123.27) while the risk of clinical spontaneous abortion (n=16) decreased (HR 0.17 CI (0.04-0.76). None of the other measured phthalate metabolites were statistically significant associated to increased risk of pregnancy loss.
Conclusions: The phthalate metabolite MEHP may be associated with increased risk of early embryonal loss. Since this is the first human study to show this association, and the sample size is small, the study needs to be corroborated in independent studies.

LOSS-TO-FOLLOW UP AND SELECTION BIAS IN A LONGITUDINAL STUDY OF CLEAN-UP WORKERS OF THE *PRESTIGE* OIL SPILL

Jan-Paul Zock, *Centre for Research in Environmental Epidemiology (CREAL) Barcelona, Spain*
Gema Rodríguez-Trigo, *Hospital Clínico San Carlos Madrid, Spain*
Emma Rodríguez-Rodríguez, *Spanish Society of Respiratory Medicine (SEPAR), Spain*
Aina Espinosa, *Centre for Research in Environmental Epidemiology (CREAL) Barcelona, Spain*
Ana Souto-Alonso, *Hospital Arquitecto Marcide Ferrol, Spain*
Francisco Pozo-Rodríguez, *Hospital 12 de Octubre Madrid, Spain*
Federico P Gómez, *Hospital Clínic Barcelona, Spain*
Carme Fuster, *Autonomous University Barcelona, Spain*
Josep Maria Antó, *Centre for Research in Environmental Epidemiology (CREAL) Barcelona, Spain*
Joan Albert Barberà, *Hospital Clínic Barcelona, Spain*

Background and Aims: Loss to follow-up may introduce bias in epidemiological assessments of chronic health effects of incidental environmental exposures. A baseline study conducted in fishermen two years after the *Prestige* oil spill (Spain) showed that clean-up workers had a higher prevalence of respiratory symptoms and bronchial hyperresponsiveness (BHR), and higher levels of the oxidative stress marker 8-isoprostane than non-exposed. A follow-up survey was conducted four years later. We evaluated how loss to follow-up may have introduced selection bias in the longitudinal study.
Methods: Repeated respiratory testing including BHR and 8-isoprostane level was done using identical methodology as in the baseline study. The associations between study participation and respiratory health status at baseline and at follow-up were studied separately for exposed and non-exposed.
Results: Participation rates were similar in exposed (158/230=69%) and non-exposed (57/87=66%). Among non-exposed, the prevalence of respiratory symptoms at baseline was higher among participants (38% vs. 11%; p=0.01) than among non-participants. This difference was not apparent for exposed (35% vs. 26%; p=0.22). The prevalence of BHR slightly increased during follow-up among exposed (15 to 18%) and strongly increased in non-exposed (11 to 33%). After adjustment for sex and age, Odds Ratios for BHR among responders were 2.2 (95% CI 0.8-6.4) at baseline and 0.6 (0.3-1.2) at follow-up. Mean EBC 8-isoprostane levels increased 14 to 19 pg/mL in exposed and 6 to 21 pg/mL in non-exposed, and the adjusted GM ratios were 2.3 (95% CI 1.4-3.6) at baseline and 1.0 (0.7-1.4) at follow-up.
Conclusions: A differential loss to follow-up related to baseline health status may have introduced selection bias. In addition, a marked deterioration of respiratory health status during follow-up among non-exposed but not among exposed may be suggestive of an initial selection bias that only has become apparent after several years of follow-up.

EXPOSURE ASSESSMENT OF WASTE MANAGEMENT: RESULTS FROM A MULTI YEAR FOLLOW-UP OF SOLID WASTE LANDFILLS

Enrico Davoli, *Istituto Mario Negri, Italy*
Elena Fattore, *Istituto Mario Negri, Italy*
Marinella Palmiotto, *Istituto Mario Negri, Italy*
Viviana Paiano, *Istituto Mario Negri, Italy*
Giorgio Celeste, *Istituto Mario Negri, Italy*
Maurizio Bonati. *Istituto Mario Negri, Italy*

Background and Aims: Potential risk to health from waste disposal in landfills is a public concern issue and this concern is based on equivocal evidence. The main conclusion of the overall assessment of the literature about waste management and health is that adverse effects evidence for population living near landfill is usually insufficient and inconclusive. A major problem is the weakness of quantitative exposure information and exposure assessment methods. We propose here exposure assessment based on a multi-disciplinary approach where emissions and ambient samples are characterized to assess exposure to potential hazards.
Methods: A multi year follow-up has been undertaken for two landfills that accepts non-hazardous solid waste. Exposure assessment was based on measured emissions from the landfill, both from landfill gas energy recovery systems and from uncontrolled surface emissions. Emissions and atmospheric concentrations have been assessed with analytical campaigns, sampling the main known carcinogenic compounds emitted from landfills coming both from landfill gas torch combustion (dioxins, furanes and PAHs) and from diffusive emissions (VCM and benzene). Exposure assessments were based on receptor's concentrations, using atmospheric dispersion models to estimate maximum concentrations and depositions in correspondence to sensitive receptors.
Results: Emissions from two different plants have been measured both for non-methanic volatile organic compounds PAHs and dioxin-like compounds. Results from diffusion modelling indicated limited exposure for identified receptors, with differences from year to year. Risk assessment has been performed both for carcinogenic and non carcinogenic assessment, showing acceptable risk.
Conclusion: Direct exposure measurements play a key role in order to improve the epidemiological studies for populations living in areas where waste management facilities are located or planned. A standardized approach, that might be discussed starting from this example, could become, within few years, a new instrument for environmental epidemiology in this complex problem, at least until reliable biomarkers will be available.

DIETARY BENZO(A)PYRENE AND FETAL GROWTH: EFFECT MODIFICATION BY VITAMIN C INTAKE AND MATERNAL *GSTP1* POLYMORPHISM

Jordi Sunyer, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain; Hospital del Mar Research Institute (IMIM), Barcelona, Spain; Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain; Universitat Pompeu Fabra, Barcelona, Spain*

Background and aims: Previous studies report reductions in fetal growth associated with maternal exposure to airborne polycyclic aromatic hydrocarbons (PAH), and with higher levels of DNA adducts reflecting total PAH exposure. The potential role of dietary PAHs, the main source of exposure to these compounds among non-smokers, remains uncertain. This study assesses associations between fetal growth indicators and maternal dietary intakes of PAH benzo(a)pyrene [B(a)P] during pregnancy, exploring the potential effect modification by dietary vitamin C and maternal *glutathione S-transferase pi1* (*GSTP1*) polymorphism, both hypothesized to influence PAH detoxification/metabolism.
Methods: 657 women in the INMA (Environment and Childhood) Project from Sabadell (Barcelona) were recruited during the first trimester of pregnancy. Dietary B(a)P intakes were estimated from food consumption data. Genotyping was conducted for the Ile105Val variant of *GSTP1*. Multivariable linear or logistic models were used to assess associations between size at birth and dietary B(a)P, stratified by vitamin C intakes and *GSTP1* polymorphism.
Results: There were significant interactions between elevated vitamin C intakes (above the mean, 189.41mg/day) and dietary B(a)P in models for birth weight and length ($P<0.05$), as well as small size for gestational age (SGA) ($P<0.10$). B(a)P intakes were associated with significant reductions in birth weight and length (coefficient±SE for a 1-SD increase in B(a)P: -101.63±34.62 g and -0.38±0.16 cm, respectively), and increased odds of SGA (OR for the top tertile of B(a)P: 3.51; 95%CI: 1.16-10.59) among women with low vitamin C intakes. Among these women, associations were strongest in those carrying the *GSTP1* Val allele, associated with lower contaminant detoxification activity.
Conclusions: Increasing intake of vitamin C in pregnancy could help to reduce the adverse effect of B(a)P exposure on fetal growth, particularly in genetically susceptible populations.

ASSOCIATION BETWEEN AIR POLLUTION AND MONTHLY RESPIRATORY PRESCRIBING IN PRIMARY HEALTH CARE

Eleni Sofianopoulou, *School of Medicine and Health, Durham University, UK*
Stephen Rushton, *School of Biology, Newcastle University, UK*
Tanja Pless-Mulloli, *Institute of Health and Society, Newcastle University, UK*

Background and Aims: Asthma and Chronic Obstructive Pulmonary Disease (COPD) are two of the most common chronic respiratory diseases. The effect size of exacerbation of respiratory symptoms triggered by daily variation of air pollution has been found to be between 1% (Atkinson 2001; Medina-Ramon 2006) and 7% (Laurent 2009) per 10µg/m^3. We aimed to assess the relationship between routinely collected respiratory prescribing and air quality at primary health care level using a multilevel statistical model including consideration of lags. Due to universal health care coverage in the UK this is a polulation based analysis.
Methods: We analysed respiratory medication (salbutamol) prescribed monthly by 64 primary care practices (400,000+ population) in the Northeast of England, (2002-2006) in two stages. Firstly, we used a harmonic dynamic regression model to reflect area-wide monthly average respiratory prescribing rates in relation to monthly temperature. Using the monthly prescribing rate as offset we then built the multilevel model using air quality, deprivation and demographic covariates by primary health care practice, using monthly respiratory prescribing rate as offset.
Results: Our final model showed that an increase of 10µg/m^3 in ambient PM_{10} was associated with an increase of 1% (95% CI, 0.1- 2%) in monthly salbutamol prescribing. We demonstrated that monthly respiratory prescribing in primary care can be used as indicator of air pollution effect on asthma and COPD, increasing the scope of its use for health surveillance.
Conclusions: The magnitude of effect found in this study was in the order that could be expected from studies of daily level associations between air pollution and asthma outcomes. The use of a multilevel model with offset provided a realistic representation of the relationship, as it allowed to both handle the grouped nature of primary care data and account for the seasonal variation of respiratory health outcomes.

and the EDEN study group

Background and Aims: There are sparse data about the potential effects of maternal exposure to tap water contaminants during pregnancy on child development and growth. As analytical chemistry is not able to identify all contaminants, a global approach could be usefully complementarily used. We studied the relationship between water consumption and infant growth, according to the source supplying tap water.
Methods: The EDEN cohort included 2002 women in the cities of Nancy and Poitiers before the 24th gestational week. Addresses were geo-localised and merged with data from Regional Health Agencies to get source of water used to produce tap water (surface, ground or mixed). Water consumption habits during the 1st trimester of pregnancy were estimated by self questionnaire. Infant postnatal weight growth during the first year was modelled using a mixture of measured and parent-reported data. We used regression models and partial correlation coefficients taking confounders such as breastfeeding, parental socioeconomic factors and anthropometric measurements into account.
Results: Women from Nancy were more exposed to surface water (52% *versus* 14% in Poitiers; $p<0.0001$). Birth weight and postnatal weight growth velocities were not significantly different between the cities. There was no significant relationship between maternal exposure to surface water and early weight growth velocities. However, weight growth velocities at one and three months were positively associated with the amount of consumed water among the women exposed to surface water ($r=0.11$, $p=0.03$ at 1 month) but not in the others ($r=0.00$, $p=0.98$; p-for-interaction=0.09). There was no interaction with child gender (all $p>0.20$).
Conclusions: We highlighted a weak association between amount of consumed water and postnatal weight growth in mothers exposed to tap water from sources of a lower global quality. These results encourage collecting data on water source in the birth cohorts. If they were replicated, incriminated compounds should be identified.

THE LEVELS OF POLYBROMINATED DIPHENYL ETHERS IN FOODSTUFFS AND HUMAN EXPOSURE

I-Fang Mao, *Department of Occupational Safety and Health, Chung Shan Medical University,110,Sec.1,Jiangguo N.Rd, Taichung,402, Taiwan (e-mail address: ifmao@csmu.edu.tw)*

Mei-Lien Chen, *Institute of Environmental Health Sciences, National Yang Ming University, Taipei, Taiwan*

Background and Aims: Polybrominated diphenyl ethers (PBDEs) have been widely used as brominated flame retardants (BFRs) for various electronics, manufactures, plastics, textiles and construction material. The structure of PBDEs are similar to thyroxin, could disrupt thyroid gland function, and the other adverse effects include neurotoxicity, developmental toxicity, reproductive toxicity and carcinogen. They could be detected in various environmental matrices, such as sediment, air, food and various organisms.The aim of the study is to determine PBDEs contaminate food stuff and to calculate daily intake in human.
Methods: This study determined 9 kinds of commonly foodstuffs in Taiwan by GC/ mass spectrometry, include milkfish, salmon, chicken, beef, pork, butter, egg, rice and milk. Analyses included BDE–28, BDE–47, BDE–99, BDE–100, BDE–153, BDE–154, BDE–183 and BDE–209, and daily food intake questionnaires were applied for 150 adults randomly.
Results: For dry weight, the pork samples has the highest ŽPBDEs levels (1.950±0.645 ng/g dry weight), and then are salmon and egg samples (1.300±0.184 ng/g dry weight and 1.100±0.369 ng/g dry weight); for lipid, the chicken samples has the highest ŽPBDEs levels (12.989±4.072 ng/g lipid), and then are pork and egg samples (11.130±3.775 ng/g lipid and 8.524±2.894 ng/g lipid); for wet weight, the butter samples has the highest ŽPBDEs levels (0.886±0.309 ng/g wet weight), and then are egg and pork samples (0.546±0.185 ng/g wet weight and 0.541±0.181 ng/g wet weight). Rice which levels of •PBDEs were all n.d. in our study.
Conclusions: The average daily dietary intake estimate of PBDEs was calculated.. the •PBDEs daily intake levels is 71.803±7.843 ng/day forTaiwanese, and the pork samples are the highest (22.186±12.470 ng/day), and then are egg and milk samples (16.342±6.902 ng/day and 15.983±18.100 ng/day).

CONCENTRATIONS OF POLYBROMINATED DIPHENYL ETHERS (PBDE) IN BLOOD OF PREGNANT WOMEN IN WESTERN AUSTRALIA

Ania Stasinska, *The University of Western Australia, Australia*
Jane Heyworth, *The University of Western Australia, Australia*
Andrea Hinwood, *Edith Cowan University, Australia*
Alison Reid, *The University of Western Australia, Australia*
Anna Callan, *Edith Cowan University, Australia*
Jon Oyvind Odland, *University of Tromso, Norway*

Background and Aims:
Exposure to brominated flame retardants has become an emerging area of health concern with epidemiological studies reporting neurobehavioural and neurotoxic effects. Research indicates concentrations of PBDE in blood are higher in North America (0.63-46 ng g^{-1} lipid) than Europe (0.24-2.4 ng g^{-1} lipid). Limited data are available on Australian levels. Research conducted in Australia on pooled samples ranged from 6.4 to 8 ng g^{-1} lipid.
The aim of this study was to determine concentrations of PBDEs in blood of pregnant women in Western Australia.
Methods:
Pregnant women, aged 18 years or older, non-smokers, not occupationally exposed to POPs and living in Western Australia (n=119) were recruited between 2008 and 2011 to the Australian Maternal Exposure to Toxic Substances (AMETS) study.
Participants completed a questionnaire on demographic and lifestyle information as well as activities that may increase exposure to PBDEs, for example age of the home, number of televisions and computers, recently bought furniture.
At 38 weeks gestation, participants were asked to provide a blood sample and these were analysed in an accredited laboratory for concentrations of BDE-47, BDE-99, BDE-100, BDE-153 and BDE-154.
STATA11 was used for the statistical analysis.
Results:
The mean age of respondents was 32 years and 42% lived in homes that were less than 10 years old. Households on average had 1.6 televisions and 19.4% of these televisions were a year old or less. Participants had on average 1.8 computers in their homes, 56% of computers were two years old or less. Sixty five percent of respondents had purchased new furniture in the past 12 months.
The laboratory analyses of the concentration of PBDEs in blood is in process.
Conclusions:
There are limited data on concentrations of PBDE in pregnant women and this study will provide data on exposure among Australian women, allowing a preliminary assessment of risk.

CORRELATION BETWEEN NOISE AND AIR POLLUTION – KNOWNS AND GAPS

Wim Swart, *(7) National Institute for Public Health and the Environment, The Netherlands*
Nino Künzli, *(8) Swiss Tropical and Public Health Institute, Basel, Switzerland, (9) University of Basel, Switzerland*

Background and aims: The co-exposure to both traffic-related noise and air pollution may entail a mutual confounding effect of these environmental stressors on common health endpoints such as cardiovascular disease. To disentangle their effects we evaluated the correlation between measured nitrogen dioxide (NO_2) concentrations and modelled noise levels ($LA_{eq,24h}$) and between 15-minute ultrafine particle counts (UFP) and 15-minute noise measurements (LA_{eq}) in the city of Girona.
Methods: Long-term averages of NO_2 were measured with passive samplers at 83 outdoor residential locations. These locations were assigned an $LA_{eq,24h}$ from a validated traffic noise model (NMPB-routes 96). Besides, we performed 15-minute simultaneous measurements of UFP and traffic-related noise at 31 sidewalk locations during non-rush traffic hours. These measurements were performed with a P-trak and a CESVA SC30 sonometre, respectively. Finally, we compared these results with other studies.
Results: The NO_2-noise correlation was 0.62 (Pearson). However, it was lower at sites with higher traffic density and in the downtown. Building density, distance to the street and traffic density were main determinants of the NO_2 and noise variability. Besides, we could evaluate the relationship between measurements of UFP and traffic-related noise (spearman rank=0.55). In Chicago and Riverside, the Pearson correlation between 2-week NO_2 and 5-minute noise measurements were 0.41 and 0.62, respectively, and between 5-min UFP and noise measurements it was 0.22 to 0.31 and 0.41, respectively (Allen et al, 2009). Other studies reported higher and lower correlations using modelled estimates and different air pollutants.
Conclusions: The specific characteristics of each city and each pollutant require evaluating this correlation in each study area prior to analysing the long-term effects of traffic-related noise and air pollution on potential common endpoints. Further studies should evaluate local traffic-related pollutants such as UFP and also compare modelled versus measured data and distinguish between low and high correlation locations.

Allen RW, Davies H, Cohen MA, Mallach G, Kaufman JD and Adar SD. The spatial relationship between traffic-generated air pollution and noise in 2 US cities. Environ.Res, 2009; 109: 334-342.

USING QUANTITATIVE MICROBIAL RISK ASSESSMENT (QMRA) FOR SAFE GREYWATER REUSE

Adi Maimon, *Ben Gurion University of the Negev, Israel*
Amit Gross, *Ben Gurion University of the Negev, Israel*

Background and Aims: Use of greywater for irrigating home gardens may potentially decrease domestic water consumption by over 50%, while contributing to sustainable garden irrigation in arid regions and in times of drought. Despite these important advantages, greywater reuse may also hold potential risks for public and environmental health. Pathogens in the water may spread disease through direct contact, consumption of produce, or may be transferred by vectors such as mosquitoes. The aim of the current study was to assess risks associated with on-site greywater reuse.
Methods: A quantitative microbial risk assessment (QMRA) framework (Haas et al, 1999) was used for the assessment of three pathogens; Rotavirus, Pseudomonas aeruginosa, and Staphylococcus aureus. Different theoretical and empirical exposure and risks scenarios were tested.
Results: Given the correlation between Rotavirus and *E. Coli* (WHO, 2006), it was postulated that in a single household, a maximum level of 10^2 *E. coli* CFU/100 ml is safe based on the World Health Organization acceptable risk of $1.4*10^{-3}$ for Rotavirus infection. The risk from *P. aeruginosa* and *S. aureus* in the tested exposure scenarios was so low, that it seems unnecessary to include them in the regulations. To reduce exposure level and consequently the risk, barriers such as sub-surface drip irrigation, prohibition of irrigation of vegetables that are consumed raw, and washing hands with soap, should be used.
Conclusions: As long as basic regulatory rules are maintained, greywater reuse in a single household poses little risk to public health. A similar approach should be taken towards the establishment of quantitative risk assessment for environmental pollutants such as salinity, organic matter and metals.

Background and aims: Information on the influence of long term exposure to (traffic-related) air pollution on medication use is sparse. Detailed maps of air pollution levels of PM10 and NO_2,, based on land use regression models became recently available for the whole of the Netherlands. We studied the relation between long term exposure to (traffic-related) air pollution and medication use, making use of routinely collected information at public pharmacies.
Methods: The Foundation for Pharmaceutical Statistics (SFK) routinely collects data about the use of pharmaceuticals in the Netherlands. Air pollution maps were linked to addresses and the average air pollution level was calculated for the 4-digit postal code area, which was the lowest possible aggregation level for which medication data was available. We obtained information on the total number of prescriptions within each postal code area for the prescription of antihypertensives and airway medication. The percentage of non-western immigrants and the average socio-economic status (SES) of the residents within each postal code area were used as potential confounders. Indirect standardization for gender and age was applied.A spatial regression model was used to assess a possible association between medicine use and air pollution exposure.
Results: The study area contains more than 1.5 million residential addresses, approximately one fifth of all addresses in the Netherlands. Both air pollution components were positively associated with prescriptions; with NO_2 levels statistically significant with prescription of antihypertensives (RR 1.04 per 10 µg/m^3; CI: 1.00 – 1.09) and airway medication (RR 1.05 per 10 µg/m^3; CI: 1.02 – 1.08).
Conclusion: The present study shows an association between increased (traffic related) air pollution levels and prescription of medication use for antihypertensives and airway diseases at a 4 postal code area level in an area in the Netherlands.

SEASONAL EFFECT OF $PM_{2.5}$ ON MORTALITY: A CASE-CROSSOVER ANALYSIS IN NINE FRENCH CITIES

Mathilde Pascal, *Institut de veille sanitaire, France*
Edouard Chatignoux, *Observatoire régional de la santé d'Île-de-France, France*
Vérène Wagner, *Institut de veille sanitaire, France*
Grégoire Falq, *Institut de veille sanitaire, France*
Magali Corso, *Institut de veille sanitaire, France*

Sabine Host, *Observatoire régional de la santé d'Île-de-France, France*
Laurence Pascal, *Institut de veille sanitaire, France*
Sophie Larrieu, *Institut de veille sanitaire, France*
Christophe Declercq, *Institut de veille sanitaire, France*

Background and aims: Short-term effects of airborne particulate matter on mortality have been consistently reported, especially for fine particles ($PM_{2.5}$), which are thought to contain the most harmful components. Recently, several studies in Europe and North America have suggested that the greatest effect of particles was observed during warm seasons. We examined the seasonal changes in the effects of $PM_{2.5}$ on mortality in nine French cities during the 2000-2006 period.
Methods: Data from urban air monitoring stations measuring $PM_{2.5}$ with TEOM were used to compute daily means of $PM_{2.5}$. For each city, we analysed by season the association between daily $PM_{2.5}$ and daily number of non-accidental deaths, using a time-stratified case-crossover design, adjusting on daily mean temperature at lags 0 and 1-7.
We also used a temperature-stratified case-crossover design to assess changes in the association by temperature quartiles. Analyses were carried out with and without adjustment on daily 8h-maximum levels of ozone. City specific results were combined using random effect models.
Results: Mean levels of $PM_{2.5}$ varied from 13.4 to 18.5 µg/m^3 across the cities. During the study period, a 10 µg/m^3 increase in $PM_{2.5}$ was associated with an estimated increase of 4% in the daily number of deaths [95% confidence interval: -0.3, 8.6] during summer, +0.5% [-0.7, 1.8] during fall, -1.4% [-2.6, -0.2] during winter and -0.4% [-1.8, 1.0] during spring. The association between $PM_{2.5}$ and mortality was also clearly stronger in the warmest days (Tmean>75th percentile of the temperature distribution). Adjustment on ozone did not modify substantially these results.
Conclusions: This study suggests that the effect of $PM_{2.5}$ on mortality increases during summer, especially on days with high temperatures. Seasonal differences in particulate matter composition and in individual's exposure could explain these variations.

EFFECT MODIFICATIONS OF SMOKING ON RISK OF MORTALITY ASSOCIATED WITH INFLUENZA

Background and Aims: Influenza is well known to cause heavy disease burden in both temperate and tropical/subtropical regions. Although smoking has been found to increase susceptibility to influenza infection, its role in modifying the mortality risk associated with influenza remains unexplored. This study examined the effect modifications of cigarette smoking on influenza-associated mortality in a cohort of older population in Hong Kong.
Methods: During 1998 to 2001, a total of 66,820 (22,679 males and 44,141 females) ambulatory persons aged 65 years or older enrolled in 18 Elderly Health Centres of the Department of Health in Hong Kong. They were interviewed, examined and followed up until December 2009 for mortality outcomes. They were stratified into three groups: never-, ex- and current-smokers. Cox regression models with time-dependent covariates were used to assess the excess risks (ER) of mortality associated with levels of influenza virus activity defined by the proportion of positive isolation in weekly specimens sent for making diagnosis to the Virology Laboratory of Queen Mary Hospital in Hong Kong. The modifying effect of smoking was assessed by Cox proportional hazard models with time-dependent interaction terms defined as the product of influenza and smoking variables with adjustment for potential confounding variables.
Results: ER of mortality for all natural causes associated with a 10% increase in influenza virus activity were 1.3% (95%CI: -1.6, 4.3), 4.8% (0.5, 9.3) and 5.3% (-0.6, 11.6) in never-, ex- and current-smokers, respectively. In models with interaction terms, changes in ER of mortality in ever (ex- and current) smokers relative to never smokers were 1.0% (-5.5, 7.9) and 6.0% (-0.9, 13.4) for males and females, respectively.
Conclusions: This study shows that smoking modifies the influenza burden on morality and provides evidence to support anti-smoking strategies in conjunction with other preventive measures such as vaccination and non-pharmaceutical interventions against influenza.

Q FEVER SEROLOGY AND PREGNANCY OUTCOME IN WOMEN EXPOSED TO LIVESTOCK ANIMALS

Stine Yde Nielsen, *Danish Ramazzini Center, Herning Hospital, Denmark*
Niels Henrik Hjøllund, *Danish Ramazzini Center, Herning Hospital, Denmark*
Kåre Mølbak, *Statens Serum Institute, Denmark*

Corresponding author:
Stine Yde Nielsen, Danish Ramazzini Center, Department of Occupational Medicine, Herning Hospital, Gl. Landevej 61, DK-7400 Herning
E-mail:stine.yde.nielsen@rm.vest.dk

Background and Aims: Q-fever is a bacterial zoonosis caused by Coxiella burnetii. Cows, goats, and sheep are the primary animal reservoirs and human infection occurs by inhalation of aerosols from animal birth products (Fournier et al 1998; Bosnjak et al 2010; Walsh MG 2011).
Pregnant women may, when infected, experience spontaneous abortion, preterm delivery, oligohydramnion, growth retardation and intrauterine fetal death (Carcopinho et al 2009).
Methods: The Danish National Birth Cohort collected blood samples and interview data from 100.418 pregnant women between 1996-2002 (Olsen et al2001).This study sampled 200 pregnant women with occupational exposure to domestic animals (veterinarians and female farmers), 200 women with domestic exposure (women living on farms with dairy cattle and/or sheep) and a random sample of 500 controls.
All samples were screened for antibodies against C. burnetii in a commercial enzyme-linked immunosorbent assay (ELISA). Samples positive either for IgG or IgM antibodies in the ELISA were confirmed with an immunofluorescence (IFA) test.
Results:
Reporting the IFA results, the proportion of women with serologic evidence of Q fever was significantly higher in the group with occupational exposure to livestock (19.1%, OR: 39.0; 95%CI : 11.9-128.4) as well as in the group with domestic exposure to livestock (11.0%, OR: 20.5; 95%CI: 6.1-69.2) when compared to pregnant women from the reference group (0.6% IFA positive).
However, the risk of spontaneous abortion was not higher among women with occupational exposure (0.52%, OR: 0.13; 95%CI: 0.02-1.05) nor among women domestically exposed (1.5%, OR: 0.41; 95%CI: 0.12-1.34).
Conclusions: These findings suggest that veterinarians, farmers and other people exposed to livestock, in this case dairy cattle and sheep, experience greater risk of C.Burnetii infection, but this study did not find any association between exposure and spontaneous abortion. However, an effect on early pregnancy loss cannot be detected in this design.

on behalf of the CHICOS occupational cohort working group

Background and Aims: Occupational maternal exposures during pregnancy may be hazardous to optimal fetal and child development. The prospective, population-based, birth cohort study design has not been used much in this field, mainly due to the rareness of exposures. However, because of prospective data collection, collection of information on many co-variates, and the follow-up of children after birth, such cohorts have important strengths. Therefore, a combined analysis with data from many European birth cohorts will be conducted as part of the CHICOS project to estimate whether risk of adverse birth outcomes is related to specific maternal occupations and physical load.
Methods: The ENRIECO inventory of birth cohorts in Europe (www.birthcohortsenrieco.net) was used to identify cohorts that collected maternal occupation information at any time during pregnancy and have already coded this into occupational codes. Combined analyses across these cohorts will determine whether specific occupations with *a-priori* risk indication (such as nurses, hairdressers, farmers) and physical load (determined through a job-exposure matrix) are associated with reductions in birth weight, risk of low birth weight, or reductions in gestational age.
Results*:*A total of 16 European birth cohorts have already coded the maternal occupational information collected through questionnaires into occupational codes. ISCO 88 appears to be the most frequently occupational code reported in the participating cohorts (n=10). The rest have used other occupational codes such as SOC 1999, SOC 2000, NYK or DISCO 88 that can be translated into ISCO 88. This study will be based on 250,000 mother-child pairs.
Conclusions:Pooling data on maternal occupation and birth outcomes across European birth cohorts will provide enough statistical power to disentangle the effects of specific occupational exposures and physical load on birth weight and gestational age and will allow evaluation of heterogeneity between countries in such effects.

ASSOCIATION BETWEEN ULCERATIVE COLITIS AND CLIMATIC FACTORS BASED ON COHORT OF NORWAY

Geir Aamodt, *Norwegian Institute of Public Health and Norwegian University of Life Sciences, Norway*
May-Bente Bengtson, *Tønsberg County Hospital, Norway*
Morten Harald Vatn, *University of Oslo, Norway*

Background and Aims:Incidence of ulcerative colitis has increased during the last decades and the disease also varies between countries. Incidence rates typically increase northwards at the northern hemisphere and southwards at the southern hemisphere. Temporal changes have been explained by the hygiene hypothesis but few parallel explanations exist for the spatial trend. Many factors are linked to latitude such as climate. In our investigation we studied the association between prevalent cases of ulcerative, identified through self-reported medication, and climatic factors such as mean annual temperature, maximal monthly temperature, precipitation, and altitude.
Methods:We used Cohort of Norway, a collection of ten different health studies conducted from 1994 to 2003 and from five different counties in Norway. We used the participants' self-reported use of medication (aminocalicylic acids) to identify individuals with ulcerative colitis. We included a sensitivity analysis where we studied the effect of misclassification and measurement error.
Results:Maximal monthly temperature was significantly related to the prevalence of ulcerative colitis. For each one-degree increase in maximal monthly temperature the odds for ulcerative colitis decreased with about 11% (95% CI: 4%-17%). None of the other climatic factors were significantly associated to the risk of ulcerative colitis.
Conclusions:We don't think that maximal temperature is directly related to the risk of ulcerative colitis, but that temperature is related to some unknown mechanism which again is causative for developing the disease. Our speculation is that this mechanism is species richness in organisms that can colonize the human gut. Temperature is one of the main forces governing species richness. Composition and biodiversity of the commensal gut flora is known to be one part in the process leading to ulcerative colitis.

ASSOCIATIONS BETWEEN FEMALE LUNG CANCER MORTALITY AND NO, NOX, AND NO2 IN KAOHSIUNG, TAIWAN

Shu-Yuan Chen, *Tzu Chi University, Taiwan (ROC)*

Chieh-Wen Chen, *Tzu Chi University, Taiwan (ROC)*

Yao-Chin Wang, *Tzu Chi University, Taiwan (ROC)*

Jen-Feng Yeh, *Tzu Chi University, Taiwan (ROC)*

Tzu-Chi Chiu, *Tzu Chi University, Taiwan (ROC)*

Background and Aims: Cancer and heart disease were the first and second leading causes of death and lung cancer was the most common cancer death in Taiwan. We investigated the associations between mortality from lung cancer and heart disease and long-term levels of PM10, SO2, CO, O3, NO, NOx, and NO2 in an industrial southern Taiwan city, Kaohsiung.

Methods: Our study areas were 11 townships which housed a continuous fixed-site air pollution monitoring station affiliated with Environmental Protection Administration each in Kaohsiung. Age standardized mortality rates in each township from 2007 to 2009 were obtained from Department of Health. Air pollution levels of each station were estimated from 2007 to 2009 (concurrent exposure), 2002 to 2004 (exposure of 5 years ago), 1997 – 1999 (10 years), and 1993 to 1995 (14 years), 4 exposure periods in a total. Three-year mean data were used in analyses. Pearson's correlation coefficients between mortality and pollutions were estimated.

Results: Declined trends of all pollutions but O3 were found from 1993 to 2009. High polluted townships were consistently higher than others during the 14 years. O3 was inversely related to others during 4 exposure periods. Female lung cancer mortality rates were significantly positively associated with concurrent CO (r = 0.69), and NO, NOx, and NO2 from 4 exposure periods with r ranged from 0.61 – 0.81, while negatively associated with O3 from 3 exposure periods. However, there were no significant linear correlations between male lung cancer mortality rates and pollutions. Nor were the linear correlations between both male and female heart disease mortality rates and pollutions.

Conclusions: Positive associations between female lung cancer mortality and NO, NOx, and NO2 shone line on the etiology of female lung cancer with low prevalence of cigarette smoking in Taiwan. Further studies to clarify these relationships were needed.

A RECORD LINKAGE STUDY OF ADVERSE BIRTH OUTCOMES, CHILDHOOD CANCER AND WATER CONTAMINATION BY ATRAZINE AND NITRATES IN THE MIDWESTERN UNITED STATES

Rachael Jones, *University of Illinois at Chicago, School of Public Health, Chicago, Illinois*
Raja Kaliappan, *University of Illinois at Chicago, College of Engineering, Chicago, Illinois*
Karl Rockne, *University of Illinois at Chicago, College of Engineering, Chicago, Illinois*

Background and Aims: There is limited evidence that exposure to atrazine and nitrates are associated with low birth weight, prematurity, birth defects and childhood cancer. Contamination of surface and ground water by atrazine and nitrates is high in Midwestern states that produce corn. This study will evaluate whether there is an association between water contamination of ground and surface water by atrazine and nitrates, and adverse birth outcomes and childhood cancer in the Midwest. A second aim is the development of methods to explore possible associations between water contamination and health outcomes by linking existing information from monitoring of water with health outcome data from birth certificates and for linking existing data from birth certificates with other registry data.
Methods: The target population for this study are all births that occurred between 2004 and 2008 in Indiana, Ohio, Michigan, Minnesota, Wisconsin, Indiana, Iowa, Illinois, and Missouri, which is estimated to include approximately 800,000 births. The study has three phases with each phase having greater ability to address spatial and temporal variations in exposure. The first phase is an ecologic study of birth certificate based outcomes including low birth weight and premature birth using estimates of exposure at the county level. In the second phase we will extend the study to include childhood cancers, and birth defects. In the 3rd we will link individual level data from birth certificates with tumor and birth defects registry data with individual level estimates of exposure.
Results: We have established agreements and are currently in the process of obtaining birth outcome and exposure data for all eight states.
Discussion: Many methodological challenges exist in both obtaining health data and estimating exposures for this study. These methodological challenges and results from the first phase of the data will be presented at the meeting.

PERSONAL EXPOSURE TO CARCINOGENIC AIR POLLUTANTS IN STOCKHOLM, SWEDEN: A COMPARISON OVER TIME

Yazar, Mine, *Institute of Environmental Medicine, Karolinska Institutet, Sweden*
Bellander, Tom, *Institute of Environmental Medicine, Karolinska Institutet, Sweden*
Merritt, Anne-Sophie, *Institute of Environmental Medicine, Karolinska Institutet, Sweden*

Background and Aims: Urban populations are exposed to a complex mixture of air pollution, including volatile organic compounds (VOC), nitrogen oxides and polycyclic aromatic hydrocarbons (PAH), which are carcinogenic or may be seen as indicators of co-emitted carcinogens. The aim of the present study was to measure personal exposure to carcinogenic air pollutants in Stockholm, Sweden, study time-trends, and to compare personal exposure levels with concentrations at outdoor reference sites.
Methods: Forty participants, 20-50 years of age, randomly selected among residents in the Stockholm municipality carried diffusion samplers close to the breathing zone for one week. Four different air pollutants were sampled; benzene, 1,3-butadiene, NO_x and NO_2. During the measurement period, the participants kept a diary of their daily activities and completed a questionnaire about living conditions and life style factors. Samplers were also placed at two outdoor reference sites during the same time period: one on a roof-top, representing urban background, and one by an inner-city road with heavy traffic. The study was conducted during 7 and 9 weeks during the heating season in 2003 and 2009, respectively.
Results: Levels of most of the measured air pollutants had decreased in this six-year period (by approx 50 percent), both for personal exposure and reference sites. At both occasions, the personal exposure levels were higher than the urban background concentrations. Personal levels did also not correlate to concurrent ambient concentrations.
Conclusions: Population exposure to combustion-related carcinogens in air has decreased in Stockholm, probably due to increasing use of catalytic converters and to decreased traffic because of congestion taxes. The results indicate that personal exposure levels cannot be evaluated directly from ambient concentrations, making personal sampling essential for risk assessment.

THE MECHANISMS OF MOTOR AND SENSORY NERVE DYSFUNCTION AFTER CHRONIC ARSENIC EXPOSURE IN RATS

Center for Occupational and Environmental Health and Preventive Medicine, National Cheng Kung University, Tainan, Taiwan

Background and Aims: Tens of millions of people are exposed to arsenic contaminated drinking water all over the world, including residents in Argentina, Bangladesh, Chile, China, Mongolia, Taiwan, etc. Previous studies have shown that chronic arsenic exposure could cause various cancers, skin diseases, neurological diseases, cardiovascular diseases and cerebrovascular diseases. Recent epidemiologic studies from Bangladesh showed that chronic arsenic exposure was associated with abnormal sensory nerve action potentials. We therefore set up an animal model to explore the mechanisms of neuropathy caused by chronic arsenic exposure.

Methods: We treated spontaneous hypertensive-prone rats with drinking water containing 133 μg/ml of arsenic (experimental group) for 40 consecutive weeks and compared them to a blank control group. At the end of exposure, we assessed motor functions by observing spontaneous locomotor behaviors (including motion distance and motion velocity) in the open field and monitored the sensory function by measuring the pain stimulation latency during the hot plate test. The enzymatic Na(+)/K(+)-ATPase activity of sciatic nerve was determined by a colorimetric assay, and the pathological changes and severity of neuropathy were be examined by hematoxylin-eosin stain. The possible mechanisms affecting heat shock protein 70 (HSP70) and C-reactive protein (CRP) on nerves were studied by immunohistochemistry. The arsenic levels of the whole blood and the sciatic nerve were measured using Inductively Coupled Plasma Mass Spectrometry and correlated with the toxic effects on the peripheral nerve.

Results: After arsenic exposure, the hot stimulation latencies prolonged statistically significantly in arsenic exposure rats (37.60±1.77 vs. 5.60±1.50 seconds, $p<0.05$). The motor functions in terms of motion distance, velocity and spontaneous locomotion did not decrease significantly. The Na+/K+-ATPase and CRP activities of the sciatic nerve were inhibited, but the HSP70 activity was enhanced.

Conclusions: Chronic arsenic exposure could affect sensory nerve functions probably via enhancing HSP70 and inhibiting Na+/K+-ATPase and CRP activities.

key words, arsenic, peripheral neuropathy, heat shock protein 70, C-reactive protein, Na+/K+-ATPase

THE ASSOCIATION OF MERCURY, FISH CONSUMPTION AND CHILD DEVELOPMENT IN AN EASTERN MEDITERRANEAN COHORT

Fabio Barbone, *DSMB, Udine University, Italy*
Francesca Valent, *DSMB, Udine University, Italy*
Darja Mazej, *Jozef Stefan Institute, Ljubljana, Slovenia*
Aiketarini Sofianou, *Institute of Child Health, Athens, Greece*

Maura Bin, *IRCCS Burlo Garofolo, SCO Neuropsichiatria e Neurologia Pediatrica, Trieste, Italy*
Milena Horvat, *Jozef Stefan Institute, Ljubljana, Slovenia*

Background and Aims: The effects of prenatal, low-level mercury exposure through fish consumption on neurodevelopment have been studied in several populations leading to inconsistent findings. To evaluate this association among residents in Italy, Slovenia, Croatia and Greece, we conducted a prospective cohort study within PHIME, EU Sixth FP.
Methods: Main exposure was total mercury (THg) concentration in mother's hair in pregnancy and in cord blood, and mother's fish intake in pregnancy. Child's neurodevelopmental outcomes were Bayley III composite cognitive, language, and motor scores at 18 months. A number of covariates were included in multivariate linear regression models.
Results: 2189 mothers were enrolled in the study during pregnancy. 1729 mother-child pairs provided information at child's birth. Follow-up at 18 months was 85%. The median mother's hair THg (ng/g) was 729. Mean ratio MeHg/THg was 0.90. Median cord blood THg was 3.75. Correlation between THg in hair and cord blood was: r=0.81. Median weekly servings of fish was 1.38. While unadjusted models showed a negative association of Bayley cognitive score with THg (in both hair and cord blood), after adjustment for country and relevant covariates, Bayley cognitive score was not associated with hair THg (β=0.00026; p=0.5157) nor with cord blood THg (0.048; p=0.6318) but positively associated with fish (β=0.8345, p=0.0162). Bayley language score was not associated with cord blood THg (β=0.0412, p=0.7037), borderline positively associated with hair THg (β=0.0008, p=0.0552) and positively associated with fish consumption in both unadjusted and adjusted models (β=0.8564, p=0.0083). Bayley motor score was negatively associated with hair THg in unadjusted models (β= - 0.00073, p=0.0022), but not in adjusted models (hair Thg: β= - 0.00017, p=0.553; cord blood: β=0.0038, p=0.9583).
Conclusions: In adjusted models, THg in hair and cord blood did not predict Bayley scores but a moderate beneficial effect of fish consumption in pregnancy was observed.

URBAN HEAT ISLAND AND SOCIO-ECONOMIC POSITION AS FACTORS THAT INCREASE THE RISK OF HEAT-RELATED MORTALITY IN ROME, ITALY

Francesca K. de'Donato , *Department of Epidemiology, Lazio Regional Health Service, Italy*
Michela Leone, *Department of Epidemiology, Lazio Regional Health Service, Italy*
Massimo Stafoggia, *Department of Epidemiology, Lazio Regional Health Service, Italy*
Claudia Marino, *Department of Epidemiology, Lazio Regional Health Service, Italy*
Roberto Fabrizi, *INSA, Ingeniería y Servicios Aeroespaciales, S.A.*
Paola Michelozzi, *Department of Epidemiology, Lazio Regional Health Service, Italy*

Background and Aim: High temperatures have an impact on health but few studies address the heterogeneity of the impact within cities. The study assesses the spatial variation in the impact of heat on mortality by socio–economic position (SEP) and urban heat island (UHI) in Rome.
Methods: A four-level UHI indicator by census block was defined using satellite data for summer (May-September) 2003-2006. Mortality data for residents 65+ years during summer 2004-2006 were analysed. Age, gender and SEP by census tract of residence where considered.
To investigate the spatial differences in mortality according to residence, the relative risk of dying in each UHI level adjusted for gender, age and SEP was estimated using a Poisson regression model.
The short-term impact of maximum apparent temperature (Tappmax) on mortality was estimated through a case-crossover analysis where the %increase in mortality for 1°C increment above the threshold (Tappmax=27°C) by levels of UHI and SEP was computed.
Results: Results from the Poisson regression model, adjusted for gender and SEP, showed a higher RR in mortality in the hottest areas compared to the cooler ones. However, adjusting for age showed no differential suggesting that the gradient was mainly attributable to higher proportion of elderly living in the hottest areas.
A gradient of risk for SEP and UHI in the impact of Tappmax on mortality was observed. The percent increase in mortality in the deprived areas was higher than in the richer areas (SEP4-5:4.5%vsSEP1-2:2.6%). The effect in the hot areas was double that of the cooler areas (UHI3-4:4.3%;CI95:2.2-6.4%;vsUHI1-2:2.1%;CI95%:0.3-3.9%). This difference increased with age. Furthermore, the differential was maintained when considering the increase in mortality by UHI level and SEP combined.
Conclusions: UHI and SEP are important risk factors to consider when identifying susceptible subgroups to whom prevention measures should be targeted.

Comparison of land use regression models with dispersion models in selected European cities

Barbara Hoffmann, *Institute for Medical Informatics, Biometry and Epidemiology, University of Duisburg-Essen, Germany*
Tom Bellander, *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*

Background and Aims: Few studies to this date have carried out comparisons between land use regression (LUR) models and dispersion models for their use in estimating exposures for epidemiological studies. Until now evidence suggest that LUR models predict the small-scale variation in air pollution concentrations as well or better than dispersion models. The ESCAPE project aims to get a better understanding of LUR and dispersion models by comparing the performance across a number of ESCAPE study areas.
Methods: In selected European cities, LUR and dispersion models were used to estimate a range of traffic-related air pollutants (NO2, NOx, PM10, PM2.5, and absorbance) at both ESCAPE monitoring sites and cohort addresses. Comparisons between the two methods were made at the ESCAPE monitoring sites (40 for NOx/NO2 and 20 for PM) between measured and the 2 modelled estimates.
Results: Preliminary results for the Bradford study area (UK) (NOx/NO2 only) show strong correlations using both methods on the 40 monitoring sites. Reported R2's for NOx were 0.88 (LUR, leave-one-out procedure) and 0.63 (ADMS-Urban) and respectively 0.80 and 0.51 for NO2. Correlations between LUR and ADMS for both pollutants were also high with R2 of 0.61. In Umea (Sweden) the NO2 LUR model and the AIRVIRO dispersion model were applied to over 1700 random receptors and the predicted concentrations show a good correlation (R2 = 0.58). In the Ruhr area (Germany) the LUR NOx background model and the EURAD-CTM dispersion model were applied to the cohort addresses also showing good correlation (Spearman R = 0.66).
Conclusions: Preliminary results in Bradford suggest that LUR performs slightly better than ADMS-Urban whereas in Umea and Ruhr area they show a good correlation between both methods at selected receptors. More comparisons will be presented from Stockholm, Copenhagen, Athens, Heraklion, Augsburg, Rome, the Netherlands and Helsinki.

DRINKING WATER CONTAMINATED WITH PERFLUORINATED CHEMICALS – THE USE OF MODELLED AND MEASURED SERUM CONCENTRATIONS IN EPIDEMIOLOGICAL ANALYSES.

Veronica Vieira, *Boston University, USA*
Ben Armstrong, *London School of Hygiene & Tropical Medicine, United Kingdom*

Background and Aims: The C8 Science Panel Community study in the Mid Ohio Valley comprises a number of inter-linked epidemiology studies on various outcomes, including cancer, in relation to PFOA exposure in contaminated drinking water. PFOA exposure is available as (1) measured serum levels and (2) annual modelled serum levels using fate/transport and pharmacokinetic models. The aim of this presentation is to explore the application of different exposure classification strategies, using a study of the prevalence of cancer to illustrate the issues.
Methods: Questionnaire data on cancer diagnosed in the ten years prior to the survey of 2005-6, covariate information on smoking, SES etc, and measurement of serum PFOA were available for 49,082 adults who had spent at least 12 months in one of 6 water districts contaminated with PFOA. To assess stability of ranking of individual serum levels over time, we compared serum PFOA in 2005/6 and 2010 in a nested sample of 755 participants. We use random effects logistic regression models to calculate the odds of the cancers in relation to both individual and water district area averages of serum levels, using the two measures of exposure.
Results: Among cancers diagnosed between 1996 and 2006 there were: prostate 259, breast 231, colon 125. Correlation of PFOA measured in 2005/6 to 2010 was very high (r=.79). Analyses are currently underway and results will be presented of confounder adjusted prevalence using different PFOA exposure metrics.
Conclusions: For epidemiological analyses, measured serum levels reflect individual differences both in exposure and in accumulation/excretion rates; modelled exposures track historical patterns of exposure, but with limited individual information on intake and none on accumulation/excretion rates; marked geographical clustering of exposure offer challenges and opportunities for confounder control. Serum levels correlate highly between 2005 and 2010 measurements partly due to the long serum half-life.

A STUDY ON BACTERIAL INFECTIONS AMONG 1-12 YEAR-OID CHILDREN HOSPITALIZED IN BU-ALI HOSPITAL IN ARDABIL,IRAN

Mohammad Taghi Ahady, *Dept. of Microbiology, Faculty of Medicine, Islamic Azad University-Ardabil Branch, Ardabil, Iran*
Afshan Sharghi, *Ardabil University of Medical Sciences, Ardabil, Iran*
Ramin Gosaili, *Faculty of Medicine, Islamic Azad University-Ardabil Branch, Ardabil, Iran*
Leila Asadi, *Dept .of Microbiology, Islamic Azad University-Ardabil Branch, Ardabil, Iran*
Somayeh Gholinezhad, *Dept of Microbiology, Islamic Azad University-Ardabil Branch, Ardabil, Iran*

Background and Aims: Urinary infection and bacterial septicemia are the most important clinical infections and syndromes which could lead to nephropathy, renal dysfunctions and mortality in children. This study was conducted to identify the bacterial causes of urinary infection and septicemia in 1-12 year-old children hospitalized in Bu-ali hospital in Ardabil, Iran.
Methods: In this descriptive and cross-sectional study, urine of 811 children and blood samples of 173 children hospitalized in Bu-ali hospital in Ardabil were cultured in order to study probable bacterial infections (between 2009 & 2010). The urine samples were cultured in BA & EMB and the blood samples were cultured in BHI & EMB culture media. On the other hand, to determine the antibiotic sensitivity of diagnosed bacteria, antibiogram technique was run by disk diffusion method in MHA plate.
Results: a) From 811 cultured urine samples, 534 cases were positive for E.coli (65.84%), 202 cases positive for Klebsiella (24.91%), 31 cases positive for Enterobacter (3.82%), 20 cases positive for Pseudomonas (2.47%), 20 cases positive for Staphylococcus (2.47%) and 4 cases were positive for Proteus (0.49%). b) From 173 cultured blood samples, 142 cases were positive for Staphylococcus (82.08%), 11 cases positive for Streptococcus (6.36%), 9 cases positive for Klebsiella (5.20%), 7 cases positive for E.coli (4.05%) and 4 cases were positive for Enterobacter (2.31%). c) Antibiogram results showed that E.coli bacteria were sensitive to Nalidixic acid & Nitrofurantoin, Klebsiella were sensitive to Amikacin & Nalixic acid and Staphylococcus bacteria showed high sensitivity to Amikacin & Nalidixic acid and Staphylococcus bacteria showed high sensitivity to Amikacin & Co-trimoxazole.
Conclusions: Escherichia coli and Klebsiella were the most prevalent bacteria in the urine samples and Staphylococcus bacteria were the highly prevalent ones in the blood samples. The most effective antibiotics were Nalidixic acid & Nitrofurantoin for E.coli, Amikacin & Nalidixic acid for Klebsiella and Co-trimoxazole & Amikacin for Staphylococcus, respectively.

GENOME-WIDE INTERACTION STUDY OF CUMULATIVE PARTICULATE MATTER EXPOSURE ON AGE-RELATED LUNG FUNCTION DECLINE IN ADULTS, THE SAPALDIA COHORT.

Ivan Curjuric, *Swiss Tropical and Public Health Institute, Switzerland and University of Basel,Switzerland*
Sally LJ Liu, *Swiss Tropical and Public Health Institute, Switzerland and University of Basel, Switzerland*
Ashish Kumar, *Swiss Tropical and Public Health Institute, Switzerland and University of Basel, Switzerland and Wellcome Trust Centre for Human Genetics, University of Oxford, United Kingdom*
Thierry Rochat, *Division of Pulmonary Medicine, University Hospitals of Geneva, Switzerland*
Nino Künzli, *Swiss Tropical and Public Health Institute, Switzerland and University of Basel, Switzerland*
Nicole M Probst-Hensch, *Swiss Tropical and Public Health Institute, Switzerland and University of Basel, Switzerland*

Background and Aims: Air pollution exposure accelerates age-related lung function decline. There is however evidence that i) genetic variation in individuals determines the susceptibility to ambient air pollution and ii) asthmatics are more prone to accelerated lung function decline than non- asthmatics. We investigated the interaction of genome-wide data with particulate matter (PM) exposure on the annual rate of lung function decline in an agnostic approach.
Methods: 2'500K single nucleotide polymorphisms (SNPs) of 455 asthmatic and 699 non-asthmatic SAPALDIA participants with individual exposure data for 11-year cumulative PM of mean diameter <10µm (PM10) was used. Annual rate of lung function decline (•) was calculated for five spirometric parameters (FEF25-75, FEV1, FVC, FEF25-75/FVC, FEV1/FVC). They were regressed on PM10, the SNP allele dosage and their interaction term adjusting for study center, sex, height, age, packyears, asthma self-report and ancestry informative covariates. We also stratified analyses by asthma status. Only SNPs with minor allele frequency (MAF) >5% were considered.
Results: In both groups combined, the top-ranking interaction signal was observed for • FEV1 ($P=4.07x10^{-8}$; MAF:6%) and contained genes *CRHR2/INMT*, both involved with lung health. Another prominent signal for • FEF25-75 was in *TRAM2*, a gene involved in collagen synthesis ($P=8.78x10^{-8}$; MAF 37%).
In non-asthmatics, a highly prevalent variant (MAF:45%) at 7q22.1 was a top-ranking interaction signal and reached $P=4.15x10^{-9}$ for • FEF25-75 (rank1), $1.31x10^{-6}$ for • FEF25-75/FVC (rank10), $3.08x10^{-6}$ for • FEV1 (rank73) and $6.98x10^{-7}$ for • FEV1/FVC (rank12).
In asthmatics, the top-ranking locus interacting with PM10 ($P=7.27x10^{-12}$, MAF: 8%) contained genes *MYO15A* , necessary for cilia function, and *DRG2*, expressed in normal fibroblasts and linked to the infectious disease progression. Variation in a locus *ZDHHC19/OSTalpha/PCYT1A* (MAF:20%) was interacting with PM10 exposure on • FVC and • FEV1 ($P=9.82x10^{-9}$; $P=1.05x10^{-8}$).
Conclusions: This preliminary evidence of interactions requires replication within the SAPALDIA cohort (N=4000) and collaborative efforts with other studies.

AIR POLLUTION AND LUNG HEALTH IN AUSTRALIAN SCHOOL CHILDREN: A PANEL STUDY

Bin Jalaludin, *Centre for Research, Evidence Management and Surveillance, Australia*
Gail Williams, *University of Queensland, Australia*
Guy Marks, *Woolcock Institute for Medical Research, Australia*
Lynette Denison, *EPA Victoria, Australia*

Background and Aims: We aimed to quantify the effect of ambient air pollution on lung function in a national sample of Australian school-children in a panel study.
Methods: We recruited children with asthma for the panel study from the cross-sectional component of the Australian Children's Health and Air pollution Study. Children were from 51 primary schools that were within 2.5km of 27 air monitoring sites in six cities. Children recorded lung function, asthma symptoms and asthma medication used twice a day in their asthma diary for a six week period. We used generalised linear models to examine associations between air pollutants and lung function and symptoms. Multi-pollutant models were examined. Mean NO_2 levels were 18.7ppb 1-hr average (range 0–69ppb) and 7.9ppb 24-hr average (0–30.8ppb).
Results: Two hundred and seventy children participated in the panel study (girls: 46%; mean age: 10 (SD=1.2) years. About 94% of the children kept a diary for at least four weeks. The most consistent results were seen with NO_2. In single pollutant models there were consistent relationships between NO_2 and night symptoms (cough, wheeze and shortness of breath) and effects were greater for NO_2 24-hr than for NO_2 1-hr. There were also more consistent relationships between NO_2 and day time symptoms and effects were greater for NO_2 24-hr than for NO_2 1-hr. Children were also more likely to use more reliever medications for asthma on days with higher NO_2 concentrations. In two pollutant models with ozone, the effects of NO_2 on lung function were increased, effects on symptoms decreased slightly and effects on daytime medication use were no longer significant.
Conclusions: In this panel of Australian school children, effects of air pollution on lung health were most consistently observed with NO_2.

ASSOCIATION BETWEEN ORGANOCHLORINE PESTICIDE EXPOSURE AND THYROID HORMONES IN FLORICULTURE WORKERS

Marina Lacasaña, *Andalusian School of Public Health, Granada, Spain ; Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain*.
Clemente Aguilar-Garduño, *Andalusian School of Public Health, Granada, Spain.*
Miguel Rodríguez-Barranco, *Andalusian School of Public Health, Granada, Spain.*
Inmaculada López-Flores, *Genetic department. Granada University School of sciences, Spain*
Julia Blanco-Muñoz*, National Institute of Public Health, Cuernavaca (Mexico*)
Susana Bassol, *School of Medicine of Torreón, Autonomous University of Coahuila, Mexico*
Mariano E. Cebrian, *Center for Advanced Studies and Research of the National Polytechnic Institute, Mexico DF, Mexico.*

Background and Aims: Different studies have shown that *p,p`*-DDE (a stable metabolite of DDT) alter thyroid hormone levels in animals and humans, although results across studies are inconsistent. The aim of this study was to assess the association between exposure to DDT and serum levels of thyroid hormones in floriculture workers.
Methods: A longitudinal study was conducted on 136 male subjects from the State of Mexico and Morelos, Mexico, which were occupationally exposed to non persistent pesticides, during agricultural periods of high (rainy season) and low (dry season) levels of pesticide application. Using a structured questionnaire, a survey was carried out on sociodemographic characteristics, anthropometry, clinical history, alcohol and tobacco consumption, residential chemical exposure, and occupational history. Blood and urine samples were taken to determine serum levels of TSH, total T_3, total T_4, and *p,p'*-DEE, and metabolites of non-persistent pesticides, respectively. The analysis of the association between *p,p'*-DEE levels and thyroid hormonal profile was carried out using multivariate generalized estimating equation (GEE) models.
Results: Our results showed an increase in both T_3 and T_4 hormones in serum associated with a increase in total *p,p'*-DEE levels in serum (*p*-trend<0.05), independently of the levels of organophosphate pesticides and other potential confounding factors.
Conclusions: These results suggest that exposure to organochlorine pesticides may be responsible of increasing T_3 and T_4 serum hormone levels, therefore supporting the hypothesis that persistent organochlorine pesticides alter thyroid function in humans.

INDOOR / OUTDOOR AIR QUALITY RELATIONSHIP IN AN URBAN ENVIRONMENT: DUBLIN CASE STUDIES.

Avril Challoner, *Trinity College, Ireland*
Dr Laurence Gilll, *Trinity College, Ireland*

Background and Aims: Legislative reductions in air pollutant limits values seek to better outdoor air quality, in turn reducing associated illnesses such as cardiopulmonary mortality, strokes and lung cancer. This study focuses on two major traffic related pollutants NO_x (NO_2 + NO) and $PM_{2.5}$. Previous research suggests that people now spend up to 90% of their day indoors yet in Ireland no legislative indoor air pollutant limits exist. A study carried out a study on 57 office environments and found 75% of our daily NO_2 exposure occurred while at work (Lee et al., 2000). This research aims to determine the relationship between exposure of staff to specific air pollutants in Irish working environments (e.g. shops, offices) and factors such as ventilation systems and door design.
Methods: NO_x data is gathered by a monitor working on Chemiluminescence principles and $PM_{2.5}$ by a monitor using light scattering and Gravimetric techniques. Monitors are placed inside and outside (roof and street levels) of the buildings and run continuously for 4 days per run.
Results: To date monitored 5 work places located on busy street canyons of the city centre in Dublin, Ireland have been monitored. Clear relationships between indoor and outdoor concentrations could be seen for sites. Results indicate that indoor concentrations can be significantly greater than outdoor concentrations, Indoor Outdoor ratios of up to 3.97 for NO and 2.13 for $PM_{2.5}$.
Conclusions: I/O indicate greater exposure to those working within the affected buildings than ambient outdoor concentrations indicate. The compliance of Ireland and many other European countries to air quality limit values is based on outdoor air quality; these results show that outdoor monitoring alone may not be enough to quantify true exposures of those working in urban areas.

URINARY CONCENTRATIONS OF PHTHALATES AND PHENOLS IN A POPULATION OF SPANISH PREGNANT WOMEN AND CHILDREN

Lidia Casas, *Center for Research in Environmental Epidemiology (CREAL), Spain*
Mariana F. Fernández, *University of Granada, Spain*
Sabrina Llop, *Valencian Center for Research on Public Health-CSISP, Spain*
Mikel Basterrechea Irurzun, *Instituto de Investigación Sanitaria BIODONOSTIA, Spain*
Adonina Tardón, *University of Oviedo, Spain*
Martine Vrijheid, *Center for Research in Environmental Epidemiology (CREAL), Spain*
Antonia M. Calafat, *Centers for Disease Control and Prevention (CDC), USA*
Jordi Sunyer, *Center for Research in Environmental Epidemiology (CREAL), Spain*

Background and aims: phthalates and phenols exposure is prevalent among the general population and of potential concern for pregnant women and children because of their suspected susceptibility to endocrine effects. In the present study, we aimed to evaluate the extent of exposure to several phthalates and phenols in a sample of Spanish pregnant women—according to their individual characteristics (age, social class, education, body mass index)—and children who participated in the INMA – Infancia y Medio Ambiente (Environment and Childhood) project.
Methods: one spot urine sample was taken during the third trimester of pregnancy from 120 pregnant women and from 30 4-year old children belonging to 5 Spanish birth cohorts, and analysed for 11 phthalate metabolites and 9 phenols.
Results: Three metabolites of di(2-ethylhexyl) phthalate, mono-2-ethyl-5-carboxypentyl phthalate, mono-2-ethyl-5-hydroxyhexyl phthalate, and mono-2-ethyl-5-oxohexyl phthalate; two metabolites of dibutyl phthalates, mono-isobutyl phthalate and mono-n-butyl phthalate; monoethyl phthalate (MEP), the main metabolite of diethyl phthalate; and two phenols, methyl paraben (M-PB) and 2,5-dichlorophenol were detected in the urine samples of all women. The highest urinary concentrations were for MEP and M-PB. Urinary concentrations of all phthalate metabolites and of 2,4-dichlorophenol, 2,5-DCP, and bisphenol A were lower in the pregnant women than in the children. Among women, a positive relationship with social class and education was shown for most of the phthalate metabolites and phenols. Almost all phthalate metabolites varied by region even after adjusting for social class and education.
Conclusions: Phthalate and phenol exposures are prevalent in a group of pregnant women and young children, two susceptible populations, and these exposures might be positively related to social class.

Hospital Landscape Design in Denmark - Staff Experiences in Using the Garden

Shureen Faris Abdul Shukor, Kjell Nilsson, Ulrika Stigsdotter, *University of Copenhagen, Denmark*
Ulrika Stigsdotter, *University of Copenhagen, Denmark*
Kjell Nilsson, *University of Copenhagen, Denmark*

Background and Aims: Healthcare occupations traditionally are stressful because they involve an overload from work demands and stress from rotating shifts. However, numerous studies have shown that gardens in healthcare facilities used by staff gave positive outcomes in terms of restoration and recovery-relief from work place stress. This study investigates hospital landscape in five acute-care hospitals located in the Capital Region of Copenhagen, Denmark. It aims to identify how the landscapes are used by the staff and their experiences of restoration while being in the garden.
Methods: The Perceived Restorative Scale (PRS) ranging from 0 (no) to 10 (completely) was used in the questionnaires and Nvivo 8 was used to organize and evaluate the interview results. A total of 183 staff answered the questionnaires and 15 staff (three from each hospital) were selected for an in-depth interview.
Results: Preliminary findings show that hospital staffs, due to their nature of work, have limited time to spend in the hospital garden. The duration of time spent in the garden ranges from five to ten minutes. The result also indicates that two of the most frequent involving the staff while in the garden are having lunch and smoking. Gardens were also utilised as a quick passing through from buildings. Majority of staff mentioned that hospital landscape should be designed with priority to the needs of patients before theirs (the staff). The results also indicate that due to the limitation of time to take breaks while working, the gardens are underutilised by staff.
Conclusions: Recommendations such as easy accessibility to gardens from their work stations and view of the garden from their work windows should be considered for the Danish hospitals.

CLIMATE CHANGE AND HEALTH IN THE EASTERN MEDITERRANEAN: POTENTIAL EFFECTS AND POSSIBLE SOLUTIONS

Eric Amster MD MPH, *Haifa University, Israel and Harvard University, USA*
Ziad Abdeen PhD MPH, *Al-Quds University, Palestine*
Aaron Bernstein, *Harvard University, USA*

Background and Aims: The effects of climate change on human health are varied and dependent on geographical location. Theses effects include alteration of infectious disease distribution, air pollution, extreme weather events, increased incidence of certain diseases, desertification, drought, and food insecurity (Haines 2004). Many of these effects are pronounced in arid climates such as the Eastern Mediterranean where water scarcity has historically been a source of political, social and economic instability. Our aims are 1) to present the literature on the health effects of climate change and its relevance to health in the Eastern Mediterranean; 2) to discuss potential for collaboration, specifically amongst Israelis and Palestinians, in addressing the shared public health hazards of climate change.
Methods: We present a literature review on the impacts of climate change on desertification, access to potable water, frequency of dust events, and prevalence of disease in the Eastern Mediterranean. Climate models for the Eastern Mediterranean region and their relevance to public health outcomes are assessed. Current mitigation strategies and potential for collaboration in adaptation measures amongst Israelis and Palestinians are explored.
Results: Recent models predict a mean temperature increase of 1.6º to 1.8ºC, a 4 to 8% precipitation reduction, and 12-88cm increase in sea level in the region by 2100 (Pe'er 2000). Collaborations on the health impacts of climate change include: coordination of meteorological, CO_2 concentration, and air pollution monitoring; coordination of disease registries and databases; and shared surveillance of water, food and vector-borne disease outbreaks.
Conclusions: National borders do not serve as protection from the potential effects of climate change on human health. The Eastern Mediterranean, given its arid climate and limited water supply, is likely to have significant public health consequences related to climate change. Further collaboration in understanding and addressing climate change is crucial to ensure the health of all people in the region.

COHORT OF NORWAY: ACIDIC DRINKING WATER AND THE RISK OF FOREARM-FRACTURE

Cecilie Dahl, *Norwegian Institute of Public Health, Norway*
Anne Johanne Søgaard, *Norwegian Institute of Public Health, Norway*
Grethe S. Tell, *University of Bergen, Norway*
Truls Krogh, *Norwegian Institute of Public Health, Norway*
Trond Peder Flaten, *Norwegian University of Science and Technology, Norway*
Geir Aamodt, *Norwegian Institute of Public Health, Norway*

Background and Aims: The prevalence of forearm fractures in Norway is high, and it increases with increasing degree of urbanization. We have investigated whether the quality of drinking water may explain this urban-rural gradient. In Norway, pH in drinking water should be 7.5-8.5. We know that pH < 7.5 could be unfavorable to bone-health, with less bicarbonate and calcium, and more heavy metals available. The relationship between drinking water and fractures has not previously been studied on a population level.
Methods:"Cohort of Norway" comprises ten population-based surveys with 174,430 participants aged 20 years or more answering 50 common questions, one concerning former forearm fractures. Geographic Information Systems were used to link the survey-information to the waterworks-registry, based on the participants' home-addresses. Analyses were limited to 126,923 individuals with valid information on exposure, outcome and relevant covariates (age, BMI, marital status, urbanization). For adjustment, we also included the acidity-level in raw-water as a proxy for non-measured water-quality factors.
Results: The pH in tap water was less than 7.5 for 72% of participants, and overall 14% reported having suffered a fracture. Water with pH < 7.5 was associated with an increased risk of forearm fracture in men, compared with pH≥7.5 (OR 1.17, 95% CI 1.12-1.21). A similar odds ratio was observed in women. Adjustment for the covariates did not significantly change these estimates. Including pH-level in raw-water weakened the association, and in women it was only borderline significant (p=0.07).
Conclusions Our results suggest that the pH in drinking water influences the risk of forearm fractures, independently of degree of urbanization and other background factors. The effect of tap water with pH < 7.5 on fracture-risk may to some extent be confounded by the quality of the raw water.

A CASE-CROSSOVER STUDY OF HOSPITAL ADMISSIONS FOR CORONARY HEART DISEASE AND METALS IN AIR POLLUTION NEAR AN ITALIAN STEEL PLANT

Fabio Barbone, *DSMB, Udine University, Italy*
Anica Casetta, *DSMB, Udine University, Italy*
Ettore Salvagni, *ARPA FVG, Italy*
Flavio Moimas, *ARPA FVG, Italy*
Gianna Zamaro, *Health Cities, Udine, Italy*

Background and Aims: Variation in the chemical composition of fine dust might entail different acute and chronic cardiovascular risks. To evaluate the association of daily levels of metals in outdoor air with acute hospital admissions for coronary heart disease (CHD), we conducted a case-crossover study in a population located near a large steel plant.
Methods: A GIS mapped residential history of Friuli Venezia Giulia population (Northeastern Italy) was completed. Among residents within 5km from the main chimney of the steel plant, we mapped cases of CHD (ICD9CM 410-414) admitted between 8/1/2002 and 3/9/2007. Concurrently, daily air concentration of Mn, Fe, Ni, Zn, Cd, Pb, Cr, V and As was measured at a monitoring station located 600 m from the chimney. We used the time-stratified approach for the case-crossover analysis, i.e., referent days were the same day of the week within the same month as the index day. As exposure we considered the average of the cumulative 0- to 2-day lag for each metal. Conditional logistic regression, adjusted for outdoor temperature and humidity, was used to estimate the OR of CHD hospitalization by quartile of exposure and to evaluate trends. Analyses were conducted for cases located within 5km, 2km, in the prevalent wind direction (to SW) and by gender. Case validation with hospital charts is underway.
Results: 274 residents in the area were hospitalized for CHD. Among cases within 5km from the point source, results did not show consistent associations. However, within 2km from the steel plant, the risk of CHD hospitalization increased significantly at higher Mn, Zn and Pb levels. Among cases residing in the SW quadrant the association was even stronger, especially among women, and involved also Cd and Cr.
Conclusions: This case-crossover study provides evidence that environmental exposure to metals may act as a trigger of CHD hospitalization.

PRECIPITATION AND VARIOUS DEGREES OF HEALTH CONSEQUENCES IN TAIWAN (1994–2008)

Mu-Jean Chen, *Department of Environmental and Occupational Health, National Cheng Kung University*

Huey-Jen Su, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, No. 138, Sheng-Li Rd, Tainan 704, Taiwan.*

Background and Aims: Precipitation intensities appeared to have increased over the recent decades. Heavier precipitations are reported to result in direct causalities or .to affect mental health indirectly. Yet, only limited studies have established the quantitative relationships between levels of precipitation and various types of public health consequences in a subtropical region like Taiwan.

Methods: Data of the daily accumulated precipitation, temperature and daily registration of cause-of-death were integrated from 352 townships between 1994 and 2008 in Taiwan. The relationship between precipitation and reporting cause-of-death on accidental deaths, excluding those from earthquake events (ICD-9: E800–E949) and suicidal death (ICD-9: E950–E959), were analyzed with Spearman correlation coefficient, Poisson regression and further mapped by geographical information system (GIS).

Results: The preliminary findings indicated a positive correlation between precipitation level and various public health consequences. Every 30mm increase of precipitation was significantly associated with an elevated risk of accidental death (RR= 1.022, 1.015–1.030) and suicidal death (RR= 1.025, 1.007–1.026) after adjusted for temperature, season and location of death registry. Results also indicated that precipitation of the very day was the significant variable, compared to that of any previous days. Risk map was constructed according to the estimated level.

Conclusions: A quantitative assessment was successfully conducted between the estimated level of precipitation and the registered deaths due to accidents and suicides. Future studies may take into account the availability of medical resources or sanitary infrastructures before concluding the exact association between precipitation intensity and various causes of death.

LOW-LEVEL ARSENIC EXPOSURE AND OBSTRUCTIVE PULMONARY DISEASE IN THE U.S. POPULATION

Eric Amster MD MPH, *Harvard University, USA*
David Christiani MD MS *Harvard University, USA*

Background and Aims: Arsenic is a known carcinogen found in drinking water throughout the world. Contaminated aquifers in parts of India, China, and Bangladesh have resulted in the poisoning of hundreds of millions of people. An unknown number of workers have occupational exposures from wood preservation, glass production, smelter operation, and semiconductor manufacturing. An emerging body of evidence suggests that exposure to inorganic arsenic may be associated with non-malignant respiratory disease.
Methods: We attempt to determine if there is an association between arsenic exposure at levels seen in the U.S. and prevalence of asthma, emphysema, and chronic bronchitis. Urinary arsenic is collected on 5,365 participants from a representative sample of the U.S. population. Linear regression analysis compares geometric means for participants with and without pulmonary disease. Logistic regression calculates odds of having pulmonary disease comparing participants with the highest and lowest quintiles of urinary arsenic. Two novel methods to adjust for the component of organic arsenic are incorporated into the statistical model
Results: Geometric mean concentration of urinary arsenic for participants with versus those without asthma (0.97;95%CI 0.94-1.01), chronic bronchitis (1.00;95%CI 0.98-1.03), and emphysema (1.00;95%CI 0.96-1.04)are not significantly different. Odds of having asthma is 0.77 (95% CI 0.4-1.47) for participants with the highest quintile of urinary arsenic (• 17.23 mcg/dl) when compared to the lowest quintile (• 3.52 mcg/dl). A significant association is found between increasing urinary arsenic concentration and decreasing age, male gender, and non-“Caucasian race”
Conclusions: After controlling for potential confounders and adjusting for organic arsenic exposure, we find no evidence of association between urinary inorganic arsenic and prevalence of asthma, chronic bronchitis or emphysema.

EFFECTS OF LIFETIME AIR POLLUTION EXPOSURE ON LUNG FUNCTION DURING CHILDHOOD

Anna Mölter, *Centre for Occupational and Environmental Health, The University of Manchester, UK*
Frank de Vocht, *Centre for Occupational and Environmental Health, The University of Manchester, UK*
Sarah Lindley, *School of Environment and Development (Geography), The University of Manchester, UK*
Raymond Agius, *Centre for Occupational and Environmental Health, The University of Manchester, UK*
Angela Simpson, *The University of Manchester, University Hospital of South Manchester NHS Foundation Trust, UK*

Background and Aims: Previous studies of effects of air pollution on lung function in children have shown heterogeneous results. Although some studies have suggested a negative association between air pollution and lung function, others found no effect, while effects for specific pollutants, for specific lung function measures or in specific subpopulation only have also been reported.
One common limitation of previous studies has been the use of pollution exposure data, which does not allow for spatial and temporal variation and may not reflect individuals' exposure. We have developed and validated a comprehensive exposure model of lifetime exposure to PM_{10} and NO_2 for children, which incorporates spatio-temporal variation by combining time-activity data with concentrations in the home, school and during home-school travel, the microenvironmental exposure model (MEEM). The aim of this study was to assess the effect of lifetime PM_{10} and NO_2 exposure on forced expiratory volume in one second (FEV_1) within the setting of a population based birth cohort study, the Manchester Asthma and Allergy Study.
Methods: Participants were recruited prenatally. FEV_1 was measured at age 5, 8 and 11 years and results were expressed as % predicted FEV_1. Children's exposure to PM_{10} and NO_2 was estimated retrospectively using MEEM. The model estimated PM_{10} and NO_2 concentrations (in $\mu g/m^3$) for a typical day for each month of the child's life. This data was aggregated to provide exposure windows of 0-5, 0-8 and 0-11 years, for approximately 400 children. Multiple linear regression was used to asses the effect of modelled exposure on lung function, adjusting for sensitisation and asthma or current wheeze.
Results: No significant associations were found between FEV_1 % predicted and lifetime PM_{10} or NO_2 exposure ($p>0.05$).
Conclusions: This study found no significant association between lung function in children and NO_2 and PM_{10} exposure, despite the use of a detailed exposure assessment methodology.

A SENTINEL CASE SERIES OF CANCER PATIENTS WITH OCCUPATIONAL EXPOSURES TO ELECTROMAGNETIC NON-IONIZING RADIATION WITH SHORT LATENT PERIODS

Yael Stein, *Hebrew University-Hadassah Jerusalem Israel*
Levy-Nativ, *Hebrew University-Hadassah Jerusalem Israel*
Elihu D Richter, *Hebrew University-Hadassah Jerusalem Israel*

Background and Aims: We have reported groups of workrers with high exposures to Non-Ionizing Radiation and short latent periods for cancer. We present a sentinel case series (n=47, 40M, 7F) of self-referred cancer patients with occupational exposures to EMF.Our aim was to report ages of first diagnosis/latency and tumor type and exposures
Methods: We categorized patients with regard to types of radiation, far or near field exposure and direct body contact**,** age of diagnosis and latency. For some we had data on frequencies, for others we provided assessments
Results: 15 patients developed cancer with latent periods < 5y and 12 patients with latent periods between 5y and 10y. The remaining 20 patients had longer latent periods In the <5y latency group there were 8 hematolymphatic cancers and 9 solid tumours – testis, head & neck (including brain) and GI tract. In both the <5y and 5-9y latency groups there were patients exposed to intense levels of EMF, to several frequencies of EMF, or to EMF in combination with IR or other exposures. There were patients with direct body contact, or were in direct line of focus from point sources, or worked in small, electronically dense environments. In the >10y latency group there were more patients with intermittent exposures or exposures at older ages.
Conclusions: The data suggest that cancer in young workers may be associated with intense severe exposures to EMF and short latent periods, especially for hematolymphatic cancers. The findings state the case for (1) more careful modelling of exposure sources and penetration into the body, (2) preventive and protective measures based on control of exposure at source, barriers, and personal protection and (3) exploring low-exposure-low risk relationships for latent periods <10 y

CONCENTRATIONS OF OZONE AND MORTALITY IN TAIWAN: PRESENT AND FUTURE

Mu-Jean Chen, *Department of Environmental and Occupational Health, National Cheng Kung University, College of Medicine, National Cheng Kung University, Taiwan.*

Szu-Yu Yeh, *Department of Environmental and Occupational Health, National Cheng Kung University, College of Medicine, National Cheng Kung University, Taiwan.*

Huey-Jen Su, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Taiwan.*

Background and Aims Global climate disruption has been implicated to influence air pollution profiles through altering atmospheric compositions and chemical processes, and result in deteriorating air quality. This study therefore aimed to examine the association between variations of temperature, ozone (O_3) concentrations and mortality in Taiwan aiming to facilitate the projection of elevated health risk in the future.

Methods Database was first set up to integrate daily temperature, humidity, O_3 concentrations and a daily registration of cause-of-death from 1994 to 2008 in six major cities (Keelung, Taipei, Taichung, Chiayi, Tainan and Kaohsiung) of Taiwan. The population from 2010 to 2060 was based on projection by Taiwan Council for Economic Planning and Development. Generalized additive models (GAMs) and meta-analysis of random effect measured the local and regional relative risks of mortality after applying the population projections of six cities to calculate the expected number of deaths above the baseline (1994–2008) for the projected period of 2035–2050.

Results A 10-ppb increase in 2-day-lag of O_3 concentrations was associated with an higher risk in non-accidental-all-causes mortality for all population (RR_{pooled}= 1.065, 1.049–1.081); yet, not for population over than 65 years (RR_{pooled}= 1.010, 0.961–1.062) in Taiwan. For projecting number of daily deaths attributable to O_3 concentrations, an average increase of 3 ppb of O_3 concentrations for all 6 cities was assumed, Having applied a steady exposure–response relationship though the period of 2035–2050, the projected increase of mortality appeared to range between 2.3% (Taichung), the lowest to 10.7% (Taipei), the highest.

Conclusions The estimated level of increased risk associating rising pollution level and mortality further justify the urgent need for both global and regional adaptation strategy.

EARLY LIFE EXPOSURE TO AIR POLLUTION AND RESPIRATORY SYMPTOMS IN CHILDREN: RESULTS FROM A BIRTH COHORT

Marina Davoli, *Department of Epidemiology, Regional Health Service, Lazio, Italy*
Francesco Forastiere, *Department of Epidemiology, Regional Health Service, Lazio, Italy*

Background and Aims: Ambient air pollution has been consistently associated with exacerbation of respiratory symptoms in schoolchildren, but the role of early exposure to traffic-related air pollution in the first occurrence of respiratory symptoms and asthma is not yet clear. We assessed the association between exposure indexes of traffic-related air pollution during early life and respiratory outcomes in a birth cohort.
Methods: A cohort of 708 newborns, residents in a district of Rome (Italy), was enrolled in 2003-2004. Direct interviews to the mother were done at birth and at 6, 15 and 48 months of life. Exposure to NO2 was assessed for each follow-up periods, using the estimates derived from a Land Use Regression model (LUR). For each residential address, GIS variables of proximity to high traffic roads (more than 10,000 vehicles/day, HTR) and traffic density were derived. We used current values of NO2 and GIS indexes for each age as well as NO2 weighted lifetime average values to take into account early pre- and post-natal exposure. Associations with respiratory symptoms (at 6, 15 and 48 months) were assessed with logistic regression (odds ratios, OR) using a cross-sectional and a longitudinal approach (GEE model).
Results: There was no association between the exposure indices and the respiratory outcomes in the longitudinal model, except for wheezing and metres of HTR (150 meters buffer) (OR=1.62; 95%CI, 1.04-2.54). A stronger association was found at 4 year for wheezing and for lower respiratory infections with distance from HTR (OR=2.84; 95%CI, 1.30-6.19 and OR=3.69; 95%CI, 1.61-8.46, respectively), and for doctor-diagnosed asthma with weighted average NO2 (OR=3.07; 95%CI, 0.99-9.54) and metres of HTR in a buffer of 150 metres (OR=3.47; 95%CI, 1.06-11.35).
Conclusions: Consistently with results from literature, some associations between respiratory outcomes and GIS variables and NO2 values were found, especially at 4 years of age.

ASSOCIATION OF TRAFFIC RELATED AIR POLLUTION AND SUBCLINICAL ATHEROSCLEROSIS IN MEDITERRANEAN TOWNS OF THE REGICOR STUDY

Background and aims: Traffic-related air pollution causes cardiovascular disease and death. Most evidence relates to short-term exposure causing acute effects like myocardial infarction and stroke. However, it is still unknown whether the long-term exposure is associated to the development of atherosclerosis. We investigated the cross-sectional association between traffic-related air pollutants and the carotid intima media thickness (IMT), an established marker of subclinical atherosclerosis, in participants of the REGICOR study, a population based cohort in Girona (Spain).
Methods: We measured the IMT by ultrasound of the carotid artery in 2,215 participants of the REGICOR study during a re-examination in 2007-2009. We assigned exposure using outdoor NO2 levels, derived with a land use regression model, and traffic proximity metrics at the participant's home address at the time of the IMT measurement. Multiple linear regression was used to assess the association of air pollution with IMT.
Results: An 11µg/m3 increase in NO2 (interquartile range) was associated with a 1.1% (95% CI: -0.17% to 0.24%) increase in IMT in the crude analysis. After adjusting for age and sex, the change in IMT was -0.17% (CI: -1.22% to 0.87%). Further adjustment for education, occupational status, marital status, smoking, hypertension, diabetes, body mass index, and physical activity did not change the results. Associations were modified by educational level with stronger estimates in the highly educated population (1.77% change in IMT, CI: -0.50% to 4.04%). There was no evidence of interactions with sex, age, smoking, hypertension or lipid-lowering medication.
Conclusions: We found no association between long-term exposure to NO2 and IMT. The interaction with socio-economic status (i.e. educational level) needs further investigations. In subsequent analyses we will assign exposure based on the participant's 10-year address history and consider adherence to Mediterranean diet as a potential effect modifier.

JAPAN ENVIRONMENT AND CHILDREN'S STUDY – PILOT STUDY AND RESEARCH LAUNCH

Kei Mori, *Ministry of the Environment, Japan*
Eisaku Toda, *Ministry of the Environment, Japan*
Takeo Fujiwara, *National Center for Child Health and Development, Japan*
Toshihiro Kawamoto, *University of Occupational and Environmental Health, Japan*
Hiroshi Nitta, *National Institute for Environmental Studies, Japan*
Hiroshi Satoh, *Tohoku University, Japan*

Background and Aims: Basic Plan of the Japan Environment & Children's Study(JECS) formulated in 2010 is aimed at identifying environmental factors affecting children's health. The study follows birth cohort studies such as the Hokkaido (20,000 children) and Tohoku (1,300 children). JECS is designed on a large scale to study multiple hypotheses concerning the impacts of environmental chemicals on pregnancy and reproduction outcomes, congenital abnormalities, psychoneurological development, the immune system and allergies, and the endocrine system.
Methods: Participants of the Study are 100,000 newborns and their parents. Recruitment of pregnant mothers will span a 3-year period commencing in January 2011 with following-up until the age of 13. A community-oriented hospital-based recruitment approach was adopted, covering more than 70% of deliveries in each 15 region. The target recruitment ratio of 70% will ensure the participation of more than 50% of the births. Regular questionnaires, biospecimens and environmental samples will be collected and analyzed. Results and medical outcome will be stored in a database and analyzed by the research group, and also made available for other studies
Results: In the pilot studies, recruitment started in two regions by four universities in February 2009. Consent was obtained from 453 pregnant women, the recruitment ratio ranging from 69.3% to 98.5%. The lessons obtained in the pilot study are incorporated into JECS continually. In JECS, many research coordinators were trained with common manuals related to informed consent, protection of personal information, etc. The recruitment and collecting data are being conducted in each 15 regional unit centers in Japan.
Conclusions: JECS will be the largest birth cohort study in Japan, and one of the largest in the world. It is expected that the Study will result in a great scientific contribution of the children's health and environment.

WHAT IS THE BEST INDICATOR OF THE ADVERSE HEALTH EFFECTS OF COMBUSTION PARTICLES: BLACK CARBON OR PARTICLE MASS?

Nicole Janssen, *National Institute for Public Health and the Environment (RIVM), Netherlands*

Bert Brunekreef, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, Netherlands*
Flemming Cassee, *National Institute for Public Health and the Environment (RIVM), Netherlands*

Background and Aims: Current air quality standards for particulate matter use the mass concentration (PM10 or PM2.5) as a metric. It has been suggested that particles from combustion sources are more health relevant. Expressed in reduction of the total mass concentration the impact of policies directed at reducing particles from combustion processes is usually relatively small. We therefore evaluated the value of black carbon particles (BCP) as an additional indicator in air quality management.
Methods. We consider different measurement methods for BCP and compare the near roadway concentration gradients of BCP with those of PM mass. We review the evidence comparing the health effects of BCP with those of PM mass. We compare the potential health benefits of a hypothetical traffic abatement measure calculated based on concentrations response functions for BCP with those based on PM2.5.
Results. Near roadway concentration gradients are much steeper for BCP than for PM mass. A relatively large part (40-70%) of the roadside increment in PM2.5 mass concentrations can be attributed to BCP. Health effect estimates from mortality and morbidity time-series studies as well as cohort studies were higher for BCP than for PM10 or PM2.5 when expressed per $\mu g/m^3$. When applying the calculated Relative Risks (RR) for all cause mortality from cohort studies, the increase in life expectancy associated with a hypothetical traffic abatement measure was four to nine times higher when expressed per achievable reduction in BCP compared to that per an equivalent amount of PM2.5 mass.
Conclusion. BCP is a valuable additional air quality indicator to evaluate the health risks of air quality dominated by primary combustion particles

COMPARISON OF LAND-USE REGRESSION MODELS OVER A THREE YEAR PERIOD IN OSLO, NORWAY

Bert Brunekreef,*The Institute for Risk Assessment Sciences (IRAS), Utrecht University, The Netherlands - Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, The Netherlands*

Background and Aims: Spatial modelling of traffic-related air pollution by the use of land-use regression models have increasingly been applied in epidemiological studies. These models provide higher spatially resolved data, but assume that the spatial contrasts are stable over longer periods of time.
Methods: We tested the stability of measured and modelled spatial contrasts over a three year period in Oslo, Norway. A land-use regression model was previously developed to estimate individual exposures in the area based on samples of traffic-related air pollution during the winter of 2005. A total of 69 of these locations were sampled during the same period in 2008.
Results: The final regression models much of the variability in the measurements with an adjusted coefficient of determination (R^2) of 0.66 for nitrogen oxides (NO_x), 0.72 for nitrogen dioxide (NO_2), and 0.56 for nitric oxide (NO). Furthermore, the measurements from 2008 correlated well with the measurements sampled in 2005 (r = 0.91 - 0.95).
Conclusions: Our study found that the spatial contrasts which applied in the model based on the 2005 samples still applied to a large extent when used to predict the samples from 2008 or vice versa (r = 0.65 – 0.85). This suggests that this land-use regression approach for modelling of small-area variation in traffic-related nitrogen dioxide can be used to describe long-term concentrations for individual exposure.

ASSOCIATIONS BETWEEN TRAFFIC AND CARDIOVASCULAR MORTALITY IN A COHORT OF CALIFORNIA WOMEN

Bart Ostro, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain
Michael Lipsett. California Department of Public Health, Richmond, California, USA
Peggy Reynolds, Cancer Prevention Institute of California, Berkeley California, USA
Debbie Goldberg Cancer Prevention Institute of California, Berkeley California, USA
Andrew Hertz, Cancer Prevention Institute of California, Berkeley California, USA
Cynthia Garcia, California Air Resources Board, Sacramento, California, USA

Background and Aim: Several studies have reported associations between exposure to traffic and cardiovascular events and mortality. We examined relationships between exposures to traffic and various measures of mortality and morbidity in a cohort of over 65,000 residentially stable female teachers and administrators participating in the California Teachers Study, who were followed from 1996 though 2005. Mean age of the cohort at inception was 54; the baseline active smoking rate was 5%, and participants had similar occupational exposures.
Methods: Participants' geocoded addresses were linked with cross-sectional measures of traffic intensity from the year 2000. We developed three measures of traffic exposure: (1) traffic density (estimated number of vehicle miles traveled within 150 m of a participant's residence; (2) proximity to a highway within versus beyond 150 m; and (3) vehicle density (number of vehicles registered in each participant's Census block group, divided by the block group area). Using Cox proportional hazards models, we examined associations between these metrics and several measures of mortality, as well as incident myocardial infarction and stroke.
Results: We observed several associations between traffic density and elevated risks of all-cause, cardiopulmonary, and cardiovascular mortality, with statistically significant risk gradients with increasing vehicle density. For example, the hazard ratio for participants in the 90^{th} percentile of traffic density in relation to those below the 50^{th} percentile was 1.20 (95% CI = 1.03, 1.39) for cardiovascular mortality. Associations were not observed between traffic density and incident myocardial infarction or stroke, or for any of the other traffic metrics.
Conclusion: This study provides additional evidence that exposure to traffic is associated with mortality from heart disease in a cohort of middle-aged and older women.

THE EFFECTS OF PARTICULATE AIR POLLUTION ON HOSPITAL ADMISSIONS FOR CARDIAC DISEASES IN POTENTIALLY SENSITIVE SUBGROUPS. A MULTICITY CASE-CROSSOVER ANALYSIS

Maria Angela Vigotti, *Dept. of Biology, University of Pisa, Italy*
Francesco Forastiere, *Dept. of Epidemiology, Regional Health Service, Lazio Region, Rome, Italy*

Backgrounds and aims. Several studies have shown that particulate air pollution with aerodynamic diameter less than 10 micrometers (PM_{10}) is associated with increased risk of hospital admissions for cardiovascular causes. However, only few studies focused on subgroups of population especially susceptible to these effects. The objective of the present study was to estimate the short-term association between PM_{10} and cardiac hospital admissions, and to identify susceptible groups.

Methods. A "time-stratified" case-crossover study was carried out in 9 Italian cities from 2001 to 2005. The associations between daily PM_{10} and all cardiac diseases (CD), acute coronary syndrome (ACS), arrhythmias and conduction disorders (ACD), and heart failure (HF) were estimated for hospitalizations of 65+ year-old subjects. The effect modification was assessed assuming age, gender and hospital diagnoses from the previous two-years as susceptibility factors.

Results. A total of 167,895 hospitalizations of 65+ year old with a diagnosis of cardiac diseases were considered. The excess risk of CD was 1.03% (95% confidence interval: 0.69-1.38) per 10 ug/m^3 PM_{10} at lag 0 and was lower on the following days. The effect was slightly higher for HF (1.37%; 0.74%-2.00%, lag 0) and ACS (1.13%; 0.37%-1.89%, lag 0-1) than for ACD (1.00%; 0.22%-1.78%, lag 0). Women were at higher risk of PM_{10}-related HF admissions (1.99%; 1.17%-2.82%; p-interaction = 0.022) and 75-84-year-old subjects were at higher risk of ACS admissions (2.61%; 1.49%-3.75%; p-interaction = 0.001). Previously diagnosed hypertension, arrhythmias and heart failure were suggested as effect modifiers of the PM_{10}-heart failure association.

Conclusions. An important effect of PM_{10} on hospitalizations for cardiac diseases was found in Italian cities. Women, 75-84 year-old subjects and subjects whit previous cardiovascular diseases were susceptible to the PM_{10} effects.

ACUTE HEALTH EFFECTS OF TRAFFIC RELATED AIR POLLUTION AND INTERDEPENDENCIES WITH PHYSICAL ACTIVITY

Background and Aims: The acute health responses in healthy populations resulting from exposure to traffic related air pollution remain unclear. Few studies have assessed simultaneously exposures and acute health markers associated with traffic related air pollution under real world conditions. Ambient factors can potentiate the adverse health responses compared to those shown in chamber studies. The role of physical activity as a potential effect modifier of such health effects is poorly understood. This project aims to determine the physiologic responses in a healthy population in Barcelona following short term exposures representative of a commuting environment under real world conditions.
Methods: Crossover study comparing the physiologic responses pre- and post-exposure to traffic related air pollution. Thirty non-smoking subjects are exposed for 2 hours to contrasting pollution levels while either cycling or resting. Each volunteer is to undergo all four conditions (high vs. low exposure; moderate physcial activity vs. resting). Personal exposure monitoring involves particulate matters of different size diameters, NOx, CO, CO2, elemental carbon (EC), and noise levels. Health endpoints measurements include pulmonary function and inflammation, cardiovascular effects like blood pressure, heart rate variability and oxygen saturation. Blood and urine sampling serves for determination of short acting biomarkers and oxidative stress levels.
Results: Preliminary descriptive analysis from first sessions show concentrations of EC, NOx, and ultrafine particles levels at the high exposure site on average 2, 4.2, and 3.2 times higher than the low exposure site, respectively. Associations with health responses in different sites will be reported in the course of the study.
Conclusions: Findings from this study are expected to inform about the health responses in different levels of air pollution associated with or without moderate physical activity as they appear in commuting, and thus allows deriving recommendations for planning transportation microenvironments that promote better physical and psychological wellbeing.

INTEGRATED ENVIRONMENTAL HEALTH IMPACT ASSESSMENT AT THE SCIENCE-POLICY INTERFACE: GENERATING POLICY-RELEVANT KNOWLEDGE

EM Kunseler, *PBL Netherlands Environmental Assessment Agency, The Netherlands*
AB Knol, *RIVM, The Netherlands*

Background and Aims: The study explores which science-policy activities have been undertaken in the case studies of two EU consortium projects funded under the EU 6th Framework Programme: INTARESE (Integrated Assessment of Health Risks of Environmental Stressors in Europe) and HEIMTSA (Health and Environment Integrated Methodology and Toolbox for Scenario Assessment). If science and policy actors communicate throughout the assessment process, this is likely to lead to more policy-relevant assessments. This implies among other things that the assessment needs to be:

- specifically targeted to address relevant policy questions and stakeholder perspectives;
- discussed with relevant stakeholders;
- expressed in indicators that are adapted to the underlying policy question and target audience

Methods: A questionnaire on science-policy activities was distributed among 11 case study groups. Responses have been collected from seven groups: two HEIMTSA case studies (on noise and heavy metals), four INTARESE case studies (on water, waste, transport and agricultural land use) and the INTARESE-HEIMTSA common case study on health impacts of climate change policies in Europe.
Results: The findings indicate that the INTARESE and HEIMTSA case studies principally use a science-based approach. The studies did not extensively consider the three science-policy challenges, outlined above, for more openness in problem framing, participation during the assessment process and the policy relevance of the assessment outcomes.
Conclusions: limited science-policy activity
The case studies were set up, primarily, to test the INTARESE and HEIMTSA methodology, and were not intended to actively engage in the science-policy process. Partly because of the methodological and expert-oriented character of the case studies, they did not extensively consider the science-policy challenges. It would be interesting to explore science-policy activities in future assessments that are driven more profoundly by actual policy questions commissioned by policymakers.

TRAINING OF HEALTH RISK ASSESSORS IN EUROPE – DEMAND, NEEDS AND SUPPLY

Capleton A, *Duarte-Davidson R & Thomas E, Health Protection Agency, Chilton, UK*
Nieuwenhuijsen M, *Centre for Research in Environmental Epidemiology, Barcelona, Spain*
Czerczak S, *Gromiec J & Palaszewska-Tkacz A, Nofer Institute for Occupational Medicine, Lodz, Poland*
Lumens M, *Institute for Risk Assessment Sciences, Utrecht, the Netherlands*
Ravazzani P, *CNR National Research Council ISIB and ICEMB UNIGE, Milan-Genoa, Italy*

Background and aims: Health risk assessment is an essential tool in protecting public health and a key aspect of EU policy and legislation. There is a lack of coordinated training opportunities for health risk assessors in Europe. The aim of the Risk Assessment and Management – European Training Programme (Risk ASSETs) project is to bring together technical specialist, including Epidemiologists, Toxicologists and Environmental Assessors to develop a suitable training programme to address this need.
Methods: A literature review and survey of health risk assessors was undertaken. From this, competencies for health risk assessors were developed and agreed at two international workshops. These were used to develop the curriculum and course module outlines. Epidemiology is a core component of the project and is integrated in all relevant teaching material. Additionally, a review of administrative frameworks for different professional development schemes is being undertaken in order to develop an administrative framework to deliver training across the EU.
Results: The training needs of health risk assessors in Europe are broad and encompass the needs of health risk assessors in regulatory bodies, public health, industry, consultancies and research. The proposed competencies aim to address this broad range of training needs. Consideration has been given to developing essential knowledge and key skill in Epidemiology within the context of health risk assessment. The proposed training scheme allows a non-specialist scientist to undertake a modular programme to qualify as a health risk assessor, with the option of tailoring their training to suit their specific role as a health risk assessor. The proposed administrative system coordinates training across Europe, allowing a trainee to undertake training in different European countries.
Conclusions: There is a substantial need for more coordinated health risk assessment training opportunities in Europe. The Risk ASSETs project provides a proposed health risk assessment training model for Europe. Such a training scheme has the potential to improve the quality of health risk assessments undertaken and, subsequently, improve public health protection.

RELATIONSHIPS BETWEEN ESTIMATED AMBIENT TEMPERATURE VARIATIONS AND MORTALITY IN THE ELDERLY

Tzu-I Sung, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Taiwan.*

Mu-Jean Chen, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan*

Huey-Jen Su, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan*

Background and Aims: The elderly may not have the effective thermoregulatory responses to heat stress, and are therefore less adapt to sudden changes in ambient temperature. This study aimed to evaluate the relationship between variations in ambient temperature from 1994 through 2008 and overall daily mortality as well as cardiovascular and respiratory mortality in the elder population of Taiwan.

Methods: Meteorological data provided by the Central Weather Bureau (CWB) of Taiwan were interpolated to create representative estimates of diurnal temperature variation of 352 townships by the kriging methods. Daily mortality data were retrieved from the Taiwan Death Registry, Department of Health. The generalized linear models and Poisson regression were used to analyze the impact of variations in mean difference of diurnal temperature on overall, cardiovascular and respiratory mortality, controlling for calendar month and demographic regions.

Results: The increasing percentiles of diurnal temperature variation appeared to be associated with mortality risk compared with 0–4th and presented a rising trend. Risk ratios of daily mortality for temperature variations of 10.5°C and 12.2°C (95th and 99th percentiles) were significantly elevated for both genders, especially in cold weather. These risks seemed to increase to a greater scale among a sub-metropolitan city, an isolated island and mountain areas. After performing stratified analyses by gender, elderly women were found to be more susceptible to extremely high temperature variations at the 99th percentiles and more likely to die of cardiovascular and respiratory diseases.

Conclusions: A positive correlation was detected between temperature variation and mortality in the elderly. The increase in death events correlated with higher percentiles of temperature variations suggests that the increasing dynamics of temperature are a valid reflection of greater risk, highlighting the need for precautionary measures.

HIGHER URINARY 1-HYDROXYPYRENE LEVELS FOR RESIDENTS LIVING CLOSER TO A PETROCHEMICAL COMPLEX

Yu-Yen Chin, *National Taiwan University, Taiwan*

Chang-Chuan Chan, *National Taiwan University, Taiwan*

Background and Aims: This study measured urinary 1-hydroxypyrene as a biomarker to assess people's exposure to polycyclic aromatic hydrocarbons (PAHs) emitted from a petrochemical complex.

Methods: We defined the downwind areas within 10 km radius of the petrochemical complex as the exposed zone and the upwind areas of 25 km away from the complex as reference zone. Residents who have lived in the chosen zones for more than 5 years were randomly selected as study subjects by three age groups, i.e. 6-15 years, 35-60 years, and 61 years and older. Spot urine samples were collected and analyzed for 1-hydroxypyrene by a HPLC-florescent method.

Results: Urinary 1-hydroxypyrene concentrations of 328 subjects in the exposed zone (0.20±0.36 • mol/mol-creatinine) were significantly higher than those of 189 subjects in the reference zone (0.08±0.06 • mol/mol-creatinine) by t-test. Combined, urinary 1-hydroxypyrene concentrations in 6-15 years age group (0.11±0.16 • mol/mol-creatinine) were statistically lower than those in the other 2 age groups (0.16±0.30 and 0.21±0.39 • mol/mol-creatinine) by ANOVA-test. And 1-hydroxypyrene concentrations were higher in residents who exposed to ETS or incense, but were not different by gender. The zone effect on urinary 1-hydroxypyrene levels remained significant after adjusting for covariates of age, sex, smoking, ETS, grilled food consuming and incenses burning in regression models.

Conclusions: The result of this study showed that residents' 1-hydroxypyrene concentrations were significantly related to zone effect, indicating their proximity to a large industrial point source of PAHs.

MATERNAL EXPOSURE TO ORGANOPHOSPHATE PESTICIDES, PON1 POLYMORPHISMS AND MISCARRIAGE

Marina Lacasaña, *Andalusian School of Public Health, Granada, Spain ; Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain.*
Julia Blanco-Muñoz, *National Institute of Public Health, Cuernavaca (Mexico*)
Beatriz González-Alzaga, *Andalusian School of Public Health, Granada, Spain.*
Clemente Aguilar-Garduño, *Andalusian School of Public Health, Granada, Spain.*
Miguel Rodríguez-Barranco, *Andalusian* School of Public Health, Granada, Spain.
Oscar Pérez-Méndez O, *National Institute of Cardiology "Ignacio Chavez". Mexico DF, Mexico*
Ricardo Gamboa, *National Institute of Cardiology "Ignacio Chavez". Mexico DF, Mexico*

Background and Aims: Although there is evidence from animal studies of impaired reproductive function by exposure to OP, the effects on spontaneous abortion have not been sufficiently evaluated in epidemiological studies. Paraoxonase (PON1) detoxifies organophosphates by cleavage of active oxons. Some *PON1* gene polymorphisms could reduce the enzyme activity and increase susceptibility to OP toxicity. The aim of this study was to asses the association between occupational exposure of women to organophosphate pesticides (OP) and miscarriage, and to evaluate the association of PON1 polymorphisms of mothers ($PON1_{55}$, $PON1_{192}$ and $PON1_{-108}$) on miscarriage.
Methods: A cross-sectional study was conducted in a population of women resident in communities highly exposed to OP. A total of 313 women, floriculture workers or spouses/couple of floriculture workers, were selected. They all had at least one pregnancy during last 10 years. We obtained information for 534 pregnancies. The $PON1_{55}$ and $PON1_{192}$ genetic variants were obtained by PCR-RFLP, while the $PON1_{-108}$ polymorphism was analyzed by RT-PCR.
Results: we do not found a significant association between occupational exposure to pesticides and miscarriage. Concerning PON1 polymorphisms, the risk of miscarriage was twice higher in mothers carrying the PON1 192RR genotype compared 192QQ genotypes (OR=2.2; 95% CI 0.93, 5.36). The $PON1_{55}$ M allele shown a higher risk of miscarriage compared with mothers carrying the $PON1_{55}$ LL genotype (OR=4,8; IC95% 1,6–14,2).
Conclusions: These results suggest that women carrying genotypes $PON1_{192}$ RR, $PON1_{55}$ MM and $PON1_{55}$ ML which are exposed to OP have higher risk of miscarriage.

WEATHER AND CHILD MORTALITY IN CAPE TOWN, SOUTH AFRICA

Sari Kovats, *London School of Hygiene & Tropical Medicine. UK*
Hassan Mahomed, *University of Cape Town, South Africa*
Pamela Groenewald, *South African Medical Research Council, South Africa*
Ben Armstrong, *London School of Hygiene & Tropical Medicine. UK*

Background and Aims: Evidence for the impacts of temperature upon daily mortality has been based upon studies on high income populations in Europe, East Asia and North America and children's mortality has been little studied. We describe the associations of heat and cold with child mortality in a population with a temperate climate, large heatlh inequalities and high rates of child mortality.
Methods: Individual mortality data for the population Cape Town (2001-2004) were divided into age and cause of death groups. The association of ambient temperature with daily mortality was analysed using Poisson regression models, adjusted for time varying confounders, including season, particulate air pollution, influenza, day of week, relative humidity and autocorrelation. To quantify the temperature effects, linear associations of lag 0-2 temperature above a heat threshold and lag 3-13 below a cold threshold were assumed. Here we focus on children (ages 0-14).
Results: Child mortality increased with heat, by 5.29% (95% CI 2.38,8.28) per °C above 19°C. The association was present for all causes of death and in particular for infectious diseases (6.68% (3.16,10.32)). Cold temperatures (below 12^{o}C) were also associated with excess mortality. The effects of heat on child mortality appear to be delayed and there is little evidence of short term mortality displacement.
Conclusions: Hot and cold weather have important associations with mortality in children in Cape Town. This suggests a large avoidable burden of heat on children in this population, and further research should be undertaken on potential public health interventions.

INCREASED FRACTIONAL EXHALED NO AND DECREASED LUNG FUNCTION ARE ASSOCIATED WITH ULTRAFINE PARTICLES AND NOT OTHER PM CHARACTERISTICS: HEALTH EFFECT ASSESSMENT IN THE RAPTES PROJECT

Maciej Strak, *National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands; Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands*

Erik Lebret, *National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands; Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands*
Bert Brunekreef, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands*
Gerard Hoek, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands*
Nicole Janssen, *National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands*

Background and aims: Epidemiological studies demonstrated adverse health effects of ambient particulate matter (PM), but it is not clear which characteristics (e.g., size, composition) or sources of PM are responsible for observed effects. The aim of RAPTES (Risk of Airborne Particles: Toxicological-Epidemiological hybrid Study) is to study effects of various PM characteristics on volunteers exposed experimentally to air pollution in several real-world settings.
Methods: Thirty healthy volunteers were exposed multiple times at different sites in the Netherlands: two traffic sites, underground train station, farm and urban background. High contrast and low correlation between PM characteristics were documented in a preceding screening phase. Exposure of volunteers and air pollution characterization took place on 30 days (March-October 2009) over five-hour sampling periods and included measurements of PM_{10}, $PM_{2.5}$, particle number concentration (PNC), trace metals, and total PM oxidative potential. Participants followed a fixed exercise protocol on stationary bicycles. Fractional exhaled nitric oxide (FE_{NO}; non-invasive marker of airway inflammation) and spirometry were measured before and at three different time points after exposure.
Results: Exposure to PNC during five-hour exposure was significantly associated with volunteers' FE_{NO}: immediately and two hours after exposure we observed an 11.6% increase over baseline in FE_{NO}, with 7.4% increase the next morning. PNC was also significantly associated with a 1% decrease in FEV_1 and FVC at most time points.
PM_{10}, $PM_{2.5}$ and total PM oxidative potential were not associated with changes in respiratory health parameters. PM characteristics were not associated with changes in PEF and FEF_{25-75}.
In multi-pollutant models, effects of PNC remained significant whereas effects of other PM characteristics still did not show (significant) associations.
Conclusions: An increase in FE_{NO} and decrease in lung function was observed in young, healthy volunteers following a five-hour exposure to ambient air pollution. These effects were specifically associated with PNC and not with other PM characteristics.

DISCORDANCE BETWEEN ONE-HOUR AND ANNUAL LIMITS OF THE WORLD HEALTH ORGANIZATION AIR QUALITY GUIDELINE (WHOAQG) FOR NO2

Hak-Kan Lai, *School of Public Health, The University of Hong Kong, Hong Kong SAR, China*
Anthony J Hedley, *School of Public Health, The University of Hong Kong, Hong Kong SAR, China*
Chit-Ming Wong, *School of Public Health, The University of Hong Kong, Hong Kong SAR, China*

Background and Aims: It is important to ensure the short-term and annual AQG are valid and robust to provide support to setting standards which, if enforced, will reliably ensure that exposure reduction targets are met effectively for health protection.
Methods: We developed a lognormal distribution model to examine the relationship between short-term and annual AQG for NO_2 using data in 2010 in Hong Kong and London. This model, which takes into account the allowable exceedances of AQG, was robust after extreme values (4 times the geometric standard deviation above the geometric mean) were excluded [2].
Results: The WHOAQG of 40• g/m^3 cannot be achieved through compliance with short-term limit of 200• g/m^3. The predicted 1-hr AQG is sensitive to the standard deviation of the ambient mass concentration, and estimated to be 140• g/m^3 and 128• g/m^3 in Hong Kong and London respectively. In the model validation using WHO 24-hr AQG for PM_{10} / $PM_{2.5}$, we obtained reliable prediction of annual AQG for PM_{10} (21.5• g/m^3) and $PM_{2.5}$ (10.3• g/m^3) in Hong Kong.
Conclusions: The large difference between WHO 1-hr limit (200• g/m^3) and the predicted limit indicates statistical discordance between the short-term and annual NO_2 limits in the current WHOAQG, in contrast to other criteria pollutants. Based on public health principles, the short- and long-term epidemiologic evidence and need to ensure validity of health impact assessments, the 1-hr AQG should be between 128 and 140• g/m^3 given the standard deviations observed in typical traffic dense environments. Factors affecting the standard deviation may include number of monitors, sampling locations, pollution sources, and meteorological factors. Data from other cities is needed.

EFFECT OF PARAOXONASE-1 (PON1) POLYMORPHISM AND PESTICIDE EXPOSURE ON BIOMARKERS OF HEPATOTOXICITY

Antonio F. Hernández, Fernando Gil, Antonio Pla Department of Legal Medicine and Toxicology, University of Granada School of Medicine (Spain),
Marina Lacasaña Andalusian School of Public Health, Granada (Spain) ; Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP),
Miguel Rodriguez-Barranco Andalusian School of Public Health, Granada (Spain)
Tesifón Parrón Council of Health at Almeria province (Spain).

Background and aims. Exposure to pesticides which are metabolically activated in the liver may elicit subtle and early biochemical changes of hepatotoxicity. This study assessed whether long-term exposure to pesticides in occupational settings (intensive agriculture within plastic greenhouses) induces changes in liver function parameters. The interaction effect between exposure to pesticide compounds and polymorphisms in pesticide-metabolizing genes is also evaluated.
Methods. A longitudinal study was conducted on a population of intensive agriculture workers from Andalusia (South Spain), during two periods of high and low-intensity levels of pesticide application. A structured questionnaire containing questions on sociodemographic and occupational characteristics was completed by workers. Blood samples were taken for the measurement of biomarkers of exposure (serum and erythrocyte cholinesterases), susceptibility (Paraxonase-1 –PON1-) and effect (liver biochemistry, including aspartate and alanine transaminases –AST and ALT, respectively-, cholestasis enzymes (gamma-glutamyl transpeptidase and alkaline phosphatase) and serum lipids –tryglycerides, total cholesterol, HDL-cholesterol and LDL-cholesterol). Interaction effects between cholinesterases and PON-1 polymorphisms on biological indicators of hepatotoxicity were performed by generalized estimating equations (GEE) models.
Results. Short-term exposure to pesticides as measured by a reduction in serum cholinesterase was associated with decreased levels of liver parameters and serum lipids with the exception of HDL-cholesterol. By the contrast, cumulated exposure to pesticides (as reflected by reduced erythrocyte cholinesterase) was associated with increased levels of AST and alkaline phosphatise and increased levels of serum lipids (tryglycerides, total cholesterol and LDL-cholesterol) and reduced levels of HDL-cholesterol. PON1 polymorphisms significantly contributed to changes in ALT. A significant interaction effect was found between the PON1-192Q allele and erythrocyte cholinesterase on triglyceride and HDL-cholesterol levels.
Conclusions. Pesticide exposure may induce a different profile of hepatotoxicity depending on the exposure (either short- or long-term). In the latter, pesticides exposure was associated with a proatherogenic lipid profile and this involved particularly the PON1-192Q allele.

INTERACTION BETWEEN PESTICIDE-METABOLIZING GENES AND PESTICIDE EXPOSURE ON BLOOD ANTIOXIDANT ENZYMES

Antonio F. Hernández, Fernando Gil, Antonio Pla Department of Legal Medicine and Toxicology, University of Granada School of Medicine (Spain),
Miguel Rodriguez-Barranco Andalusian School of Public Health, Granada (Spain)
Marina Lacasaña Andalusian School of Public Health, Granada (Spain) ; Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP),
Tesifón Parrón Council of Health at Almeria province (Spain).

Background and aims. Pesticide-induced oxidative stress may be a possible mechanism of toxicity involved in certain health effects. This study evaluates the potential involvement of pesticide exposure on oxidative damage by assessing levels of erythrocyte antioxidant enzymes and serum uric acid in a population of workers occupationally exposed to pesticides.
Methods. A longitudinal study was conducted on a population of intensive agriculture workers from Andalusia (South Spain), during two periods of high and low-intensity levels of pesticide application. A structured questionnaire containing questions on sociodemographic and occupational characteristics was completed by workers. Blood samples were taken for the measurement of biomarkers of exposure (serum and erythrocyte cholinesterases), susceptibility (Paraxonase-1 – PON1-) and effect (erythrocyte antioxidant enzymes, including superoxide dismutase, catalase, glutathione peroxidase, glutathione reductase, glucose-6-phosphate dehydrogenase) and serum uric acid. Interaction effects between cholinesterases and PON-1 polymorphisms on biomarkers of oxidative stress were performed by generalized estimating equations (GEE) models.
Results. Lower levels of serum cholinesterase (indicating short-term exposure to pesticides) were associated with decreased glutathione reductase, glucose-6-phosphate dehydrogenase and uric acid and with raised catalase and glutathione peroxidase levels. By contrast, cumulated pesticide exposure, as measured by a reduced erythrocyte cholinesterase, was linked to a decreased catalase activity. PON1-192 genotype was associated with catalase and to a lesser extent with uric acid. A gene-environment interaction was found between PON1-192 polymorphism and short-term exposure to pesticides on antioxidant enzymes, because reduced serum cholinesterase was associated with glutathione peroxidase, glutathione reductase and uric acid, especially in carriers of the PON1 102QR genotype.
Conclusions. Pesticide exposure appears to induce oxidative stress particularly after short-term exposure. These results suggest an association between pesticide exposure and enzymatic antioxidant defenses in individuals with certain PON1 polymorphisms, raising the possibility of a genetic risk factor for developing certain oxidative stress-induced degenerative diseases upon exposure to pesticides.

SOCIAL INEQUALITIES IN CHILDREN'S ENVIRONMENTAL QUALITY: THE IMPACT OF INDIVIDUAL SOCIAL CHARACTERISTICS AND FACTORS OF THE NEIGHBOURHOOD SOCIOECONOMIC CONTEXT

Inke Thiele, *Department of Occupational and Environmental Health, Bavarian Health and Food Safety Authority, Munich, Germany*
Gabriele Bolte, *Department of Occupational and Environmental Health, Bavarian Health and Food Safety Authority, Munich, Germany*
for the GME Study Group

Background: Social disparities in housing conditions and environmental exposures have increasingly been recognized as major contributing factor for health inequalities.
Aim: To simultaneously assess the impact of individual and neighbourhood socioeconomic factors on children's environmental quality.
Methods: Data on perceived exposures to air pollution and noise, impairment due to lack of access to green space, and socioeconomic position were collected by self-administered questionnaires during three consecutive cross-sectional surveys 2004-2007 in the city of Munich, Germany. In total, the study population comprised 3700 children aged 5-6 years living in 19 school districts. Data on neighbourhood socioeconomic factors of the resident population of these school districts were obtained from Munich's statistical office. Adverse environmental quality was defined as parental report of at least 2 out of the 3 items moderate to very strong impairment due to air pollution, noise, or lack of access to green space in the residential environment. Multilevel analysis was applied to analyse the association of individual (level 1) and neighbourhood socioeconomic factors (level 2) with adverse environmental quality.
Results: Bivariate analyses yielded significant relations between individual indicators of low socioeconomic position (parental unemployment, low household income, low parental education, single-parent family, foreign nationality) as well as contextual socioeconomic characteristics of socially disadvantaged residents (high percentage of low-income households, low education) and adverse environmental quality. In multilevel analyses, among the individual indicators only household income was associated with children's adverse environmental quality (low income: OR 1.71, 95% CI 1.23-2.39). Even controlled for the individual characteristics high percentages of low income households in the neighbourhood (OR 2.50, 95% CI 1.24-5.05) and of single parent families (OR 0.39, 95% CI 0.19-0.78) were related to adverse environmental quality.
Conclusions: Parent's perceived adverse residential environmental quality of children is associated with small-area socioeconomic characteristics of the residential population independently of individual socioeconomic position.

FETAL EXPOSURE TO POLYBROMINATED DIPHENYL ETHERS (PBDES) AND ATOPIC DERMATITIS IN INFANTS

Naoki Shimojo, *Department of Pediatrics, Graduate School of Medicine, Chiba University, Chiba, Japan*

Yoichi Kohno, *Department of Pediatrics, Graduate School of Medicine, Chiba University, Chiba, Japan*

Background and Aims: Polybrominated diphenyl ether (PBDE) is one of the brominated flame retardants. Some of the PBDE congeners or isomers are reported to have high toxicity and endocrine disrupting effects. The health effects of PBDEs have been reported to be different among the congeners and isomers. Our previous studies revealed that Japanese fetuses were exposed to PBDEs. In Japan, the number of allergic disease patients is rapidly increasing among children. To find the reason of this rapid increase, an association between the occurrence of atopic dermatitis (AD) among the infants and the fetal exposure to PBDE congeners and isomers was examined.

Methods: One hundred and thirteen umbilical cords (UC) were collected in Chiba City (Japan) at deliveries. The concentrations of PBDE congeners and isomers in the 55 UC was measured by GC/MS. Medical doctor's diagnosis in follow-up study showed that 18 infants were AD and 37 infants were non-AD at 7-months old. This study was approved by the "Congress of Medical Bioethics" of Chiba University and all the samples were obtained after receipt of written informed consent.

Results: We found significant correlation between the occurrence of AD and the concentration of total PBDEs ($t<0.05$), TriBDE ($t<0.05$), TetraBDE ($t<0.01$), PentaBDE ($t<0.01$) and PentaBDE #99 ($t<0.05$). Our findings indicate that there are strong or weak association between some congeners and isomers of PBDEs and the occurrence of AD in infants.

Conclusions: Our present data suggest the possibility that there is some association between fetal exposure to PBDEs and the occurrence of AD among infants. However, it is unclear if the association is due to combined effects of PBDEs and other chemicals or due to the fetal exposure or exposure though breast milk. We need further studies to clarify this association.

OCCUPATIONAL RISK ASSESSEMENT AND HEALTH MONITORING AMONG VETERINARY DOCTORS

Ligia Maria Stoica, *National Institute of Public Health, Regional Center of Public Health, Cluj-Napoca, Romania*
Mihai Cristescu, *University of Agriculture Sciences and Veterinary Medicine, Cluj-Napoca, Romania*

Background and Aims : The veterinary profession is regarded as a high-risk group for occupational hazards, the most important being the infectious risk (risk of contracting zoonosis).
Methods : A cross-sectional study was carried out among 59 veterinary doctors employed in a veterinary department from Transylvania. A special individual medical questionnaire was individually applied, regarding occupational history, actual and past animal exposure, chemical exposure, work-related health problems, chronic diseases. Clinical examination and blood pressure measurement were performed. Lung function tests, hematological and biochemical tests among laboratory staff were performed.
Results : This professional group is exposed mainly to biological hazards (bacteria, viruses, parasites, mycosis, protozoa), animal allergens and risk of trauma associated with animal contact during occupational activity. Chemical risk exposure was present to the laboratory staff , mainly to volatile organic compounds and respiratory irritants. The results of questionnaire analysis and medical documents have showed that previous diseases and/or accidents related to animal exposure were reported, more frequent among subjects over 10 years of activity. A few cases of rabies contact were reported every year. Allergic diseases due to animals allergens were also reported. The most frequent chronic diseases registered were musculoskeletal disorders (work-related to cold exposure, repetitive musculoskeletal injuries), high blood pressure, ischemic heart disease, obesity and diabetes. Laboratory staff complains of work-related irritative respiratory syndrome in a few cases. Unfortunately in the past these diseases and/or accidents were not registered as occupational diseases or work-related diseases in most cases.
Conclusions : Veterinary doctors are exposed to a multitude of occupational risk factors and they experience a lot of health problems related to their professional activity. A specific methodology for risk assessment and health monitoring for this professional category is necessary to be elaborate and applied.

Aaron Blair, *National Cancer Institute, USA*

Background and Aims: Chronic exposure to pesticides has endocrine, immunologic and neurologic disrupting properties and other toxic effects believed to be associated with certain cancers, unfavorable reproductive outcomes, neurologic disorders and other health outcomes. Farming and other agricultural jobs are among the occupations with the highest exposures to pesticides. AGRICOH is a consortium of agricultural cohort studies that offers the opportunity to investigate the role of pesticides, and other exposures, in the etiology of several health outcomes. This poster presentation provides a description of AGRICOH to disseminate its formation and future research plans.
Methods: Characteristics of the cohorts integrating AGRICOH, data harmonization plans and research concepts to be studied will be illustrated in the poster presentation including the construction of pesticide crop exposure matrices.
Results: AGRICOH is a consortium of 22 agricultural cohort studies initiated by the US National Cancer Institute (NCI) and coordinated by the International Agency for Research on Cancer (IARC) since October 2010. The consortium includes cohorts from 9 countries: South Africa (1), Canada (3), Costa Rica (2), USA (6), Korea (1), New Zealand (2), Denmark (1), France (3) and Norway (3). AGRICOH aspires to promote and sustain collaboration and pooling of data to investigate the association between a wide range of agricultural exposures and a wide range of health outcomes, with a particular focus on associations that cannot easily be addressed in individual studies because of rare exposures (e.g. use of infrequently applied pesticides) or relatively rare outcomes (e.g. certain types of cancer, neurologic and auto-immune diseases).
Conclusions: AGRICOH represents a great resource for studying cancer, respiratory, neurologic, and auto-immune diseases as well as reproductive and allergic disorders, injuries and overall mortality in association with a wide array of exposures, prominent among these the application of pesticides.

THE EFFECTIVENESS OF HEALTH-RELATED PHYSICAL FITNESS INTERVENTION PROGRAM TOWARD ELEMENTARY SCHOOL CHILDREN: AN EXPERIENCE OF HEALTH PROMOTING SCHOOL IN TAIWAN

Li-Feng Lin,*Institute of nursing, Central Taiwan University of Science and Technology,Taichung city ,Taiwan(ROC)*
Tzu-I Chiu,*School of Nursing, Central Taiwan University of Science and Technology, Taichung city ,Taiwan(ROC)*
Fu-Hui Lee,*Department of Nursing, Central Taiwan University of Science and Technology, Taichung city ,Taiwan(ROC)*
Tsai-Yun Yeh, *Yu Ying Elementary School, Yuanlin Township, Changhua County, Taiwan (ROC)*

Background and Aims: For children the elementary school is the important stage to development healthy life-style and exercise habit, that promotes health-related physical fitness. The purpose of this study was to explore the effectiveness of health-related physical fitness intervention program toward Elementary School children.
Methods: The study subject was chosen from Yu Ying elementary school at Changhua County in Taiwan. The participants all are the grades six students a total 136, the health-related physical fitness intervention program was conduct to promotes healthy life-style and develop exercise habit. According to exercise interest of students the school children had set classified into a jogging group and dodge ball group. For the jogging group, the school teacher and exercise tutor lead student to do jogging exercise every morning for 30 minute, for the dodge ball group, the athletics teacher guided they do dodge ball exercise for 60 minutes after finish class everyday. For the other students they have no intervention.
Results: The average BMI of dodge ball group was 19.28, not only lower than jogging group (19.39) and non participants (21.25) but the percentage of overweight of dodge ball group was also the lowers. For the non participants, they have highest percentage of overweight (34.99%). The further evaluation the number of school-children had passed “physical fitness medal”, they get prize ratio for the students who participant in health-related physical fitness intervention program was 18.38%, it’s higher than non participants 8.57%, According to the results, the intervention program had already show an effect.
Conclusions: This study may be of impotence in applied health-related physical fitness intervention program to promote healthy life-style and develop exercise habit among elementary school children. As well as providing health educator with a better understanding of how to promote physical fitness intervention program in elementary school.

IS THERE AN ADDITIONAL HEALTH EFFECT DUE TO SUSTAINED HEAT DURING HEAT WAVES?

Antonio Gasparrini, *London School of Hygiene and Tropical Medicine, UK*
Ben Armstrong, *London School of Hygiene and Tropical Medicine, UK*

Background and Aims: studies assessing the health effects of heat typically divide into two categories: episode analysis and continuous-temperature analysis. In the former, the focus is on the increased risk during extreme events of protracted heat, usually defined heat waves. In the latter, temperature is instead modelled as a continuous variable. Few studies have included terms for both factors in a time series analysis, assuming an additional effect during heat waves beyond that explained by temperature. General wisdom dictates that this additional burden, due to sustained heat, is substantial. However, its estimate critically depends on model assumptions and flexibility.
Methods: we address this issue using data from 108 communities in the United States during 1987–2000. The additional wave effect was quantified including an indicator variable defined by combinations of temperature thresholds and days of duration, and then as a smooth function of consecutive heat-wave days. The model also included a main temperature effect estimated through distributed lag nonlinear functions of temperature, summarized for this context as the relative risk between the median city-specific temperature during heat wave days and the 75th percentile of the year-round distribution. City-specific main and added wave effects were pooled through meta-analytic techniques.
Results: the added wave effect was small (0.2%–2.8% excess relative risk, depending on wave definition) compared with main temperature effect during waves (4.9%–8.0%). Using a smooth function of consecutive heat wave days, the added wave effect is null for short episodes and increases only after 4 consecutive days.
Conclusions: the additional health effect during heat waves in United States is limited to very long episodes, and, on average, the excess risk from heat during and outside heat waves is well summarized and predicted by a continuous function of temperature, if non-linearity and lagged effects are allowed for.

THE ASSOCIATION BETWEEN GEOMAGNETIC STORMS, SOLAR PARTICLE EVENTS AND HOSPITAL ADMISSIONS FOR FIRST MYOCARDIAL INFARCTION

Jone Vencloviene, *Lithuanian University of Health Sciences, Kaunas, Lithuania*
Ruta Marija Babarskiene *Lithuanian University of Health Sciences, Kaunas, Lithuania*
Rimvydas Slapikas *Lithuanian University of Health Sciences, Kaunas, Lithuania*

Background and Aims: Recent studies suggested that geomagnetic storms (GS) and Forbuch decreases increase risk of myocardial infarction (MI), cardiovascular death, and stroke. One of product's of eruption in the Sun is solar proton events (SPE). We analyze the association between GS, SPE and daily hospital admission for first MI.
Methods: We use daily number of all emergency admissions for first MI (I21), hospitalized in Kaunas Universality of Medicine clinic during 2004.01.01-2005.12.31. The daily geomagnetic activity we assessed by Ap indices; GS determine as minor or major storm: Ap• 30. The SPE define as proton >10MeV energies fluency > 864 000 proton/(cm^2-day-sr); daily proton fluencies are measured by satellite GOES and presented in NGDC database. Using Poisson regression we assessed risk of admission on MI with ST-elevation (STMI) and on MI non ST-elevation (NSTMI) in days of GS with SPE; GS and no SPE; no GS and SPE, compare with days (no GS and no SPE), controlling for seasonal variation, weekdays and meteorological factors.
Results: We analyzed data of 2 008 patients. STMI composes 1132 (56.4%) and NSTMI – 876 **(**43.6%) of total emergency admissions for first MI. Among patients with MI were 63% men and 52.7% older than 65 years age. During days of GS accompanied by SPE, the risk of admission on STMI increased in 37% (RR=1.37 95% CI 1.00-1.88). Two days after the GS with SPE, GS without SPE, SPE without GS, the relative risk of admission on NSTMI was respectively 1.41 95% CI 1.00-1.98, 0.92 95% CI 0.67-1.26 and 1.75 95% CI 1.26-2.43.
Conclusion: These data suggest that GS with SPE increase the risk of emergency admissions for MI; effect of these events show later for NSTMI. GS without SPE no affect on risk of emergency admission for MI. The SPE without GS increase the risk of NSTMI.

MATERNAL EXPOSURE TO DESINFECTION BY- PRODUCTS DURING PREGNANCY AND MICRONUCLEI IN MATERNAL AND CORD BLOOD LYMPHOCYTES

Background and Aims: Exposure to disinfection by-products (DBPs) in drinking water has been associated with cancer risk in adults. We evaluated maternal exposure to DBPs in relation to micronuclei (MN) frequency in mother and newborns. MN are formed as a result of chromosome breakage or loss and are a marker of genetic instability. High levels of MN have been associated with increased cancer incidence in adults.
Methods: The mother-child birth cohort in Crete enrolled 1359 women at the third month of pregnancy. Effects on DNA were assessed in lymphocytes from 218 maternal and 239 umbilical cord blood samples, collected at birth, by the cytokinesis-block MN assay. Information on personal water related habits was obtained from questionnaires administered during pregnancy. Tap water samples were collected in representative mother homes, and were analysed for major DBPs including trihalomethanes (THMs). Negative binomial models were used to examine the association between MN in mothers and newborns with estimates of DBP exposure.
Results: A high percentage of women reported using bottled water during their pregnancy at home (72%) and outside of their home (98%). Exposures to THMs in tap water were found to be low (<20 micrograms/L) and were primarily brominated (BR) compounds. A strong positive association ($p=0.004$) was observed in univariate analysis between MN in binucleated cells from the mother's blood and THM or BR levels in tap water. This association was weaker but remained significant ($p=0.02$) after adjustments for maternal age and other potential confounders. MN in the children was not found to increase with any measures of THM exposure.
Conclusion: Findings from this study suggest a potential impact of DBP exposures on the frequency of MN in mothers but not in newborns. Exposures to DBPs were very low in this cohort, which may explain the lack of positive findings in children.

Do satellite tropospheric NO_2 data improve modelling of ground level ambient NO_2 concentrations?

Background and aims

In recent years, land use regression modelling has increasingly been applied to model the concentration of pollutants such as nitrogen dioxide (NO_2), particles smaller than 2.5 or 10 micrometer (PM2.5 or PM10). For large study areas, modelling the regional background trend is challenging in LUR modelling. The aim of our study is to assess the value of satellite observations of NO_2 in modelling annual average NO_2 concentrations across the Netherlands.

Methods

We used 2007 ground level NO_2 concentrations and geographic information system data from 144 monitoring sites spread over the Netherlands. In total, 26 sites were regional background, 78 sites urban background and 40 were close to major roads. For the 144 monitoring sites, we obtained the annual average tropospheric NO_2 concentration for 2007 from the Ozone Monitoring Instrument (OMI) on board of the NASA Aura satellite. Annual average OMI data reflect a spatial scale of about 10x10 km^2.

We calculated the correlation between measured satellite and ground level NO_2 concentrations for all sites and for background sites only. We next evaluated whether adding satellite observations improved land use regression models.

Results

Annual average satellite observations of tropospheric NO_2 correlated very well with annual average urban and regional background (R=0.74) and especially regional background surface NO_2 concentrations (R=0.88). As expected, fine scale variation in surface concentration related to traffic within 100s of meters was not well represented. A LUR model including satellite NO_2 observations to represent regional variation explained 84% of the variability in surface NO_2 at background locations. LUR models including geographical coordinates or indicator variables instead of satellite NO_2 had lower overall R^2 of 74 and 65%.).

Conclusion

Satellite NO_2 observations agreed well with measured surface concentrations at background locations and improved land use regression models including regional indicators or functions of geographic coordinates.

URINARY COTININE TO ASSESS EXPOSURE TO ENVIRONMENTAL TOBACCO SMOKE

Background and Aims: Tobacco smoke is a major source of exposure to thousands of chemicals and may represent a relevant confounder in biomonitoring studies aimed to assess exposure to environmental pollutants. In this study we compared urinary cotinine and self-administered questionnaire to investigate tobacco smoke habit and environmental tobacco smoke (ETS).
Methods: One hundred and sixty eight working individuals of a medium size city of Northern Italy entered the study. A self-administered questionnaire was used to evaluate tobacco smoke exposure. Urinary cotinine was measured by LC/MS/MS.
Results: Based on questionnaire 21% of the investigated subjects classified themselves as active smokers, 32% as ex-smokers and 47% as never smokers (total 79% present non-smokers); additionally 13% of subjects declared to be ETS exposed (6% active smokers).
Considering urinary cotinine as a gold standard, subjects were re-classified using a cut-off value of 50 µg/l: on this base 20% and 80% of individuals were identified as true smokers (S) and true non-smokers (NS), respectively. On this base 1.2% of subjects self-classified as never or ex-smokers were identified as S. The false self-classification was confirmed after further interview.
Among NS a further classification in subjects with and without ETS exposure was attempted (yesETS and noETS). Based on questionnaire 69% of subjects declared to be noETS, while 11% yesETS. with median urinary cotinine (5^{th}-95^{th} percentile) of 0.5 (0.2-2.0) µg/l and 1.3 (0.2-38.4) µg/l. Possible cotinine cut-off values to classify ETS exposure of 1.0, 1.5 and 2.0 µg/l were evaluated. In all cases higher specificity than sensitivity was found, with values ranging from 0.83 to 0.95, and from 0.56 to 0.37, respectively.
Conclusions: Our study confirms urinary cotinine as a good biomarker of tobacco smoke exposure, and the cut-off of 50 µg/l appropriate to classify active smokers; the classification of ETS exposure is critical, and needs further investigation.

COMPARISON OF TOENAILS AND URINE AS MATRICES FOR BIO-MONITORING OF METAL LEVELS IN EXPOSED WORKERS

Juan Alguacil, *Universidad de Huelva, Spain*

Background: Urine and blood are the preferred matrices to monitor the presence of metal exposure at the workplace, which for most of the metals represent short term exposure. Toenails would reflect cumulative exposure to longer periods of time. The objective of the present study was to explore the correlation between metals levels analyzed in urine and toenail samples in a group of workers exposed to metals, and a group of unexposed workers.
Methods: We measured metal levels in toenails and urine samples of 56 chemical/metal industry workers and 42 service workers unexposed to metals. Metal levels were measured in both matrices by multielemental analysis with emission spectroscopy by ICP-MS for As, Ba, Be, Cd, Co, Cu, Hg, Li, Mo, Pb, Se, Sr, Tl, V, W and Zn. The median for each metal was compared between the two exposure groups by the U Mann-Whitney test. The correlation between metals measured with the two matrices was estimated with the Spearman's rho.
Results: The comparison of the median levels of metals between the group exposed to metals and the unexposed one resulted in statistically significant ($p<0.01$) differences for toenails measurements in As, Ba, Be, Cd, Co, Cu, Hg, Li, Mo, Pb, Se, Sr, Tl, V, and W. The same comparison using urine samples revealed only statistically significant ($p<0.01$) differences for Li, Pb, Tl and V. We found direct correlations between metals levels in urine and toenails samples in the group of exposed workers for As (rho: 0.43; $p=0.001$), Li (rho: 0.283; $p=0.03$), Pb (rho: 0.56; $p<0.001$), and W (rho: 0.27; $p=0.04$). Only a correlation with borderline significance was observed in the group of unexposed workers for Hg (rho: 0.28; $p=0.069$)
Conclusions: Multielemental analysis of toenail samples properly captures occupational exposure to metals, and might be useful when long term bio-monitoring be of interest.

LEAD EXPOSURE IN AFRICA: GIVE IT THE ATTENTION IT DESERVES

Youssef Oulhote, *EHESP-School of Public Health / IRSET-Environmental & Occupational Health Institute / INSERM-French National Institute of Health and Medical Research, U625 (GERHM), Rennes, France*
Denis Zmirou-Navier, *EHESP-School of Public Health / IRSET-Environmental & Occupational Health Institute, Rennes / INSERM-French National Institute of Health and Medical Research, U954, Nancy Medical School, France*

Background and Aims: Lead is one of the most studied toxicant in scientific literature. Great decreases in lead concentrations in environmental media in developed industrialized countries have been achieved, and therefore, BLLs have decreased drastically in last decades. This has been considered as one of the greatest public health successes. However, in developing world, especially in African countries, lead still being an important public health concern. The demographic transition, in addition to the great efforts maintained to eradicate infectious diseases, gave rise to an epidemiologic transition in African countries, moving to more chronic diseases. The aim of this study was to assess efforts accomplished to eradicate lead poisoning in African countries, evaluate how public health actors deal with this issue and in a wider objective, how environmental health hazards are perceived.
Methods: We have reviewed the literature concerning lead exposure issue in African countries. As conducted studies in these countries are few, we extended the research to reports from international organizations such as WHO, UNEP and UNIDO and some newspaper articles.
Results: Except in South Africa where many studies have dealt with this issue, there is few and sparse data from other counties. Sources of lead exposure in Africa remain various, and range from mining and recycling activities to leaded paints and some cosmetics and medicinal products. No African country has a national lead surveillance program.
Conclusion: As in developed countries, BLLs have decreased in African countries during the last years thanks to ban of leaded gasoline. However, they are still very higher (i.e. 26% of South African children have BLLs>10µg/dL, 2009). In general, environmental health issues are neglected in health politics compared to endemic communicable diseases and new approaches are needed to deal with these issues still considered as inconsequential issues. Lead exposure remains a public health problem of global dimensions in Africa knowing its interactions with educational, social and economic growth. Developed countries have an important role in promoting new visions and to export accumulated knowledge through exchange programs in education, health economics and prevention.

MODIFYING EFFECT OF THE COUNTY LEVEL HEALTH INDICES ON CARDIOPULMONARY EFFECTS ASSOCIATED WITH WILDFIRE EXPOSURE

Ana G. Rappold, US EPA
Wayne E. Cascio, US EPA
Susan L. Stone, US EPA
Vasu Kilaru, US EPA
Lucas Neas, US EPA
David Diaz-Sanchez, US EPA
Robert B. Devlin, US EPA

Background and Aims: Socioeconomic status (SES) is a known risk factor for cardiopulmonary health and some studies suggest SES may be an effect modifier for health effects associated with exposure to air pollution. We investigated the synergistic impact of health disparities on cardiopulmonary outcomes associated with the 2008 North Carolina wildfire.
Methods: A population-based study was performed using daily Emergency Department visits reported through a syndromic surveillance program. Health disparities were defined through The County Health Rankings based on composite measures of Health Outcomes (mortality, morbidity) and Health Factors (Health Behavior, Clinical Care, SES, Physical Environment). Estimates of $PM_{2.5}$ produced by the HYSPLIT model were used to define exposure. Poisson log-linear regression was used to estimate relative risk.
Results: Significant increases in relative risk for Asthma[8.9% per 10 • g/m^3 increase in two day average $PM_{2.5}$concentration] and heart failure (HF)[6.54%] were observed in the counties ranked below the median in Health Outcomes while no change was observed in the better ranked counties. Similarly, counties ranked below the median Health Factor Index also experienced significant increases for Asthma[9.12%] and HF[7.81%] with statistically significant risk from the better ranked counties. Both indices were independent of the exposure. A significant association was observed for COPD, pneumonia and acute bronchitis, and cardiopulmonary symptoms, but these outcomes were less numerous at the county level to be considered for interaction with health disparity measures.
Conclusions: This study suggests that health disparities may play an important role in the distribution of risk associated with exposure to emissions from wildfires. Climate related changes coupled with human land use practices are expected to increase the frequency of wildfires worldwide. The results of this study support the concern that the health burden may be shared disproportionately among the population.

This abstract of a proposed presentation does not necessarily reflect EPA policy.

TRIHALOMETHANE LEVELS IN RELATION TO RATES OF STILLBIRTH AND LOW BIRTH WEIGHT: AN INTERVENTION STUDY

Nina Iszatt, *MRC-HPA Centre for Environment and Health, Department of Epidemiology and Biostatistics, Imperial College London, London, UK*
Mark J. Nieuwenhuijsen, *Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
James Bennett, *MRC-HPA Centre for Environment and Health, Department of Epidemiology and Biostatistics, Imperial College London, London, UK*
Mireille B. Toledano, *MRC-HPA Centre for Environment and Health, Department of Epidemiology and Biostatistics, Imperial College London, London, UK*

Background and aims: In the North West of England, water is supplied to 7 million people by the water company United Utilities. During 2003 and 2004, the company introduced enhanced coagulation (EC) to some treatment works, reducing DBP formation potential. This intervention provided a unique opportunity to study the effect of DBPs on birth outcomes, whilst reducing socioeconomic confounding. The aim was to compare the rates of stillbirth, low and very low birth weight three years before (2000-2002) the treatment changes with rates three years after (2005-2007).
Methods: Exposure metrics for EC and trihalomethane concentration change were created for each water zone. Births and stillbirths were extracted from the national birth registers and linked via postcode of maternal residence at birth to the water zone using geographical information systems. Differences in small-area rates of stillbirth, low and very low birth weight before and after treatment changes were modelled against change to enhanced coagulation and low, medium and high trihalomethane change (all water zones together and then stratified by EC) using Poisson regression. Differences between rate changes were tested using an interaction term between before/after and EC or trihalomethane change.
Results: Change to EC was not associated with a significant reduction in rates of the birth outcomes investigated. Areas with the greatest decrease in chloroform, compared with areas with lower chloroform decrease, showed a greater reduction in rates of stillbirth (non-significant), low birth weight (7 %, p =0.02 areas without EC) and very low birth weight (20 %, p = 0.02 all water zones regardless of EC status).
Conclusion: Chloroform concentration appears to be associated with stillbirth, low birth weight and very low birth weight rates. Although the intervention design reduced potential confounding from deprivation, it is possible that factors related to ethnicity could explain some of the rate reductions.

IMPACT OF SMOKE-FREE LEGISLATION ON CHILDREN'S SECONDHAND SMOKE EXPOSURE

Gabriele Bolte, *Department of Occupational and Environmental Health, Bavarian Health and Food Safety Authority, Munich, Germany*
Lana Hendrowarsito, *Department of Occupational and Environmental Health, Bavarian Health and Food Safety Authority, Munich, Germany*
Hermann Fromme, *Department of Chemical Safety and Toxicology, Bavarian Health and Food Safety Authority, Munich, Germany*
for the GME Study Group

Background: Exposure to secondhand smoke (SHS) is a serious health hazard for children. Thus, protecting children from SHS is an important public health target. However, smoking bans in public places may lead to changes in parental smoking behaviour and subsequently to even increased SHS exposure of children at home.
Aim: To determine whether smoke-free legislation in Bavaria, Germany, is associated with changes in parental smoking behaviour at home and children's SHS exposure.
Methods: Cross-sectional surveys were performed before and after implementation of smoke-free legislation at 01.01.2008. The study population comprised parents with children aged 5-6 years in three urban and three rural districts. Data were collected with self-administered questionnaires. The response rates were 78% (N=6350, first survey 2004-2005), 73% (N=6206, second survey 2005-2006), and 60% (N=5336, third survey 2008-2009). Exposure to SHS at home was defined as smoking of any person within the home excluding smoking exclusively on the balcony or terrace.
Results: Before smoke-free legislation, 14% (first and second survey) of children were exposed to SHS at home. After implementation of smoke-free legislation, 13% of children were exposed (third survey). SHS exposure in cars slightly decreased from 11% (first survey) and 9% (second survey), respectively, to 6% (third survey). As expected, there was a considerable decrease in children's SHS exposure at hospitality venues from 72% and 68%, respectively, to 24%. Among families with at least one smoking parent, the majority (74%) had smoke-free homes independent of smoking bans in public places. Further 17% reported no change in their smoking behaviour at home since smoke-free legislation and 8% a decrease in the amount or even a stop of smoking at home. Only 1% reported increased smoking.
Conclusions: Restriction of smoking in public places in Germany did not increase children's SHS exposure in their homes or in cars.

WHEN IS A CUCUMBER LIKE A MOBILE PHONE? SCIENCE AND POLICY IN WATER SCARCITY AND WATER REUSE

Maya Sadeh, *Environment and Health Fund, Israel*
Ruth Ostrin, *Environment and Health Fund, Israel*

Background and aims: Israel is a semi-arid country experiencing water scarcity, with a long tradition of intensive agriculture. Israel is also a world leader in the use of treated wastewater for irrigation. More than 80% of the sewage is treated and reused for irrigation of edible and non-edible crops. The current regulations in Israel and worldwide regarding use of reclaimed wastewater for irrigation largely address microbiological quality and do not address anthropogenic chemical contaminants including pharmaceutical and personal care products (PPCPs). Recent research indicates that some of these chemicals persist in soil, in crops, and infiltrate groundwater. The population is exposed to low levels of these chemicals through the food chain and the drinking water. The health implications of this exposure are not known. There is no comprehensive assessment of the exposure and little epidemiological or toxicological research. Policy recommendations or recommendations to the public have not been made.
Israel is also a leader in the per capita use of mobile phones. Research on the health impact of mobile phone use has yet to reach conclusive results, however the Ministry of Health has issued public recommendations, applying a precautionary approach to justify its recommendations.
Methods: In order to address the question of what a precautionary approach might look like under conditions of water scarcity and intensive water reuse, we conducted an international survey of policy makers and researchers. We ask about the difference between applying precaution regarding mobile phones as opposed to the use of recycled wastewater. We address the issue of how environmental health policy is best determined in such a case of scientific uncertainty.
Results and conclusions: The results of the international survey on applying precaution in developing environmental health policy for the use of treated wastewater will be presented.

Background and aims: The fetus is dependent on maternal thyroid hormones during pregnancy and an adequate thyroid function is essential for the normal brain development. The effects of subclinical hypothyroidism and mild hypothyroxinemia during pregnancy are poorly known. We aimed to assess the association between thyroid function in healthy pregnant women from the general population and the neurodevelopment of their children, and the role of the iodine status in this relationship.
Methods: We conducted a population-based cohort in Spain and Greece. Participants included 1638 and 318 children and their mothers from Spain and Greece, respectively. Levels of free thyroxine (free T4) and thyrotropin (TSH) in serum were measured during pregnancy. Urinary iodine concentrations (UIC) were measured in a subsample of 1386 women from Spain. Mental and motor development of their offspring was assessed using Bayley's Scales at 14 (Spain) and 18 (Greece) months of age.
Results: In participants from Spain, low free T4 levels were associated with a decrease in the mental score. When stratifying by urinary iodine level, the highest decrease was observed in those children from mothers with free T4 levels below the 2.5th percentile and UIC above 150µg/L (coefficient (SE): -10.1 (3.6)). No effect of low free thyroxine was observed when UIC were below 150µg/L. In participants from Greece, low free T4 and high thyrotropin levels were also associated with a decrease in some Bayley's scales.
Conclusions: Low free T4 and high TSH levels in healthy pregnant women had an adverse effect on offspring's neurodevelopment. High UIC exacerbate the adverse effect of low free T4 on mental score. This study reinforces the need to screen thyroid function in pregnant women, even in iodine sufficient areas.

EVIDENCE OF OXIDATIVE DNA DAMAGE IN CHILDREN WORKING IN THE SURGICAL INSTRUMENTS INDUSTRY IN SIALKOT, PAKISTAN

Muhammad Sughis, *Department of Public Health, KULeuven, Belgium, Centre of Research for Public Health, Pakistan, Lahore College of Pharmaceutical Sciences, Pakistan*
Tim S. Nawrot, *Centre for Environmental Sciences, Hasselt University, Belgium, Department of Public Health, KULeuven, Belgium*
Asad Amjad, *Centre of Research for Public Health, Pakistan, Lahore College of Pharmaceutical Sciences, Pakistan*
Ihsan-ul-Haque Syed, *Centre of Research for Public Health, Pakistan, Lahore College of Pharmaceutical Sciences, Pakistan*
Haufroid Vincent, *Laboratory of the Industrial Toxicology and Occupational Medicine Unit, Université Catholique de Louvain, Belgium*
Nemery Benoit, *Department of Public Health, KULeuven, Belgium*

Background and Aims: A considerable part of the worldwide production of surgical instruments takes place in Sialkot. Many children also work in this industry without protective measures. In a cross-sectional study, we investigated the possible health effects of occupational exposure in these children as compared with schoolchildren living in Sialkot, Pakistan.
Methods: We studied 145 male children (mean age 12.1 years): 75 children from a school in Sialkot and 70 children working in surgical instruments subcontracting units. A respiratory questionnaire was administered, spirometry was performed with an electronic hand-held spirometer, and blood pressure was measured with an automated device. Spot urine samples were collected and concentrations of metals were measured by inductively coupled plasma-mass spectrometry (ICP-MS) and 8-hydroxy-2'-deoxyguanosine (8-OHdG) by ELISA. Urinary 8-OHdG is an indirect reflection of oxidative DNA damage.
Results: The working children reported more asthma (7% vs 0%; p=0.01) and dry cough at night (36% vs 20%; p=0.03) than the schoolchildren, but there were no significant differences in spirometry or blood pressure between the two groups. Urinary concentrations of ten metals (Cr, V, Mn, Ni, Cu, Se, Mo, Cd, Sn, and Sb) were higher in children working in surgical instruments manufacturing units than in controls. In the working children, the geometric mean concentration of Cr was 25.6 µg/g creatinine (95% CI 17.8 to 36.8) which was 39-fold the value found in schoolchildren (0.66 µg/g creatinine; 95% CI 0.55 to 0.80). According to the ACGIH, the Biological Exposure Index for Cr is 10 µg/L. For the other metals the fold-differences between working children and schoolchildren ranged from 1 to 7. Urinary levels of 8-OHdG were 24% higher in working children compared with school children (22 vs 18 ng/g creatinine). Urinary 8-OHdG was positively associated with urinary concentrations of Cr (r=0.2; p= 0.01).
Conclusion: This first biomonitoring study of metal exposure among children working in the surgical instruments manufacturing industry reveals a substantial exposure to several metals, especially chromium, which is an established carcinogen. Exposure to chromium was associated with evidence of increased oxidative DNA damage.

HYPOINSULINEMIA IN THE PATHOGENESIS OF PCB-INDUCED TYPE 2 DIABETES

Christine Dalgård, *University of Southern Denmark, Odense, Denmark*
Flemming Nielsen, *University of Southern Denmark, Odense, Denmark*
Pal Weihe, *Faroese Hospital System, Torshavn, Faroe Islands*

Background and aims: Some persistent environmental chemicals are suspected of causing an increased risk of type 2 diabetes mellitus. We examined early stages of diabetes development in the elderly of a fishing population with elevated exposure to marine contaminants.
Methods: In 713 Faroese residents aged 70-74 years (64% of eligible population), we determined fasting plasma concentrations of glucose and insulin and the relative concentration of glycosylated hemoglobin. Lifetime exposure to persistent environmental chemicals from pilot whale and other traditional food was determined from dietary questionnaire and by analysis of blood samples for polychlorinated biphenyls (PCBs) and other food contaminants.
Results: Septuagenarians with type 2 diabetes or impaired fasting glycemia tended to have higher PCB concentrations and higher past intakes of traditional food. In non-diabetic subjects, the fasting insulin concentration decreased by 7% (95% CI: -12, -2.1) for each doubling of the PCB concentration after adjustment for sex and body mass index at age 20. Conversely, the fasting glucose concentration in these subjects increased by 6%; (95% CI: -1, 13) for each doubling in PCB.
Conclusions: Exposure to persistent lipophilic food contaminants may contribute to the development of type 2 diabetes through impaired insulin secretion.

Background and Aims: One of the objectives of Escape is to assess the health effects of road traffic related air pollution with adjustment of road traffic noise. For four areas in Escape the correlation between traffic-related noise and NO2 was studied.
Methods: In the Netherlands noise levels and air pollution concentrations were predicted for the whole population using the EMPARA-model. In Girona (Spain), a CADNA-A-based noise model and measured annual mean NO_2 concentrations at 83 addresses were used. For two Danish cities the noise model SoundPLAN and the AirGIS dispersion model for NO_x were applied. In the Ruhr area a categorical noise map and land use regression models were used. Noise and air pollution values were assigned to home addresses and the correlation was evaluated.
Results: The noise exposure in the Netherlands has an arithmetic mean of 52 dB (IQR=9), in Girona 63 dB (IQR=8 dB) and in Denmark 58 dB (IQR=10 dB). The majority of the population in the Ruhr Area had the reference value (below 55 dB). The mean NO_2 concentration in the Netherlands was 24.8 µg/m^3 (IQR=7.8 µg/m^3), in Girona 26.9 µg/m^3 (IQR=12.2 µg/m^3), in Denmark (mean NO_x) 30.2 µg/m^3 (IQR=10.2 µg/m^3), and in the Ruhr area 30.2 µg/m^3 (IQR=6.2 µg/m^3). In the Netherlands and the Ruhr area the correlation between the NO_2 concentrations and road traffic noise is fair (0.38/0.34). In more urban study areas, like Girona and Copenhagen, correlations were substantial (0.62 and 0.79). In the Netherlands, in rural study areas in the vicinity of motor ways, the correlation was moderate (0.53).
Conclusions: The correlation between traffic-related noise and NO_2 for mixed study areas is in general fair. However, the correlation is area-specific, thus in urban areas or in the vicinity of motor ways stronger correlations can occur and confounding can not be excluded.

ARSENIC METHYLATION AND SQUAMOUS CELL CARCINOMA IN A US POPULATION BASED CASE-CONTROL STUDY

Diane Gilbert-Diamond, *Dartmouth Medical School, USA*
Jay Gandolfi, *University of Arizona, USA*
Ann Perry, *Dartmouth Medical School, USA*
Steven Spencer*, Dartmouth Medical School, USA*
Jason Moore*, Dartmouth Medical School, USA*
Margaret Karagas, *Dartmouth Medical School, USA*

Background and Aims: Some studies suggest that increased arsenic methylation ability may reduce the risk of skin cancer, though previous studies failed to differentiate between basal cell carcinoma and the less common, but potentially more agressive, squamous cell carcinomas (SCC). Here, we examine whether arsenic methylation ability, measured as the ratio of dimethylarsinic acid/ monomethylarsonic acid (Secondary Methylation Index, SMI) reduces the risk of SCC in a population with moderate exposure via bedrock wells in the state of New Hampshire (NH), US.
Methods: Cases of primary invasive SCC were identified by a collaboration with dermatologists and pathologist serving the NH population. Potential controls were chosen from the NH Department of Transportation driver's license and Medicare enrolment files of state residents. Urine samples from cases and controls were analyzed for arsenic metabolites using HPLC/ICP-MS, and from which total arsenic (sum of inorganic arsenic, MMA and DMA) and DMA:MMA were calculated.
Results: Of the 354 SCC cases and 339 controls, 88 cases and 87 controls had water levels of arsenic above 1 ug/L, and were included in our investigation of urinary arsenic species. Urinary MMA averaged 7.1 µg/L (range: 0.1, 45.8) and SMI averaged 8.3 (range: 0.8, 97.0) Having a urinary MMA concentration above the mean was associated with a higher odds of SCC (adjusted odds ratio = 1.55, 95% CI: 1.04, 2.32). After adjustment for total urinary arsenic, having a 10 unit higher SMI was associated with a decreased odds of SCC (odds ratio = 0.70, 95%CI: 0.49, 1.00).
Conclusions: This study suggests that the ability to methylate MMA to DMA may reduce an individual's risk of SCC in populations with moderate arsenic exposure in the US.

LONG TERM EXPOSURE TO TRAFFIC RELATED AIR POLLUTION AND MORTALITY IN A GREEK COHORT STUDY

Konstantina Dimakopoulou, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Michail Katsoulis, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Xanthi Pedeli, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Alexandros Gryparis, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Antonia Trichopoulou, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Klea Katsouyanni, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*

Background and Aims: Several studies have showed that traffic-related air pollution, using NO_x and particulate matter (PM) concentrations, is a potential risk factor for public health. The present study aims to evaluate the effect of exposure to traffic-related air pollution on all cause, cause specific mortality and incidence in a Greek cohort.
Methods: Data from the on-going prospective study on nutrition and cancer (EPIC Project) in 10 municipalities of the greater Athens area with 2,756 subjects followed from 1997 to 2009 was used. Air pollution exposure was estimated using a Geographical Information System (GIS) approach to link geocoded residential addresses to a road database and estimate the exposure to NO_2 and PM_{10} at the subjects' home addresses. We conducted Cox proportional hazards survival regression analysis, adjusting for potential confounders.
Results: NO_2 and PM_{10} yearly averaged individual exposure estimates were associated with increased cardiovascular (CVD) and coronary heart disease (CHD) mortality. Hazard ratios (95% confidence intervals) for a 10• g/m3 increase in NO_2 and PM_{10} were 1.61 (0.92 – 2.80) and 3.97 (1.06 – 14.84) respectively for CHD mortality. There were no clear associations with respiratory and lung cancer mortality, however the number of events was very small.
Conclusions: The present study suggests that long-term exposure to traffic-related air pollution has an impact on mortality.

JOINT MODELING OF DAILY CRASH COUNTS AND THE RISK IMPACT OF TRAFFIC EXPOSURE AND WEATHER CONDITIONS IN THE NETHERLANDS

Xanthi Pedeli, *Department of Hygiene, Epidemiology and Medical Statistics, University of Athens, Medical School & Department of Statistics, Athens University of Economics, Greece*
Klea Katsouyanni, *Department of Hygiene, Epidemiology and Medical Statistics, University of Athens, Medical School, Greece*
Dimitris Karlis, *Department of Statistics, Athens University of Economics, Greece*

Background and Aims: Various approaches have been suggested to model time-series crash count data. However, most of them do not explicitly account for the significant autocorrelation present in the data. We consider the joint modeling of daily crash counts in Schiphol, De Bilt and Soesterberg, in the Netherlands for the year 2001. Vicinity of the three areas implies that the data share some similar environment, for example weather conditions and road characteristics. Thus, the accidents series are also expected to be cross–correlated. For the above reasons the joint modeling of the three series can prove to be useful in practice. Moreover, we aim to investigate the risk impact of traffic exposure and weather conditions on the daily crash counts.
Methods: Data were modelled through an extension of the recently popular INteger-valued AutoRegressive (INAR) models to the multivariate setting. The models that arise under alternative distributional assumptions were compared in terms of their fit and plausibility. Estimates of the unknown model parameters were obtained through the method of composite likelihood. A binary variable for weekends vs. weekdays was used as proxy for the day-of-the-week variability in traffic exposure. Weather conditions were expressed through the mean daily temperature in degrees Celsius.
Results: The multivariate INAR(1) regression model with trivariate negative binomial innovations proved to be the best model among those fitted to our data. Our findings are consistent with evidence from earlier research and confirm the greater frequency of crashes on weekdays as compared to weekends (• =-0.375, p<0.001) as well as the negative, highly significant relationship between the absolute temperature and the number of crashes (• =-0.015, p=0.001).
Conclusions: Multivariate INAR processes can provide a useful framework for modeling simultaneously more than one correlated count time series. Additional risk factors, e.g. precipitation, sunshine and visibility, could lead to greater improvement in fit, or even remove the need for a complicated distribution like the multivariate negative binomial.

THE INTERACTION OF OZONE AND HIGH SUMMER TEMPERATURES ON DAILY MORTALITY AND THE URBAN HEAT ISLAND EFFECT

Massimo Stafoggia, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Francesca de' Donato, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Annunziata Faustini, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Paola Michelozzi, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Francesco Forastiere, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*

Background and Aims: health effects of ozone and high temperatures on mortality are well-established in the epidemiological literature. However, the extent to which the two exposures act independently or interact synergistically on mortality remains unclear. Furthermore, the spatial distribution of the ozone effects inside urban areas is still unexplored. We aimed at investigating: 1) the effect modification of summer temperatures on the ozone-mortality relationship; 2) the heterogeneity of the ozone-mortality association between nighttime warmer and cooler areas (urban heat island, UHI) of Rome, Italy.
Methods: all subjects aged 65+ years, resident of Rome and deceased in the city during 2001-2009, April-September, were considered. Information on maximum 8-hr daily ozone concentrations was provided by two Regional Environmental Protection Agency monitoring stations. Daily mean apparent temperature (AT) was derived by combining air and dew point temperature from an airport monitoring station. Finally, a two-level indicator of the UHI was obtained at the census-block level from AATSR satellite data. We performed a case-crossover analysis to estimate the effect of ozone on mortality in the whole population, according to daily AT percentiles, and according to the UHI indicator.
Results: 76,056 deaths occurred in the study period: 48% in warmer areas and 37% in cooler ones (15% missing). The overall ozone effect was high (lag 0-5, 1.36% increase of risk, 95%CI=0.63-2.10). It displayed a strong gradient according to daily mean AT levels (0.18%, 0.05%, 1.75% and 3.63% increases of risk in strata of AT below 50^{th} percentile, 50^{th}-75^{th}, 75^{th}-90^{th} and above 90^{th} percentile, respectively). The overall ozone effect was double in warmer areas (2.05%, CI=0.84-3.28) as compared to cooler ones (1.12%, CI=0.06-2.19).
Conclusions: ambient ozone and high temperatures interact on mortality, representing a relevant public health challenge. Ozone prevention measures should be targeted on elderly people residing in the warmest part of urban areas.

LONG TERM EXPOSURE TO ORGANOCHLORINE PESTICIDES AND THYROID HORMONE LEVELS IN CHILDREN FROM CIDADE DOS MENINOS, RJ, BRAZIL

Carmen Freire, *National School of Public Health, Oswaldo Cruz Foundation, Brazil; San Cecilio University Hospital, University of Granada, Spain.*
Rosalina Koifman, *National School of Public Health, Oswaldo Cruz Foundation, Brazil.*
Paula Sarcinelli, *National School of Public Health, Oswaldo Cruz Foundation, Brazil.*

Sergio Koifman, *National School of Public Health, Oswaldo Cruz Foundation, Brazil.*

Background and Aims: Disruption of thyroid hormone (TH) homeostasis by organochlorine compounds (OCs) has been demonstrated in several animal studies. However, a consistent association has not been established yet in humans. We aimed to investigate the effect of exposure to OC pesticides on TH levels in children from Cidade dos Meninos village (Duque de Caxias municipality, RJ, Brazil), an area highly contaminated with OC pesticides since 1961.
Methods: Serum concentration of 19 OC pesticides (HCH, HCB, DDT and others) and TH levels (free T4 [fT4], total T3 [tT3] and TSH) were measured in 193 children <15 years of age from Cidade dos Meninos. Linear regression was conducted to examine differences in TH levels according to quintiles of OC exposure, controlling for age, gender and serum lipid content.
Results: Children presented high prevalence and exposure levels of most of the pesticides; fT4 and TSH levels were within reference values, whereas tT3 was above the reference range (>180 ng/dL) in 28% of the children. Excepting for heptachlor and methoxychlor, tT3 levels showed an increasing linear trend ($p<0.05$) across pesticide exposure categories. Increased fT4 was only related to *p,p'*-DDD, endosulphan I, and dieldrin levels. No significant trend was found for TSH.
Conclusions: Contrary to what has been generally reported in the literature, a consistent increase in tT3 according to OC exposure was observed. Positive associations between OCs and T3 or T4 levels has been scarcely reported, as mentioned according to *p,p'*-DDE and tT3 among adults (Meeker et al., 2007). Long-term continuous exposure to high OC pesticide levels in Cidade dos Meninos has probably generated a quite different exposure setting than that dealt in other studies. Hence, we hypothesize that the thyroid metabolism in children continuously exposed in utero and afterwards to high OC pesticides levels can respond similarly as reported among exposed adults.

Meeker JD, Altshul L, and Hauser R. Serum PCBs, p,p'-DDE and HCB predict thyroid hormone levels in men. Environ Res 2007;104:296-304.

OCCUPATIONAL EXPOSURE AND AMBIENT AIR CONTAMINATION BY NATURALLY OCCURRING ASBESTOS IN VALMALENCO (ITALY)

Andrea Cattaneo, *Department of Occupational and Environmental Health, Universita` degli Studi di Milano, Italy*
Anna Somigliana, *Environmental Protection Agency of Lombardy Region (ARPA), Italy*
Mauro Gemmi, *Department of Earth Sciences "Ardito Desio", Universita` degli Studi di Milano, Italy*

Pier Alberto Bertazzi, *Department of Occupational and Environmental Health, Universita` degli Studi di Milano, Italy*

Background and Aims: asbestos fibers naturally present in rocks and soils can be released into the atmosphere by occupational and other human activities, as well as by meteorological agents. The aim of this work was the evaluation of the occupational exposure levels and ambient concentrations of airborne fibers of naturally occurring asbestos (NOA) in quarries and processing facilities of Valmalenco serpentinites, in the neighbourhood of the facilities and in the nearest urban centres.
Methods: occupational exposures to NOA were studied through personal and static monitoring carried out during the more critical working activities. An analytical protocol composed by coupled TEM-SAED and SEM-EDS was specifically developed in order to improve specificity thanks to the crystallographic discrimination between chrysotile and other polymorphs. Airborne asbestos fiber concentrations were measured by SEM-EDS and only WHO fibers were counted according to the WHO criteria (length > 5 µm, diameter < 3 µm; aspect ratio > 3).
Results: air contamination from chrysotile fibers (amphiboles were never detected) in the selected occupational and life environments was site-dependent, as the degree of asbestos contamination of Valmalenco serpentinites is highly variable from place to place. Working activities associated with the highest exposures and airborne contaminations included cutting of non-foliated serpentinites with multiple blades or discs and drilling at quarries located in the area with rocks highly contaminated by chrysotile veins. On the contrary, working activities conducted on foliated serpentinites were related with airborne chrysotile concentrations comparable with ambient levels. Environmental chrysotile concentrations were always below 2 ff/l, except for one sample collected on a dirt road.
Conclusions: the present study would be useful for encouraging the development of an effective and harmonized policy for proper use of contaminated rocks and protection of public health. This work was supported by Regione Lombardia.

AIRBORNE moulds measured by quantitative PCR in relation to asthmatic symptoms in school pupils in Taiyuan, China

Zhuohui Zhao, *Fudan University, Key Laboratory of Public Health Safety, P.R.China*
Björn Mälarstig, *ZnoZona, Sweden*
Aleksandra Sebastian, *Lund University, Sweden*
Lennart Larsson, *Lund University, Sweden*
Gunilla Wieslander, *Uppsala University, Sweden*
Dan Norbäck, *Uppsala University, Sweden*

Background and Aims: Indoor mould may influence children's respiratory health.
Methods: In this study, we used real-time quantitative PCR to measure fungal DNA in airborne dust collected by Petri-dishes during 7 days in 39 classrooms in 10 schools in Taiyuan city, Shanxi province, China. A questionnaire survey (90.2% response rate) was performed in 1993 pupils (average age 13y).
Results: Totally 29.8% had daytime attacks of breathlessness, 8.4% wheeze (last 12 months) and 39.3% respiratory infections (last 3 months). All classrooms had detectable mould (total mould) (median 626,000, range 1,840~2,410,000 cell equivalents (CE)/m2/day), 72% had mould genera Aspergillus/Penicillum (Asp/Pen) (median 5,410, range 820~85,700 CE/m2/day) and 23% with Stachybotrys Chartarum (median 7,790, range 3,230~22,400 CE/m2/day). The total mould was highly correlated with muramic acid (MuA) in the settled dust ($P<0.01$). By hierarchical multiple logistic regression analyses, airborne total mould was positively associated with pupils' wheeze (odds ratio 1.48, 95% CI 1.03-2.12). MuA was negatively associated with pupils' daytime attacks of breathlessness and wheeze. No significant association was found for Asp/Pen or S.Chartarum.
Conclusions: Petri-dish method can be used to detect airborne fungal DNA. The correlation between airborne mould and microbial components in the settled dust suggested the complexity of indoor exposure to compounds of biological origin.

EMERGENCY AMBULANCE DISPATCHES AND APPARENT TEMPERATURE: A TIME-SERIES ANALYSIS WITH DISTRIBUTED LAG NONLINEAR MODELS

Ester Alessandrini, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy; Department of Statistics, University of Bologna, Italy*
Stefano Zauli Sajani, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*
Antonio Gasparrini, *Department of Social and Environmental Health Research, London School of Hygiene and Tropical Medicine, London, United Kingdom.*
Rossella Miglio, *Department of Statistics, University of Bologna, Italy*
Fabiana Scotto, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*
Stefano Marchesi, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*
Paolo Lauriola, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*

Background and Aims: To properly understand the full public health significance of heat-related health effects, as well as develop an effective surveillance system, it is important to investigate the impact of stressful meteorological conditions on non-fatal events. The objective of our study was to evaluate the exposure-response curve of ambulance dispatch data in relation to biometeorological conditions by using time series techniques.
Methods: Daily data of Emergency Ambulance Dispatches (EAD) for people aged 35 or older in the summer periods of 2002 to 2006 were collected for the chief towns of the Emilia-Romagna region. The city-specific relationship between daily EAD and increasing apparent temperature (AT), was explored using distributed lag nonlinear functions and then approximated by linear splines in Generalized Additive Models, controlling for air pollution, seasonality, long-term trend, holidays and weekends. The effects of high temperature on health were evaluated for all non-traumatic as well as for respiratory and cardiovascular disease. City-specific effects were then combined in fixed and random effects meta-analyses.
Results: DLNM showed a greater effect of AT on EAD in the current day. The delayed effects decreased with time. On the current day of exposure the percent change in EAD associated with every 1°C increase of mean AT between 25°C and 30 °C was 1.50% (95%CI:0.67,2.34) for non-traumatic disease and 2.90% (95%CI:0.65,5.20) for respiratory disease. The percent rise in risk was greater on days in which the mean AT exceeded 30°C (8.77%, 95%CI:5.87,11.75 for non-traumatic disease EAD). The risks increased with age and reached 12.04% for non-traumatic 75+ EAD compared to 5.63 % for those aged 35-64.
Conclusions: Time series analysis techniques have been adopted for the first time to investigate EAD data to evaluate risks associated with biometeorological discomfort. Our findings show a strong relationship at short lags between ambulance dispatches and biometeorological conditions.

Background and Aims: Associations between particulate air pollution and cardiovascular emergency room visits and hospital admissions have been consistently shown. It is, however, still not fully investigated which size fraction of particles might be responsible for this relationship, especially in Asia. We explored the association between daily cardiovascular emergency room visit counts and number concentrations (NC) or mass concentrations (MC) of particles of different size fractions in Beijing, China.

Methods: Standard medical forms recording date of visit and diagnosis were obtained. Cases of all cardiovascular diseases and cause-unknown sudden deaths together were referred as “total circulatory emergency room visits, ERVT”; severe cases of ischemic heart diseases, arrhythmia, heart failure and cerebrovascular diseases together were referred as “circulatory emergency room visits, ERV”. Particle number size distributions were continuously measured

between 3nm to 10µm and the data was used to calculate daily mean NC and MC by size fraction. Confounder-adjusted semi-parametric Poisson regression models were used to estimate the effects of lag 0 to lag 4, as well as the 5-day moving average NC and MC.

Results: Mainly particle NC of the size-fractions 10 to 30nm, 30 to 50nm, and 50 to 100nm showed adverse delayed effects (with lag 4) on ERV and ERVT; the relative risks (RR) ranged from 1.03 (95% confidence intervals (CI): 1.00-1.06) to 1.06 (95% CI: 1.02-1.10). For MC, most size-fractions showed significant effects on ERVT, predominantly at lag 0 with RR of about 1.03 (95% CI: 1.00-1.06). With MC in the size fraction 1000-2500nm also significant 1-day, 2-day and 4-day lagged effects (RR 1.02 (95% CI: 1.00-1.04) each) on ERVT were observed. However, no effects of MC were found for ERV.

Conclusions: Results from this analysis show an elevated risk of cardiovascular emergency room visits from short-term exposure to different size-fractions of particle NC and MC.

NONRESPONSE BIAS IN EPIDEMIOLOGICAL SURVEYS: DIFFERENCES BETWEEN RESPONDERS AND NON-RESPONDERS ACCORDING TO CHRONIC CONDITIONS AND ENVIRONMENTAL EXPOSURES

Massimo Stafoggia, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Nera Agabiti, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Giulia Cesaroni, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Francesco Forastiere, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*

Background and Aims: in the last decades, several cross-sectional studies have been designed to investigate the association between air pollution and respiratory or cardiovascular diseases. However, the differences between responders and nonresponders according to the study outcome and exposure have been neglected. Our aim was to address the nonresponse bias issue in the PREDICTOR study.
Methods: the PREDICTOR study is a population-based survey designed to estimate the prevalence of heart failure in the population aged 65-84 years in Rome. Subjects received an invitation to perform a clinical examination and an echocardiogram at the local hospital. For each subject, information was available on: age, gender, a list of chronic conditions derived from the past 9-year hospitalizations. In addition, multiple air pollution indicators were collected at the census-block level: proximity to high traffic roads; meters of streets and traffic density within a 150-m buffer; average NO_2 concentrations as estimated from land-use regression; average concentrations of PM_{10} and ozone, as estimated from dispersion modeling. Odds ratios of nonresponse were estimated in relation to individual and environmental variables, from logistic regression models adjusted for age and gender.
Results: the study population consists of 3,753 subjects: 1,512 responders and 2,241 nonresponders. Responders were younger (mean age=73 years) than nonresponders (mean age=75), and were males in higher proportion (52% versus 40%). Patients with previous respiratory failure, cerebrovascular, and neurological disorders were less likely to respond. No difference emerged in the responding rate of patients with or without past heart failure. With regard to air pollution exposure, responders and nonresponders were similar for all the parameters collected.
Conclusions: we found a differential response rate with regard to demographic and some disabling chronic conditions, but not to air pollution exposure. The health effects of air pollution in the PREDICTOR study should not be affected by differential response rate.

SOCIOECONOMIC STATUS AND ENVIRONMENTAL TOBACCO SMOKE EXPOSURE OF CHILDREN IN KOREA.

Background and Aims: Exposure to environment tobacco smoke (ETS) can have serious health consequences, especially for children. It was reported that most of ETS exposure occurred at home and lower parental socioeconomic status (SES) increased a risk of ETS exposure at home. This study aims to investigate the relationship between individual level SES of parents and children's ETS exposure, to examine the effects of individual level SES depending on the characteristic of residential areas, and to evaluate the interactive effects of area level and individual level SES in Korea.
Methods Whether ETS exposure was associated with parental SES was evaluated using information on 7,059 children aged 6–13 years from the Children's Health and Environment Research (CHEER) study in Korea. First, bivariate and multivariate associations between parental SES and children's ETS exposure were examined using logistic regression analysis. Secondly, to evaluate the effects of parental SES on children's ETS exposure by deprivation level of residential areas, we estimated the model including the interaction term of deprivation level of residential areas with parental SES.
Results: After adjustment for possible confounding variables, paternal education was found to be highly correlated with children's ETS exposure, especially among children whose father had less than 12 year education living in the most deprived area (Odds ratio=2.82, 95% CI=(2.02–3.94)).
Conclusions: Our findings suggest that characteristics of residential areas may influence ETS exposure of children directly and interactively with parental SES in Korea. Findings from this study could inform policy decision making of evidences regarding the associations of community as well as individual level socioeconomic factors with ETS.

Göran Pershagen, *Institute of Environmental Medicine, Karolinska Institutet, Sweden*

Background and Aims: Long-term exposure to community noise has been suggested to contribute to the development of cardiovascular diseases. However, the evidence is inconclusive. We investigated cardiovascular effects of living near busy roads and railways with regard to noise exposure.
Methods: The study population consists of 25.851 men and women, aged 18-80 years, who had lived in Sweden for at least five years. All subjects participated in a National Environmental Health Survey, performed in Sweden in 2007 (response rate 59.4%), in which they reported on health, annoyance reactions and environmental factors. Self-reported doctor's diagnosis of hypertension and/or of cardiovascular disease were used as outcomes. Exposure to road traffic was assessed as Road Traffic Work, expressed as millions of vehicle kilometers per year (Mvkm/y), within radii 50, 250 and 500m around each participant's residential address. For a subsample (n= 2.496), we also assessed road and railway noise as the L_{den} level at the most exposed façade of the dwelling, based on digital noise maps produced in accordance with the European Environmental Noise Directive. Multiple logistic regression was used to assess prevalence Odds Ratios and 95% Confidence Intervals.
Results: No statistically significant associations were found between Road Traffic Work in any of the three radii (average 0.02, 0.81 and 3.42 Mvkm/y) and self-reported hypertension or cardiovascular disease, adjusting for sex, age, country of birth, education, smoking and air pollution (PM_{10} and NO_2). In the subpopulation, there were no associations between road traffic noise (average 56 dB) and the outcomes. A borderline statistically significant trend was found per 5 dB increase in railway noise in relation to cardiovascular disease (OR 1.21; 95% CI 0.99 to 1.48), however, there was no clear dose-response pattern.
Conclusions: In this study, community noise exposure was not significantly associated with an increased risk of hypertension or cardiovascular disease.

THE STUDY OF IMPACT OF BATHING IN RESERVOIRS ON THE PROBABILITY OF ADVERSE HEATH EFFECTS IN CHILDREN

Sergey V. Kuzmin, *Rospotrebnadzor Agency in the Sverdlovsk Region, Russia*
Elena A. Kuzmina, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*

Vitaliy V. Veprencev, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*
Alexey S. Chagin, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*

Background and Aims: The objective was to assess children's health risks related to the chemical contamination of local reservoirs and accidental swallowing of water when bathing in them.
Methods: The studies have been conducted in 2006-2011 in the city of Yekaterinburg, a large industrial center of the Sverdlovsk Region, Russian Federation. Chemical contamination of 5 natural reservoirs has been studied for the past 5 years. We assessed the total mutagenic activity of waters using the Ames mutagenicity test, the ecotoxicity using the Ecolum test-system and a Daphnia magna survival test. In order to specify the exposure parameters (the duration and frequency of exposure, and the body weight) to assess the oral exposure, we questioned 198 children aged 8-9. The health risks were assessed based on the highest and average exposure values.
Results: Concentrations of some chemicals in the study reservoirs exceeded Russian permissible levels. The maximum concentrations found (in mg/dm^3) were 0.05 for lead, 0.002 for cadmium, 0.01 for arsenic, and 3.2 for aluminum. Concentrations of copper, nickel, and lead exceeded their permissible values in silt and sediments. The Ames test registered the excess (compared to background) number of reverse mutants without metabolic activation on stains of microorganisms TA-98 (1.8-2.26) and TA-100 (2.08-2.69); the death rate of Daphnia magna exceeded 50 % (52-75%). The cumulative personal cancer risks from cadmium, arsenic, and lead varied from $1.53 * 10^{-7}$ to $6.30 * 10^{-6}$ based on maximum exposure values and from $1.37 * 10^{-8}$ to $5.38 * 10^{-7}$ based on average exposure values. Hazard indices of contaminants were <1.
Conclusions: Taking into account a short duration of summer exposure and oral exposure only, chemical contamination of water reservoirs posed children's health risks close to acceptable ones. The findings are used to identify sources of contamination and to develop health risk management actions.

RISK OF METABOLIC SYNDROME AMONG PEOPLE PARTICIPATED IN CLEAN-UP WORK 1 YEAR AFTER HEBEI SPIRIT OIL SPILL

Ik-jin Lee, *Taean Environmental Health Center, Taean. Korea Rep.*
Woo-Chul Chung, *Taean Environmental Health Center, Taean, Korea Rep.*
EunYoung Cho, *Taean Environmental Health Center, Taean , Korea Rep.*
Jongil Hur,*Taean Environmental Health Center, Taean , Korea Rep.*

Yong-Bae Kim, *Department of Preventive Medicine, College of Medicine, Soonchunhyang University, Cheonan, Korea Rep.*
Yong-Jin Lee, *Department of Occupational Medicine, College of Medicine, Soonchunhyang University, Cheonan, Korea Rep.*

Background and Aims: Since many kinds of hazardous substances were released by oil spill accident, various potential health effects including cardiovascular and metabolic effect may have occurred. However, few studies have been conducted on the medium and long-term health effects of oil spill. We aimed to assess the risk of metabolic syndrome in people exposed to the spilt oil during clean-up work 1 year after the accident of Hebei Spirit oil spill in 2007, Taean, Korea.
Methods: The study was carried out from February 2009 to August 2009. A total of 9,035 adults including 3,755 males and 5,280 females participated in the study. Health examination (height, weight, blood pressure, body mass index) and blood test (total cholesterol, Triglyceride, HDL, fasting blood sugar) were performed. The information of duration of the clean-up work, drinking, smoking, physical exercise, and health behavior were obtained by a questionnaire interview. The logistic regression model adjusted for age, gender, smoking history was used to estimate the risk of metabolic syndrome associated with the level of oil spill exposure.
Results: The prevalence of metabolic syndrome was 24.6% in the males and 26.8% in the females. High blood pressure showed the highest prevalence among the risk factors of metabolic syndrome (46.8%), followed by body mass index, hypertriglyceridemia, low HDL-cholesterol, and high fasting blood sugar level. High blood pressure, hypertriglyceridemia, and high fasting blood sugar level showed a higher prevalence in the males and at the ages of fifties and sixties. The metabolic syndrome prevalence was higher according to the increase of duration of the cleaning work. The risk of metabolic syndrome in people who participated in the clean-up work for more than 125 days, compared with people who did not participate in the cleaning work was significantly higher (OR=1.45, 95% CI=1.20-1.74), with a significant dose-response relationship for days of clean-up work (p-trend<0.001). Moreover, the risk of metabolic syndrome in people who reside in the region within 0.5 km from the coastline, compared with those who reside in the region far from the coastline by more than 2.5 km was significantly higher (OR=1.35, 95% CI=1.18-1.55), with a significant inverse trend with distance from coastline (p-trend<0.001).
Conclusions: This study showed that there was a significant association between exposure to oil spill during the clean-up work and the risk of metabolic syndrome with a dose-response manner.

SHIFT-WORK AND CANCER RESEARCH: PRINCIPLES, PITFALLS AND PERSPECTIVES OF „WHITE-BOX“ EPIDEMIOLOGY

Thomas C Erren, *Institute and Policlinic for Occupational Medicine, Environmental Medicine and Prevention Research, University of Cologne, Germany. tim.erren@uni-koeln.de*

Peter Morfeld, *Institute for Occupational Epidemiology and Risk Assessment (IERA)*

Evonik Industries AG, Germany

Background and Aims: The 2007 IARC [International Agency for Research on Cancer] classification “Shiftwork that involves circadian disruption is probably carcinogenic to humans (Group 2A)” substantially rests on “sufficient evidence in experimental animals for the carcinogenicity of light during the daily dark period (biological night)”. Remarkably, a series of biologically plausible causal mechanisms suggested by experiments provides a unique case for “white-box” epidemiology. This presentation identifies principles, pitfalls and perspectives of necessary epidemiological research in coming years.
Methods: A synthesis of key results from a selective literature search into the issues concerned will be provided.
Results: That epidemiologists can use tantalizing mechanistic and experimental findings to refine studies is an asset of “white-box” epidemiology. Clearly, studies can be enhanced by employing biological insights to improve measurements of exposure, relevant covariates, cancer endpoints, and their relation. Equally clearly, strong experimental evidence should not mislead us to accept lower quality and replication standards of observational studies in this research area. In this vein, a critical pitfall to avoid is that biological plausibility may be invoked to facilitate publication of studies of inappropriate quality.
Conclusions: To contribute to much-needed quality studies, recommendations regarding how epidemiological research into biologically plausible links between shift-work and cancer should be (i) designed, (ii) reported and (iii) interpreted are provided. Key information to include in future studies will be the chronotype which may determine the susceptibility of individuals to work conditions at unusual biological times. Moreover, industry-based studies should be pursued with priority, allowing us to consider shift-work but also other occupational factors in appropriate detail, completeness and accuracy. Ultimately, individual shift-work histories that were collected in an independent fashion, rather than relying on post-hoc interview information, will be imperative to reliably assess - or exonerate - possible cancer risks for shift-workers.

ARSENIC BIOMONITORING IN RURAL NOVA SCOTIA, CANADA

Elizabeth Spangler, *Atlantic Veterinary College – University of Prince Edward Island, Canada*

Background and Aims

Groundwater arsenic remains a significant global public health concern. Rapid, portable, noninvasive biomonitoring methods to assess chronic exposures in human populations are not currently available. The purpose of this investigation was to survey arsenic exposures for selected subjects in communities with historically elevated groundwater arsenic concentrations. Collaborators tested biological samples for arsenic concentration and genetic damage to determine relationships among the laboratory test results and survey exposures.

Methods

Study participants (n=179) were from 2 Nova Scotia communities, selected in consultation with government hydrogeologists, with documented high levels of arsenic in drinking water from residential wells. Participants completed a previously validated, 24-hour recall dietary survey (adapted for Nova Scotia based on pilot study responses), and allowed collection of a well water sample, which was tested by inductively coupled plasma mass spectrometry. Other possible arsenic exposures (eg. medications, smoking) were also included in the survey.

Results

Water arsenic concentrations ranged from below detection limits (0.07 µg/L) to 309 µg/L (median: 4.00 µg/L, 95% CI: 1.03 – 8.27 µg/L), with 41% ≥10 µg/L. Daily water arsenic consumption ranged from 0 µg – 1,799 µg (median: 2.86 µg, 95% CI: 1.1 – 12.9 µg). Estimated daily food arsenic consumption ranged from 0 µg – 1,606 µg (median: 19.6 µg, 95% CI: 14.70 – 59 µg). Estimated total arsenic ingestion ranged from 0 µg – 2,874 µg (median: 80.2µg, 95% CI: 53.6 – 125 µg). Linear regression analyses indicated that water arsenic concentration, rice consumption, and seafood consumption were significant predictors of total arsenic consumption (*p-value* <0.01), with no other exposure, demographic or location factors remaining significant in the final model.

Conclusions

The study population had 41% of water arsenic concentrations ≥10 µg/L (recommended maximum, World Health Organization), but well within reported levels for Canadian populations. The main sources of arsenic in this population were water, seafood and rice.

AMBIENT AIR POLLUTION MODELS: IMPACT ON ESTIMATED EXPOSURE AND RELATIONSHIP WITH FETAL GROWTH, THE EDEN MOTHER CHILD COHORT

Background and Aims: We previously reported that, although moderately correlated, nitrogen dioxide (NO_2) atmospheric levels estimated by air quality monitoring stations (AQMS) and a geostatistical model, showed similar associations with birth weight (BW). We extended this comparison by also considering a dispersion model, and PM_{10} levels.
Methods: We focused on women from the Eden cohort recruited in two French maternity hospitals, living less than 5km away from a permanent monitoring station in two areas of about 500km^2 in which we implemented dispersion and geostatistical models. NO_2 and PM_{10} pregnancy average levels were available for 770 and 452 women, respectively. We estimated Kappa coefficients of concordance (K) to compare the exposure estimates (categorized in tertiles), and used adjusted linear regression to estimate the association between exposure levels and BW.
Results: Mean ±sd exposure levels (µg/m^3) during pregnancy were 29±10 for NO_2 and 19±2 for PM_{10}, as estimated by the AQMS model, 24±8, and 18±3 respectively for the dispersion model, and 24±5 for NO_2 as estimated by the geostatistical model. The dispersion model showed a stronger agreement with the geostatistical (K_{NO2}=0.52) than with the AQMS model (K_{NO2}=0.37 K_{PM10}=0.41). Agreement between dispersion and AQMS models improved within 2 and 1km of an AQMS. Each PM_{10} increase by 10µg/m^3 during the pregnancy was associated with an adjusted BW decrease of 123g (95% confidence interval, -273; 27g) as estimated by the AQMS model and 79g (-202; 44g) as estimated by the dispersion model. Results for NO_2 showed statistically weaker associations with BW, but were consistent among the three exposure models.
Conclusion: Dispersion model NO_2 estimates were in moderate agreement with the geostatistical model but exhibited similar associations. PM_{10} levels from the AQMS and the dispersion models were fairly concordant, and associations with BW were somewhat statistically stronger for the AQMS model.

Background and aims: In many developing countries, gold mining is performed using mercury. Mercury is used to extract gold from ore. Mercury exposure leads to negative health effects. The aim of this study was to provide a common data base using data from existing studies in gold mining areas to be able to compare with data from other areas.
Methods: Data of several existing studies from Indonesia, Mongolia, Philippines, Tanzania, and Zimbabwe were combined to analyze the relation between exposure in small-scale gold mining areas and body burden (n=1278). Relating to their intensity of contact with mercury four groups were formed: (i) a non exposed control group; (ii) a low exposed group with participants only living in mining areas, but not working as miners; (iii) a medium exposed group, miners living in exposed areas and working with mercury without smelting amalgam; and (iv) a high exposed group, miners living in exposed areas and smelting amalgam. Kruskal–Wallis test was used to test for possible differences over all groups. Mann-Whitney U test was used to compare the different exposure groups with the control group.
Results: Participants living in exposed areas and miners working in highly exposed areas have significant higher levels of mercury in urine, hair and blood compared to the non-exposed control group ($p < 0.001$). In urine the median mercury value is < 0.2 µg/l for the control group and 11.9 µg/l (max. 5240 µg/l) for the high exposed group. In blood the median mercury value is < 1 µg/l for the control group and 7.61 µg/l (max. 429 µg/l) for the high exposed group. In hair the median level is 0.21 µg/g for the control group and 2.43 µg/g (max. 792 µg/g) in the high exposed group. The mercury levels are different between the different countries. Reasons are diverse background burdens due to different fish eating habits and different work place methods. The mercury levels of exposed participants are in a high percentage above threshold limits.
Conclusions: Gold miners in small scale gold mining areas in Indonesia, Mongolia, Philippines, Tanzania and Zimbabwe have high levels of mercury in urine, blood and hair.

COMPARISON OF 3 EUROPEAN COUNTRIES (UNITED KINGDOM, THE NETHERLANDS AND FRANCE) IN TERMS OF EPIDEMIOLOGICAL RESPONSE AND PREPAREDNESS FOR A DISASTER

Marta Sala Soler, *Institut de Veille Sanitaire, Saint-Maurice, France*
Philippe Pirard, *Institut de Veille Sanitaire, Saint-Maurice, France*
Yvon Motreff, *Institut de Veille Sanitaire, Saint-Maurice, France*
Pascal Empereur-Bissonnet, *Institut de Veille Sanitaire, Saint-Maurice, France*

Background and Aims: Disasters constitute a major public health challenge as they can have direct and indirect consequences on the health of the populations and consequently impact health systems. After a disaster, governmental and relief organizations must identify the priorities needed for orientating actions in order to limit health consequences at short- and long-term. Health risk assessment and epidemiology can be useful tools to obtain information for such a task.
Based on the comparison of responses to three disasters in three European countries, the objective was to identify and discuss common epidemiological challenges that public health institutions around Europe face in their response to disasters.
Methods: The disasters chosen for comparison were the 2001 AZF factory explosion in Toulouse (France), the 2000 Enschede fireworks disaster (the Netherlands) and the 2005 London Bombings (United Kingdom). A literature review was done and exchanges between public health institutes were made.
Results: The three case studies stressed the same key points: acute health risk assessment, adequate and timely environmental samples, health registering in emergency, interaction with local stake holders and victims, finding reference levels for comparison, low participation rate to epidemiological studies… Some interesting solutions could be identified as answers to these issues: steering and scientific committee, field Advice-Information Centres, Automatic Medical Registrations.
Conclusions: The comparison has stressed the fact that the challenge of assessing the health situation can only be addressed by a combination of methods (health risk assessment, surveillance and surveys). Furthermore strong interaction between local stakeholders, decision makers and epidemiologists is the only way to guarantee relevant, in time, high quality and useful health impact information. Such targets can only be reached by a strong upstream preparation of post-accident management organisations. Institutes must reinforce their sharing of methodologies and their cooperation at the European level for improving post disaster epidemiological preparation.

COARSE AND TRAFFIC-RELATED PARTICULATE MATTER AND THE HUMAN MICROVASCULATURE *IN VIVO* ASSESSED VIA RETINAL IMAGING: THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS

Background and Aims: Airborne particulate matter may affect cardiovascular health via underlying vascular disease. While recent evidence links fine particles ($PM_{2.5}$) to microvasculature changes, associations with larger coarse particles ($PM_{10-2.5}$) and traffic-related particles remain unknown.
Methods: Associations between retinal arteriolar diameters, a microvasculature measure, and chronic residential concentrations of $PM_{10-2.5}$ mass, $PM_{10-2.5}$ copper (an indicator of motor vehicle brake wear), and residential proximity to major roadways were examined among Chicago-based Multi-Ethnic Study of Atherosclerosis participants. Subjects aged 46 to 87 years and without clinical cardiovascular disease at enrollment (2000-2002) underwent retinal photography between 2002-2003. Participant-specific concentrations were estimated using speciated $PM_{10-2.5}$ data and a universal kriging spatial prediction model. A binary nearness to major roadways variable was also calculated. All associations were examined using linear regression models adjusted for age, sex, race/ethnicity, education, income, smoking status, alcohol use, physical activity, body mass index, family history of cardiovascular disease, diabetes, serum cholesterol, glucose, blood pressure, emphysema, C-reactive protein, and medication use. Secondary analyses included control for long-term concentrations of $PM_{2.5}$.
Results: Among 779 participants with complete data, retinal arteriolar diameters were not associated with $PM_{10-2.5}$ concentrations but were associated with traffic-related exposures. Narrower arterioles were found among persons residing near roadways (-3.0 µm, 95% CI: -5.1 to -0.8) and among persons living in areas of higher $PM_{10-2.5}$ copper concentrations (-1.2 µm per 4 ng/m^3, 95% CI: -2.7 to 0.2). Control for $PM_{2.5}$ strengthened the associations with $PM_{10-2.5}$ copper (-2.4 µm per 4 ng/m^3, 95% CI: -4.7 to -0.1), whereas associations with residential proximity to roadways were unaffected.
Conclusions: Higher exposures to traffic as assessed by residential proximity and $PM_{10-2.5}$ copper concentrations, but not $PM_{10-2.5}$ mass, were associated with narrower retinal arteriolar diameters in older individuals. This suggests that the retinal microvasculature is sensitive to traffic pollution but not coarse particulate mass.

ROAD TRAFFIC NOISE AND SOCIOECONOMIC STATUS: ENVIRONMENTAL INEQUALITIES AT THE SMALL-AREA LEVEL IN MARSEILLES, FRANCE

Pierre Verger, *INSERM, U912 (SE4S), Marseille, France ; Université Aix Marseille, IRD, UMR-S912, Marseille, France ; ORS PACA, Observatoire Régional de la Santé Provence Alpes Côte d'Azur, Marseille, France.*
Sébastien Cortaredona, *INSERM, U912 (SE4S), Marseille, France ; Université Aix Marseille, IRD, UMR-S912, Marseille, France ; ORS PACA, Observatoire Régional de la Santé Provence Alpes Côte d'Azur, Marseille, France*
Aurélie Bocquier, *INSERM, U912 (SE4S), Marseille, France ; Université Aix Marseille, IRD, UMR-S912, Marseille, France ; ORS PACA, Observatoire Régional de la Santé Provence Alpes Côte d'Azur, Marseille, France*
Boutin Céline, *Soldata Acoustic, Lyon, France*
Bigot Alexis, *Soldata Acoustic, Lyon, France*
David Aude, *Soldata Acoustic, Lyon, France*

Background and Aims: Although numerous studies show that ethnic minorities and people with low socioeconomic status (SES) are more exposed than others to some environmental risks (e.g., proximity to hazardous facilities and air pollution), few have focused on environmental noise exposure despite its significant potential non-auditory health effects (sleep disturbance, psychological distress, and cardiovascular diseases). This study analyzed the associations between SES and potential exposure to road traffic noise at the small-area level in Marseilles, France's second largest city.
Methods: Five SES variables were constructed at the census block level from census data: a deprivation index, 3 thematic indicators (economic, social, and national origin), and a residential mobility index. In accordance with European Directive 2002/49/EC, we calculated two indicators of potential exposure to road traffic noise with the noise propagation prediction model CadnaA: L_{den} for 24-hour and L_n for night periods. Loess diagrams described the associations between SES and noise exposure, which were further analyzed by regressions controlling for spatial autocorrelation (simultaneous autoregressive or SAR models). Sensitivity analyses were conducted with different models (SAR_{lag}, SAR_{err}, and SAR_{mix}) and neighborhood matrices.
Results: Only the mobility index was linearly related to noise indicators. SAR models showed that L_{den} and L_n were both higher in the intermediate than in the least deprived class. Results were similar for the economic index, and no relation at all was observed for the social index. A significant link with noise was found for areas with the lowest, but not the highest, percentages of non-French residents. L_{den} and L_n increased with residential mobility. Sensitivity analyses confirmed these results.
Conclusions: This study reports original results about noise-related environmental inequalities and about methods of adjustment for spatial autocorrelation. The results are discussed in relation to theoretical mechanisms of environmental inequalities and Marseilles's historical development.

IMPACT OF BIOGAS DIGESTERS ON COOKHOUSE VOC EXPOSURE IN KENYAN FARMWOMEN

Carolyn Dohoo, *Dalhousie University, Canada*
Dr. John VanLeeuwen, *University of Prince Edward Island, Canada*
Dr. Mark Gibson, *Dalhousie University, Canada*
Dr. Judy Guernsey, *Dalhousie University, Canada*
Dr. Kim Critchley, *University of Prince Edward Island, Canada*
Neil Brewster, *Dalhousie University*

Background and Aims: Women living on rural Kenyan farms rely on wood for cooking. These women are exposed to elevated concentrations of volatile organic compounds (VOC) and respirable particles due to a combination of poor ventilation in the cookhouse and inefficient wood combustion. Biogas digesters anaerobically convert livestock manure into methane for cooking, reducing the need for traditional open-fire cooking, and potentially reducing wood smoke exposure. The objective of this project was to compare VOC exposure for Kenyan smallholder farmwomen with and without biogas digesters.
Methods: A sample of 31 farms with biogas digesters and 31 farms without digesters (matched on family size, farm size, and the age of the cooking woman) were selected. The woman responsible for the majority of the cooking on each farm wore a passive thermal desorption tube (TDT) for 7 days whenever cooking. The TDTs were packed with a Tenax TA™ polymer sorbent. Participants recorded the time spent each day cooking with either wood or methane. The TDTs were analyzed, in Canada, by thermal desorption-gas chromatography with flame ionization/electron capture detection to determine the VOC concentrations in each cookhouse.
Results: The control group spent significantly more time ($p<0.01$) exposed to wood smoke compared to the biogas group, but similar amounts of time cooking ($p>0.2$). Of the 54 individual VOCs tested, 20% ($n=11$) had concentrations that were significantly different between the two groups ($p<0.05$), with X VOCs being significantly higher in the control group. These concentrations were also significantly higher than levels in the ambient environment ($p<0.05$).
Conclusions: Compared to women without biogas digesters, women with biogas digesters spent less time exposed to wood smoke, and had lower concentrations of some VOCs in their cookhouses. Continual off gassing from the cookhouse structures could be responsible for the similarities in the other VOC concentrations.

IMPACT OF CLIMATE CHANGE ON HEAT RELATED MORTALITY AND MORBIDITY IN EUROPE

Christofer Åström, *Umeå University, Sweden*
Hans Orru, *University of Tartu, Estonia*
Kristie Ebi, *Stanford, USA*
Gustav Strandberg, *SMHI, Sweden*
Bertil Forsberg, *Umeå University, Sweden*

Background and Aims: Public health concerns about the health effects of extreme temperatures have risen because of the intense heatwaves of 2003 and 2006 in Europe. Climate change projections indicate that average temperatures are rising and that the intensity, frequency, and duration of extreme heat events will increase. As a part of the Climate-TRAP project we used emission scenarios, models and epidemiological data to assess heat related health impacts under a changing climate.
Methods: Gridded climate data were obtained as a 50x50km grid for Europe using two global climate models (HADCM3 and ECHAM4) regionally downscaled over Europe with the RCA3. Modelled temperature and humidity data for the time periods 1961-1990 and 2021-2050 was used to represent the recent and future climatic conditions. Data for the A1B and A2 greenhouse gas emission scenarios (modelled with HADCM3 and ECHAM4 respectively) were used to illustrate possible outcomes for different climate scenarios. We used exposure response functions determined for a number of European cities within the PHEWE-project.
Results: Future temperatures are predicted to increase the expected annual mortality for Europe in 2021-2050 compared to 1961–1990 by 1.15% and 1.28% for the A1B and the A2 scenarios, respectively. The increase differs between countries, with a range from no increase in heat-related mortality for the Baltic countries to increases above 3% for Spain, Slovenia and Portugal. For hospital admissions, the expected increase is substantially lower than the estimations for mortality with increases ranging up to 0.66% in Spain.
Conclusions: This study suggest that the expected annual increase in heat related mortality in 2021-2050 compared to 1961–1990 in Europe is in the same order of magnitude as the excess number of heat related deaths during the 2003 heatwave over Europe .

URINARY BISPHENOL-A AND HEMOGLOBIN A1C LEVELS IN U.S. ADULTS USING DATA FROM NHANES 2003/08

Monica K. Silver, *Department of Environmental Health Sciences, School of Public Health, University of Michigan, Ann Arbor, MI, USA*
Marie S. O'Neill, *Departments of Epidemiology and Environmental Health Sciences, School of Public Health, University of Michigan, Ann Arbor, MI, USA*
Sung Kyun Park, *Departments of Epidemiology and Environmental Health Sciences, School of Public Health, University of Michigan, Ann Arbor, MI, USA*

Background: Bisphenol A (BPA) is a ubiquitous environmental contaminant. Low dose negative effects of BPA have been demonstrated in many organ systems, especially as an endocrine disruptor. BPA exposure may lead to insulin resistance and development of type-2 diabetes through its over-activation of the insulin-producing pancreatic β- cells. Previous epidemiological studies have linked urinary BPA and type-2 diabetes.
Methods: We examined 4,389 adults who participated in the National Health and Nutrition Examination Survey (NHANES) from 2003 to 2008 to further explore the association between BPA exposure and type-2 diabetes. We investigated if higher urinary BPA was associated with higher hemoglobin A1c (HbA1c), a biological measure of the glycemic index, using survey-weighted generalized linear models.
Results: For the total sample of 4,389, log-transformed urinary BPA levels were highly associated with HbA1c (β estimate= 0.034% (95% confidence interval (CI), 0.002% to 0.066%) for an interquartile range increase in log(BPA), 1.41 ng/mL), after controlling for age, sex, race/ethnicity, education, household income, smoking, body mass index, waist circumference, and urine creatinine concentrations. However, such a significant association was found only in the 2003/04 cycle of NHANES (n=1,364) (β=0.097% (95% CI, 0.040% to 0.154%)). No association was found in NHANES 2005/06 or 2007/08. The observed significant association in NHANES 2003/04 seems to be driven by a larger significant association among participants who were taking diabetes medication (n=119, weighted percentage=6%, β=0.324% (95% CI, 0.055% to 0.592%)); for non-medication-users (n=1,245, weighted percentage=94%, β=0.003% (95% CI, -0.042% to 0.047%)).
Conclusions: Although we found a significant association between higher urinary BPA and elevated HbA1c in a pooled analysis, this was driven by data from only one NHANES cycle. Additional studies, especially with a longitudinal design, are needed to further elucidate the association between BPA and HbA1c and type-2 diabetes.

MATERNAL OCCUPATION AND THE RISK OF PRETERM BIRTH AND LOW BIRTH WEIGHT IN LOS ANGELES COUNTY, CALIFORNIA

Ondine von Ehrenstein, *University of California, Los Angeles, USA*
Anthony Wang, *University of California, Los Angeles, USA*
Jokay Ghosh, *University of California, Los Angeles, USA*
Michelle Wilhelm, *University of California, Los Angeles, USA*
Christina Lombardi, *University of California, Los Angeles, USA*
Beate Ritz, *University of California, Los Angeles, USA*

Background and Aims: Several studies from different countries have linked certain maternal occupations during pregnancy with adverse birth outcomes, though some reports showed no associations. We investigated risks associated with a range of maternal occupations for preterm birth (PTB) and low birth weight (LBW) in a population based nested case-control study in Los Angeles County.
Methods: From 58,316 birth records for children born in 2003 to mothers residing in 111 Los Angeles County zip codes, we selected all cases of LBW (<2500 g) and PTB (<37 weeks completed gestation) and an equal number of randomly sampled matched controls (weight ≥2,500g and full-term). We conducted a survey 3 to 6 months after birth with 2,543 of the 6,374 women originally sampled from the cohort asking about their primary job (defined as the job where she worked the longest and for the most hours per week during pregnancy); other demographic and pregnancy-related variables were collected by survey and from birth certificates. We classified women according to occupation with a coding scheme adapted from the U.S. Census Occupational Category Codes. Effects of various occupational exposures on PTB and LBW were examined using multivariable logistic regression models.
Results: Preliminary findings indicate that most examined occupational categories were not associated with an increased risk for PTB and LBW. However, there was some suggestion that nurses may have higher odds of preterm delivery compared to clerks (presumably low exposed) with an odds ratio of 2.50 (95% CI 0.95, 6.60), adjusted for relevant confounders.
Conclusion: Preliminary findings suggest that in our sample the odds for PTB or LBW were not increased for the investigated occupations during pregnancy. This may indicate a 'healthy pregnant worker' effect.

HOSPITAL ADMISSIONS AND MORTALITY AS COMPLEMENTARY OUTCOMES IN EVALUATING THE SHORT-TERM EFFECTS OF AIR POLLUTION ON RESPIRATORY HEALTH

Francesco Forastiere *Department of Epidemiology, Local Health Authority Rome E, Rome, Italy*
on behalf of the EPIAIR collaborative Group*.

Backgrounds and aims: It is well known that air pollution affects respiratory health, increasing both hospitalisation and mortality. To complete a previous assessment of air pollution effects on respiratory mortality in Italy (Faustini et al, ERJ, 2011), we studied the impact of particles (PM_{10}) and nitrogen dioxide (NO_2) on hospitalisations. A combined outcome, including both hospitalisations and deaths, was also analysed for chronic obstructive pulmonary disease (COPD).
Methods: We analyzed emergency hospitalizations and out-of-hospital deaths for respiratory diseases among those aged 35+, who resided in six Italian cities. The associations with PM_{10} and NO_2 in the years 2001-2005, using a time-stratified case-crossover analysis, was evaluated.
Results: There were 106,792 hospitalisations for respiratory diseases and 5,490 respiratory deaths. The risk of hospitalisation for respiratory diseases increased by 0.63% (95% Confidence Intervals, CI, 0.18-1.09) for a 10• g/m^3 PM_{10} increase and by 1.14% (95% CI, 0.26-2.03) for a 10• g/m^3 NO_2 increase, both at lag 0. The strongest associations were observed between NO_2 and hospitalizations for COPD (1.27%; lag 0) or pneumonia (2.34%; lag 2-5). Lower effects, but with the same pattern, were observed for PM_{10}. The risk of dying increased by 4.72% for PM_{10} and by 7.44% for NO_2, both at lag 2-5. The combined outcome showed an increased risk at lag 0 for PM_{10} (0.67%) and at lag 0-5 for NO_2 (1.58%). In the warm season (April-September) all the effects were stronger than in the cold season.
Conclusions: We confirmed a respiratory health effect of air pollution in Italian cities. The combined effect was present for both PM_{10} and NO_2; they were immediate for COPD hospitalisations and delayed for hospitalisations due to respiratory infections and out-of-hospital deaths in COPD patients.

THE CONTRIBUTION OF WITHIN AND BETWEEN VARIATIONS OF URINARY METABOLITE MEASUREMENTS IN PREDICTING CHILDREN'S PESTICIDE EXPOSURES

Kathleen Attfield, *Harvard School of Public Health, USA*
Xihong Lin, *Harvard School of Public Health, USA*
Chensheng (Alex) Lu, *Harvard School of Public Health, USA.*

Background and Aims: Organophosphate pesticides are employed in wide broadcast agricultural use, and while some are banned for use in households, off market use and residues from imported fruits and vegetables provide additional sources of exposure to children. At acute exposure levels, these pesticides are known for their neurological and neurodevelopmental effects and evidence is building for neurological affects with chronic low level exposures. Studies of children's pesticide exposures often use models utilizing single spot urine sampling and boost study power by increasing enrollment. However, this design has the central assumption of greater between subject than within subject variances. With the availability of repeated measures data over a 12-month period, this assumption can be tested.
Methods: Repeated measurements of urinary metabolite data from the Children Pesticide Exposure Study - Washington (CPES-WA) was employed for an analysis of dietary malathion exposure with linear mixed effects modeling including season, age, and gender as covariates and accounting for values below the limit of detection with maximum likelihood estimation.
Results: Within subject variance exceeded between subject variance by a factor of eight: 16 versus 2. Season is a significant contributor to the model at $p<0.001$, while gender and age were not statistically significant covariates.
Conclusion: Analysis of components of variance for repeated measures showed eight-fold greater contribution of within subject variation to predicting malathion pesticide exposure levels than between subject. Therefore, repeated measures with fewer subjects may be a more efficient design for understanding children's pesticide exposure levels than single spot urine measurements involving a great number of study participants.

EXPOSURE ASSESSMENT OF A RETROSPECTIVE COHORT OF RESIDENTS NEAR INCINERATORS IN ITALY: A GEOGRAPHICAL APPROACH

Andrea Ranzi, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy*

Paola Angelini, *Regional Health Authority, Emilia-Romagna, Italy*
Silvia Candela, *Epidemiology Unit, Local Health Authority of Reggio Emilia, Italy*
Paolo Lauriola, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy*
Francesco Forastiere, *Department of Epidemiology, Regional Health Service, Lazio, Italy*

Background and Aims: Health effects of exposure to incinerators are controversial. In Emilia-Romagna region (northern Italy), a multisite project (MONITER project) is focusing on the environmental and health impact of eight municipal solid waste plants (MSW). Effects of past exposures on mortality and cancer incidence are under study. In the first stage a large retrospective cohort of residents has been set up and characterized.
Methods: Study areas were defined as the 4 km zones around the six MSW incinerators, that were already active before 1995. Follow-up period ranged from 1995 (first availability of health data) to 2006. Exposure assessment to incinerators was performed by means of pollution map of particulate, provided by ADMS dispersion model outputs. Collection of past emission data were used as inputs for models. Different models were constructed for each plant, according to renewals during study period. Exposure levels at enrolment (1995) were used, since cumulative exposure could not be estimated as complete residential history since start of the plants were not available. Simulations of pollutants dispersion were also performed for all other sources in the areas (traffic, heating, industries, agriculture). Deprivation index was calculated at census tract level. Exposure estimates at home location were calculated using G.I.S.
Results: A total of 219,615 residents were involved (2,157,390 person/years). During the study period 27,573 deaths for natural causes (mortality rate: 1278x100.000pys), and 14,287 cases of cancer occurred (incidence rate: 758x100.000pys). Mean exposure to particulates from incinerators at enrolment was 6.24 nanograms/m3 [s.d. 14.29]. Mean exposure to NO2 from all other sources was 56.63 micrograms/m3 [s.d. 32.09]. No relation between deprivation index and exposure to incinerators was observed.
Conclusions: We constructed a large retrospective cohort of residents near incinerators with a geographical approach for exposure assessment. Possible misclassification due to assignment to exposure at a specific time (enrolment) is under study.

ARE HEAT PREVENTION PROGRAMS EFFECTIVE? A PRE-POST ANALYSIS OF THE EFFECT OF TEMPERATURES ON MORTALITY OF THE ELDERLY IN 16 ITALIAN CITIES

Schifano Patrizia *Department of Epidemiology, Lazio Regional Health Service, Italy*
Leone Michela *Department of Epidemiology, Lazio Regional Health Service, Italy*
de'Donato Francesca *Department of Epidemiology, Lazio Regional Health Service, Italy*
Bargagli Anna Maria *Department of Epidemiology, Lazio Regional Health Service, Italy*
D'Ippoliti Daniela *Department of Epidemiology, Lazio Regional Health Service, Italy*
Michelozzi Paola *Department of Epidemiology, Lazio Regional Health Service, Italy*

Background and Aims: Since 2004, Heat Health Warning System (HHWWS) and heat prevention programs have been implemented in Italy. This study evaluated changes in the impact of temperature on summer mortality among elders, before and after the introduction of heat plans.
Methods: We analyzed daily all-cause mortality of 65+ years old residents in 16 Italian cities with an active HHWWS at summer 2004. Studied years were 1996-2002 and 2006-2009 for the period preceding and following the HHWWS start, respectively. Exposure was defined as the difference between maximum apparent temperature (tappmax) and a city-specific threshold (90^{th} percentile of June; range 29.9°-35.2°). The lag for exposure was defined for each city using a constrained distributed-lag model. We performed a non-linear city-specific analysis using a generalized Poisson equation, with a penalized cubic smooth function with 6 df for exposure. We predicted the percent (%) change in mortality for three-degree step variations in the exposure. We used a random effect meta-analysis to produce the overall estimate.
Results: No differences in the overall percent increase in mortality were observed between the two periods for increases in the tappmax below the threshold. On the other hand, above this point a significant reduction in the effect of heat was observed in the post-period. An increase in tappmax over the threshold of 3° C was associated with a %change in the pre and post period of 16.73% (IC95%:13.90–19.56) and of 5.26% (IC95%:3.14–7.38), respectively. The reduction was greater when considering more extreme temperatures, ranging from +46% for temperature around the threshold to +70% for higher values.
Conclusions: The study shows a reduction in the effect of high temperature on mortality, when HHWWS are activated, suggesting that heat prevention programs can mitigate the impact of heat on health. Alternative explanations should be evaluated, including use of air conditioning.

LONG-TERM EXPOSURE TO AIR POLLUTION ($PM_{2.5}$ AND NO_2) AND MORTALITY: RESULTS OF THE ROME LONGITUDINAL STUDY (ROLS)

Cesaroni G. *Department of Epidemiology, Lazio Regional Health Service, Italy*
Gariazzo C. *Italian Workers' Compensation Authority (INAIL), Italy*
Sozzi R. *Regional Environmental Protection Agency, Italy*
Badaloni C. *Department of Epidemiology, Lazio Regional Health Service, Italy*
Davoli M. *Department of Epidemiology, Lazio Regional Health Service, Italy*
Forastiere F. *Department of Epidemiology, Lazio Regional Health Service, Italy*

Background and aims: There are few longitudinal studies evaluating the role of chronic exposure to air pollutants within the same urban setting. We analyzed the association of long-term exposure to $PM_{2.5}$ and NO_2 with mortality in a large cohort.
Methods: The Rome Longitudinal Study is a fixed cohort enrolled at the 2001 census. We selected subjects aged 45-80 years at the baseline who had not changed their address in the previous five years (n=684,204). Exposure at residence to $PM_{2.5}$, was predicted by means of a chemical transport model (FARM) (1 km^2 grid) using 2005 emissions data. Spatial levels of NO_2 were derived from a specific land use regression model (R^2=0.66). We had information on age, gender, education, occupation, place of birth, and area-based socioeconomic position at baseline. All subjects were followed till December 31, 2006. Cox regression models were used to study the association between the exposure and cause-specific mortality, taking several confounders into account.
Results: During the study period, 45,006 natural deaths occurred (33% cardiovascular, 5% respiratory disorders, 3.3% diabetes, and 12% lung cancer). The average exposure was 23 (sd 4) $\mu g/m^3$ for $PM_{2.5}$ and 44 (8) $\mu g/m^3$ for NO_2. The correlation of the two exposure indicators was 0.75. With increased exposure of $PM_{2.5}$ and NO_2 there was an increased risk of dying for natural causes: 7% (95%CI:4%-9%) for 10$\mu g/m^3$ increase of $PM_{2.5}$, and 9% (95%CI:6%-13%) for 10$\mu g/m^3$ increase of NO_2. The relationships were linear with no evidence of a threshold. The strongest associations were found for cardiovascular diseases and diabetes.
Conclusions: This is one of the largest European urban cohort study on $PM_{2.5}$. The results indicate that long-term exposures to $PM_{2.5}$, and NO_2 at residence are associated with mortality in Rome and the effect estimates are very similar to what has been suggested in studies from the USA.

TRANSPORTION, AIR POLLUTION AND PHYSICAL ACTIVITIES (TAPAS), A 6-CITY INTEGRATED HEALTH RISK ASSESSMENT PROGRAM OF ACTIVE TRAVEL POLICIES: THE WARSAW CASE STUDY

Marko Tainio, *Systems Research Institute, Warsaw, Poland; National Institute for Health and Welfare (THL), Kuopio, Finland.*
Piotr Holnicki, *Systems Research Institute, Warsaw, Poland*
Katarzyna Juda-Rezler, *Warsaw University of Technology, Warsaw, Poland*
Artur Badyda, *Warsaw University of Technology, Warsaw, Poland*
Magdalena Reizer, *Warsaw University of Technology, Warsaw, Poland*
Katarzyna Iwinska, *Collegium Civitas, Warsaw, Poland*
Krzysztof Skotak, *National Institute of Public Health - National Institute of Hygiene, Warsaw, Poland*
Krzysztof Cichocki, *Systems Research Institute, Warsaw, Poland*
Zbigniew Nahorski, *Systems Research Institute, Warsaw, Poland*
Audrey de Nazelle, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
on behalf of the TAPAS team.

Background and Aims: Within the TAPAS research program, quantitative assessments are developed for six case study cities in Europe, linking determinants of active travel to potential co-benefits and co-risks of modal shifts from motorized to non-motorized modes of travel. We describe here the Warsaw case study.

Methods: The collection of required data is made as collaboration between different research institutions and city authorities. In addition to already existing data, data from measurements and from the questionnaires will be collected in this and in connected projects. The stakeholder will be contacted in the near future to discuss the data, available policy options and the use of the results. The assessing of uncertainties in the TAPAS model will be special focus.

Results: Warsaw, capital city of Poland, has officially 1.7 million inhabitants. The total population of the city is unknown and it is possibly much larger than official one. During the week days and weekends only 0.9% and 1.7% of the trips, respectively, are made with bicycles. Approximately 20% of the trips are made by foot. Large different between walking and bicycling activity is likely to be due to infrastructural issues. The climate in Warsaw is typical central-European climate with daily mean temperature of 8.2°C and annual Precipitation of 495 mm. Thus, the climate is good for both walking and for cycling most of the year. However, Warsaw bike lane network is fragmented and safe bicycle parking places are rare. Both of these will decrease the usability of bicycles inside the city. Therefore the relevant policies we are considering for assessment include 1) the development of the bike lane network; 2) bicycle parking; 3) bicycle renting system.

Conclusions: Warsaw is an interesting case for studying a city where the use of bicycles is low but on the same time bicycle infrastructure is under construction.

VARIATION OF ELEMENTAL COMPOSITION OF PARTICULATE MATTER BETWEEN AND WITHIN 20 STUDY AREAS IN EUROPE

Ming-Yi Tsai, *(1) Swiss Tropical and Public Health Institute, Basel, Switzerland, (2) University of Basel, Switzerland, (3) University of Washington, Seattle, USA*
Regina E. Ducret-Stich, *(1) Swiss Tropical and Public Health Institute, Basel, Switzerland, (2) University of Basel, Switzerland*
Harish C. Phuleria, *(1) Swiss Tropical and Public Health Institute, Basel, Switzerland, (2) University of Basel, Switzerland*
Gerard Hoek, *Institute for Risk Assessment Sciences, Utrecht University, The Netherlands*
L.-J. Sally Liu, *(1) Swiss Tropical and Public Health Institute, Basel, Switzerland, (2) University of Basel, Switzerland, (3) University of Washington, Seattle, USA*
on behalf of the **ESCAPE WP2 group**

Background and Aims:
Recent research has indicated the importance of particulate matter (PM) composition on adverse health effects. Furthermore, knowledge of PM composition can be used to apportion pollution to its sources. In 20 study areas of the ESCAPE project, 2-week integrated PM sampling was conducted in 3 different seasons at 20 locations per area in 2008-2010. At the European level, these filters will reveal differences in elemental composition by city, season, size fraction, and site type; thereby, allowing potential determination of likely sources. Moreover, if elemental data can be spatially modelled, it can be linked with health data from cohort studies within ESCAPE.

Methods:
The filters from PM areas are being analyzed by x-ray fluorescence (XRF) to determine their elemental composition. Currently, a total of 1043 filters have been analyzed from the 1st year of sampling for 48 individual elements. As more analyses results are received and data are linked with filter information, trace element data will be examined by city, season, size fraction, and site type. We expect to observe groupings of correlated elements related to different sources; eg, traffic impacts reflected in Fe/Ba/Zn/Cu. Other aspects examined will include: mass contribution of elements to total PM; seasonal contributions of biomass burning (K) and road-salt use (NaCl).

Results:
An overview of all 950 analyzed sample filters, with an average mass of 535.5µg, shows an average elemental contribution of 14.2% of total mass. A correlation matrix of these filters already indicates several common groupings: Al/Si/Ca/Fe/Ti (crustal), Fe/Zn/Cu (traffic), Na/Cl (road/sea-salt). The strength of these correlations is currently buried by the aggregation of all filters.

Conclusions:
Examination of trace element composition of PM will reveal within and between area compositional differences over Europe, which may be associated with health effects. This is particularly notable as all the monitoring was done in a harmonized manner.

MATERNAL CONTAMINANT EXPOSURE IN CANADA: CONVENIENCE AND RANDOM SAMPLING COMPARISONS

Jay Van Oostdam, *Health Canada, Healthy Environments and Consumer Safety Branch, Chemicals Surveillance Bureau, Ottawa, Canada*
Bryan Adlard, *Health Canada, Ottawa, Canada*
Tara Leech, *Health Canada, Ottawa, Canada*
Meredith Curren, *Health Canada, Ottawa, Canada*
Warren Foster, *McMaster University, Hamilton, Canada*
Shawn Donaldson, *Health Canada, Ottawa, Canada*

Background / Aims

Recently the Canadian Health Measures Survey (CHMS) and a Health Canada study have examined in southern Canada a similar group of contaminants in women of child bearing age (WCBA) and mothers, respectively. This paper will examine the differences in these contaminants between a random sample of WCBA and a convenience sample of mothers, both Canadian born and non-Canadian born.

Methods

The CHMS a national health survey of over 5000 individuals has concentrations of contaminants in women of child bearing age in a stratified random population sample (n=285, 2007-2009). The Health Canada study has collected a convenience sample of first time mothers from five Canadian centres and includes both Canadian born and non-Canadian born mothers (n=125, 2005-2007). Concentrations of total mercury, lead, several polychlorinated biphenyl congeners, and various organochlorine pesticides are compared.

Results

Initial data analysis has found that the concentrations for many of these contaminants are age dependent, increasing with age and that mothers born in Canada had lower concentrations of many contaminants compared to mothers not born in Canada. The concentration of many of these contaminants in WCBA from the CHMS is intermediate between these two groups of mothers. Further analyses of the WCBA will explore the differences seen in the Canadian vs non-Canadian born mothers to see if there are contaminant pattern differences between mothers and WCBA.

Conclusions

Both women of child bearing age and first time mothers have a similar suite of contaminants in their blood. In-depth analysis has found that there are significant differences between mothers born in Canada and mothers born outside of Canada

VARIATION AND LAND USE REGRESSION MODELS FOR PM_{10}, $PM_{2.5}$ AND SOOT CONCENTRATIONS IN 19 EUROPEAN STUDY AREAS

Audrey de Nazelle, *CREAL, Barcelona, Spain*

Gerard Hoek, *IRAS, Utrecht, The Netherlands*

on behalf of the ESCAPE WP2 group

Background and aims :ESCAPE will assess the relationship between long-term exposure to outdoor air pollution using prospective health studies in different European countries, to contribute to revisions of PM standards in the European Union. We will report on between and within study area variation of measured concentrations and performance of the land-use regression (LUR) models.

Methods: We measured $PM_{2.5}$, $PM_{2.5}$absorbance and PM_{10} between October 2008 and April 2011 in 19 European study areas in a harmonized manner. In each study area, 20-40 sites were selected to represent a range of within-city contrasts in population density and nearby traffic intensity. Each site was measured during three 14-day periods spread over the year, using Harvard impactors. Results were averaged, correcting for temporal variation using a centrally located reference site, which was operated year-round. LUR models were developed to explain spatial variation as a function of population density, land-use and traffic intensity near the site.

Results: In all study areas currently available (Ruhr area, Munich, Catalunya and The Netherlands) we found substantial variability of annual averages between and within study areas. For all components, contrasts between background and traffic concentrations were greatest in Barcelona, with ranges of 8.45-24.39µg/m³ for $PM_{2.5}$, 17.78-49.27µg/m³ for PM_{10} and 0.93-4.93m^{-1} for $PM_{2.5}$absorbance). For $PM_{2.5}$, spatial contrasts were smallest in Munich (9.75-17.64ug/m3), while for PM_{10} and $PM_{2.5}$absorbance spatial variation was lowest in Ruhr area (22.50-33.60µg/m³ and 1.04-2.58m^{-1} respectively). Explained variance of LUR models ranged from 71% in The Netherlands to 88% in Ruhr area for $PM_{2.5}$, and from 69% in Ruhr area to 90% in Barcelona for PM_{10}. $PM_{2.5}$absorbance models explained 86% of spatial variation in Barcelona and 97% in Ruhr area.

Conclusion : Contrasts between background and street sites within cities were greater than contrasts between the background levels of different cities. LUR models explained a large amount of spatial variation within all study areas.

DIFFERENT LAG EFFCTS OF ASIAN DUST EVENTS ON CARDIORESPIRATORY MORBIDITY AND MORTALITY IN SEOUL, KOREA

Hyunsuk Hong, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University,* Republic of Korea
Ho Kim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University,* Republic of Korea

Background and Aims: The effects of Asian dust events on morbidity and mortality has been assessed in the previous studies from East Asia. However, only a few studies have evaluated the effects of Asian dust events on both morbidity and mortality.
Methods: We investigated the associations between Asian dust events and mortality and hospital admissions in Seoul, Korea for the periods 1992–2009 and 2001–2006 after adjusting for daily mean PM10 concentration, temperature, relative humidity, day of the week, trends in time. We employed generalized linear model with natural cubic splines.
Results: During study period, a total of 173 Asian dust events were observed and 596,549 deaths were identified along with 797,021 and 894,907 admissions for cardiovascular and respiratory diseases, respectively. We found that the Asian dust events causes 2.57% (95% CI: -1.28~6.58) increase in cardiovascular admissions at lag 3 day and 3.93% (95% CI: 0.03~7.97) for deaths due to cardiovascular disease at lag 6 day.
Conclusions: This study suggests that Asian dust events have short lag effects on morbidity than mortality. .

Background and Aims: Terbuthylazine (TBA) is a herbicide widely used in maize cultivation, one of major crop in Northern Italy. Aim of this work was to evaluate short-term and long-term exposure to TBA in agriculture workers and in rural residents.
Methods: Ten farmers, 13 rural residents, and 17 urban residents entered the study. Urine samples were collected before starting the application season for all subjects (March, T0) and after the application of TBA in farmers only, in two moments: at bed time the day of the application (April, T1), and the next day in the morning (T2). Hair samples were collected for all subjects at T0, and at the end of the application season (July, ES). TBA and its metabolite desethylterbutylazine (DET) in urine and hair were measured by LC/MS/MS in the presence of deuterated internal standards.
Results: At T0 median urinary TBA and DET was <0.25 µg/L in all subjects; in farmers urinary DET significantly increased to 1.81 and 2.95 µg/L at T1 and T2, respectively ($p<0.001$), urinary TBA was always <0.25 µg/L.
Hair DET was always <0.010 ng/mg. At T0 median TBA in urban residents was <0.010 ng/mg hair, such level was lower than 0.010 ng/mg measured in both farmers and in rural residents ($p=0.004$). At ES median TBA was 0.073>0.011>0.010 ng/mg hair in farmers, rural residents and urban residents, respectively ($p<0.001$).
No correlation was observed between urinary DET and hair TBA, while significant or borderline significant correlations were found between hair TBA and age or application time ($p = 0.021$ and p 0.081).
Conclusions. Urinary DET and hair TBA seem to be promising candidates for biomonitoring short- and long-term exposure to TBA. The use of this herbicide in agriculture impacts the exposure of rural residents.

SPATIAL CLUSTERING ANALYSIS OF NON-HODGKIN'S LYMPHOMA IN DOGS AND IN HUMANS IN THE CITY OF SAO PAULO, BRAZIL.

Background and Aims: Lymphoma is a malignant clonal expansion of lymphoid cells. This paper aimed to study lymphoma both in humans and in dogs, showing areas of low and high risk in different regions of the city of São Paulo through the mapping Geographic Information System (GIS).
Methods: It was collected 556 cases of lymphoma in dogs and 629 cases of lymphoma in humans. Data included were race, gender, age, anatomic localization, stage of lymphoma and the zip code. Simultaneously, 84 control cases and 83 dogs diagnosed with lymphoma were analyzed through an epidemiological questionnaire applied to their owners.
Results: The spatial clustering analysis showed a similarity in distribution of lymphomas in both species which showed a higher prevalence of the disease in the areas with higher socio-economic development. The distribution cartographic showed a weak association between slums, sewers and water and the lymphoma clusters. It showed that infectious and parasitic diseases probably could not be correlated with the development of lymphomas, enhancing the cartographic standard for chronic diseases. The strong socio-economic factor of patients and of the owners of dogs with lymphoma may be related to areas with increased urbanization and pollution.
Epidemiological results of the questionnaire showed that dogs with lymphoma over 10 kg which are permanently kept outdoor and near busy street or avenue had a higher risk for development of this disease (OR: 3.1, 95% CI:1.4 – 6.9, p=0,005) suggesting that there is a strong correlation with external environmental factors, like pollution.
Conclusions: These findings suggested that environmental factors, such as pollution, may increase the risk of developing canine and human malignant lymphoma. This reinforces the need for further investigations to clarify such evidence and the relationship between environmental contaminants and lymphoma in humans and in dogs.

A LONGITUDINAL STUDY OF EXPOSURE TO LIVESTOCK ODOR AND SYMPTOM REPORTS IN CHILDREN

Virginia Guidry, *University of North Carolina at Chapel Hill, USA*
Steve Wing, *University of North Carolina at Chapel Hill, USA*

Background and Aims: Industrial livestock operations are sources of dusts and gasses that can affect respiratory health. Associations between school proximity to industrial hog operations and prevalence of asthma-related illness in children have been seen in cross-sectional studies. We conducted a longitudinal study of air pollution from industrial hog operations and symptom reports.
Methods: 340 children aged 11-15 attending schools near industrial hog operations completed daily diaries in science class for 3-5 weeks in February-November 2009. Odor was reported for the previous 24 hours in each diary record. Participants recorded the current strength of eleven symptoms on a five-point scale (none, barely there, present, strong, or very strong). Logistic fixed effects models were used to examine within-person associations between livestock odor and binary symptoms with adjustment for concurrent reported odors of vehicle exhaust and smoke from fires.
Results: Livestock odor was reported by 255 participants (75%) during follow-up. The median proportion of study days participants reported livestock odor and strong livestock odor was 29% and 12%, respectively. Reported livestock odor in the previous 24 hours was associated with increased symptom reports for respiratory and irritation symptoms. Log odds (±standard error) following exposure to livestock odor were 0.44±0.25 for chest tightness, 0.57±0.26 for shortness of breath, 0.40±0.13 for cough, 0.36±0.15 for sore throat, and 0.46±0.18 for burning eyes or nose. Children reporting current wheeze at baseline (N=65) experienced stronger effects of livestock odor on chest tightness, shortness of breath, and wheeze than children not reporting current wheeze. Among participants with allergies (N=83), logs odds for burning eyes or nose increased to 0.97±0.29, while other associations were similar.
Conclusions: These associations are consistent with cross-sectional studies of respiratory conditions in children and a previous longitudinal study of symptoms in adults living near industrial hog operations.

STUDYING POTENTIAL HEALTH EFFECTS IN CLEAN-UP WORKERS INVOLVED IN THE GULF OF MEXICO DEEPWATER HORIZON OIL SPILL: THE GULF STUDY

Dale Sandler, National Institute of Environmental Health Sciences / NIH, USA
Richard Kwok, National Institute of Environmental Health Sciences / NIH, USA
Larry Engel, University of North Carolina at Chapel Hill, USA and National Institute of Environmental Health Sciences / NIH, USA
Aubrey Miller, National Institute of Environmental Health Sciences / NIH, USA
Aaron Blair, National Cancer Institute / NIH, USA

Background and Aims: The Gulf Long-term Follow-up Study (GuLF STUDY) will investigate potential short- and long-term health effects associated with clean-up activities following the Deepwater Horizon disaster in the Gulf of Mexico. Crude oil, burning oil, and the dispersants used during clean-up efforts contain a range of known and suspected toxins. Over 100,000 persons have participated in clean-up activities related to the spill. While most of these individuals participated in active clean-up efforts, others did not. Exposures among clean-up workers range from negligible to potentially significant, especially for those involved in tasks associated with direct exposure to crude or burning oil, or to chemical dispersants. The potential health effects associated with the levels of exposure experienced by clean-up workers are largely unstudied. Heat and stress experienced by these workers may also have adverse long-term health effects. In addition to the oil itself, the widespread economic and lifestyle disruption caused by the oil spill may contribute to mental health problems among this population.
Methods: The GuLF STUDY has begun enrollment of 55,000 workers and controls across the United States through a telephone interview. Approximately 20,000 of these workers will undergo additional follow-up through a home visit where anthropometric, physiologic, biologic and environmental measurements are collected. We intend to study a wide range of health outcomes particularly respiratory, neurological, hematologic, and psychological or mental health.
Results: We will present preliminary results from the first six months of enrollment and data collection.
Conclusions: The GuLF STUDY is the largest study of its kind and will provide valuable information on potential exposures and health effects associated with this and future oil-spill clean-up efforts.

PHTHALATES IN FOOD ON THE BELGIAN MARKET: OCCURRENCE AND POSSIBLE CONTAMINATION PATHWAYS

Mirja Van Holderbeke, *VITO - Flemish Institute for Technological Research, Belgium*
Lieve Geerts, *VITO - Flemish Institute for Technological Research, Belgium*
Tine Fierens, *VITO - Flemish Institute for Technological Research, Belgium*
Kelly Servaes, *VITO - Flemish Institute for Technological Research, Belgium*
Guido Vanermen, *VITO - Flemish Institute for Technological Research, Belgium*
Isabelle Sioen, *Ghent University – Department of Public Health, Belgium*

Background and Aims: Phthalates are used in many industrial and consumer products. High-molecular-weight phthalates are primarily used as plasticizers to soften PVC products, while low-molecular-weight phthalates are widely used as solvents to hold colour and scent in products. Phthalates have been detected in food and also measured in humans.
This study investigated phthalates in food products on the Belgian market in order to explore possible contamination pathways.
Methods: 650 Representative samples of widely consumed foods were purchased in Belgian shops. The levels of eight phthalates were determined and product specific properties were stored in a database. This database was used to explore the contamination pathways by identifying relations between sample properties (e.g. fat content, pH and packaging) and measured phthalate concentrations.
Results: The results of the measurement campaign show a wide variety of phthalate concentrations in the food samples. Concentrations are higher in high-fat food products like butter, oil and cheese compared to low-fat food products, like vegetables and juices. Higher phthalate concentrations were also detected in some cardboard packed food, probably due to migration from inks and glues. Aluminium inner package seems to be a good barrier for migration. A wide range of phthalate levels in bread was found and further research is necessary.
Conclusions: A wide variety in phthalate concentration was found. The fat content of the food product, the composition of the food as well as the composition and properties of the packaging material have been identified as possible contamination causing conditions. In a next phase of this study, we will use these data to quantify the dietary intake of phthalates for the Belgian population.

SIZE DISTRIBUTION OF PARTICLE-BOUND *n*-ALKANES AND POLYCYCLIC AROMATIC HYDROCARBONS AT AN URBAN MEDITERRANEAN LOCATION

Galindo, Nuria *Miguel Hernandez University, Spain*
Montse Varea, *Miguel Hernandez University, Spain*
Juan Gil-Moltó, *Miguel Hernandez University, Spain*
Carolina Chofre, *Miguel Hernandez University, Spain*

Background and Aims: Different studies have demonstrated that the hydrocarbons present in the atmospheric particulate matter (PM), specifically those with anthropogenic origins, are primarily associated with particles smaller than 1.5 µm and, as such, pose elevated risks to human health. These studies have been conducted in highly populated and industrialised cities, in which the fine particle concentration to the total atmospheric particulate matter is very elevated. In the south Spanish Levant, however, the contributions of coarse particles (>2.5 µm) from natural phenomena, like resuspension or Saharan intrusions, can be very significant. This could change the hydrocarbon contribution to different size fractions of suspended particles.
Methods: PM1, PM2.5 and PM10 samples collected with low volume samplers (2.3 m^3/h) at two sites in the city of Elche (southeastern Spain) from October 2008 until March 2009 were analyzed to determine the concentrations of 11 polycyclic aromatic hydrocarbons (PAHs) and *n*-alkanes from C_{20} to C_{40}. One sampling site, classified as urban background, was located on the roof of a building at the Miguel Hernández University, adjacent to a major city avenue, in a highly ventilated area. The other was placed at a palm tree garden in the city centre.
Results: Average total PAH concentrations were 0.99, 1.36 and 1.16 ng/m^3 for PM1, PM2.5 and PM10, respectively. The dominant PAHs in the three size fractions were benzo[*b*]fluoranthene, benzo[*k*]fluoranthene and chrysene, representing ~ 40% of the total PAH content. The benzo[a]pyrene equivalent concentration, used as an indicator of the PAH toxicity, was 0.11, 0.13 and 0.11 in PM1, PM2.5 and PM10, respectively. Mean total *n*-alkane levels in PM1, PM2.5 and PM10 were, respectively, 14.0, 20.2 and 21.3 ng/m^3. The *n*-alkanes C_{29} and C_{31} were the most abundant congeners in PM10, while PM1 and PM2.5 fractions were dominated by *n*-alkanes C_{23}-C_{25}. The average CPI (carbon preference index), similar for all size fractions, was ~ 1.5. The plant wax contribution to odd carbon numbered homologues was 37% for PM10 and ~ 31% for PM1 and PM2.5.
Conclusions: Approximately 70% of PAHs were mainly associated with submicron particles (<1 µm) which can easily reach the alveolar region of the respiratory system increasing their potential health effects. The major source of PAHs in the city was traffic since the most abundant congeners (benzo[*b*]fluoranthene and benzo[*k*]fluoranthene) have been identified as tracers of vehicle emissions.
CPI values and percentages of plant wax *n*-alkanes showed predominant contributions of anthropogenic sources during the cold season, although biogenic emissions must not be considered negligible, especially in inner city sampling sites with high vegetation.

7-Year Neurodevelopmental Consequences of Prenatal Exposure to Chlorpyrifos, a Common Organophosphate Pesticide

Virginia Rauh *Columbia University, USA*

Srikesh Arunajadai *Columbia University, USA*

Megan Horton *Columbia University, USA*

Frederica Perera *Columbia University, USA*

Lori Hoepner *Columbia University, USA*

Dana Barr *Emery University, USA*

Robin Whyatt *Columbia University, USA*

BACKGROUND AND AIMS: First registered in 1965 for agricultural and pest control purposes, chlorpyrifos is a broad-spectrum, chlorinated organophosphate (OP) insecticide. Early concerns about the possible neurotoxicity of OP insecticides for humans derived from animal studies showing that prenatal and early postnatal exposures to CPF were associated with neurodevelopmental deficits. In humans, prenatal exposures to chlorpyrifos (CPF) have been associated with neurodevelopmental problems in young children from different populations. The goal of the study was to determine the relationship between prenatal CPF exposure and 7-year neurodevelopment in an urban population.

METHODS: In a sample of 265 children (participants in a propsective study of air pollution), we measured prenatal CPF exposure in umbilical cord blood (pg/g), and 7-year neurodevelopment,using the Wechsler Intelligence Scales for Children (WISC-IV). Estimates of effect were obtained from multiple and logistic regression, adjusted for income, sex, race/ethnicity, home environment, child anxiety, secondhand smoke (ETS) and polycyclic aromatic hydrocarbons (PAH).

RESULTS: Prenatal CPF exposure was associated with 7-year deficits in Full-Scale IQ (p=0.02), Working Memory (p=0.002), and Verbal Comprehension (p=0.08). On average, for each standard deviation (4.61 pg/g) increase in exposure concentration, Full-Scale IQ declined by 1.7%, and Working Memory declined by 2.7%. CPF increased the risk of borderline function (< 80) on Full-Scale IQ (OR=1.13, 95% CI 1.04--1.23, p=0.005), Working Memory (OR=1.10, 95% CI 1.01--1.19, p=0.03), and Verbal Comprehension (OR=1.09, 95% CI 1.00--1.18, p=0.05).

CONCLUSIONS: We report significant 7-year deficits in Full-Scale IQ and Working Memory, as a function of prenatal CPF exposure. Higher exposure increased risk of borderline function in IQ, Working Memory, and Verbal Comprehension, with implications for learning and school achievement. These findings are important in light of continued widespread use of CPF in agricultural settings.

AIR POLLUTION AND RISK OF PARKINSON DISEASE IN A LARGE PROSPECTIVE STUDY OF WOMEN

Natalia Palacios, *Harvard University, USA*
Francine Laden, *Harvard University, USA*
Alberto Ascherio, *Harvard University, USA*

Background: Very little is known about the effects of air pollution on neurological outcomes, particularly in the area of Parkinson's disease (PD) epidemiology. The toxins in air pollution are thought to cause damage to human health by evoking an inflammatory response[19] and by increasing oxidative stress, and inflammation is thought to play an important role in the pathogenesis of PD.
Methods: We assessed whether exposure to air pollution is related to risk of PD in the Nurses Health Study (NHS), a large prospective study of women. Data on cumulative exposure to air pollution before onset of PD was obtained using geographical information systems (GIS) to link an individual place of residence at different ages with location-specific air pollution levels. We prospectively followed 121,701 women in the NHS and used Cox proportional hazards models to estimate the risk of PD associated with exposure to PM_{10} (particulate matter less than 10 micrometers in diameter) and $PM_{2.5}$ (particulate matter less than 2.5 micrometers in diameter) air pollution.
Results: In models adjusted for age in months, and pack years of smoking, we did not observe a significant association between PM_{10} or $PM_{2.5}$ air pollution and risk of incident PD. The relative risk (RR) for a 10 ug/m^3 increase in PM10 was 1.01 (95% CI: 0.82, 1.24). For a 10 ug/m^3 increase in $PM_{2.5}$, the RR of incident PD was 1.14 (0.70, 1.77).
Conclusions: In this study, exposure to PM_{10} and $PM_{2.5}$ was not related to risk of PD. Other measures of air pollution, such as exposure to specific pollutants with relation to risk of PD should be further explored.

TRIGGERING OF TRANSMURAL INFARCTIONS BY AMBIENT FINE PARTICLES, ROLE OF SECONDARY VERSUS PRIMARY PARTICLE SPECIES MASS FRACTIONS

Natasha Hodas, *Rutgers University, School of Environmental and Biological Sciences, New Brunswick, NJ, USA*
Barbara Turpin, *Rutgers University, School of Environmental and Biological Sciences, New Brunswick, NJ, USA*

Background: Previously, we reported an increased risk of transmural, but not non-transmural, infarctions associated with increased $PM_{2.5}$ concentrations in the previous 24 hours. We then hypothesized that this acute response to $PM_{2.5}$ differed by $PM_{2.5}$ species.

Methods: We used all ER admissions for first myocardial infarctions (2004-2006) of New Jersey residents living ≤10km from a $PM_{2.5}$ monitoring site (n=1563), measured daily $PM_{2.5}$ mass concentrations, and daily $PM_{2.5}$ species mass fractions estimated by Community Multiscale Air Quality modeling (CMAQ). Using daily bias adjusted CMAQ mass and species averages we calculated the mass fractions of sulfate, nitrate, ammonium, elemental carbon (EC), and organic carbon (OC) and ranked each daily species mass fraction into tertiles. Using a time-stratified case-crossover design and conditional logistic regression adjusted for apparent temperature, we then estimated the risk of a transmural infarction associated with each 10.8 $\mu g/m^3$ increase in measured $PM_{2.5}$ concentration in the previous 24 hours within each tertile of each species (e.g. high, middle, and low sulfate; high, middle, and low EC, etc.).

Results: We found the largest relative risk estimates on the days with the highest tertile of sulfate (OR=1.13; 95% CI = 1.00, 1.27), nitrate (OR=1.15; 95% = 0.98, 1.35), and ammonium (OR=1.13; 95% CI = 1.00, 1.28), and the lowest tertile of EC (OR=1.17; 95% CI = 1.03, 1.34). "High ammonium" and "low EC" appear to represent the same days, as they have the same mean temperature (15 ± 11°C) and $PM_{2.5}$ composition (29% sulfate, 21% OC, 15% ammonium, 14% nitrate, 7% EC, 14% other).

Conclusions: EC is a tracer for primary $PM_{2.5}$ (including primary OC) and secondary OC is often correlated with sulfate. Thus, this suggests the acute effect of ambient $PM_{2.5}$ on transmural infarctions is greatest on days with a larger fraction of secondary PM (sulfate, nitrate and/or secondary OC).

PAEDIATRIC COMPUTED TOMOGRAPHY EXPOSURE AND RADIATION-INDUCED CANCER: SETTING UP OF THE FRENCH COHORT OF CHILDHOOD CT SCAN

Marie-Odile Bernier *IRSN, DRPH, SRBE, Laboratoire d'épidémiologie, BP17, 92262 Fontenay-aux-Roses Cedex, France*.
Hervé Brisse *Radiology Department, Institut Curie, France*
Jean-Luc Rehel *IRSN, DRPH, SER, Medical Radiation Protection Expertise Unit, BP17, 92262 Fontenay-aux-Roses Cedex, France.*

Sylvaine Caer-Lorho *IRSN, DRPH, SRBE, Laboratoire d'épidémiologie, BP17, 92262 Fontenay-aux-Roses Cedex, France*
Bernard Aubert *IRSN, DRPH, SER, Medical Radiation Protection Expertise Unit, BP17, 92262 Fontenay-aux-Roses Cedex, France.*
Dominique Laurier *IRSN, DRPH, SRBE, Laboratoire d'épidémiologie, BP17, 92262 Fontenay-aux-Roses Cedex, France*

Background and aims: The increased use of computed tomography (CT) scans for paediatric patients raises the question of a possible impact of such ionising radiation (IR) exposure on the occurrence of secondary leukaemia and cancers. We describe the preliminary results of an ongoing cohort study of children exposed to CT in France, performed in collaboration with the "Société Francophone d'Imagerie Pédiatrique et Prénatale". This cohort will be included in the trans-national collaborative EPI-CT project.
Materiel and Methods: In 19 of the most important French paediatric radiology departments, demographic and IR exposure information concerning children less than 5 years, who underwent at least one CT scan between 2000 and 2006, were collected. Inclusion of patients will continue from 2007 to 2013 according to the EPI-CT project. Absorbed organ doses are calculated with the "CT-expo" software.
Results: Until now, 28,190 children free of cancer or leukaemia at the first CT scan examination have been included. Age at first CT scan exposure was less than 1 year for 42% of the population. The mean number of CT examination per child was 1.5 (min 1, max 30) and concerned head in 66% of the cases, thorax in 22%, abdomen and pelvis in 10% and other localisations in 2%. Highest cumulated organ doses were observed for brain and lens during head exposure and mean absorbed doses were 27 mGy (range: 2.8 - 478 mGy) and 30 mGy (0.5 -620 mGy), respectively.
Conclusion: This cohort allows to better characterizing organ doses associated with CT scan exposure in childhood. Relatively high doses to radiosensitive organs (lenses, ovaries, breast, etc…) have been observed, as well as large dose ranges according to the protocols used. The follow-up of the cohort will be first based on cancer incidence up to age 15 to quantify a possible excess paediatric cancer risk.

METHODS FOR TRACKING EXPOSURES TO DRINKING WATER CONTAMINANTS IN CALIFORNIA

Craig Wolff, *California Environmental Health Tracking Program (California Department of Public Health), United States of America*

Background and Aims: While infrastructure and regulations help assure the quality of drinking water to millions of California citizens, there continue to be areas where existing contaminant levels may pose residual risks to the population. To assess the extent of suspected exposures to continuing waterborne hazards, and the concurrent linkages to disease, requires several pieces of information. We aimed to enumerate this information in the context of available exposure assessment methods and with the goal of developing an ongoing tracking system.
Methods: Through literature review, targeted communications with technical experts, and needs assessment, we identified and prioritized methods for linking individuals or small populations to specific water supplies and for estimating exposures to contaminants, given available water quality observations. We assessed the feasibility of developing a drinking water quality tracking system in terms of cost, effort, expertise, information systems infrastructure, and external factors which affect the ability to use a method or to acquire additional related drinking water quality and delivery information.
Results: In California, 85% of the population receives its drinking water from regulated community water systems, while 15% use unregulated private sources. The most promising method for assessing exposures to populations on regulated water supplies involves modeling tap water quality from existing water quality monitoring records. The primary impediment to implementing this method is the lack of complete and high resolution geospatial information available for describing water purveyor service boundaries and for characterizing zones of homogeneous water quality within distribution systems.
Conclusions: To better analyze water contaminant exposures in California, a frequently updated and time-dependent geospatial reporting system is proposed for capturing water system service areas and hydraulically isolated distribution sub-zones. Once a complete statewide coverage of regulated supplies is attained, the remaining unregulated areas can be analyzed with respect to disease outcomes and risk-attributable ambient conditions.

INFLAMMATORY RESPONSES TO AMBIENT ULTRAFINE AND FINE PARTICLES IN PATIENTS UNDERGOING CARDIAC REHABILITATION

David Q. Rich, *University of Rochester Medical Center, Rochester, New York, USA*
William Beckett, *Mt. Auburn Hospital, Cambridge, Massachusetts, USA*
Philip K. Hopke, *Clarkson University, Potsdam, New York, USA*
Yungang Wang, *Clarkson University, Potsdam, New York, USA*
David Oakes, *University of Rochester Medical Center, Rochester, New York, USA*
Mark W. Frampton, *University of Rochester Medical Center, Rochester, New York, USA*
Wojciech Zareba, *University of Rochester Medical Center, Rochester, New York, USA*
Mark J. Utell, *University of Rochester Medical Center, Rochester, New York, USA*

Background: Airborne particle concentrations have been associated with myocardial infarction and cardiac arrhythmia, but the mechanisms underlying these associations are not completely understood. Therefore, we examined associations between markers of inflammation and ambient concentrations of fine and ultrafine particles in a panel of exercising patients with recent acute cardiovascular events.
Methods: We enrolled 75 patients from the Cardiac Rehabilitation program at the University of Rochester Medical Center, who had a recent coronary event (myocardial infarction or unstable angina). Ninety percent had undergone stenting or bypass. Counts of particles 10 to 500 nm were measured continuously outdoors at the site. Fine particle concentrations ($PM_{2.5}$) were measured continuously ~5km from the site. The exercise program involved supervised, graded twice weekly exercise sessions for 10 weeks, with fibrinogen, white blood cell count (WBC), and C-reactive protein (CRP) concentrations measured in blood samples taken once/week. Using mixed models, we examined changes in fibrinogen, CRP, and WBC associated with interquartile range (IQR) increases in mean ambient concentrations/counts of PM2.5 and particles 10-500nm (UFP) over the previous five 24 hour periods (lag hours 0-23, 24-47, 48-71, 72-95, and 96-119).
Results: Each IQR increase in UFP was associated with significant increases in CRP (lag hours 0-23; 0.067 mg/L; 95% CI = 0.000-0.133 mg/L) and fibrinogen (lag hours 24-47; 0.13 g/L; 95% CI = 0.05-0.21 g/L), while each IQR increase in PM2.5 concentration was associated with a significant increase in fibrinogen (lag hours 24-47; 0.09 g/L; 95% CI = 0.01-0.16 g/L). Smaller non-significant increases in fibrinogen and CRP were observed at other lag times. WBC was not associated with UFP or PM2.5 at any lag time.
Conclusions: In patients undergoing cardiac rehabilitation, ultrafine/fine particles were associated with increases in inflammation markers, factors predisposing to increased risk of cardiovascular events in post-infarction patients.

THE ASSOCIATION BETWEEN SHIFT WORK SCHEDULE AND SLEEP QUALITY AND MENTAL HEALTH IN SOUTH OF TAIWAN FEMALE NURSES

Pei-Chen Lin, *Graduate Institute of Occupational Safety and Health, Kaohsiung Medical University, Kaohsiung, Taiwan*
Research & Training, Kaohsiung Municipal Hsiao-Kang Hospital, Kaohsiung, Taiwan
Hsin-Chia Hung, *Department of Nursing, Meiho University, Pingguang, Taiwan*
Chih-Hong Pan, *Institute of Occupational Safety and Health, Council of Labor Affairs, Executive Yuan, Taipei, Taiwan*
Yao-Mei Chen, *Department of Nursing, Kaohsiung Municipal Hsiao-Kang Hospital, Kaohsiung, Taiwan*
Ming-Tsang Wu, *Graduate Institute of Occupational Safety and Health, Kaohsiung Medical University, Kaohsiung, Taiwan*
Center of Environmental and occupational Medicine, Kaohsiung Municipal Hsiao-Kang Hospital, Kaohsiung, Taiwan

Background and Aims: To investigate the relation between shift work, and sleep quality and mental health in female nurses in south Taiwan. Meanwhile, the nurses with rotation shift were further explored the association between types of shift work schedule and sleep quality and mental health and one year to understand the association between the variances of sleep quality and mental health and change of nightshift days
Methods: This study recruited 1360 female nurses registered in Kaohsiung area and 407 with rotation shift working schedule were followed and responded the second questionnaires. Data was measured by a self-administered questionnaire including demographic variables, shift type, sleep quality and mental health. The sleep quality was measured by Pittsburgh Sleep Quality Index (PSQI) and mental health measured by Chinese Health Questionnaire-12 (CHQ-12).
Results: The nurses with rotation shift appeared to have the worst sleep quality and mental health than nurse with day work. Compared to nurses with day work, nurses of nightshift were associated with increased odds ratio of reporting poor sleep quality and mental health (OR: 2.26, 95%CI: 1.57~3.28; OR: 1.91, 95%CI: 1.39~2.63 respectively). Among rotation shift nurses, we found that 2 days off after the last night shift, the sleep quality and mental health were significantly improved, with decreased of 1.23 on PSQI and 0.86 on CHQ-12 score, respectively, after adjustment of other factors. Compared with the first and second survey of sleep quality, the sleep quality was aggravated among nurses with increased nightshift days only.
Conclusions: Female nurses of rotation shift are experiencing poor sleep quality and mental health and 2 or more days off after the last nightshift might improve their sleep quality and mental health. The 2 days off after the last nightshift need application to the manger of nursing department of the hospital and a suitable load of cumulative nightshift days was also considered.

HEALTH IMPACT ASSESSMENT OF A CADMIUM, ARSENIC AND LEAD SOIL POLLUTION, CASSIOPÉE STUDY, AVEYRON, FRANCE

Nicolas SAUTHIER, Regional office of the French institute for public health surveillance (Cire) Midi-Pyrénées, Toulouse, France
Cécile DURAND, Cire Midi-Pyrénées, Toulouse, France
Valérie SCHWOEBEL' Cire Midi-Pyrénées, Toulouse, France
Frédéric DOR, French institute for public health surveillance (InVS), Saint-Maurice, France

Background and Aims
Important pollution was observed in Viviez (south-west of France) due to 150 years of smelting activity. Median concentration in surface soil of private gardens was respectively 20, 3 and 5 times higher than the reference value for cadmium, arsenic, and lead. Maximum cadmium concentrations in locally-homegrown vegetables reached 11 times the European regulation value. Thus, a global public health assessment was carried out in order to estimate the health impact of this pollution and to formulate recommendations.

Methods
Data from a regional register of renal insufficiencies and national data on causes of deaths were analysed to describe geographical variations in incidence or mortality. A screening for lead poisoning was proposed to children and pregnant women of Viviez. A measurement of urinary cadmium was proposed to all inhabitants in order to estimate the proportion exceeding a medical threshold. Finally, an exposure study to cadmium and arsenic was carried out in order to better understand residents' exposure.

Results
As compared with other parts of the district, no excess incidence of renal insufficiencies was observed in Viviez, but excess of mortality due to renal diseases particularly in the oldest periods. No case of lead poisoning was identified among 14 participants. Among 596 adult residents, 5% exceeded 2µg of cadmium/g.creatinine and 23% 1µg/g.creatinine: they were recommended to consult their doctor. These proportions were higher than those observed in an unexposed population (4% and 0%). Results of the exposure study suggested the influence of environmental factors such as ingestion of local food and inhalation or ingestion of polluted dust and soils.

Conclusions
Results of this assessment establish the health impact of the soil pollution among the residents of Viviez. This warrants to propose medical follow-up for the exposed population, and to limit further exposure by implementing soil treatment of private gardens, stopping the consumption of locally-homegrown products and adopting hygiene precautions.

PAEDIATRIC COMPUTED TOMOGRAPHY AND SUBSEQUENT CANCER: SETTING UP OF THE EUROPEAN PROJECT EPI-CT

MO Bernier *IRSN, DRPH, SRBE, Laboratoire d'épidémiologie, Fontenay-aux-Roses, France.*
S Baatout *SCK.CEN, Mol, Belgium*
E Cardis *CREAL, Barcelona, Spain*
M Hauptmann *Netherlands Cancer Institute, Amsterdam, Netherlands*
C Maccia *CAATS, Bourg la Reine, France*
MS Pearce *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, UK*
I Thierry-Chef *International Agency for Research on Cancer, Lyon, France*
A Kesminiene *International Agency for Research on Cancer, Lyon, France*
In behalf of the EPI-CT project group

Background and Aims

The growing use of computed tomography (CT) scans for paediatric patients raises the question of a possible impact of ionising radiation exposure on leukaemia and other cancers. The European collaborative EPI-CT project aims to pool data from several national cohorts of children having undergone a CT examination.

Material and methods

Following recommendations of a pilot study (Child-Med-Rad) which demonstrated the feasibility of setting up an international cohort study of paediatric CT patients and developed a common protocol, the project EPI-CT was launched in February 2011. EPI-CT will build or extend national cohorts with the aim of performing pooled analyses. Children, exposed in nine European countries to CT scan, will be included both retrospectively and prospectively until 2013. About one million children (Belgium, Denmark, France, Germany, Netherlands, Norway, Spain, Sweden and the United Kingdom) will be recruited. Individual patient dose reconstruction will be performed using hybrid mathematical phantoms of children of various ages. Cross-linkage with national cancer registries will allow to calculate cancer incidence in the pooled cohort and to compare it to baseline rates. In parallel, the biological effect of CT-scan will be estimated on blood and saliva.

Results

The study methodology and details of the biological studies will be presented. Patterns of use of CT scanning in different countries and over time will be assessed. Analyses planned for the year 2015 will have sufficient statistical power to evaluate the risk between exposure to CT scans in childhood and the cancer risk, particularly leukaemia.

Conclusion

This project will provide, for the first time, direct epidemiological evidence on the potential cancer risk due to ionising radiation exposure from paediatric CT scans in a large multinational European cohort. Results will inform radiation protection and patient dose optimisation. This project is supported by the EU FP7 Euratom grant agreement n°269912.

LONG-TERM CONCENTRATIONS OF AMBIENT AIR POLLUTANTS AND RISK OF DEATH AMONG SUBJECTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD).

Zuhair Natto, *Loma Linda University, USA*
David Shavlik, *Loma Linda University, USA*
W. Lawrence Beeson, *Loma Linda University, USA*
Mark Ghamsary, *Loma Linda University, USA*
Samuel Soret, *Loma Linda University, USA*
Lie Chen, *Loma Linda University, USA*
Seiji Matsumoto, *Loma Linda University, USA*
Synnove Knutsen, *Loma Linda University, USA*

Background : Studies show mixed results concerning the association between ambient particulate matter (PM) air pollution and outcomes among persons with chronic obstructive pulmonary disease (COPD). These variations could be due to the challenges in estimating accurate ambient air pollution levels for each subject. The AHSMOG study (N=6,338) has previously found associations between ambient air pollution and COPD using the inverse distance weighted (IDW) interpolation method from the nearest fixed monitoring station to residence and workplace.
Methods : Using data from the Adventist Health Study-2, a cohort of 97,000 US subjects, we identified 5,494 subjects with self-reported doctor- told COPD at baseline who have had the same residence address throughout follow-up. Subjects were enrolled between 2001 and 2006 and completed a 50 page questionnaire at enrolment including medical history, time spent outdoors, exercise, smoking and diet. A total of 159 subjects have died of natural causes during an average of 7 years of follow-up. The analyses controlled for a number of potential confounding factors including age, race, education, BMI, smoking and lifestyle. The Cox proportional hazard model was used for survival analysis. Inverse distance weighting (IDW) with interpolation to residence address was used to estimate individual level ambient air pollution. Cumulative monthly averages from 12 months prior to enrolment until one month before censoring were used.
Results and Conclusion: For each 10 • g/m^3 increase in $PM_{2.5}$, the hazard ratio (HR) for death due to any cause was 2.35 (95% confidence interval (CI): 1.08-5.13) in the single-pollutant model and 2.40 (95 % CI: 1.10-5.23) in the two-pollutant model with O3. No associations were found with each 10 ppb increase in Ozone either in single or two-pollutant models (HR's and 95 % CI were 1.15 (0.71-1.89) and 1.20 (0.74-1.94) respectively). These findings could have implication for policy regulations.

PERSISTENT NEUROBEHAVIORAL EFFECTS IN SCHOOLCHILDREN AND ADULTS AFTER THREE DECADES OF EXPOSURE TO DRIFT CONTAINING ORGANOPHOSPHORUOS PESTICIDES

Amit Ophir, *Neurology and Toxicology Service and Unit, Shaare Zedek, Medical Center, Jerusalem, and Institute of Drug Research, School of Pharmacy, Hebrew University of Jerusalem, Israel*

Elyakim Doitsch, *Neurology and Toxicology Service and Unit, Shaare Zedek, Medical Center, Jerusalem, Israel*
Uri Wormser, *Institute of Drug Research, School of Pharmacy, Hebrew University of Jerusalem, Israel*
Yoram Finkelstein, *Neurology and Toxicology Service and Unit, Shaare Zedek, Medical Center, Jerusalem, Israel*

Background and Aims: Studies by our group in 1987-1991 showed in-season reversible neurobehavioral effects of low-level, long-term exposure to organophosphorous (OP) pesticides in a cohort of agricultural workers and residents of rural communities in the Hula Valley, Israel. The residents were exposed to pesticide-drift caused by the proximity of the communities to the sprayed fields. This study aimed to review the neurobehavioral effects after three decades in the same cohort and in 8-12 years-old schoolchildren, 75% of whom are "second generation", as at least one of their parents belonged to the original adult cohort.
Methods: Neurobehavioral tests included questionnaire, Trail Making Tests A and B, Digit Span (forward and backward), Digit Symbol Tests and Purdue Pegboard.
Results: Cognitive changes were observed in 98 individuals of the original adult cohort. Performance on both Trail Making Tests was significantly poorer than in the general population. The performance in Trail Making Test B was inversely correlated with the duration of OP pesticide exposure ($r=-0.231$; $\alpha<0.01$). Digit span tests were poor. Females were affected but yet performed better than males in all the tests.Preliminary analysis suggests that approximately 40% of the tested children or one of their siblings was diagnosed in the past with attention span and concentration deficits or Attention Deficit/Hyperactivity Disorder (ADD/ADHD).
Conclusions: The preliminary results demonstrate persistent late neurotoxic effects of lengthy daily OP pesticide exposure in both children and adults. There may be environmental-susceptibility interactions mediating the emergence of ADHD in populations with low-level endemic exposure to OP pesticides.
Disclosure: No conflicts of interest are related to this manuscript.

INDOOR AIRPOLLUTANTS ANDRESPIRATORY HEALTH IN THE UNITED ARAB EMIRATES (UAE)

Karin Yeatts, Mohamed El Sadig, David Leith, FatmaMaskiri, TaoufikZoubedi, Ivan Rusyn, David Couper, Bill Funk, Jackie MacDonald, Andy Olshan. UNC-Chapel Hill, UAE University.

Background and Aims:In the last forty years, the UAE has undergone rapid transition to become an industrialized nation. Little is known about theindoor air pollutant exposures and potential health effects in the Arab Gulf region.
Methods: We conducted a cross-sectional study in a stratified sample of 628 households in urban and rural areas and all seven emirates in the UAE from October 2009 to May 2010.Indoor air pollutants (nitrogen dioxide NO_2, sulfur dioxide SO_2, hydrogen sulfide H_2S) were measured using passive diffusion samplers over a seven-day period in a common living area.Information on environmental exposures, respiratory symptomswas collected from selected household members in each family via in-person interviews using validated questionnaires.
Results: A total of 1590 adults (n=1009), adolescents (n=330), and children (n=253) from 628 households were surveyed. Thirty percent (n=548) of our study sample lived in households with detectable sulfur dioxide (range 0.010-0.507ppm), and 9% lived in households with detectable indoor NO2 (range 0.006-048ppm). Indoor SO_2 was associated with ever wheezing, Prevalence odds ratio (POR) 1.79 [95% confidence interval (CI) 1.05, 3.05];wheezing in the last 4 weeks POR 4.63 [95% CI 1.33-16.19]; speech limiting wheeze in the last 12 months 3.53 [95% CI 1.06-11.74]; and diagnosed asthma POR 1.95 [95% CI 1.13-1.36]. Indoor NO_2 was associated with diagnosed asthma(POR) 2.34 [95% Confidence Interval (CI) 1.11, 4.93];dry cough not from cold, POR 1.90 [95%CI 1.0-3.60];and sinus infections in the last 12 months POR 1.77 [95% CI 1.07-2.94].
Conclusions: Our research found in this Gulf nation population, those living inhouseholds with measurable SO_2 and NO_2 experienced increased frequency of respiratory related symptoms and diagnosed asthma.Further research is needed to better characterize both the sources of exposure and the health effects of indoor air pollutants in the home.

MERCURY EXPOSURE OF BREAST FED INFANTS IN A SMALL SCALE GOLD MINING AREA IN ZIMBABWE

Stephan, Bose-O'Reilly, *University for Health Sciences, Medical Informatics and Technology (UMIT), Austria*
Beate Lettmeier, *University for Health Sciences, Medical Informatics and Technology (UMIT), Austria*
Dennis Shoko, *University of Zimbabwe, Zimbabwe*
Jennifer Baeuml, *University for Health Sciences, Medical Informatics and Technology (UMIT), Austria*
Viktoriya Baskova-Schilling, *University for Health Sciences, Medical Informatics and Technology (UMIT), Austria*

Gustav Drasch, *Ludwig-Maximilians-University (LMU), Germany*
Uwe Siebert , *University for Health Sciences, Medical Informatics and Technology (UMIT), Austria; Harvard Medical School, USA; Harvard School of Public Health, USA*

Background and Aims: In Kadoma (Zimbabwe) gold is extracted from ore based on a simple technology using mercury. Women are exposed whilst living in an exposed area, or even more working directly with mercury. Breast fed infants are burdened via contaminated milk and the general environmental exposure. The aim of the study was to prove the hypothesis that the uptake of mercury via breast milk is a relevant pathway of exposure.
Methods: In 2006, an environmental epidemiological field study with 120 mother –child pairs was conducted. A non exposed control group (n=42) was compared medium exposed group (n=51) and a high exposed group (occupational exposure, n=27). Urine and hair samples from mother and infants plus breast milk samples were analyzed for total mercury. 120 breast milk samples were analyzed. Chi-square (Pearson), ANOVA, T-test Kruskal Wallis, Mann-Whitney test, and Spearman's rank correlation coefficient test were used. The daily uptake of mercury via breast milk was calculated. The reference dose of 0.3°[µg Hg/kg BW/d] was used to compare the burden of the infants.
Results: Breast milk median (maximum) concentrations [µg Hg/l] were (i) control group < 0.50 (1.55), (ii) medium exposed group 1.10 (10.48), (iii) high exposed group 1.20 (24.80) ($p<0,001$). Urine and hair results are distributes similarly for infants and mothers. All specimen results correlated significantly with another, indicating that the exposure of the infant correlates with the burden of the mother and the breast milk. No infant from the control group, but 17.6% of the medium and 18.5% of the high exposed group were above the reference dose ($p<0.001$).
Conclusions: Mercury in breast milk is generally elevated in small scale gold mining areas. Breast fed infants are burdened with toxic mercury via breast milk, which is an important public health issue.

ASSOCIATION BETWEEN TRAFFIC-RELATED BLACK CARBON EXPOSURE AND THE CONNER'S CONTINUOUS PERFORMANCE TEST (CPT) AMONG URBAN CHILDREN IN A PROSPECTIVE BIRTH COHORT

Yueh-Hsiu Mathilda Chiu, *Harvard School of Public Health, USA*
Robert O. Wright, *Harvard School of Public Health, Channing Lab, Harvard Medical School and Children's Hospital Boston, USA*
Michelle Bosquet Enlow, *Children's Hospital Boston, USA*
Rosalind J. Wright, *Harvard School of Public Health, Channing Lab, Brigham & Women's Hospital and Harvard Medical School, USA*

Background and Aims: Associations between ambient air pollution exposure and children's cognitive domains are only beginning to be examined and analyses have not accounted for community-level psychosocial stressors that may co-vary with pollution exposures. We assessed the relationship of exposure to black carbon (BC), a marker of traffic particles, with attention and vigilance domains while adjusting for exposure to community violence (ETV), among 192 children aged 6-12 years in a Boston-based prospective birth cohort.
Methods: BC levels were estimated using a validated spatio-temporal land-use regression model based on residence during the child's lifetime, then categorized into quartiles. Exposure to violence (ETV) in these neighborhoods was ascertained using the My Exposure to Violence survey, which was categorized into tertiles. Attention and vigilance were measured using the Conner's Continuous Performance Test (CPT). Primary outcomes included: omission errors, commission errors, hit reaction time (HRT), HRT standard error (SE), HRT block change, and HRT SE block change (higher scores indicating worse performance or slower reaction time). Multiple regression analyses were used to determine effects of BC levels on outcomes.
Results: Children were primarily Hispanic (55%) and Caucasians (42%). We found a positive association between BC levels with commission errors and HRT ($p<0.05$), adjusting for age, gender, maternal education, ETV, and blood lead level. Higher-level ETV was associated with lower commission errors ($p<0.05$). Additional inclusion of children's IQ, prenatal smoking, and postnatal secondhand smoke exposure did not alter these results. Gender-stratified analysis suggested that the effects of BC on CPT measures were stronger in boys ($p<0.05$) for both commission errors and HRT, than in girls ($p>0.2$).
Conclusions: In this population of urban children, we found a relationship between increased BC exposure with increased commission errors and slower reaction time. Effects of traffic-related pollution on attention domains may be stronger in boys.

SMALL-AREA STUDIES OF ENVIRONMENT AND HEALTH IN ITALY: ACCOUNTING FOR SOCIOECONOMIC DEPRIVATION

Pasetto R, *Istituto Superiore di Sanità, Rome, Italy*
Caranci N, *Regional Agency for Health and Social Care, Emilia-Romagna Region, Italy*
Pirastu R, *Sapienza Università di Roma, Italy*

Background and Aims: Data for small-area studies in Italy are available at census tract and municipality level. The aim of the present contribution is to ascertain whether an *ad hoc* developed Deprivation Index (DI) can adjust for deprivation in SENTIERI, a multicentric small-area study at municipality level in Italian Polluted Sites – IPS.
Methods: The DI adopted in SENTIERI is based on four socioeconomic variables from the 2001 census, already included in a National DI. Each IPS' municipality was assigned to a quintile of DI on the basis of the distribution of the sum of Z scores, for the selected variables computed at regional level. Standardized Mortality Ratios (SMR) (1995-2002) with regional reference were computed for either gender, for each municipality, both crude and adjusted for deprivation. Conditions for potential confounding were verified by selecting outcomes with probable causal association with both pollution and socioeconomic status, and by analyzing the most and the less deprived municipalities.
Results: First results for lung cancer in two IPSs selected as above explained, showed a change in SMR estimates as expected when adjusting for DI. In the selected least deprived municipality crude and adjusted SMR were respectively 123 (IC 90% 108-138) and 131 (116-147) for males; the corresponding estimates for females were 148 (109-197) and 155 (114-207). In the most deprived municipality crude and adjusted SMR were respectively 120 (109-132) and 106 (96-116) for males; the corresponding figures for females were 134 (115-156) and 102 (87-119).
Conclusions: The results suggest that the adopted DI adjusts for socioeconomic status. The interaction between deprivation and environmental exposures should be better investigated. Also the effect of *resilent* areas and reverse causality phenomena on risk estimates should be better clarified.

AMBIENT AND PERSONAL PM_{10} EXPOSURE IN WOMEN IN RELATION TO TIME ACTIVITY, SOCIOECONOMIC STATUS, AND LOCATION OF RESIDENCE IN DELHI, INDIA.

Anisha Misra, Institute of Health Society, *Newcastle University, UK**
Mukesh Khare, *Indian Institute of Technology, Delhi, India*
Tanja Pless-Mulloli, *Institute of Health and Society, Newcastle University, UK*

Background and Aims: Many megacities in developing countries are undergoing rapid economic growth, with direct effects on their air quality particularly particulate matter (PM). In Delhi reductions in PM_{10} after 2001, when all modes of Public Transport (PT) in Delhi were converted to compressed natural gas (CNG), have since been outweighed by the increase in car ownership (average annual Delhi PM_{10} levels: in 1994, before PT ran on CNG, around 275µg/m3; in 2001 when all PT was converted to CNG, around 125µg/m3; levels in 2010, around 225µg/m3). A previous study investigated indoor and outdoor PM_{10} levels (Kulshreshtha), however, there are no studies of *personal* exposure. This study aims to quantify PM_{10} levels in women with different individual and area characteristics of socio-economic status (SES). This pilot study aims to inform future, large scale investigations.

Methods:

- 'Shadowing' 6 women (2 with high personal SES living in rich areas, 2 from low SES living in rich areas, and 2 from low SES living in poor areas), and recording their personal PM_{10} exposure using a 'Sidepak' monitor for 6 hours (10am to 4pm), on 3 days.
- Time Activity Diary filled every 15 minutes during recording period.
- Systematic neighbourhood observation using proforma.

Results: Personal and Ambient PM_{10} exposure affected by residential location, and socioeconomic status. Time activity diary, proforma reveal when and why personal PM_{10} levels vary through the study period.

Conclusions: This study contributes to the observation of the relative impact of economic growth, socioeconomic status, and residential location on personal PM_{10} exposure, emphasising the need for continued vigilance, and larger scale studies on the topic. Also, perhaps studies need to be done at different seasons. Seasonal differences in indoor and outdoor PM_{10} levels we recorded in previous studies.

Background and Aims: Brazil is the world's largest sugarcane producer. The predominantly manual harvesting exposes workers to a series of health risk factors, such as physical exertion, heat and pollutants. This study aimed to evaluate the occurrence of adverse cardiovascular effects and possible mechanisms involved in these events on sugarcane workers.

Methods: Twenty-eight sugarcane harvesters, Caucasian, healthy, male, and residing in the countryside of São Paulo state were evaluated in the harvest period (when the sugarcane is burned) and in the non harvest period (when the sugarcane is not burned) through blood markers, twenty-four hours ambulatory blood pressure monitoring, heart rate variability by twenty-four hours electrocardiography monitoring, and muscle sympathetic nerve activity in the peroneal nerve. We measured fine particles and weather variables in the sugarcane fields in both periods. Data were compared using statistical tests for repeated measurements. Multivariate linear regression analyses were used to evaluate the effect of working during the harvest period controlling for covariates.

Results: The participants aged 31 ± 6.3 years and had worked for about 9.8 ± 8.4 years in this activity. During the harvest period, the concentration of fine particles was higher (84.7 ± 23.9 vs 53.2 ± 14.8, $p<0.001$), and workers presented lower serum levels of C-reactive protein (0,25 *vs* 0,44 mg/dl, $p<0,001$). However, working in the harvest period was significantly associated with higher systolic blood pressure (120.1 ± 10.3 *vs* 117.0 ± 10, $p= 0.047$). The reduction of 10 ms in SDNN was associated to increases of 0.73 and 0.62 mmHg in systolic and diastolic blood pressures, respectively. Also, an increase of 10 burst/min in sympathetic activity led to increases of 1.8 and 1.6 mmHg in systolic and diastolic blood pressures, respectively.

Conclusions: Work in burnt sugarcane harvesting was associated with higher blood pressure which may be linked to autonomic imbalance.

A SIMPLE DEVICE FOR TEACHING CAUSAL CONCEPTS

George Maldonado, *University of Minnesota, USA*

Background and Aims: We present a simple device for teaching causal concepts in epidemiology. Originally developed for a lay audience, it has proven to be illuminating for graduate students also.
Methods: We use a simple, non-health example so that: (1) "truth" is known, and (2) the conditions that cause valid and invalid results can be easily understood. Let the total study group consist of 4 flashlights. The question we ask is, "Does moving the switch from the 'off' position to the 'on' position cause a flashlight to light?" We know that the simultaneous occurrence of the following conditions is sufficient to produce light in a flashlight (when switched "on"): (1) good battery; (2) good bulb; (3) unbroken circuit from switch to battery to bulb to switch; and (4) good switch. Let one of the flashlights have all four of these component causes in place; let the other three be missing one or two of these component causes. We vary the definition of the target population to illustrate different concepts.
Results: We show how, with this device, it is easy to illustrate the following: what is a causal contrast; the importance of the target population in causal inference; what is effect-measure modification; counterfactuals; that confounding results from imperfect substitution for a counterfactual outcome frequency; and the combined impact of confounding, selection errors and measurement errors on study results. In addition, we show with this device the following, which some find surprising: an observed effect measure can be simultaneously confounded and unconfounded, matching on causal factors does not guarantee that confounding is absent, absence of perfect matching on causal factors does not guarantee that confounding is present, and in some situations it appears that a DAG can give the wrong indication about the presence of confounding.

NANOTECHNOLOGY AND HUMAN HEALTH: SCIENTIFIC EVIDENCE AND RISK GOVERNANCE

Marco Martuzzi, *World Health Organization, Regional Office for Europe, Rome Office, Italy*
Steffen Foss Hansen *Technical University of Denmark, Copenhagen, Denmark*
Khara Grieger *Technical University of Denmark, Copenhagen, Denmark*
C. Vyvyan Howard *University of Ulster, Coleraine, UK*

Background and aims: Besides the promise of great benefits of nanotechnology, concerns exist on adverse health consequences. As complexity and uncertainty are large, evidence-based policy will be elusive, and models of risk governance are needed.
Methods: WHO/EURO is conducting a critical assessment of key evidence on possible health implications of nanomaterials, with a view to identify options for risk governance and policy formulation.
Results: Current evidence is far from being conclusive but a cautionary approach in policy may be appropriate for several reasons: (i) humans have limited evolutionary experience of nanomaterials- a possible reason for the diminishing ability of cells to interact with particles as their size decreases to nanoscale; (ii) nanoparticles can enter the body relatively easily, especially through inhalation and gastro-intestinal assimilation, and are very mobile once inside the body; (iii) several chemical-physical mechanisms resulting in cell damage have been reported; (iv) effects are often dependent on particle size, with a tendency to become more active as the particle size decreases; (v) population exposure to nanomaterials is not well known, but may be or become high, for example through cosmetics, food additives, or from airborne nanoparticles; (vi) potential adverse effects include a broad spectrum of adverse effects, specific and a-specific. The need for caution is reinforced by the reported asbestos-like action of carbon nanotubes in animal models and, to a lesser extent, by a few episodes of human health impacts following localised acute exposures.
Conclusions: Assessing the risks for human health impacts of nanotechnology is challenging. One must take into account the unique complexities of the interaction between nanomaterials and the human body. Innovative models and frameworks for risk assessment and risk governance are being developed and applied in order to organise the available evidence on biological and health effects of nanomaterials in ways to inform policy.

THE RELATIONSHIP OF BREAST CANCER SURVIVAL WITH TRAFFIC-RELATED POLLUTION EXPOSURES

Robin Puett, *University of South Carolina, Columbia, SC, USA*
Swann Arp Adams, *University of South Carolina, Columbia, SC, USA*
Michele Nichols, *University of South Carolina, Columbia, SC, USA*
James Hibbert, *University of South Carolina, Columbia, SC, USA*
Susan Bolick, *South Carolina Central Cancer Registry, Columbia, SC, USA*
Deborah Hurley, *South Carolina Central Cancer Registry, Columbia, SC, USA*
Jonathan Savoy, *South Carolina Central Cancer Registry, Columbia, SC, USA*
John Vena, *University of Georgia, Athens, GA, USA*
James R.Hebert , *University of South Carolina, Columbia, SC, USA*

Background and Aims: In the US, breast cancer is the most frequently diagnosed cancer among women, and African-American (AA) women have much worse than average survival. Few studies have examined the relationship of breast cancer with air pollution exposures, which can lead to inflammation and lowered immune response. Fewer still have explored the additional impact of race on breast cancer survival and air pollution exposure.
Methods: Using data from the SC Central Cancer Registry, we examined the relationship of breast cancer survival with residential proximity to roads, a proxy for traffic-related air pollution exposures, and potential effect modification by race. This study included all cases of breast cancer among female residents >19 years old, diagnosed from 2000 to 2006. A Geographic Information System (GIS) was used to determine distance from the geocoded residence at diagnosis to the nearest US Census feature class A1-3 road (interstates - secondary roads). Women were followed until a second cancer, the end of the study, loss to follow-up or death through 2007. Deaths were determined from the SC Vital Registry.
Results: Of the 11,573 women with available geocoded residential and smoking status classified as AA (23.4%) or European-American (EA) 949 developed a second cancer, and 1,657 died during the follow-up period. Mean age was ≈60 years, and the median distance to nearest A1-3 road was 636.3 meters. In models adjusting for age, race, and smoking status, women living 50 to 99 meters from roads were more likely to die (Hazard Ratio: 1.30, 95%CI: 1.05,1.62) than women living 200 or more meters away. Models stratified by race, showed AA women were disproportionately impacted (AA HR: 1.54, 95%CI: 1.11,2.14 versus EA HR: 1.19, 95%CI: 0.90,1.58).
Conclusions: Our preliminary study findings suggest that AA women living closer to roads may experience worse survival rates from breast cancer.

TERRESTRIAL GAMMA RADIATION IN RELATION TO THE POPULATION DISTRIBUTION IN WESTERN SWEDEN

Martin Tondel, MD, PhD, ***Occupational and Environmental Medicine, Department of Public Health and Community Medicine, University of Gothenburg, Gothenburg, Sweden***

e-mail: Martin.Tondel@amm.gu.se

Background and Aims: After excluding contribution from radon, 42% of the average effective dose from natural background radiation in Sweden comes from terrestrial gamma radiation (TGR). In the county of Vastra Gotaland, western Sweden, the TGR is relatively high and originates mainly from granite, but the county has also areas with low TGR (0-500 nGy/h). This study aims to investigate the distribution of TGR in relation to the population (population-weighted average).

Methods: Data for the study comes from aerial measurements in the database at the Swedish Geological Survey. The digital database has unique measurements for each 200 x 200 meter grid for uranium, thorium and potassium, respectively. TGR can be calculated in nGy/h with conversion factors for the three nuclides. Each individual in Vastra Gotaland (n=1.5 million) was retrieved from the population registry with the dwelling coordinates. Using the Geographical Information System the coordinates of the individual's home was matched with the level of TGR. TGR for each municipality in the county was calculated as 1) an average of the grid cells (surface-weighted average) and 2) the population-weighted average, respectively.

Results: The population-weighted average of TGR for Vastra Gotaland was 56 nGy/h. There was a tendency of higher population-weighted municipality average compared to the surface-weighted average i.e. the population distribution was skewed towards regions with higher TGR. In the 49 municipalities the median population-weighted average was 55 nGy/h, Sotenas had the highest 118 nGy/h and the Trollhattan municipality had the lowest average of 37 nGy/h.

Conclusions: This study shows that the population-weighted average of TGR for the municipalities in Vastra Gotaland was higher than the surface-weighted average. This is probably a random phenomenon, but important to keep in mind when designing and evaluating ecological studies.

SEXUAL DIFFERENCES IN THE ACCUMULATION OF MERCURY IN THE INFANT POPULATION OF MENORCA

Mercè Garí, *Institute of Environmental Assessment and Water Research (IDÆA-CSIC), Barcelona, Catalonia, Spain*
Joan O. Grimalt, *Institute of Environmental Assessment and Water Research (IDÆA-CSIC), Barcelona, Catalonia, Spain*
Maties Torrent, *Àrea de Salut de Menorca, IB-SALUT, Menorca, Spain; Fundació Caubet-CIMERA, Bunyola, Mallorca, Spain*
Jordi Sunyer, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Catalonia, Spain*

Background and Aims: Mercury can cause severe neurological damage to children (Grandjean *et al*., 1997). Humans are exposed to mercury basically through fish consumption. This research focuses on the presence of mercury in the infant population of Menorca, in the Western Mediterranean area, whose inhabitants are usual fish and seafood eaters.
Methods: The research is based on 198 hair samples of four-year old children from the Menorca island collected within the INMA study (Ribas-Fito *et al*., 2006). Determination of total mercury (tHg) in hair was performed using inductively coupled plasma mass spectrometry.
Results: The mean tHg in hair of children from Menorca was 1.3 µg/g. Girls had higher tHg levels than males (1.4 vs. 1.1 µg/g, statistically significant). The observed differences were also maintained when controlling for diet (fish consumption) and breastfeeding. Regarding fish intake, mean tHg values among frequent fish consumers (more than three times per week) were almost three-fold higher than among non-consumers (1.6 vs. 0.58 µg/g).
These results have been compared with those of other organic persistent pollutants, such as organochlorine compounds (OCs). As described by Grimalt *et al.* (2010), female children could have a higher retention capacity for the incorporation of OCs through breastfeeding. Mercury could also have a sexual accumulation pattern similar to OCs, but in this case, fish consumption is the main ingestion route. In any case, comparison with gender differences observed from other cohorts (Batista *et al*., 1996; Kim *et al*., 2008) shows that more research is needed to identify the cause of this differential accumulation.
Conclusions: The present study identifies a case of significant differential accumulation of tHg in children, by gender. The main causes of this difference are explored considering dietary habits (mainly fish intake) and breastfeeding. Gender differences in the accumulation of other persistent pollutants, such as organochlorine compounds, in the same population are also considered.

ASSOCIATION BETWEEN THYROID HORMONE LEVELS AND POLIBROMODIPHENYL ETHER CONCENTRATIONS IN PREGNANT WOMEN FROM VALENCIA, SPAIN

Grimalt Joan O. *Institute of Environmental Assessment and Water Research (IDÆA), Catalonia, Spain*

Background and Aims: Some studies have suggested that polybromodiphenyl ethers (PBDEs) may alter thyroid function during critical periods of thyroid hormone-dependent brain development. The aim of the present study was to investigate the association between maternal concentrations of PBDEs and thyroid hormone status during the first trimester of pregnancy.
Methods: The study sample (n=159) was drawn from a prospective mother-infant cohort established in Valencia as part of the INMA (Environment and Childhood) project. Thyroid-stimulating hormone (TSH), total triiodothyronine (TT3) and free thyroxine (FT4) were measured as biomarkers of thyroid function in maternal serum samples at 12 weeks of pregnancy. PBDE concentrations (PBDE 47, 99, 153, 154, 209) were measured by gas chromatography (GC) coupled to a mass spectrometer (MS) operating in negative ionization mode (NICI). Association among maternal PBDE serum concentrations and thyroid hormone levels were assessed using multivariate linear regression analyses adjusting for potential confounders.
Results: Serum TT3, FT4, and TSH concentrations ranged from 1.5 to 4.1 nmol/L, 8.1 to 16.4 pmol/L and 0.05 to 9.3 µU/mL respectively. Median of total PBDEs was 7.6 ng/g lipid (range between not detected and 87.4 ng/g lipid). A significant positive association was found between total PBDEs and TSH (β=0.30; 95% CI=0.07-0.53) after adjustment for confounders. FT4 tended to be lower in mothers with higher PBDE concentrations but the trend was not statistically significant. No association was found between PBDEs and TT3.
Conclusions: PBDE concentrations in maternal serum were positively associated with increases in maternal TSH levels. Concentrations of FT4 were negatively, but not statistically significant, associated to PBDE concentrations. TT3 levels did not seem to be influenced by exposure to PBDEs. These findings suggest that PBDEs may interfere with the thyroid system of pregnant women.

THE USE OF CLEANING PRODUCTS DURING PREGNANCY AND LOWER RESPIRATORY TRACT INFECTIONS AND WHEEZING IN THE FIRST YEAR OF LIFE

Lidia Casas, *Center for Research in Environmental Epidemiology (CREAL), Spain*
Jan Paul Zock, *Center for Research in Environmental Epidemiology (CREAL), Spain*
Anne-Elie Carsin, *Center for Research in Environmental Epidemiology (CREAL), Spain*
Ana Fernandez-Somoano, *Universidad de Oviedo, Spain*
Ana Esplugues, *Centre for Public Health Research (CSISP), Spain*
Adonina Tardon, *Universidad de Oviedo, Spain*
Ferran Ballester, *Centre for Public Health Research (CSISP), Spain*
Loreto Santa Marina, *Health Research Institute (BIODONOSTIA), Spain*
Mikel Basterrechea, *Health Research Institute (BIODONOSTIA), Spain*
Jordi Sunyer, *Center for Research in Environmental Epidemiology (CREAL), Spain*

Background and aims: Analysis of the ALSPAC birth cohort (UK) study suggested that the use of household chemicals during pregnancy may increase the risk of wheeze in the offspring. We aimed to evaluate the effects of household use of cleaning products during and after pregnancy on wheezing and lower respiratory tract infections (LRTI) during the first year of life in the INMA project.
Methods: In the Spanish INMA birth cohorts of Asturias (n=450), Gipuzkoa (n=556), Sabadell (n=578) and Valencia (n=707), the use of 9 cleaning products in the home was reported during the third trimester of pregnancy in the four cohorts, and at infant's age of 12-14 months in Asturias and Valencia cohorts. Respiratory symptoms and LRTI were reported by the mothers when the infants were 12-14 months old. Logistic regression analyses adjusting for potential confounders were performed for each of the 4 cohorts, and the combined Odds Ratios (OR) were obtained by random-effects meta-analyses.
Results: Prevalence of LRTI during the first year of life was overall 32% and was higher if the mother had used sprays (OR 1.3; 95% confidence interval (CI) 1.0-1.6) or air fresheners (OR 1.3; CI 1.0-1.6) during pregnancy. Prevalence of wheezing was 35% and the risk increased with household use of sprays (OR 1.4; CI 1.1-1.7) and solvents (OR 1.3; CI 1.0-1.6). These results were homogeneous across the four cohorts (p for heterogeneity >0.3). Analyses excluding specific use during the first year of life showed an increased risk of LRTI and wheezing when sprays or air fresheners had been used only during pregnancy.
Conclusion: The use of cleaning sprays, air fresheners or solvents during pregnancy may increase the risk of respiratory symptoms and infections in the offspring. This effect is unlikely to be fully explained by post-natal use of these products in the home.

INFLUENCES ON PERSONAL AIR POLLUTION EXPOSURE. HOW CAN WE REDUCE EXPOSURE MISCLASSIFICATION?

Gioia Mosler, *Imperial College London, UK*
Dr. John Gulliver, *Imperial College London, UK*
Dr. Kees De Hoog, *Imperial College London, UK*

Background and Aims: Most epidemiological studies today work with exposure estimates that are at best based on outdoor air pollution averages at address locations. The aim of this study is to increase the knowledge of personal exposure, and to reduce potential exposure misclassification.
Methods: High resolution monitoring data of PM2.5 and PM10 has been simultaneously collected for personal, indoor, and outdoor pollution levels during 43 days of a daily routine for one individual; the indoor and personal monitoring data are accompanied by diaries. Relationships of personal, residential outdoor and residential indoor pollution are analyzed. Furthermore campaigns of simultaneous monitoring in transport micro-environments have been undertaken for bus-cycling comparisons (2 routes, 18 repeats each), as well as for walking-cycling comparisons (2 routes, 8 repeats each), accompanied by GPS recordings. Influences of traffic environments on personal exposure are investigated.
Results: Major differences between personal and residential outdoor pollution can be observed for the range and standard deviation of PM2.5 and PM10 levels, with personal exposure to PM2.5 showing a range (R) of 38.64µg/m³ and a standard deviation (St. D.) of 4.17µg/m³ (PM10: R = 175.13µg/m³, St. D. = 18.26 µg/m³) compared to 15.78µg/m³ (R) and 3.12µg/m³ (St. D.) at the residential outdoor location (PM10: R = 40.25µg/m³, St. D. = 8.74µg/m³). Comparisons both for the cycle-bus, as well as for the cycle-walk campaign show a higher mean and higher variation of pollution for the cyclist on all routes.
Conclusions: Comparing personal and residential outdoor pollution indicates that using residential outdoor PM levels as a proxy for personal exposure ignores the variation and the peak values of exposure a person might be exposed to during a daily routine, i.e. in traffic environments.

ROAD TRANSPORT'S NOISE IMPACT ON POPULATION HEALTH IN A RISKY ENVIRONMENTAL AREA IN THE REPUBLIC OF BULGARIA

Jeni Nikolova, *Regional Health Inspectorate, Bulgaria*
Jeni Nikolova, *Pleven Medical University, Bulgaria*
Rositsa Chilingirova, *Regional Health Inspectorate, Bulgaria*

Background and aims: Noise, as a factor in the contemporary urban environment, is characterized by multifaceted influence, equivalent on negative effect of the rest environmental contaminants.
The largest share of noise has the road transport. Constant increasing traffic from vehicles and mistakes in urban planning create the unfavourable acoustic environment in urban settlements.
The combined impact of environmental components, especially in ecologically vulnerable areas, such as area of the town of Kardzhali (with mining processing and metallurgical industry) increases the morbidity of the exposed population.
The purpose of this study was to determine the impact of transport noise on human health in the town of Kardzhali the period 2001-2010.
Methods: Analyzed were the data from the monitoring of street noise in the town for the period 2001-2010 and morbidity of the population (0-17 and over 18 years old) from Municipality of Kardzhali in the same period in the main classes of diseases ICD provoked by noise pollution, followed in dynamics.
For statistical processing of data is using nonparametric correlation of Spearman.
Results: Adverse trends in factors influencing the acoustic environment in the town are confirmed by the noise characteristics for the past ten years. They show sustained increasing of noise pollution, and prevailing are rates in the range 68-72 dB (A), at the limit rate of 55-60 dB (A).
The data analysis shows a large significant correlation (• • 0.01) for both age groups between the average level of noise and diseases of the nervous system. Among the adult population with such a correlation are diseases of the ear and mastoid process.
Conclusions: The assessment is a base for implementation of mandatory measures related to the optimization of the acoustic environment to improve the health of the population in the area, exposed parallel and to air pollution.

CONCENTRATION-RISK RELATIONSHIP FOR VOLATILE ORGANIC COMPOUNDS IN INDOOR AIR AND RESPIRATORY HEALTH OF CHILDREN IN LEIPZIG, GERMANY

Uwe Schlink, *Helmholtz Centre for Environmental Research UFZ, Leipzig, Germany*
Carolin Rösch, *Helmholtz Centre for Environmental Research UFZ, Leipzig, Germany*
Ulrich Franck, *Helmholtz Centre for Environmental Research UFZ, Leipzig, Germany*
Stefan Röder, *Helmholtz Centre for Environmental Research UFZ, Leipzig, Germany*
Michael Borte, *Klinik für Kinder- und Jugendmedizin, Städtisches Klinikum St. Georg, Leipzig, Germany*
Olf Herbarth, *Institute of Environmental Medicine & Hygiene, Faculty of Medicine, University of Leipzig, Germany*
Irina Lehmann, *Helmholtz Centre for Environmental Research UFZ, Leipzig, Germany*

Background and Aims: To assess the form of associations between respiratory illness in young children and domestic exposure to volatile organic compounds (VOC) and to apply a novel approach to reduce exposure-misclassification.
Methods: Data were gathered in 2004/2005 from the Life style Immune System Allergy (LISA) birth cohort in Germany, which investigates the influence of life style and environmental factors on the maturation of the immune system and the allergy risk in childhood. The present analysis includes only healthy full-term neonates of German descent living in Leipzig. Selected items from parent-completed questionnaires of the health status of their child in the 4th year of life are combined with VOC measurements collected by passive samplers during a 4-weeks period starting 2 (±1) weeks before the 3rd birthday.
Results: Rumchev et al. (2004) suggested an exponential concentration-risk relationship for the respiratory effects of VOC in children. This relationship is empirically validated in the present study by means of (i) a minimum-criterion approach and (ii) a generalized additive model, accounting for the confounding of gender, educational level, domestic animals, and atopic predisposition. 463 datasets were used for the statistical analysis. Associations between respiratory symptoms and VOC concentrations are significant, but only when the seasonal correction suggested by Schlink et al. (2004) was applied. Especially benzene and chloro-benzene are associated with adverse effects, such as wheezing (OR=1.5 per 1 µg benzene / m³).
Conclusions: Our empirical results confirm the previously postulated exponential concentration-risk relationship and suggest that no thresholds can be observed that might be easily used for the definition of limit values for health protection. An important pre-processing of VOC data measured in Germany, which avoids exposure misclassification, is to adjust for the strong seasonal variation of indoor VOC concentrations. The occurrence of this seasonality, however, depends on the geographical region (Jia et al., 2008).

PESTICIDE HANDLING AND ASSOCIATED HEALTH RISK AMONG AGROCHEMICAL RETAILERS IN OSUN STATE, NIGERIA

Mosudi Sosan, *Department of Crop Production and Protection Obafemi Awolowo University,, Nigeria*
Olufunmilayo Oni, *Department of Crop Production and Protection Obafemi Awolowo University,, Nigeria*

Background and Aims: In Nigeria, agriculture provides revenue for farmers and field workers. In order to maintain or improve crop yield on both small and large scale farms, agrochemicals are extensively used. The distribution of pesticide for agricultural purposes is mainly through privately owned retailing shops. The aim of the survey was to assess the knowledge, attitude and practice of agrochemical retailers in Osun State, Nigeria with respect to pesticide handling and their associated health risks.
Methods: The study was conducted in retail outlets of agrochemicals in nine towns in Osun state, southwestern Nigeria. A structured questionnaire was used to collect quantitative information from selected agrochemical retailers and supplemented with oral interviews.
Results: Pesticides of different brands comprising organochlorines, organophosphates, carbamates, pyrethroids and fumigants were stocked for sale by the retailers. Personal habits like eating, chewing kolanut and cigarette smoking were observed among the retailers in their shops with Personal Protective Equipments (PPE) not commonly used by them. The various symptoms experienced by some of the retailers include feeling dizzy or dazed (33%), severe headache (26%), feeling weak (23%), nausea (20%) restlessness (20%) among others are all indicators of possible poisoning due to exposure to organophosphate pesticides.
Conclusions: The evidence from this study shows that the retailers were likely to have been exposed to pesticide mainly through inhalation as a result of continuous exposure to these chemicals in the course of running their business. It is suggested that the existing legislation on pesticide registration in Nigeria should be enforced to control the irresponsible marketing strategies by pesticide companies that promote inappropriate purchasing and distribution. Regular training of the retailers on pesticide handling and management by chemical companies should also be emphasized and monitored while regular biological monitoring study to ascertain the exposure level and possible health effects on the retailers are strongly advocated.

Association between particulate air pollution and methylation of transcript variants of mRNA in an elderly cohort: Veterans Administration Normative Aging Study

Marie-Abele Bind, *Harvard School of Public Health, US*
Andrea Baccarelli, *Harvard School of Public Health, US*
Letizia Tarantini, *University of Milan, Italy*
Helen Suh, *Harvard School of Public Health, US*
Pantel Vokonas, *Boston University School of Medicine, US*
Joel Schwartz, *Harvard School of Public Health, US*

Background and Aims: The mechanisms of particle effects are still being elucidated but may include epigenetic changes. We investigated the association between exposure to $PM_{2.5}$ and methylation of transcript variants of mRNA in the elderly, a suspected risk group.
Methods: We examined the relationship between $PM_{2.5}$ and methylation of transcript variants of mRNA in leukocytes in 141 men participating in the NAS study (1999-2007). We selected 1258 transcripts variants of mRNA (out of 24211) that displayed the largest variance across participants. We randomly split our data set in a test set (n=79) and a validation set (n=62). We investigated the intermediate- (24h-mean, 2, 7, and, 30 days moving average (MA_{2days},MA_{7days},MA_{30days})), and long-term (1 year moving average (MA_{1year})) effects of $PM_{2.5}$ adjusting for age, body mass index, smoking, temperature, season, and percentages of neutrophil and lymphocyte in differential blood count.
Results: We found a significant positive association between $PM_{2.5}$ (MA_{7days}) and methylation of ubiquitin-conjugating enzyme E2A (p_{test}=0.017,$p_{validation}$=0.009). This enzyme is required for post-replicative DNA damage repair and plays a role in blood pressure regulation. We observed a significant positive association between $PM_{2.5}$ (MA_{7days}) and methylation of ATP-binding cassette (p_{test}=0.032,$p_{validation}$=0.007).
$PM_{2.5}$(MA_{30days}) was associated with methylation of dual specificity phosphatase 10 (p_{test}=0.010,$p_{validation}$=0.015).
We found a significant negative association between $PM_{2.5}$ (MA_{1year}) and methylation of microsomal triglyceride transfer protein (MTTP) (p_{test}=0.035,$p_{validation}$=0.011). MTTP is a common genetic variation in multiple metabolic pathways which influences susceptibility to low HDL-cholesterol and coronary heart disease. We observed a significant positive association between $PM_{2.5}$ (MA_{1year}) and methylation of immunoglobulin-like and fibronectin type III domain containing 1 (p_{test}=0.0008,$p_{validation}$=0.0313). We obtained a significant positive association between $PM_{2.5}$ (MA_{1year}) and methylation of cerebellin 1 precursor, a cerebellum-specific protein (p_{test}=0.005,$p_{validation}$=0.019).
Conclusions: Our results suggest an association between intermediate- and long-term exposures to particulate air pollution and methylation transcript variants of mRNA.

ARE OBESITY AND OVERWEIGHT CLUSTERED? SPATIAL EXAMINATION OF OLDER WOMEN IN THREE STATES

Kosuke Tamura, *Department of Health and Kinesiology, Purdue University, Lambert Fieldhouse, West Lafayette, USA*

Heather A. Whitcomb, *Department of Health and Kinesiology, Purdue University, West Lafayette IN, USA*
Jaime E. Hart, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School, Boston MA, USA, and Department of Epidemiology, Harvard School of Public Health, Boston MA, USA*
Francine Laden, *Departments of Environmental Health and Epidemiology, Harvard School of Public Health, Boston MA, USA, and Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School, Boston MA, USA*
Philip J. Troped, *Department of Health and Kinesiology, Purdue University, West Lafayette IN, USA*

Background and Aims: Spatial analyses have been applied to examine relationships between the built environment and obesity. However, few studies have examined this relationship from the aspect of spatial clustering. The purpose of this study was to identify spatial clustering of obesity and overweight/obesity in relation to demographics and the built environment.
Methods: Data for 23,449 Nurses' Health Study participants (mean age = 70.3 ± 6.9 years) in California, Massachusetts, and Pennsylvania were used in this analysis. Binary outcomes were created for obesity (BMI≥30.0) and overweight/obesity (BMI≥25.0). Built environment variables were created for population density, intersection density, and densities of facilities (e.g., restaurants, physical activity facilities). A spatial scan statistic was used to test for spatial clustering (i.e., areas with high or low risk at county level) of obesity and overweight/obesity in unadjusted models and models adjusted for demographic (e.g., age, education) and built environment variables.
Results: Statistically significant ($p<0.05$) spatial clusters of high and low risk of obesity and overweight/obesity were identified in California and Pennsylvania. Of the two high-risk clusters identified in California, participants had a 34-36% greater risk of overweight/obesity, and in the other a 16-17% greater risk. Of the high-risk clusters in Pennsylvania, participants had a 14-16% greater risk of obesity. Of the one low-risk cluster in California, participants had a 25% lower risk of overweight/obesity. Of the two low-risk clusters in Pennsylvania, participants had a 19-20% lower risk of obesity and in the other, a 12% lower risk of overweight/obesity. Adjusting for demographic and built environment variables did not alter the locations of clusters.
Conclusions: Preliminary findings suggest that obesity and overweight/obesity outcomes were spatially clustered and that clusters were not explained by the covariates examined. However, further investigation of neighborhood socioeconomic and built environment variables that might account for clustering needs to be conducted.

Background and Aims. Associations between air pollution and cardio-respiratory health have been well established; but direct human data to support biological mechanisms are limited. We investigated biological responses, at the biomarker level, to air quality changes brought by unprecedented control measures implemented during the Beijing Olympic period, compared with before and after periods.
Methods. Biomarkers reflecting multi-pathways hypothesized to underlie adverse cardio-respiratory effects of air pollution were serially obtained in 125 non-smokers. We used mixed-effects models to estimate changes in biomarker levels by period and to examine associations between biomarkers and pollutants, controlling for ambient temperature, RH, sex, and day of week.
Results. We observed 13% to 60% decreases in mean concentrations of particulate and gaseous pollutants in During-Olympic Period compared to Pre-Olympic Period. In Post-Olympic Period, mean concentrations of most pollutants increased to levels similar to or higher than Pre-Olympic levels. Simultaneously we observed significant decreases from Pre-Olympic Period to During-Olympic Period in levels of FeNO (-51%), exhaled breath condensate (EBC) nitrate (-38%), nitrate + nitrite (-26%), and malondialdehyde (-26%), plasma sCD62p (-34%) and sCD40L (-6%), and von Willebrand factor (-13%). The proportions of above-detection values for EBC 8-isoprostane and plasma C-reactive protein were lower in During-Olympic Period than in Pre-Olympic Period. We observed significant increases in levels of many of these from During-Olympic Period to Post-Olympic Period. Moreover we found most biomarkers significantly associated with $PM_{2.5}$ mass and constituents and/or gaseous pollutants measured on the same day and/or 1 to 5 days prior to biomarker measurement. We observed weak associations for a few autonomic tone biomarkers.
Conclusions. In response to drastic air quality changes**,** healthy young adults demonstrated changes in biomarkers of pulmonary and systemic inflammation, oxidative stress, and platelet activation. Our findings provide mechanistic data to support actions to improve air quality and public health.

ABSTRACT - DEMOGRAPHIC DETERMINANTS OF EXPOSURE TO HAZARD IN FOODS IN ISRAEL

Rachel Raanan, *The Hebrew University, Israel,*
Prof. Elliot Berry, *The Hebrew University, Israel*,
Prof. Ya'acov Ritov, *The Hebrew University, Israel.*,
Dr. John Young, *USA.*

Background and Aims: Effectively addressing exposures to hazardous substances in foods, including pesticides residues and other environmental contaminants, requires accurate information on the diets of individuals, which vary widely. Aggregating consumption data across a population can obscure different patterns of diet and of corresponding dietary risk. Neither the central tendency nor the extreme values of the overall population are likely to be representative for members of the subgroups comprising that population.

In the development of the latest generation of probabilistic dietary exposure assessment models, a need was identified to replace a priori groupings with an analysis of the demographic factors that actually distinguish between dietary consumption patterns.

Methods: Our study population included 3,246 Arabs and Jews, from a representative sample of Israeli adults. An extended set of statistical tools, including innovative data mining tools, allowed characterization of the natural sub populations.

Results: The most important drivers of consumption patterns were not consistent with previously defined subgroups. For example, season was found to be a more important determinant of the amount of fresh (unprocessed) vegetables and fruit eaten than region, nationality (Jews and Arabs), ethnicity, or sex, despite the year-round availability of many, if not most, foods.

Conclusion: A natural binning of population, for exposure to environmental contaminators reveals different binning than traditionally believed. This contributes to a more accurate risk assessment of environmental contaminants in Israel.

Keywords: environmental exposure assessment, dietary patterning, sensitive subpopulations, pesticides, contaminants.

PESTICIDE SALES AND PARKINSON DISEASE IN BRAZIL

Aline de Souza Espindola Santos, *Federal University of Rio de Janeiro, Brazil*
Ronir Raggio Luiz, *Federal University of Rio de Janeiro, Brazil*
Armando Meyer, *Federal University of Rio de Janeiro, Brazil*

Background and Aims: Pesticide exposure has been implicated in several environmental and health problems, including Parkinson's disease (PD). Pesticide use in Brazil has increased so significantly in the last 2 decades that it is been considered the top consumer of these substances in the world. The present study aimed at evaluating the association between the per capita sales of pesticides in 1996 and hospitalization rates by PD between 1997 and 2007.
Methods: Data on every hospitalization by PD, between 1997 and 2007, among individuals 20 years or older, were retrieved from Brazilian Hospitalization System, and used to estimate PD hospitalization rates in each of the 500 Brazilian micro regions. Spearman correlation coefficients were than calculated between PD hospitalization rates and the per capita sales of pesticides in the same micro regions. Correlation coefficients were calculated according to three age strata (20-49; 50-69; and _ 70 years old), sex, and rural/urban micro region status. In addition, micro regions were grouped based on quintiles of per capita pesticide sales, PD hospitalization rates were calculated for each quintile. Rate ratios (RR) were then calculated using the first quintile as reference.
Results: Correlation between per capita sales of pesticide and PD hospitalization rates for all 500 micro regions was just moderate (20-49: $r=0.336$, $p<0.001$; 50-69: $r=0.418$, $p<0.001$; ≥ 70: $r=0.490$, $p<0.001$). However, when correlation analysis was performed only for the rural micro regions, the magnitude of the coefficients slightly increased (20-49: $r=0.383$, $p<0.001$; 50-69: $r=0.450$, $p<0.001$; ≥ 70: $r=0.540$, $p<0.001$). Finally, it was observed that the higher the per capita sales of pesticides in rural micro regions, the higher the risk to be hospitalized by PD (2nd vs. 1st quintile: RR 1.14; 3rd vs. 1st quintile: RR 3.18; 4th vs. 1st quintile: RR 6.05; and 5th vs. 1st quintile: RR 5.84). Risk estimates were even higher among women, when,
depending on quintile, it was 7 fold higher.
Conclusions: In agreement with recent international evidences, our results suggest that pesticide exposure may increase the risk of PD.

CHANGES IN WOMEN'S WATER USAGE DURING PREGNANCY IN THE BORN-IN-BRADFORD (BIB) COHORT

Susan C. Edwards[1]*, Mark Nieuwenhuijsen[2], Rachel B. Smith[1], Shaheen Akhtar[3], Pauline Raynor[3], John Wright[3], Nicky Best[1], Mireille B. Toledano[1]

[2] Center for Research in Environmental Epidemiology (CREAL), Environmental Epidemiology, Barcelona, Spain

[3] Bradford Institute for Health Research, Bradford Royal Infirmary, Bradford, UK

Background and Aims: We study the relation between prenatal exposure to chlorination disinfection by-products (DBPs) in tap water and reproductive outcomes, in a prospective cohort of 13,750 women recruited in Bradford between 2007 and 2010.
To assess exposure to tap water, we have developed an exposure metric which combines area-level DBP concentrations modelled over each woman's gestation period, with individual water use information collected via questionnaire at enrolment (second trimester).
Because earlier work demonstrated that individual water usage is the main driver of differences in exposure between individuals in Bradford (due to limited spatial variability), we collected repeat questionnaire data to assess variability in water usage over the course of late pregnancy.

Methods: We mailed out 619 and 617 repeat water use questionnaires, modelled on the baseline questionnaire, in hard-copy to English speaking women between 29-32 ("Q1") and 35-38 ("Q2") weeks pregnant, respectively. This work was approved by the Bradford Research Ethics Committee.

Results: Overall response rate was 26% as of January 2011. Of the total number of Q2 responses received to date (N=66), 85% were repeat responses.
The responses showed that women in their late third trimester of pregnancy (mean= 37.30±1.12 weeks) increased their tap water intake at home compared to women earlier in their third trimester (mean=31.34 ±1.32 weeks).
Overall, women ingested less liquids of any sort (tap water/bottled water/tea/coffee/squash) at work per day, showered more often and for longer, but swam less often and for shorter times as pregnancy progressed.
Full results will be presented.

Conclusions: Little is known about women's water use behaviour in late pregnancy, a critical window of exposure as the rate of foetal growth dramatically accelerates. This study provides new information regarding third trimester water use behaviours, to be incorporated in our epidemiologic models and help minimise exposure misclassification.

Association Between Blood Lead and Walking Speed in the National Health And Nutrition Examination Survey (NHANES)

John Ji,
Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA
Alexis Elbaz,
INSERM, U708, Paris, France

Marc G. Weisskopf,
Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA
Department of Epidemiology, Harvard School of Public Health, Boston, MA, USA

Background and Aims: Walking speed is increasingly used as a simple and reliable measure of motor function in older people. Slower walking speed is associated with adverse health effects including falls, disability, admission to hospital and mortality. Lead is a toxicant that has been shown to adversely affect human health, particularly the neurological and vascular systems. We explored the hypothesis that lead can adversely affect the motor system manifesting as slower walking speed.
Methods: We used US National Health and Nutritional Examination Survey (NHANES) cross-sectional data from 1999-2002. The time to walk 20ft (walking speed) was measured among 1,795 men and 1,798 women 50 years of age and older. The association with blood lead concentration (sex-specific quintiles) was assessed with linear regression separately in men and women, adjusting for age, education, ethnicity, alcohol use, smoking status, height and waist circumference.
Results: Mean blood lead was 3.26 (sd=2.79) ug/dl in men and 2.21 (sd=1.86) ug/dl in women. Mean walking speed was 3.27 ft/s (sd=0.76) in men and 3.15 ft/s (sd=0.82) in women. Among women, walking speed decreased steadily with increasing blood lead quintile. Women in the highest quintile of blood lead had a walking speed that was 0.107 ft/s slower (95% CI:-0.008, -0.206) than women in the lowest quintile. Walking speed was 0.032 ft/s slower (95% CI: -0.049,-0.015) per ug/dl of blood lead, the same as 1 year of age in these data. Among men, walking speed increased through quintile 4 of blood lead (0.14 ft/s faster [95% CI: 0.05, 0.24] than those in quintile 1), but quintile 5 was not different from quintile 1.
Conclusions: We found higher blood lead level to be associated with decreased walking speed in women. The pattern in men was less clear. A contribution of healthy-worker effect to the pattern in men cannot be ruled out.

SERUM DIOXIN CONCENTRATIONS AND RISK OF DIABETES IN THE SEVESO WOMEN'S HEALTH STUDY

Marcella Warner, *University of California, United States*
Brenda Eskenazi, *University of California, United States*
Steven Samuels, *State University of New York, United States*
Larry Needham, *Centers for Disease Control and Prevention, United States*
Donald Patterson, *EnvironSolutions Consulting, Inc, United States*
Paolo Brambilla, *University of Milano-Biccoca, Italy*
Paolo Mocarelli, *University of Milano-Biccoca, Italy*

Background and Aims: 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD), a widespread environmental contaminant, is a known endocrine disruptor. Animal evidence suggests TCDD affects glucose transport and increases lipids and blood pressure. Limited epidemiologic studies suggest an association between dioxin and diabetes, but no studies have included women.
On July 10, 1976, as a result of a chemical explosion, residents of Seveso, Italy, experienced the highest levels of TCDD in a human population. In 1996, we initiated the Seveso Women's Health Study (SWHS), a retrospective cohort study of the reproductive health of the women. In 2008, we followed up the SWHS cohort. We examined the relation of TCDD exposure with diabetes over the 32 year follow-up period.
Methods: In 1996, we enrolled 981 women who were 0 to 40 years in 1976, resided in the most contaminated areas, Zones A and B, and had adequate archived sera collected soon after the explosion. For each woman, TCDD concentration was measured in archived serum by high-resolution mass spectrometry. A total of 833 women (85%) participated in the 2008 follow-up study. Diabetes cases were defined by self-report of diagnosis or fasting serum glucose ≥126 mg/dL at follow-up. We examined the relation of serum TCDD with diabetes using the Cox proportional hazards regression model.
Results: In total, 53 (5.4%) cases of diabetes were diagnosed. The geometric mean serum TCDD level for the 53 cases (45.9 ±3.6 ppt, lipid-adjusted) was significantly lower than for non-cases (n=927, 71.2 ±4.2 ppt) (ANOVA for $\log_{10}$TCDD: p = 0.03). The unadjusted hazard ratio for diabetes associated with a ten-fold increase in serum TCDD concentration ($\log_{10}$TCDD) was non-significantly decreased to 0.78 (95% CI 0.47, 1.31).
Conclusions: Preliminary analyses suggest an inverse association between serum TCDD and diabetes in the SWHS. Multivariate results will be presented and interpreted in light of study advantages and limitations.

HOME INDOOR AIR QUALITY EFFECTS ON A COHORT OF NEW SOUTH WALES PRIMARY SCHOOL CHILDREN

Aim: To determine whether, in children aged 7 to 11 years, the presence and use of an unflued gas heater in the home and the use of gas cookers in the home result in worse respiratory health outcomes.
Methods: Primary school children from 22 schools in colder areas of New South Wales were recruited (n=418). We collected information about use of unflued gas heaters (UFGH) and/or gas for cooking. We recorded FEV_1, peak expiratory flow (PEF), respiratory symptoms and use of bronchodilators twice daily for six weeks at school. Atopic status was assessed by skin prick tests. Analysis was by generalised estimating equations.
Results: The prevalence of reported asthma was 15% and 44 % were atopic. The presence of UFGH was associated with lower FEV_1 measured in the morning (-0.087 L, 95% CI -0.167 to -0.007 L) and in the afternoon (-0.072 L, 95% CI -0.142 to -0.002). The effect of UFGH on daytime cough differed between atopic and non-atopic subjects (P=0.038), with a trend towards a more adverse effect in atopic subjects. However, the effect of UFGH on cough during the day was not significant in either atopic subjects (odds ratio 1.53, 95% CI 0.78 to 3.02) or non-atopic subjects (OR 0.66, 95% CI 0.35 to 1.24). Use of gas for cooking was associated with increased reliever use during the night (OR 3.61, 95% CI 1.34 to 9.77) but the effect on use of reliever during the day differed between atopic and non-atopic subjects (P=0.019) and was more adverse in non-atopic subjects. No significant adverse effects were noted for wheeze or cough during the night.
Conclusions: Exposure to gas appliances in the home has an adverse effect on symptoms and lung function with some evidence that these effects are modified by atopic status.

MATERNAL EXPOSURE TO POLYCHLORINATED BIPHENYLS AND LOW BIRTH WEIGHT AMONG RESIDENTS OF ANNISTON, ALABAMA

Melanie S. Dove, *the Anniston Environmental Health Research Consortium University of California, Irvine, United States*
Herman R. Foushee, *the Anniston Environmental Health Research Consortium University of Alabama-Birmingham, United States*
Scott M. Bartell, *the Anniston Environmental Health Research Consortium University of California, Irvine, United States*

Background and Aims: Previous studies suggested an association between polychlorinated biphenyls (PCBs) and birth weight. We investigated the association between maternal PCBs, preterm birth and low birth weight (<2500 grams) in a population with elevated exposure to PCBs.
Methods: From 2005-2006, the Anniston Community Health Survey collected maternal blood for total PCBs (sum of 35 congeners) and self-reported information on potential sources of PCB exposure including consumption of local fish, livestock and clay by in-person questionnaire. For each child born between 1936 and 2006, women self-reported information on preterm births (yes vs. no) and birth weight. Multiple imputation was used to impute missing values for PCB's, birth weight, and covariates. This resulted in a sample size of 604 mothers and 1477 infants. To take into account the correlation between infants with the same mother we included a random intercept for each mother using generalized estimating equations, specifying a binomial distribution and logit link.
Results: Adjusted for covariates, we did not observe an association between log transformed total PCBs and preterm births, low birth weight, or low birth weight among term infants. However, consumption of local fish was associated with an increased adjusted odds of low birth weight (OR=1.9, 95% CI: 1.2, 3.1) and low birth weight among term infants (OR=2.1, 95% CI: 1.1, 3.9). Consumption of local livestock was associated with an increased adjusted odds of preterm birth (OR= 2.3, 95% CI: 1.4, 3.7), low birth weight (OR= 2.2, 95% CI: 1.3, 3.5), and low birth weight among term infants (OR= 1.8, 95% CI: 0.96, 3.2).
Conclusions: In the Anniston population, maternal consumption of local fish and livestock was associated with infant preterm birth and low birth weight. Questionnaire responses regarding local exposure routes may be a better proxy for historical PCB exposures than current serum concentrations.

ENDOTOXIN EXPOSURE, TLR4 MUTATIONS, SMOKING, AND WORK-RELATED BEHAVIORS: PULMONARY FUNCTION DEFICITS AMONG POTENTIALLY SUSCEPTIBLE SUBGROUPS OF AGRICULTURAL WORKERS IN COLORADO AND NEBRASKA

Background and Aims: Organic dust inhalation has been associated with adverse respiratory responses among agricultural workers. Susceptibility to the adverse health effects resulting from these agricultural exposures may be related to: constituents of the dust, e.g. endotoxin; intrinsic factors, e.g. genetic traits; and extrinsic factors, e.g. smoking and work-related behaviors.
Methods: This study quantified breathing-zone personal work shift exposures to inhalable dust, endotoxin, and its 3-hydroxy fatty acid (3-OHFA) constituents, and evaluated pulmonary function before and after the work shift among 136 cattle feedlot, dairy, grain elevator, and corn farm workers. General linear models were used to assess the multivariable relationships between dust exposures and lung function (forced vital capacity, FVC; forced expiratory volume in 1 second, FEV_1; and the FEV_1/FVC ratio). Genotyping of SNPs in two polymorphisms in the TLR4 gene (TLR4 299 and 399) was performed.
Results: Geometric mean dust levels were similar among feedlot (1.53mg/m^3; n=59), dairy (1.45mg/m^3; n=15), and farm (1.58mg/m^3; n=9) employees and elevated among grain elevator operators (2.03mg/m^3; n=53). Endotoxin concentrations were similar across all facility types. Increased dust exposure was associated with work shift decrements in FVC and FEV_1. These relationships were stronger among current smokers and those reporting application of pesticides/herbicides at work or home (interactions between dust and smoking and between dust and pesticide use, p• 0.05); however, no evidence of increased susceptibility was observed among those living on a farm. Interactions between dust/endotoxin exposures and genetic mutations were observed ($p<0.05$), although the small number of participants with genetic mutations limits interpretation. Further analyses will identify additional factors that may confer increased susceptibility to the adverse pulmonary effects (cross-shift and pre-shift) of agricultural exposures.
Conclusions: A better understanding of factors leading to increased susceptibility for the development of adverse respiratory outcomes is needed to optimize prevention strategies among agricultural workers.

SELENIUM AND MERCURY OPPOSING INFLUENCES IN FISH-EATING POPULATIONS OF THE BRAZILIAN AMAZON

Donna Mergler, *Centre de recherche interdisciplinaire sur la biologie, la santé, la société et l'environnement (CINBIOSE), Université du Québec à Montréal, Canada*

Background and Aims: Amazonian riverside communities have the highest reported mercury (Hg) exposure in the world today. Selenium (Se), an essential element, is involved in several body functions through selenoprotein expression. Some studies suggest that selenium (Se) may be protective for Hg toxicity, however, data from animal and human studies are inconsistent and some epidemiological studies show toxic effects of elevated Se, notably hyperinsulinemia, aloplecia and paraesthesia. The objective of the present study was to examine the relations between biomarkers of Se and visual and motor functions, taking into account co-variables and Hg exposure.
Methods: Participants (n = 448, 15-87y), were recruited from 12 communities along the Tapajós River. B-Se, P-Se and blood Hg (B-Hg) were measured by ICP-MS. Interview-administered questionnaires served to collect information on socio-demographics and medical history. All participants underwent a complete visual examination and performed several tests of motor functions.
Results: Se status ranged from normal to high (B-Se median: 228µg/L, range 103-1500µg/L). Few participants reported diabetes (1.1%), and despite high levels of Se in some individuals, no signs and symptoms of Se toxicity were observed. P-Se concentrations were associated with beneficial outcomes: lower prevalence of age-related cataracts, better near visual acuity and motor performance; regression estimates were stronger when adjusting for B-Hg. When stratifying at the median B-Hg concentrations, P-Se consistently presented associations with the outcomes only at high B-Hg concentrations.
Conclusions: In this population with high Hg exposure, Se intake may play a role in offsetting some deleterious effects of Hg, but the beneficial effects of Se may not be present in populations with low Hg exposure, and Se may not offset all Hg-induced toxic effects in fish-eating populations. Further studies should address the risks and benefits of dietary Se in order to better understand the complex Se-Hg interactions in human populations.

ASSESSMENT OF VOLATILE ORGANIC COMPOUNDS IN NEWBORN BABIES' HOMES: AN ENVIRONMENTAL INVESTIGATION IN THE PARIS BIRTH COHORT

Background and Aims: There is a growing public health concern about indoor air quality. Until now few data on indoor chemical pollutants in dwellings are available, although relations between exposure to indoor chemical air pollutants and respiratory/allergic diseases are suspected. Moreover exposure in the first months of life is determinant because of the infants' vulnerability. The aim of this study was to document airborne volatile organic compounds (VOCs) levels in Paris dwellings.

Methods: An environmental investigation was conducted in homes of a random sample of newborn babies (n=196) from the PARIS *(Pollution and Asthma Risk: an Infant Study)* birth cohort. The VOCs measurements were repeated at 1, 6, 9 and 12 months of age. Air samples were collected in the child's bedroom, over one week using passive devices (Radiello®). Twelve VOCs were identified and quantified by gas chromatography/mass spectrometry. Annual levels defined as average of seasonal levels were calculated for all compounds to assess exposure to VOCs throughout one year.

Results: Aromatic hydrocarbons (benzene, toluene, *m,p*-xylenes, *o*-xylene, 1,2,4-trimethylbenzene, ethylbenzene, and styrene), aliphatic hydrocarbons (decane, undecane), and chlorinated hydrocarbons (trichloroethylene, tetrachloroethylene, and 1,4-dichlorobenzene) were quantified in all dwellings. Toluene was the most abundant compound, its annual median level was 17.2$\mu g/m^3$ (interquartile range-IQR: 12.8-24.6$\mu g/m^3$) followed by aliphatic compounds. Median levels of decane and undecane were 7.6$\mu g/m^3$ (IQR: 4.9-13.9$\mu g/m^3$) and 9.3$\mu g/m^3$ (IQR: 6.4-17.5$\mu g/m^3$) respectively. Trichloroethylene levels were the lowest indoors, its median was 0.7$\mu g/m^3$ (IQR: 0.5-1.0$\mu g/m^3$). The highest range of VOCs values was for chlorinated hydrocarbons. Trichloroethylene, tetrachloroethylene and 1,4-dichlorobenzene levels ranged from 0.25 to 104.7$\mu g/m^3$, 0.6 to 124.2$\mu g/m^3$ and 1.3 to 783.4$\mu g/m^3$ respectively, the highest levels being probably due to specific occupants activities.

Conclusion: This study provides helpful information on chemical contamination in dwellings. Identification of determinants levels will allow the building of predictive models to estimate infant exposure to pollutants.

THE POPULATION-LEVEL ESTIMATE OF THE EFFECT OF PRENATAL EXPOSURE TO TRAFFIC ON PRETERM BIRTH

Amy M. Padula, Ph.D., M.Sc., *University of California, Berkeley, US*
Kathleen M. Mortimer, Sc.D., M.P.H., *University of California, Berkeley, US*
Ira B. Tager, M.D., M.P.H., *University of California, Berkeley, US*

Background and Aims: Preterm birth is an important marker of health both in the neonatal period, through childhood and possibly into adulthood. In the U.S., 12-13% of births are preterm (Goldenberg 2008) – a public health problem that costs society at least $26 billion a year (Behrman 2007). Associations between prenatal exposure to traffic and a variety of adverse birth outcomes including preterm birth have been reported (Shah 2011), but a causal relationship has not been established (HEI 2010). The aim of this study is to use causal inference estimators to evaluate the marginal (population-level) effect of traffic density on preterm birth in a cohort of over 300,000 births in four counties in the Central Valley of California during years 2000-2006.
Methods: Preterm birth was defined as less than 37 weeks gestation as reported on the birth certificate. Traffic density was based on distance-decayed annual average daily traffic volumes. Targeted maximum likelihood estimation (TMLE) was applied to estimate the counterfactual probability of preterm birth had everyone been exposed to each quartile of traffic density. In addition, a population intervention model (PIM) was applied to estimate the potential change in preterm birth given a hypothetical intervention in which traffic density in the population was fixed at each quartile.
Results: The estimated probability of preterm birth is 11.9% had everyone been exposed to the highest quartile of traffic density, compared to 10.8% had everyone been exposed to the lowest quartile of traffic density. The PIM showed that if a hypothetical intervention could reduce the entire population's exposure to that of the lowest quartile, the population would have a reduction in preterm birth of 0.45% compared to what is observed.
Conclusion: Semi-parametric causal inference methods applied to these data support findings from previous studies that prenatal exposure to traffic adversely affects birth outcomes.

COMBINING NEWBORN BLOOD CONCENTRATIONS AND QUESTIONNAIRE DATA TO ESTIMATE INDIVIDUAL CUMULATIVE PRENATAL METHYLMERCURY EXPOSURE AMONG CHILDREN WITH AUTISM, DEVELOPMENTAL DELAY, AND TYPICAL DEVELOPMENT

Stephen McKean, *University of California, Davis, United States*
Irva Hertz-Picciotto, *University of California, Davis, United States*
Peter Green, *University of California, Davis, United States*
Scott Bartell, *University of California, Irvine, United States*

Background and Aims: Methylmercury (MeHg) is an environmental contaminant and a known developmental neurotoxicant. Because biomarker and questionnaire data have different limitations as estimates of exposure, there is increased interest in methods that combine these two types of information in order to gain the advantages of both. The aim of this study is to estimate the cumulative gestational dose of MeHg for each individual in our study population using both newborn bloodspots and seafood consumption questionnaire data collected from the Childhood Autism Risks from Genetics and the Environment (CHARGE) study, and to compare the cumulative dose among cases and controls.
Methods: CHARGE is a comprehensive, population-based case-control study with participants sampled from three strata: children with autism, children with developmental delay but not autism, and the general population. We measured total mercury concentrations in newborn bloodspots using inductively coupled plasma mass spectrometry (ICP-MS). To estimate seafood MeHg concentrations and corresponding doses for each study participant, we utilized a regression model based on a discrete one-compartment pharmacokinetic model that assumed a piecewise-constant ingestion rate. Cumulative dose was estimated based on the area under the exposure-time curve over the gestational period. Cumulative exposure was compared among the autism, developmental delay, and typically developing groups using the Kruskal-Wallis test.
Results: The regression-estimated average consumed MeHg fish concentration was 0.045 ppm. Cumulative dose did not differ significantly among the three developmental groups (p=0.97).
Conclusions: Our regression model estimated an average MeHg fish concentration that is consistent with several commonly consumed species in the United States, especially those that are lower in MeHg. Although cumulative exposure may be a more relevant exposure metric than biomarker concentration alone, neither measure was associated with neurodevelopmental outcomes in the CHARGE study.

NEWBORN BLOOD MERCURY CONCENTRATION AND AUTISM RISK

Stephen McKean, *University of California, Davis, United States*
Peter Green, *University of California, Davis, United States*
Robin Hansen, *University of California, Davis, United States*
Sally Ozonoff, *University of California, Davis, United States*
Irva Hertz-Picciotto, *University of California, Davis, United States*

Background and Aims: Because mercury is a neurotoxin, it has been investigated as a potential cause of autism, but little information is available on the association with prenatal mercury exposures. In this study, we (1) addressed the relationship between maternal third trimester fish consumption (the primary source of methylmercury) and bloodspot mercury concentration, (2) determined if there is an association between bloodspot mercury concentration and the development of autism, and (3) assessed if child's glutathione S-transferase class M1 (GSTM1) genotype modified the relationship between bloodspot mercury concentration and autism risk.
Methods: Childhood Autism Risks from Genetics and the Environment (CHARGE) is a comprehensive, population-based case-control study with participants sampled from three strata: children with autism, children with developmental delay but not autism, and the general population. We measured total mercury concentrations in newborn bloodspots (representing prenatal exposures) using inductively coupled plasma mass spectrometry (ICP-MS). To predict bloodspot mercury concentration, we fit linear regression models with maternal fish consumption. Multiple logistic regression models were fit to assess the association between bloodspot mercury concentration and developmental outcome (autism versus typical development), adjusting for potential confounders, and assessing for effect modification by the inclusion of a product term between bloodspot mercury concentration and GSTM1 genotype.
Results: Maternal third trimester fish consumption significantly predicted bloodspot mercury concentration. With regard to developmental outcome (autism vs. typical development), the OR for a one unit natural log increase in bloodspot mercury concentration was 0.79 (0.50, 1.23). In the GSTM1 active and null strata, ORs for developmental outcome for a natural log increase in blood mercury concentration were 0.94 (0.53, 1.68) and 0.77 (0.45, 1.32), respectively.
Conclusions: We did not find a significant association between bloodspot mercury concentration and autism risk. Mercury concentration did not increase autism risk in GSTM1 active or null subgroups. Investigation into other potentially genetically vulnerable subgroups is warranted.

IMPACT OF CLIMATE CHANGE ON OZONE INDUCED MORTALITY IN EUROPE

Hans Orru, *Umea University, Sweden; University of Tartu, Estonia*
Christofer Åström, *Umea University, Sweden*
Camilla Andersson, *Swedish Meteorological and Hydrological Institute, Sweden*
Kristie Ebi, *ClimAdapt, USA*
Joakim Langner, *Swedish Meteorological and Hydrological Institute, Sweden*
Bertil Forsberg, *Umea University, Sweden*

Background and Aims: Ozone is a highly oxidative pollutant, associated with respiratory morbidity and mortality. All else (e.g. ozone precursors) being equal, ground-level ozone will increase as temperatures increase with climate change. As a part of the Climate-TRAP project we used CO_2 emission scenarios, models and epidemiological data to assess ozone-related health impacts under a changing climate.
Methods: European ozone concentrations were modelled at a grid size of 50x50 km using MATCH-RCA_3. Projections from two climate models, $ECHAM_4$ and HADLEY, were used, assuming greenhouse gas emission scenarios A2 and A1B, respectively. With $ECHAM_4$ (A2) two periods were compared: the baseline period as 1961–1990 and future as 2021–2050. With HADLEY (A1B) two additional periods were included: the current situation as 1990–2009 and further future as 2041–2060. The impact on mortality (short-term effect) was calculated for exposures above a daily maximum 8-hour concentrations of 70 μgm^{-3}. We used a European-wide exposure-response function with country-specific baseline mortality.
Results: Comparing the current situation with the baseline period (HADLEY (A1B)), the largest increase in ozone-associated mortality due to climate change (~4%) occurred in Belgium, Ireland, Netherlands and UK. Comparing the baseline period and the future, the increase is projected to be biggest in Belgium, France, Spain and Portugal (10–14%) and the effect will be stronger for the A2 scenario (using $ECHAM_4$). However, in Nordic and Baltic countries the scenarios suggest a decrease in ozone-related mortality of the same magnitude. Furthermore, there were regional differences in climate change projections, depending which of the climate models ($ECHAM_4$ or HADLEY) were implemented. Also interactions between temperature and air pollution may need to be included.
Conclusions: The current study suggests that projected effects of climate change on ozone levels could differentially influence mortality and morbidity across Europe.

MAPPING HUMAN HEALTH VULNERABILITY TO CLIMATE CHANGE IN MEXICO

Horacio Riojas-Rodríguez, *Instituto Nacional de Salud Pública, Cuernavaca, México*
Magali Hurtado-Díaz, *Instituto Nacional de Salud Pública, Cuernavaca, México*
Grea Litai Moreno-Banda, *Instituto Nacional de Salud Pública, Cuernavaca, México*
Aldo Castañeda Martínez, *Instituto Nacional de Salud Pública, Cuernavaca, México*

Background and Aims: Mexico is particularly vulnerable to climate change and climate variability due to its geographical location topography, hydrology and other factors like urbanization, deforestation and relative growth of poverty. For this reason we are building a human health vulnerability atlas, in order to assisting decision-makers in identifying risk, and planning and mapping a future, which would be more resilient to the changing climatic conditions in México.
Methods: The first stage of the analysis was to obtain baseline data of climatic variables (1970-1999) and epidemiological data from acute diarrheal disease (ADD) and dengue (1998-2005). Secondly we generated a regionalized climate change projections for Mexico, from the downscaling of the results of General Circulation Models (GCMs): HadCM3, GFDL and ECHam4, and the A2 scenario. Finally we projected the incidence of ADD and dengue in 2030, including information of precipitation, temperature and human vulnerability.
Results: Our study predicts that in 2030 the states of Veracruz, Tabasco and Chiapas will have high risk to ADD and almost all costal states will have high risk to dengue. There will be an increase in 2030´s rate ratios from the month of June and September for ADD and dengue, respectively.
Conclusions: The preliminary results indicate that in 2030 there will be an excess for ADD and dengue cases attributable to climate change. Climate change will add to the burdens of those who are already poor and vulnerable.The results of the analysis are thus indicative only. Even so, they are useful for several purposes.

RISK ASSESSMENT OF EXPOSURE BY $PM_{2,5}$ FROM THE BIOMASS BURNING IN CHILDREN OF BRAZILIAN AMAZON: ESTIMATIVE OF POTENTIAL DOSE AND RISK TOXICOLOGY

Beatriz Fátima Alves de Oliveira, *National School of Public Health, Brazil*
Eliane Ignotti, *State University of Mato Grosso, Brazil*
Paulo Artaxo, *University of São Paulo, Brazil*
Sandra Hacon, *National School of Public Health, Brazill*

Background and Aims: Exposure to fine fractions of particulate matter ($PM_{2,5}$) was associated with increased hospital admissions for respiratory disease and cardiovascular disease in children and elderly (Pope III and Dockery 2006; Gouveia et al 2006). This study aims to estimate the toxicological risk of $PM_{2,5}$ from the burning biomass in children between 6 to 14 years of age in Tangará da Serra, a municipality of Subequatorial Brazilian Amazon.
Methods: Study of Risk Assessment of $PM_{2.5}$ by estimated the potential dose and risk quotient in two scenarios of exposure according to local seasonality. The exposure scenarios were defined using the average of concentrations $PM_{2,5}$ during the dry and rainy season. The potential dose of $PM_{2,5}$ was estimated using Monte Carlo simulation, according age, gender, asthma and Body Mass Index (BMI).
Results: The children incorporated a potential average dose of $PM_{2.5}$ of 2.05 µg/kg.dia (CI 95%: 1.91-2.18) in dry season and 0.32 µg/kg.dia (CI 95%: 0.31-0.34) in the rain scenario. During dry season, children and adolescents showed toxicological risk to $PM_{2.5}$ of 2.41 (CI 95%: 2.25-2.57). In the rain scenario, the exposure to $PM_{2.5}$ not configured toxicological risk (RQ=0.54; CI 95%: 0.52-0.56).
Conclusions: Children and adolescents living in the Subequatorial Brazilian Amazon region were exposed to higher potential average doses of $PM_{2.5}$, resulting in toxicological risk for this pollutant.

THE ASSOCIATION OF BODY SHAPE, COMPUTER-USING TIME AND PHYSICAL ACTIVITY AMONG COLLEGE STUDENTS IN TAIWAN

Fu-Hui Lee, *Central Taiwan University of Science and Technology, Taichung city, Taiwan*
Tzu-I Chiu, *Central Taiwan University of Science and Technology, Taichung city, Taiwan*
Li-Feng Lin, *Central Taiwan University of Science and Technology, Taichung city, Taiwan*

Background and Aims: The utilization of computer and internet has become widespread among college students in Taiwan. Previous articles found that the degree of internet addiction of male college students had a significant negative correlation with the physical activity mass. The purpose of this study was to explore the computer-using time and physical activity of college students, and to determine whether gender and body shape were associated with computer-using time and physical activity among college students in Taiwan.
Methods: A cross sectional survey was conducted and the subjects were chosen from one college in central Taiwan by cluster sampling. The instrument to evaluate the physical activity in this study was Bouchard's 3-day Physical Activity Log. An anonymous closed end self-report questionnaire was designed and the data collected from the questionnaire was analyzed with statistical methods.
Results: 260 male and 830 female students with mean age of 19.29±1.02 years were investigated. The mean BMI was 20.91±3.21 and the mean calorie expenditure was 2334±722 Kcal for weekday and 2315±758 Kcal for weekend. The percentage for overweight was 11.9% of male and 6.7% of female students, and obesity rate was 11.5% of boys and 3.4% of girls, in the meantime the weekday and weekend computer-using time of boys(149 and 197 minutes per day) were higher than girls(113 and 141 minutes per day). The findings indicated that the weekday computer-using time of students with obesity were higher than students with underweight and the weekend computer-using time of students with overweight were higher than students with underweight.
Conclusions: The findings of this research showed that the less time students spent in computer, the more physical active they were. The study may be important in providing health educator with a better understanding of how to promote college students to be more physical active in campus.

RESULTS FROM THE CHAMACOS STUDY OF CHILDREN'S ENVIRONMENTAL HEALTH

Brenda Eskenazi, *University of California, United States*
Maryse Bouchard, *University of Montreal, Canada*
Kim G. Harley, *University of California, United States*
Asa Bradman, *University of California United States*
Amy Marks, *University of California, United States*
Katie Kogut, *University of California, United States*
Celina Trujillo, *University of California, United States*
Nina Holland, *University of California, United States*
Dana Boyd Barr, *Emory University, United States*

Background and Aims: Organophosphate (OP) pesticides are acute neurotoxicants. In the US, they are widely used in agriculture. We present the associations of OP exposure during pregnancy and neurodevelopment of children in the CHAMACOS study, a longitudinal birth cohort study of primarily Latino farmworker families living in California.

Methods: We enrolled 601 pregnant women during pregnancy and conducted neurodevelopmental assessments of their children at 1 and 6 months and 1, 2, 3.5, 5, 7, and 9 years. The children are currently undergoing the 10.5 year assessment. OP pesticide exposure in the mother during pregnancy and of the children were assessed by measures of urinary dialkyl phosphate metabolites (DAPs). We also examined the association and effect modification of PON1 genotype and phenotype.

Results: We found that DAP metabolites of the mother during pregnancy are related to abnormal reflexes in the neonate on the Brazelton Scale, lower mental development on the Bayley Scales and pervasive developmental disorder as reported by their mother at age 2, and lower verbal abilities at 3.5 and 5 years. When the children reached school age, we reported an association between maternal DAPs and poorer attention as reported by the mother and as measured on a continuous performance test. In addition, by age 7 years, we found that there is a significant negative relation between all subscales of the WISC IQ and maternal DAP levels but not child levels. We will also present on results with autonomic nervous system reactivity and with PON1 genotype and phenotype.

Conclusions: We have found significant associations between OP exposure as measured by DAPs and child neurobehavioral development in a population living in an agricultural community. Maternal urinary DAP concentrations were higher, but nonetheless within the range of levels measured in the general U.S. population.

TITTLE DEVELOPING MODLES OF RESIDENTIAL AND PARA-OCCUPATIONAL EXPOSURE TO PESTICIDES FOR AGRICULTURAL FAMILIES

Anne-Marie Nicol, *University of British Columbia, Canada*
Caitlin Blewitt, *University of British Columbia, Canada*

Background and Aims: CAREX Canada is a national occupational and environmental surveillance project estimating the number of Canadian exposed to carcinogens. Agricultural pesticide estimates are being developing to calculate cancer risks across the country. To facilitate these risk assessments, we examined the state of the literature on residential and para-occupational exposure and its implications for pesticide risk assessment.
Methods: A search was undertaken in the published literature for data on exposures in farm homes as well for spouses and children of farmers and farmworkers, including exposure assessments and epidemiologic studies. Papers were limited to research from North America. Environmental and biological sampling and epidemiological data from these studies (n=42) were critically examined and catalogued in a matrix.
Results: Para-occupational and residential pesticide exposures are clearly documented in North America. The studies showed increased exposures for farm children compared to non-farm children. A smaller increase was seen in some studies of farm spouses. Major sources of exposure included workers' boots, clothes and vehicles. Children who were present during spraying showed even higher levels of exposure. Proximity of the home to spraying locations explained some, but not all, of the home exposure reported. Epidemiologic studies showed higher rates and risks of cancer and decreased neurobehavioral performance in children whose parents had occupational exposure to pesticides.

We propose the need for a stratified farm community risk assessment model, with low (farm spouse), medium (children not present for spraying) and high (children present for spraying) exposure categories.

THE EFFECTS OF A SEXUAL HEALTH LIFE-SKILL TEACHING PROGRAM ON SEXUAL HEALTH KNOWLEDGE, ATTITUDE AND BEHAVIOR INTENTION OF THE ADOLESCENTS IN TAIWAN

Fu-Hui Lee, *Central Taiwan University of Science and Technology, Taichung city, Taiwan*
Ya-Mei Chang, *Chung-Cheng Elementary School, Taichung city, Taiwan*

Background and Aims: The purpose of this study is to investigate the effects of life-skills teaching program in sexual health education on the seventh grade students' sexual health knowledge, attitude, and behavior intension in a high school in Taiwan.
Methods: A quasi-experimental research method was used in this study. In total, 133 students in a junior high school in Central Taiwan were recruited by purposive sampling. The subjects were divided into the experimental group (n=69) and control group (n=64). The students in the experimental group received five units of teaching courses for ten hours while the students in the control group did not. A self-administered structured questionnaire was designed to serve as the pre-test and post-test instrument. The questionnaire consists of scales of knowledge (r = 0.70), attitude (Cronbach's α = 0.84), and behavioral intention (Cronbach's α = 0.87). All the participants took the pretest one week before the intervention and the posttest one week after the intervention, and the post posttest was conducted eight weeks after the intervention.
Results: One week after the intervention, the sexual health knowledge, attitude, and behavior intention of the experimental group showed instantly significant improvement. Eight weeks after the intervention, the sexual health knowledge and attitude of the experimental group continued to make progress, while the sustainability of the sexual health behavior intention was not significant.
Conclusions: The results indicated that the sexual health life-skills teaching program had positive effects on adolescents. The results of this study shall serve as a reference for the school health educators to implement the sexual heath education program.

AIR POLLUTION IN THE BRAZILIAN AMAZON AND SEX SECONDARY RATIO

Pãmela Rodrigues, *Federal University of Mato Grosso, Brazil*
Eliane Ignotti, *University of State of Mato Grosso and National School of Public Health, Brazil*
Sandra Hacon, *National School of Public Health, Brazil*
Karla Longo, *National Institute of Spatial Research, Brazil*
Saulo Freitas, *National Institute of Spatial Research, Brazil*

Background and Aim: Air pollution has been related to changes in the sex ratio in industrial areas. The aim of this study is to analyze the correlation between secondary sex ratio, and exposure to fine particulate matter from biomass burning in the Brazilian Amazon.
Methods: Ecological study of the correlation between the indicators: annual hours (AH%) of fine particulate matter ($PM_{2,5}$) and secondary sex ratio (SSR) in the Brazilian Amazon region in 2004 and 2005. The database for the exposure indicator, i.e. the percentage of annual hours of $PM_{2.5}$ above the thresholds of 25• g/m^3, 50• g/m^3 e 80• g/m^3, representative of the air pollution levels of concentration of were produced by the Weather Forecasting and Climatic Study Center of the Brazilian Space Research Institute (CPTEC/INPE). To calculate the indicator of RSS we used the database of the Information System of Birth (SINASC) for all municipalities in the Brazilian Amazon.
Results: The states of Rondonia and Mato Grosso presented the highest levels of particulate matter during the study period. The Spearman correlation of every cut-off points for AH% was not statistical significant with the RSS. The averages of RSS were 1.08 and 1.07 in 2004 and 2005 respectively that represents 8 to 7% more males than females. Conclusion: The secondary sex ratios were not related to the levels of pollutants from biomass burning in the Brazilian Amazon during 2004 and 2005.

COMPARING DIFFERENT EXPOSURE MEASURES OF TRAFFIC-RELATED POLLUTION: A STUDY OF TERM LOW BIRTH WEIGHT IN LOS ANGELES COUNTY, CALIFORNIA

Jo Kay Ghosh, University of California, Los Angeles, *650 Charles E. Young Dr. South, CHS 71-254, Los Angeles, CA 90095-1772, jokay@ucla.edu*

Michelle Wilhelm, University of California, Los Angeles, Los Angeles, CA
Jason Su, University of California, Berkeley, Berkeley, CA
Daniel Goldberg, University of Southern California, Los Angeles, CA
Myles Cockburn, University of Southern California, Los Angeles, CA
Michael Jerrett, University of California, Berkeley, Berkeley, CA
Beate Ritz, University of California, Los Angeles, Los Angeles, CA

Background and Aims: Few birth outcomes studies have examined associations with air toxics in traffic exhaust, such as benzene, toluene, ethyl benzene, and xylene (BTEX). Additionally, land use-based regression (LUR) provides estimates of small area variation in air pollution and contributes to an understanding of the spatial distribution of traffic-related air pollution. We compare effect estimates for term low birth weight (LBW) based on LUR-modeled estimates, and criteria pollutant and air toxics data.

Methods: We included births from 1/1/1995-12/31/2006 to women residing within 5 miles of a California Air Resources Board air toxics monitoring station in Los Angeles County, California. LUR-modeled estimates of NO, NO_2 and NO_x based on >200 field measurements were seasonalized using monitoring station data, and extracted for geocoded residential addresses. We examined associations with term LBW (≤37 weeks completed gestation and <2500g birth weight) using logistic regression adjusted for maternal age, race/ethnicity, education, parity, and infant gestational age and gestational age squared.

Results: We analyzed 8,181 term LBW cases and 370,922 term normal-weight non-cases. For LUR-estimated and air toxics exposures, the strongest associations were seen for the third trimester, the entire pregnancy, and the last pregnancy month averages. Adjusted odds ratios (ORs) for a 10ppb increase in NO, NO_2 and NO_x, respectively, were 1.02 (95%CI=1.01, 1.03), 1.05 (95%CI=1.02, 1.08), and 1.01 (95%CI=1.00, 1.02) for third trimester seasonalized LUR-estimated exposures, and 1.06 (95%CI=1.03, 1.09), 1.12 (95%CI=1.05, 1.19), and 1.04 (95%CI=1.02, 1.07) for unseasonalized LUR estimates. Third trimester BTEX exposures were associated with term LBW when stratifying by closest monitoring station, for women living within 5 miles of north Long Beach, Burbank, and downtown LA stations.

Conclusions: Using spatial contrasts (e.g. unseasonalized LUR estimates) and temporal contrasts (e.g. monitoring station estimates, stratified by station), we provide additional evidence that traffic-related air pollution increases the risk of term LBW.

ESTIMATING THE EFFECT OF RAINFALL AND INDICATOR BACTERIA IN AN EPIDEMIOLOGICAL STUDY

Andreas Tornevi, Umeå University, Sweden
Bertil Forsberg, Umeå University, Sweden

Background and Aims: Climate change scenarios point to the fact that Sweden will be affected by more extreme temperatures and more extreme precipitation. This may indicate that water treatment plants will face larger risks since more pathogens are expected to enter the raw water system. Göta River, running in the south-west of Sweden, is a fresh water supply to the population of Gothenburg. Turbidity and indicator bacteria are frequently studied to decide if the water is appropriate to produce drinking water. Our first objective is to study the potential associations between rainfall, turbidity and indicator bacteria and assess if effects are delayed in time, in order to subsequently conduct time series analysis on acute gastrointestinal (AGI) illnesses in the population.
Method: We have used a distributed lags non-linear (DLNM) regression model, which describes simultaneously the relationship along the space and the lag dimension of the predictor. We have daily mean values from online turbidity measures which were accessible between 2001 and 2010. 3 various types of indicator bacteria are sampled 2-4 times a week in raw water and available data were accessed between 2004 and 2010. Data of daily precipitation were accessible 30 kilometers upstream (2001-2010).
Results: When controlling for time trends and seasonal patterns, autoregressive Gaussian models shows significant effects of rainfall on both turbidity and indicator bacteria. Turbidity is predicted to increase with factor 1.15 (1.4) at 20mm (50mm) rain and significant effects are visible at lag 1- 4 while peaks at lag 2. Coliform bacteria increase with factor 2.4 (95% CI: 2.0, 2.6) at 20 mm of rain at lag 2.
Conclusion: Results confirm that precipitation is a good predictor to both turbidity and indicator bacteria in Göta River and will be used in the next phase where AGI will be studied.

CONCENTRATIONS OF POLYFLUOROALKYL CHEMICALS DURING GESTATION AND SERUM LIPIDS AT AGE 7 IN GIRLS ENROLLED IN THE AVON LONGITUDINAL STUDY OF PARENTS AND CHILDREN

Mildred Maisonet, *National Center for Environmental Health, CDC ; Rollins School of Public Health, Emory Unversity*
Adrianne Holmes, *National Center for Environmental Health, CDC*
Antonia Calafat, *National Center for Environmental Health, CDC*
Michele Marcus, *National Center for Environmental Health, CDC; Rollins School of Public Health, Emory Unversity*

Background and aims: Polyfluoroalkyl chemicals (PFCs) are commercially synthesized chemicals used in consumer products. Exposure to PFCs is widespread and some PFCs may disrupt signaling processes involved in the control of lipid metabolism. We explored associations of maternal concentrations of perfluorooctane sulfonate (PFOS), perfluorooctanoate (PFOA), and perfluorohexane sulfonate (PFHxS) during gestation with serum lipid concentrations at age 7 in girls.
Methods: Analyses were conducted on a sample of 227 singleton girls and their mothers participating in the Avon Longitudinal Study of Parents and Children. PFC concentrations were measured in serum samples obtained from the mothers at pregnancy. Cholesterol, low density lipoprotein (LDL), high density lipoprotein (HDL) and triglycerides were measured in serum samples obtained from the girls at age 7. Linear regression models were used to estimate the average change in lipids levels for each 1-unit increase in the natural logarithm (Ln) of the PFCs after adjustment for covariates.
Results: PFOS (median 19.8 ng/mL), PFOA (median 3.7 ng/mL), and PFHxS (median 1.6 ng/mL) were detected in 100% of samples. A 1-Ln unit increase in PFOS was associated with a 9 mg/dL (95% confidence interval [CI]: 1,18) increase in cholesterol concentrations and with a similar increase in LDL concentrations (9 mg/dL; 95% CI: 2,16) in girls. A 1-Ln unit increase in PFOA was associated with a 9 mg/dL (CI: 3,16) increase in LDL concentrations. PFOS and PFOA concentrations were not associated with HDL or Triglycerides. PFHXS concentrations were not associated with any of the outcomes.
Conclusions: Gestational exposures to PFOS and PFOA may have a persistent influence in lipid metabolism during childhood.

TRANSIENT EXPOSURE TO VEHICLE EXHAUST PLUMES INSIDE NEW DELHI AUTO-RICKSHAWS

Joshua S. Apte, *University of California, Berkeley, CA, USA*
Julian D. Marshall, *University of Minnesota, Minneapolis, MN, USA*
William W Nazaroff, *University of California, Berkeley, CA, USA*

Background and Aims: Air pollution exposures in roadway microenvironments are of concern in part because of the large number of people exposed, high concentrations, and close proximity between people and vehicle emissions. Few studies have investigated the characteristics of short-duration exposure to vehicle exhaust on roadways. We use data from New Delhi to explore the nature of transient on-roadway exposures to high pollutant concentrations.
Methods: We measured real-time (1 Hz) exposure to fine particle (PM2.5) and black carbon (BC) mass and ultrafine particle number (PN) concentrations inside auto-rickshaws, a common type of unenclosed vehicle in India. The dataset consists of 180 h of driving during 62 trips along a single route in New Delhi; we investigate here transient (~ 15 – 60 s) concentration variations. To quantify the contribution of these peak exposure events to cumulative on-roadway exposure, we use a moving window function to mathematically separate distinct spikes from the baseline on-roadway concentration.
Results: Peak instantaneous exposures contribute substantially to total on-road exposure. For the median trip, incremental exposure attributable to transient concentration spikes accounted for 16%, 41%, and 50%, respectively, of trip-integrated PM2.5, BC, and PN exposures. After subtracting simultaneously measured urban background concentrations, transient spikes accounted for ~50% of on-roadway PM2.5 exposure and ~60% of on-roadway BC and PN exposure.
Conclusions: For the dataset under consideration, transient exposures to poorly diluted vehicle exhaust plumes constitute an important fraction of the total on-roadway air pollution exposure. The health effects of such short duration (< 1 min) exposures to peak levels of vehicle air pollution are poorly understood. However, the possibility for nonlinearity in dose-response relationships suggests that this aspect of on-roadway exposure may merit further attention.

EFFECTS OF TRAFFIC-RELATED AIR POLLUTION ON THE BRAIN IN THE CARDIOVASCULAR HEALTH STUDY

Erin Semmens, *Department of Epidemiology, University of Washington, USA*
Annette Fitzpatrick, *Department of Epidemiology, University of Washington, USA*
Helene Margolis, *Department of Internal Medicine, University of California-Davis, USA*
Fred Lurmann, *Sonoma Technology, Inc., USA*
Adam Szpiro, *Department of Biostatistics, University of Washington, USA*
Will Longstreth, *Division of Neurology, University of Washington, USA*
Victor Van Hee, *Departments of Medicine and Environmental and Occupational Health Sciences, University of Washington, USA*
Joel Kaufman, *Departments of Epidemiology, Medicine and Environmental and Occupational Health Sciences, University of Washington, USA*

Background and Aims: Compelling evidence links air pollution to cardiovascular disease. Although the brain is susceptible to pathways mediating these adverse effects, comparatively little is known about the influence of air pollutant exposure on brain health. We will examine traffic-related air pollution effects on risk of dementia and MRI-detected brain abnormalities in the Cardiovascular Health Study (CHS), a large, longitudinal study of coronary heart disease and stroke in older adults, the age-group at greatest risk for dementia.
Methods: The proposed study will include approximately 3,600 men and women aged 65 years and older, living in 4 geographically-diverse communities who were recruited into the CHS between 1989-93 and who participated in annual clinical exams through 1999. Air pollution exposure will be characterized using 1) already-calculated monthly individual estimates of NO_2, CO, O_3, SO_2, and PM_{10} exposure and 2) residential roadway proximity. Dementia was classified by neurologist/psychologist committee review. Brain infarcts and white matter changes, both of which are associated with elevated risk of cognitive decline and stroke, were measured twice by cerebral MRI. The impact of air pollution on risk of dementia and MRI findings will be evaluated in adjusted Cox proportional hazards and logistic regression models.
Results: 227 participants were classified as having prevalent dementia at study entry, and 480 incident cases were identified during follow-up. Over 30% of subjects had a brain infarct on first scan, and, of the subjects without an infarct at the initial scan who had a second scan, nearly 20% developed an infarct. Approximately 30% of participants who completed both scans experienced worsening white matter grade.
Conclusions: The proposed work is a highly novel, targeted study that takes advantage of an extraordinary resource in the CHS. This study has the potential to provide important knowledge regarding the impact of air pollution on the brain.

RAINFALL AND EMERGENCY DEPARTMENT VISITS FOR ACUTE GASTROINTESTINAL ILLNESS IN NORTH CAROLINA, 2006-2008

Christopher D. Heaney, Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-7435, USA
David Richardson, Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-7435
Jyotsna S. Jagai, Epidemiology Branch, Environmental Public Health Division, United States Environmental Protection Agency, Research Triangle Park, NC, USA

Background & Aims: Climate models suggest the frequency of extreme rainfall events will continue to rise in coming decades. We aim to investigate the temporal relationship between daily variability of rainfall and acute gastrointestinal illness (AGI) in North Carolina (NC).
Methods: County-level rainfall and emergency department (ED) visits data were obtained from the NC Climate Retrieval and Observation Network of the Southeast and NC Disease Event Tracking and Epidemiologic Collection Tool databases, respectively. We examined associations between daily average rainfall (mm) and daily counts of ED visits for AGI at the county-level in NC between Jan. 1, 2006 and Dec. 31, 2008, controlling for time trends, seasonal patterns, and region. Using Poisson models, rates for AGI per unit change in rainfall (mm) were calculated for lags of 0-15 d. Age and water source were examined as potential modifiers.
Results: Statewide, the crude rate of AGI was 511 per 100,000 person-years (pyr) with variability by season (winter: 619/100,000 pyr; summer: 408/100,000 pyr), age (infants ≤1 yr: 2,814/100,000 pyr; children 10-14 yr: 240/100,000 pyr), sex (females: 583/100,000 pyr; males: 436/100,000 pyr), and region (Piedmont: 646/100,000 pyr; Coastal Plain: 385/100,000 pyr). A 25-mm (~1 inch) increase in daily average rainfall at a lag of 5 d was associated with 13.99 additional AGI ED visits per 100,000 pyr (95% CI = 13.95-14.02), with a higher rate among seniors (≥65 yr) (rate = 44.77; 95% CI = 44.68-44.86) and counties with >75% surface water source (rate = 19.16; 95% CI = 19.12, 19.19).
Conclusions: The observed temporal lag (5 d) between daily rainfall and AGI is consistent with waterborne transmission. (This abstract does not necessarily reflect EPA policy. The NC Public Health Data Group and NC DETECT do not take responsibility for the scientific validity or accuracy of methodology, results, statistical analyses, or conclusions presented.)

AIR POLLUTION, MALODOR, AND HEALTH IN A COMMUNITY BORDERING A LANDFILL

Christopher D. Heaney, *Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, USA*
Steve Wing, *Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, USA*
Robert L. Campbell, *Rogers-Eubanks Neighborhood Association, USA*
David Caldwell, *Rogers-Eubanks Neighborhood Association, USA*
Barbara Hopkins, *Rogers-Eubanks Neighborhood Association, USA*
David Richardson, *Institute for the Environment, University of North Carolina USA*
Karin Yeatts, *Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill,USA*

Background and Aims: Municipal solid waste landfills are sources of air pollution that may affect the health and quality of life of neighboring communities. We aim to investigate health and quality of life concerns of neighbors related to landfill air pollution.
Methods: Landfill neighbors were enrolled and kept twice-daily diaries for 14 days about odor intensity, alteration of daily activities, mood states, and irritant and other physical symptoms between Jan–Nov, 2009. Concurrently, hydrogen sulfide (H_2S) air measurements were recorded every 15-min. Relationships between H_2S, odor, and health outcomes were evaluated using conditional fixed effects regression models.
Results: Twenty-three participants enrolled and completed 878 twice-daily diary entries. H_2S measurements were recorded over a period of 80 d and 1-hr average H_2S = 0.22 ppb (SD = 0.27; range = 0–2.30 ppb). Landfill odor increased 0.67 points (on 5-point Likert-type scale) for every 1 ppb increase in hourly average H_2S when the wind was blowing from the landfill towards the community (standard error (SE) = 0.19; t-value = 3.49). Odor was strongly associated with reports of alteration of daily activities (odds ratio (OR) = 9.0; 95% confidence interval (CI) = 3.5, 23.5), negative mood states (OR = 5.2; 95% CI = 2.8, 9.6), mucosal irritation (OR = 3.7; 95% CI = 2.0, 7.1) and upper respiratory symptoms (OR = 3.9; 95% CI = 2.2, 7.0), but not positive mood states (OR = 0.6; 95% CI = 0.2, 1.5) and gastrointestinal (GI) symptoms (OR = 1.0; 95% CI = 0.4, 2.6)).
Conclusions: Results suggest air pollutants from a regional landfill negatively impact the health and quality of life of neighbors.

WHEN POLLUTION GETS PERSONAL: DEVELOPING PROTOCOLS FOR BIOMONITORING RESULTS COMMUNICATION WITH INPUT FROM STUDY PARTICIPANTS

Rachel Morello-Frosch, *University of California Berkeley, School of Public Health and Department of Environmental Science, Policy and Management*

Holly Brown-Williams, *Health Research for Action, School of Public Health, University of California, Berkeley*

Kathy Simpson, *Health Research for Action, School of Public Health, University of California, Berkeley*

Background: Advances in biomonitoring methods have enabled environmental health scientists to measure ever-lower concentrations of environmental contaminants in human blood, urine, breast milk, and other tissues. Yet our ability to detect chemicals in humans has rapidly outpaced our capacity to interpret what personal exposure results mean for health effects, sources or toxicity. This situation raises ethical and scientific challenges related to reporting biomonitoring results to individual study participants and their communities. California's Biomonitoring Program is required by law to provide individual chemical exposure results to those participants who want them.
Methods: We developed individual report-back materials that are scalable to a statewide biomonitoring program involving participants from diverse cultural backgrounds and literacy and numeracy levels. We recruited study participants from the Chemicals in Our Bodies Project, a biomonitoring study conducted by UC Berkeley, UCSF and Biomonitoring California, which is testing for chemicals in pregnant mothers and their newborn babies. Upon recruitment, study participants were asked to participate in usability testing of prototype report-back materials that assessed whether and how messages about chemical exposures and scientific uncertainty regarding health effects and sources are understood and interpreted.
Results: Participants valued getting their personal biomonitoring results and were able to identify their exposure levels from the text and graphs provided in the prototype materials. Participants understood the scientific uncertainty regarding the implications of exposures for health effects. Key challenges were distilling results from the large number of chemical analytes tested and communicating the meaning of reference levels.
Conclusion: Although medical ethics have favored reporting only clinically significant biomonitoring results, public policy and community concern regarding the ubiquity of chemical exposures is beginning to broaden the ethical focus toward participants' right-to-know. This shift will necessitate more research on developing effective report-back protocols that are accessible and transparent to linguistically and culturally diverse groups.

WATER AND SANITATION INFRASTRUCTURE FAILURES AND THE MICROBIOLOGICAL AND CHEMICAL SAFETY OF WATER IN A COMMUNITY BORDERING A REGIONAL LANDFILL

Christopher D. Heaney, *Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, USA*

Karin Yeatts, *Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, USA*

Background and Aims: A historically Black community straddles unincorporated boundaries of two municipalities in Orange County, North Carolina and predates a regional landfill sited along its border. Community members and university partners aimed to investigate long-standing concerns about the microbial and chemical safety of drinking and surface water quality in the community.
Methods: Households in the community were surveyed to collect information about structural signs of well vulnerability (well pump failure; problems with cloudiness, taste, odor; history of well disinfection) and septic system failure (pumping septic tank ≥1 per year; a wet yard due to drain-field during non-rainfall periods), and drinking and surface water samples were collected, geo-coded, and analyzed for parameters of microbial and chemical water quality. Relationships between distance to the landfill and concentrations of water quality parameters were evaluated using conditional fixed effects land-use regression models, adjusted for total rainfall in the previous 24 hours.
Results: Of 73 households identified in the community, 27 responded to the survey, and 20 provided drinking water samples. Households reported pervasive signs of well vulnerability (100%) and septic system failure (68%). The microbiological safety of well water was poor compared to public drinking water supplies. Wells exceeded microbiological standards protecting health, whereas public water supplies did not. The presence of volatile organic compounds and heavy metals was also detected in well water supplies. Each 100-meter unit increase in distance from the landfill was associated with a 334 MPN/100 ml decrease in average enterococci concentrations in surface water (95% confidence interval (CI) = -710, 41).
Conclusions: Pervasive private household water and sanitation infrastructure failures were identified, suggesting a need for improved water and sanitation services in this predominantly Black community bordering a regional landfill.

RESIDENTIAL EXPOSURE TO PARTICULATE MATTER AND MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

Lewin Eisele, *Institute of Medical Informatics, Biometry and Epidemiology*

Barbara Hoffmann, *Institute of Medical Informatics, Biometry and Epidemiology*
on behalf of the Heinz Nixdorf Recall Investigative Group.

Background and Aims: Monoclonal gammopathy of undetermined significance (MGUS) is a precursor condition leading to hematological malignancies. An association of MGUS with inflammatory disorders was reported. As particulate matter (PM) can induce chronic inflammation, we asked whether there is an association of PM exposure and MGUS.
Methods: We screened baseline and 5-year follow-up serum samples of the Heinz Nixdorf Recall Study, an ongoing cohort study of 4,814 participants aged 45-75 years in Germany. Serum electrophoresis and immunofixation (Hydragel 12 IF, Penta-Kit, Sebia, Fulda, Germany) was used to detect MGUS. The individual one-year average $PM_{2.5}$ and PM_{10} exposure prior to baseline was assessed using a dispersion and chemistry transport model (EURAD). We calculated distance from participants' home addresses to highly trafficked roads. PM values were categorized in quartiles. Poisson regression was used to model incident MGUS adjusting for sex and age. Logistic regression was used to calculate odds ratios (OR) for prevalent MGUS at follow-up adjusted for distance, age, sex, BMI, education, smoking status, and physical activity.
Results: At baseline 165 MGUS cases were identified among 4,702 screened participants (prevalence 3.5%, 95%-CI 3.0-4.1). Among 3,862 participants free of disease at baseline, 50 (1.3%) new MGUS were identified. Median one-year $PM_{2.5}$ and PM_{10} concentrations were 16.6µg/m³ (IQR 2.4) and 20.7µg/m³ (IQR 4.0), respectively. Age- and sex-adjusted relative risk of incident MGUS in increasing quartiles of $PM_{2.5}$ exposure was 2.78 (95%-CI 1.09-7.11), 1.58 (0.56-4.44), and 3.33 (1.33-8.34), respectively. Fully adjusted ORs for prevalence of MGUS at follow-up in increasing quartiles of $PM_{2.5}$ were 1.02 (0.65-1.62), 0.98 (0.62-1.56), and 1.54 (1.02-2.34). Effect estimates for PM_{10} showed a positive trend.
Conclusions:
We provide first data suggesting that residential exposure to particulate matter may increase risk of MGUS and thus linking chronic particle exposure with cells of the adaptive immune system.

L.E. received funding from the "Internes Forschungsprogramm für Kliniker (IFORES)" of the Medical Faculty of the University Duisburg-Essen

The study presented here was in part funded by the Deutsche Forschungsgemeinschaft (JO 170/8-1) and by a research grant from Celgene, Munich, Germany

The original Heinz Nixdorf Recall study was funded by the Heinz-Nixdorf foundation and the German Federal Ministry of Research and Technology (BMBF)

LONG-TERM EXPOSURE TO TRAFFIC NOISE AND TRAFFIC-RELATED AIR POLLUTION AND CORONARY HEART DISEASE MORTALITY

Wenqi Gan, *University of British Columbia, Canada*
Hugh Davies, *University of British Columbia, Canada*
Mieke Koehoorn, *University of British Columbia, Canada*
Lillian Tamburic, *University of British Columbia, Canada*
Paul Demers, *University of British Columbia, Canada*
Michael Brauer, *University of British Columbia, Canada*

Background and Aims: In metropolitan areas, road traffic is a major contributor to ambient air pollution, and also the dominant source of environmental noise. Therefore, observed associations between air pollution and adverse cardiovascular outcomes may be confounded by coexistent traffic noise or vice versa. This population-based cohort study investigated the independent and joint effects of traffic noise and traffic-related air pollution on coronary heart disease (CHD) mortality.
Methods: This study included a 5-year exposure period and a 4-year follow-up period. All residents aged 45-85 years who resided in Metropolitan Vancouver during the exposure period and without known CHD at baseline were included (n = 445,795). Individual exposures to traffic noise and traffic-related air pollutants including black carbon, $PM_{2.5}$, NO_2, and NO were estimated at subjects' residences using a noise prediction model (Cadna A) and land use regression models, respectively. CHD deaths during the follow-up period were identified from the provincial death registration database.
Results: Traffic noise level was moderately correlated with black carbon (0.44), but weakly correlated with $PM_{2.5}$ (0.14), NO_2 (0.33), and NO (0.39). After adjusting for baseline age, sex, preexisting comorbidity, neighborhood socioeconomic status, $PM_{2.5}$, NO_2, and black carbon, a 10 dBA elevation in residential noise was associated with a 9% (95% CI: 1-17%) increase in CHD mortality; subjects in the highest noise decile (>70 dBA) had a 19% (95% CI: 2-40%) increase in CHD mortality compared with those in the lowest decile (≤57 dBA). After similar adjustments including noise, an interquartile range (0.97×10^{-5}/m) elevation in black carbon concentration was associated with a 4% (95% CI: 1-8%) increase in CHD mortality. We did not find any interaction between traffic noise and black carbon on CHD mortality.
Conclusions: Traffic noise and black carbon may both be independently responsible for observed associations between exposure to road traffic and adverse cardiovascular outcomes.

EPIDEMIOLOGIC AND MICROBIOLOGIC ASSOCIATIONS BETWEEN FLIES AND DIARRHEA

Stefan Collinet-Adler, *Tufts Medical Center, USA*
Sudhir Babji, *Christian Medical College, India*

Deepthi Kattula, *Christian Medical College, India*
Honorine Ward, *Tufts Medical Center, USA*
Gangandeep Kang, *Christian Medical College, India*
Vinohar Balraj, *Christian Medical College, India*
Elena N. Naumova, *Tufts University, USA & Christian Medical College, India*

Background and Aims: Diarrhea is the cause of death in almost 23% of Indian children under 5. Flies carry enteric pathogens and may mediate food-borne enteric infections. This study aims to characterize fly densities as a determinant of infectious diarrhea.
Methods: We recorded number and duration of diarrheal episodes for families of Vellore, India in an ongoing year-long cohort of 160 urban and 80 rural households with 1274 individuals (27% - under 5y.o.) accumulating 198795 person-days. Household questionnaires on living conditions were completed. ELISA, light microscopy, bacterial culture, and multiplex PCR were performed on stools. Fly abundance was measured in 2 seasons using fly ribbons placed in kitchens. PCR for enteric bacteria, viruses, and protozoan were performed on flies. Multivariate log-linear models were used to explore the relationships between diarrhea and fly densities, demographics, hygiene, and human/animal interactions.
Results: 91 (89% - in under 5s) episodes of diarrhea occurred from 8/6/2010 to 1/31/ 2011. Stool pathogens isolated in 24 of 77 (31%) of samples included *E.coli*, *Shigella* spp., *Vibrio* spp., *Giardia*, *Cryptosporidium spp.*, and Rotavirus. 43 of 60 (72%) fly samples were positive for pathogens including *E.coli*, *Salmonella* spp., Norovirus, and Rotavirus. Fly abundance was 2.56 times higher during the dry season compared to monsoon ($p<0.0001$). Trash disposal close to homes and rural living were significant risk factors for high fly densities. The adjusted relative risk (RR) of diarrhea associated with 75th percentile of fly density was 1.10[95%CI:1.03,1.19]. An increase in fly density to 75th percentile was associated with longer duration of diarrhea, RR 1.11[95%CI:1.05,1.18]. Indoor latrines were protective against high fly densities and diarrhea.
Conclusions: Flies harbored enteric pathogens including Norovirus, a poorly documented pathogen on flies. Fly densities were significant predictors for diarrhea. Both diarrhea and fly densities may exhibit seasonality to be confirmed with study completion.

ENVIRONMENTAL INDICATORS OF INFECTIOUS DIARRHEA IN VELLORE, INDIA

Stefan Collinet-Adler, *Tufts Medical Center, USA*
Rajiv Sarkar, *Christian Medical College, India*
Deepthi Kattula, *Christian Medical College, India*
Venkata Mohan, *Christian Medical College, India*
Honorine Ward, *Tufts Medical Center, USA*
Elena N. Naumova, *Tufts University, USA & Christian Medical College, India*
Vinohar Balraj, *Christian Medical College, India*

Background and Aims: Diarrhea is an important source of morbidity and mortality in resource poor settings. Transmission of enteric pathogens is only partially understood. This study aims to characterize environmental drivers in transmission of enteric infections in 80 rural and 160 urban households in Vellore, India.
Methods: Diarrheal episodes were investigated with microbiologic analysis of stool collected weekly in an ongoing 1-year open cohort study from August 6-January 31, 2010.Information on demographics, hygiene, human/animal interactions, and water sources was collected by questionnaires. Household water was examined for fecal contamination using fecal coliform counts. Fly densities were measured using sticky ribbons placed in kitchens. Log linear multivariate analyses were performed to examine the role of these indicators on the incidence and duration of diarrhea.
Results: There were 91 episodes of diarrhea over 198795 total person days (PD). There were substantial fluctuations in monthly diarrheal incidence from 0.15 to 0.92 per 1000PD. Fecal contamination was found in the majority (81%) of public water samples in rural areas. Water samples collected from household storage containers had fecal coliforms present in 67% and 74.6% of samples from rural and urban areas respectively. The use of private wells, house-taps, and increased fly densities were associated with diarrheal episodes. Risk factors for increased duration of diarrhea included animals in living quarters, family size, private well or house-tap use, nails not trimmed, and increased fly densities, while rural living, indoor latrine use and better education were protective. The adjusted relative risk associated with house-tap use was 3.07[95%CI:2.01,4.67] for increased diarrheal episodes and 2.69[95%CI:1.14,5.14] for a longer episode duration.
Conclusions: Several environmental risk factors for increased diarrhea were identified including water sources, living conditions, hygiene, and fly densities. The seasonality of diarrhea should be confirmed by completion of the study.

RISK OF DEATH FOR RESPIRATORY AND CARDIOVASCULAR DISEASES ASSOCIATED WITH AIR POLLUTION IN VOLTA REDONDA CITY, RIO DE JANEIRO STATE, BRAZIL

Marcio Oliveira, EPJSV/FIOCRUZ
Inés Mattos, ENSP/FIOCRUZ
Sergio Koifman, ENSP/FIOCRUZ

Background and Objective: For many years we have observed that fast technological advancement has brought an increase in the quantity and variety of pollutants in the atmosphere, which are affecting the quality of life on our planet. By virtue of the many roles that it plays, the respiratory system is particularly exposed to aggressive environments and is often the organ most affected by exposure to air pollutants. After him the cardiovascular system is the most affected. This study aimed to evaluate the effects of PM_{10}, SO_2 and O_3 on deaths from respiratory and cardiovascular diseases among the elderly in Volta Redonda city, Rio de Janeiro State, Brazil.
Methods: This ecological time-series study used data on daily deaths from respiratory and cardiovascular diseases (ICD-10: J00-J99 and I00-I99) of people. These data were organized, average concentrations of PM_{10}, SO_2 and O_3, minimum temperature and relative humidity for the period from January, 2002 to December, 2006. The data were analyzed using generalized additive Poisson regression, with constrained distributed lag models adjusted for long time trend, weekdays and holidays. The quality of fit for the final model was estimated using residual deviance analysis and the Akaike criteria.
Results: An increase of 10μg/m^3 in PM_{10} and SO_2 concentrations were associated with an increased risk of death from respiratory and cardiovascular diseases around 5.23%. For O_3, did not have an association with risk of death in Volta Redonda city.
Conclusion: The results showed an association between ambient PM_{10} and SO_2 concentrations and an increased risk of death for respiratory and cardiovascular diseases. Additionally, the greatest increased risk was in elderly people.

AIR NICOTINE CONCENTRATIONS AND RESPIRATORY AND SENSORY SYMPTOMS AMONG BAR AND RESTAURANT WORKERS IN SANTIAGO, CHILE

Enrique Barilari, *Ministry of Health, Chile*
Ana Navas-Acien, *Bloomberg School of Public Health, Johns Hopkins University, USA*

Bakground and Aim: The current smoking ban legislation in Chile does not protect workers in pubs, bars and restaurants. The aim of this study was to assess the relation between exposure to secondhand smoke, as measured by air nicotine concentrations, with self-reported respiratory and sensory symptoms in workers of these venues.

Method: A total of 206 workers recruited from 59 bars and restaurants (24 smoking allowed, 25 mixed and 10 smoke-free) were recruited between September 2010 and January 2011. An interviewer-administered questionnaire collected demographic and smoking data as well as self-reported information on respiratory and sensory symptoms in the last 4 weeks (irritated eyes, runny nose, sore throat, wheezing, shortness of breath, morning cough, daytime cough, phlegm). In addition to individual symptoms, a composite variable by adding the eight symptoms was generated. Vapor-phase nicotine concentrations were measured over a 1-h sampling period at a time of peak activity. The association of air nicotine with the presence of symptoms was estimated using Poisson regression models.

Results: Workers median age was 30 years. 60.7% were men and 56.8% were waiters. 52.4% were current smokers and the median number of years at work was 1 (interquartile range 0.33 to 4) year. Overall, 86.6% of participants reported having experienced at least one symptom in the past 4 weeks. After adjustment for age, sex, smoking status, home exposure and number of years working in the venue, a change in 1 $\mu g/m^3$ in air nicotine concentrations were associated with the prevalence of respiratory or sensory symptoms (Prevalence ratio 1.12; 95% 1.04 – 1.20).

Conclusion: These findings support that exposure to secondhand smoke in bars and restaurants impact sensory symptoms and respiratory health of workers. Laws that ensure smoke-free workplaces in hospitality venues should be implemented promptly in Chile.

THE EFFECTS OF INDOOR MOLDS AND GENETIC POLYMORPHISMS ON WHEEZING ILLNESS IN CHILDREN

I-Jen Wang, *Taipei Hospital, Department of Health, Taipei; China Medical University, Taichung, Taiwan*
Ching-Hui Tsai, *National Taiwan University College of Public Health, Taipei,* Taiwan
Nai-Wei Kuo, *National Taiwan University College of Public Health, Taipei,* Taiwan
Kuan-Yen Tung, *National Taiwan University College of Public Health, Taipei,* Taiwan
Yungling L. Lee, *National Taiwan University College of Public Health, Taipei, Taiwan*

Background and Aims: Evidence has shown that climate may contribute to different prevalence of asthma in different geographic areas. In subtropical area, indoor dampness is a risk factor for respiratory symptoms and constitutes a significant public health problem. However, little is known about the effects of dampness and genetic polymorphisms on asthma. In this study, we evaluated the effects of home dampness and β2-adrenergic receptor (ADRB2) genetic polymorphisms on asthma and wheeze.
Methods: We investigated 6078 schoolchildren by a standard questionnaire for respiratory symptoms and environmental exposures. Multiple logistic regressions were performed to assess the association between ADRB2 polymorphisms and home dampness frequency and degree (visible mold on the wall, mildewy odor, water stamp on the wall, and water damage) on asthma phenotypes, after adjusting for potential confounders.
Results: The frequency mildewy odor, the number of walls with water stamp, and the duration of water damage were associated with increased risk of awakened at night due to wheeze (p<0.05). ADRB2 Arg16Gly showed significant interactive effect with home dampness on current wheeze (p for interaction=0.04) and awakened at night due to wheeze (p for interaction=0.007). The frequency and degree of home dampness was associated with increased risk of current asthma, current wheeze, medication use, and awakened at night in an exposure-response manner among children with ADRB2 Arg/Arg genotype (p<0.05).
Conclusion: ADRB2 genetic polymorphisms may be responsible for differences in susceptibility to childhood asthma and wheeze with regard to household dampness.

Keyword: asthma, ADRB2, home dampness, gene-environmental interaction

HEAVY METALS IN BLOOD OF PRE- AND PERI-PUBERTAL GIRLS IN CALIFORNIA, BY DEMOGRAPHIC CHARACTERISTICS

Gayle C. Windham, *CA Dept of Public Health, Richmond, CA, USA*
Dina Dobraca, *CA Dept of Public Health, Richmond, CA, USA*
Ryszard Gajek, *CA Dept of Public Health, Richmond, CA, USA*
Frank Barley, *CA Dept of Public Health, Richmond, CA, USA*
Cassandra Aldsworth, *Zero Breast Cancer, San Rafael, CA, USA*
Lawrence Kushi, *Kaiser Permanente Division of Research, Oakland, CA, USA*

Background and Aims: The Breast Cancer and the Environment Research Centers are investigating whether exposures to potential hormonally active chemicals affect the onset of puberty, which influences later health, including risk of breast cancer. Higher lead levels have been associated with delayed puberty, but other metals have not been examined. The aim of this analysis was to determine the distribution of blood metals, such as cadmium, lead, and mercury, in young girls, and their variation by key variables.

Methods: In California, girls were recruited at ages 6-8 for the longitudinal study that includes annual anthropometry, tanner staging, questionnaire completion and bio-sampling. Nearly 350 baseline blood samples were assayed for a metal panel using high through-put ICP-MS with low detection limits. The distributions were examined and geometric means compared for lead and mercury across categories of race/ethnicity, age (at time of blood draw), BMI, care-giver education, care-giver income and home ownership, in adjusted models. Cadmium was examined as detected or not in logistic regression models.

Results: Lead and mercury were detected in over 98%; lead levels were similar to children in NHANES 2005-06 (median 0.92 vs. 0.97 ug/dL), but mercury levels were higher (median 0.56 vs. 0.41 ug/L, respectively). Blood lead levels were higher among Black and Hispanic girls and those living in rented homes, still significant after adjustment. Blood mercury levels were much higher among Asians than Whites and lower among Hispanics and the youngest girls. Cadmium was detected in 51%; the detection frequency varied by age, race and parental education. The adjusted OR for Asians was 5.2 (95% CI 2.1-13.2) and among 9 versus 6 year olds was 0.33 (95% CI 0.12-0.93).

Conclusions: Metals were detected with a high frequency among young girls and levels varied by characteristics that may be related to puberty, which will be examined further.

WHO IS WHO IN BRAZILIAN ENVIRONMENTAL HEALTH? IDENTIFICATION AND CHARACTERIZATION OF ACADEMIC GROUPS AND CIVIL SOCIETY ORGANIZATIONS

Carlos Machado de Freitas, *ENSP/FIOCRUZ, Brasil*
Ana Maria Testa Tambellini, *IESC/UFRJ, Brasil*
Gabriel Eduardo Schultz, *ENSP/FIOCRUZ, Brasil*
Valéria Andrade Bertolini, *UNB, Brasil*
Francisco Franco Netto, *ENSP/FIOCRUZ, Brasil*

Background and Aims: In this paper we present the results of the first phase of the project Who is Who in Brazilian Environmental Health. The aim of this project is to identify and characterize the Academic Groups and Civil Society Organizations acting on the field of environmental health that are able to contribute both to the strengthening of its technical and scientific basis, and to the dialogue with organized civil society.
Methods: The identification took place through the data source available at CNPq (Research Groups Directory), ABONG (Brazilian Association of Non-Governmental Organizations), FBOMS (Brazilian Forum of NGOs and Social Movements for Environment and Sustainable Development) and RBJA (Brazilian Network for Environmental Justice).
Results: The results were presented and discussed based on time evolution, geographic distribution and areas of research and action.
Conclusions: Final considerations point to the great potential for dialogue between experts and non experts, governmental and non-governmental, in order to create the foundation for a extended peer community capable of combining policies, knowledge, technologies and actions, seeking the comprehension and search of solutions to the establishment of health as a prerequisite and X a result of well being and full life.

EFFECTS OF LONG-TERM AMBIENT HYDROGEN SULFIDE EXPOSURE ON ASTHMA AND LUNG FUNCTION

Michael N Bates, *School of Public Health, University of California, Berkeley, CA, USA*
Nick Garrett, *Faculty of Health, Auckland University of Technology, Auckland 1142, New Zealand*
Julian Crane, *School of Medicine and Health Sciences, University of Otago, Wellington, New Zealand.*
John Balmes, *School of Public Health, University of California, Berkeley, USA.*
John McKeogh, *School of Medicine and Health Sciences, University of Otago, Wellington, New Zealand.*

Background and Aims: The health effects of long-term, low-level H_2S exposures are unknown. This study took place in Rotorua, New Zealand, the world's largest city built on a geothermal field (population >55,000). Geothermal gas, including H_2S, emission sources are distributed throughout the city.
Methods: Participants were adult Rotorua residents, each of whom performed spirometry. H_2S exposure was estimated from networks of passive samplers distributed throughout the city in the summer and winter. The monitoring results were used to generate concentration surfaces across the city, from which H_2S concentrations at participants' current residential addresses were estimated.
Results: A total of 739 participants was used in this analysis, of whom 169 (23%) reported a doctor's diagnosis of asthma. H_2S exposure was divided into quartiles based on estimated residential concentrations averaged over winter and summer. The asthma diagnosis rate was lower in the highest exposure group (16.6%) than in the other three groups combined (24.8%) (p=0.07). Logistic regression analysis for asthma, adjusted for smoking, age, BMI and ethnicity showed the 3 highest H_2S exposure quartiles to have odds ratios of 1.21 (95% CI:0.75-1.95), 0.94 (0.58-1.53), and 0.70 (0.41-1.88), in order of increasing residential H_2S exposure. Participants with asthma had higher adjusted FEV_1 measures associated with higher residential H_2S exposures on a continuous scale (p=0.02), whereas there was no association with H_2S for those without an asthma diagnosis (p=0.79).
Conclusions: This study presents evidence of reduced asthma risk and higher FEV_1 in asthmatics living in higher H_2S exposure areas. This might be a direct effect on the airways of asthmatic subjects, as recent animal studies have shown inhaled H_2S can reduce inflammation (Faller et al 2010), or it could be a healthy survivor bias.

Traffic of Vehicles and urban noise in Itajuba, Brazil: annoyance evaluation

Luiz Felipe Silva, Federal University of Itajuba
Jonas Maciel, Federal University of Itajuba

Background and aims: In the urban-oriented track delimited by the BR-459 highway, in urban area of Itajuba, Brazil, there is an important traffic of vehicles. This scenario makes noise and may be a annoyance source for the neighbourhood .
Methods: This work makes a survey and analysis of noise levels in this region. Through measurements and calculations, along with questionnaires aimed to conduct a comparative analysis regarding the annoyance effect between two different regions given the importance of traffic noise from vehicles.
Results: The average values of L10, L50, L90 and LAeq were 67, 58, 51 and 63 dB (A), respectively, was observed an average flow of 99 light vehicles and 14 heavy over a period of 10 minutes. These values exceed the limits set by the NBR and the State Law 10.151/2000 10.100/1990. A questionnaire based on ISO / TS 15.666/2003 was applied in a random sample of 40 residents on the highway (exhibition area) and 40 neighboring background (non-exposure area). There was a 92.5% return of questionnaires distributed to 67.5% for exposed and unexposed, and found that 55.7% of respondents say they are bothered by traffic noise when they are home with the windows and doors; when open, the percentage of troubled reaches 68.3%.
Conclusions: Factors such as age, gender and place of residence (highway or side streets) had no significant association with the level of disturbance in the interviews.

Renin-Angiotensin System Polymorphism modulates outdoor temperature related variation in blood pressure

Background and Aims: Outdoor temperature related variation in blood pressure has been considered to play a role in excess cardiovascular mortality in extreme weather. The aim of this study is to evaluate the role of Renin-Angiotensin System gene polymorphisms (the Angiotensin converting enzyme (ACE) insertion/deletion (I/D), angiotensinogen (AGT) M235T, and angiotensin II type 1 receptor (AT1R) A1166C polymorphism) in modulating outdoor temperature dependent blood pressure (BP) responses.

Methods: Data including meteorological information, RAS gene polymorphisms, and BP were collected for 4,903 subjects from February 2003 to August 2004 in a university hospital. The generalized additive and linear models were used to examine the influence of genetic variants of RAS on the association between outdoor temperature and blood pressure

Results: Outdoor temperature (°C) was inversely associated with systolic BP (SBP) and diastolic BP (DBP) (SBP; β=-0.099, p=0.07, DBP; β=-0.100, p=0.006). These inverse relationship were found to be stronger in the subjects with ACE DD, AGT TT and AT1R AA genotype (SBP; β=-0.416, p=0.003, DBP; β=-0.320, p<0.001 for ACE DD, SBP; β=-0.204, p=0.003, DBP; β=-0.154, p<0.001 for AGT TT, , SBP; β=-0.133, p=0.024, DBP; β=-0.121, p=0.002 for AT1R AA polymorphism). In the subjects with ATR1 AC/CC polymorphism, significantly positive temperature-dependent BP responses were found in the temperature above 21.4 °C (SBP; β=2.208, DBP; β=1.250, each p<0.05), but the associations disappeared in the temperature range below 21.4 °C (SBP; β=-0.044 DBP; β=-0.020, each p>0.05).

Conclusions: This study suggests that RAS gene polymorphism modulates the relationship between outdoor temperature and BP. Genetic status of ACE DD, AGT TT and AT1R AA was associated with higher risk of blood pressure elevation when exposed to cold temperature, whereas AT1R genotype was found to be susceptible genotype for blood pressure elevation in hot temperature.

TRAFFIC-RELATED AIR POLLUTION INCREASES THE RISK OF EMERGENCY DEPARTMENT PRESENTATION WITH ASTHMA AMONG YOUNG CHILDREN IN WESTERN AUSTRALIA

Gavin Pereira, *Cooperative Research Centre for Asthma and Airways, Sydney, Australia; Centre for the Built Environment and Health, School of Population Health, University of Western Australia*

Background and Aims: Previous studies have reported associations between air pollution and exacerbation of respiratory disease but very few have examined the influence on emergency department presentations (ED). The aim of this study was to determine whether changes in city-wide levels of traffic-related air pollution increases the risk of hospital ED presentations for asthma among children

Methods: The study group were 603 children and young adults aged less than 19 years who had presented at any public ED within Perth, Western Australia between 2002 and 2006. A time-stratified case-crossover design was applied using city-wide estimates of background air pollution from a local air monitoring network.

Results: Previous day exposure to nitrogen dioxide and carbon monoxide resulted in the most significant risk of ED presentation for asthma among children aged less than 5 years. An interquartile range increase in nitrogen dioxide resulted in an odds ratio of 1.70 (1.08, 2.69). For carbon monoxide, an interquartile range increase in this pollutant resulted in an odds ratio of 1.40 (1.06, 1.84).

Conclusions: These results help quantify the extent to which very young children are vulnerable to the effects of air pollution, which are notably higher than those reported by previous studies.

Berna van Wendel de Joode, *Universidad Nacional, Costa Rica*

Introduction: At banana plantations, weekly aerial applications of mancozeb, a ethylene bisdithiocarbamate (EBDC) fungicide, are performed to protect bananas from Sigatoka disease. This study aims to identify environmental factors that determine prenatal mancozeb exposure in infants living nearby banana plantations.
Methods: The study population consists of 450 mother-child pairs from the Infants' Environmental Health Study (ISA, for its acronym in Spanish), living in 40 villages with intensive large-scale banana farming from the Matina County, Limón. Using GIS, maps were elaborated for the communities, including house-locations of the study participants. Distances from banana plantations to houses were calculated, and meteorological stations were used to obtain data on wind direction and other climatologic factors. In addition, information on socio-economical and occupational factors was obtained by administering structured interviews during the first, second and third trimesters of pregnancy. During pregnancy, repeated urine samples were obtained for 450 women and subsequently ethylenethiourea (ETU) levels were determined. ETU is a specific metabolite of EDBC fungicides.
Results: Maps showed that 10 out 40 villages are immersed in banana plantations, and located less than 100 meters from the fields. We observed frequent aerial spraying above public roads, playing areas and houses: a disobedience of the current legislation of a minimum distance of 30 meters when a natural barrier is present, or 100 meters in case a natural barrier is absent. We will present the results of environmental factors affecting prenatal mancozeb exposure in approximately 250 infants, using ETU as a biomarker for exposure.
Conclusions: GIS form a powerful tool to unravel pesticide exposure determinants. To achieve compliance of current legislation of pesticide applications with light aircrafts or helicopters, governmental supervision mechanisms of aerial pesticide applications should be revised.

TRAFFIC-RELATED AIR POLLUTION INCREASES THE RISK OF FETAL GROWTH RESTRICTION IN PERTH, WESTERN AUSTRALIA

Gavin Pereira, *Cooperative Research Centre for Asthma and Airways, Sydney, Australia; Centre for the Built Environment and Health, School of Population Health, University of Western Australia*

Background and Aims: The aim of this study was to investigate the risk of fetal growth restriction in relation to exposure to motor vehicle traffic emissions about the residential address. While most past studies have relied on monitoring station measurements very few have used more accurate methods such as land-use regression.
Methods: Records were obtained for singleton births in the period 2000-2006 in Perth, Western Australia (N=23,452). Small for gestational age and sex (SGA) was investigated in relation to nitrogen dioxide as a marker for motor vehicle traffic emissions using multivariate logistic regression. Ambient nitrogen dioxide was estimated using land-use regression. Adjustment was made for maternal and pregnancy risk factors and for ambient temperature stress. The sub-populations investigated were: women who spent the most time at home, women who did not move house, women with respiratory or circulatory morbidity, and women living in low, medium and high socioeconomic areas.
Results: An IQR increase in second trimester nitrogen dioxide (16.97ppb) was associated with an adjusted OR 1.17 (0.98, 1.39) for SGA. This effect increased to OR 1.35 (1.08, 1.69) for women who did not move during pregnancy and hence had minimal exposure misclassification. Major roads (>40k veh/day) and semi-major roads (>20k veh/day) within 50m were highly predictive of nitrogen dioxide levels at home.
Conclusions: Exposure to motor vehicle traffic emissions in mid-pregnancy was associated with constrained fetal growth among a population in Perth, Western Australia.

TEMPERATURE, AIR POLLUTION AND PEDIATRIC HOSPITALIZATIONS IN MEXICO CITY

Magali Hurtado-Díaz, *National Institute of Public Health of Mexico; Cuernavaca, México*
Horacio Riojas-Rodríguez, *National Institute of Public Health of Mexico; Cuernavaca, México*
Alhelí Brito-Hernández, *National Institute of Public Health of Mexico; Cuernavaca, México*
Washington Junger, *Rio de Janeiro State University; Rio de Janeiro, Brazil*

Background and Aims: Studies have documented associations between temperature and mortality or hospital admissions. Impacts may be exacerbated in cities with high levels of air pollution, like Mexico City (MC). Thus, the objective of this study is to evaluate the association between increased temperature and pediatric hospital admissions in MC due to all causes and respiratory diseases during: dry-cold, dry-warm, and wet season adjusting for air pollution.
Methods: An ecological study was conducted using a retrospective time series analysis of daily admissions records from 11 pediatric hospitals, temperature, humidity, ozone (O_3) and particulate matter less than 10 microns (PM_{10}) in MC from 2000 to 2002. The accumulated risk of hospital admissions due to temperature was evaluated using generalized additive models (GAM) with Poisson regression, adjusting for seasonal trends, holidays, humidity, 8-hr maximum moving average of O_3 and average PM_{10} with natural spline functions and different degrees of freedom per year.
Results: A total of 37,018 hospital admissions were evaluated for all causes of illness, of which 9,067 corresponded to respiratory illnesses. During the study period, the maximum average temperature was 23.7°C, 27.5°C and 24.8°C during the dry-cold, dry-warm and the wet period, respectively. The O_3 concentration was 165.25 ppb during the dry-warm period. During this same period, for every 1°C increase in temperature a percentage increase risk of hospital admissions for children under 5 years old was 2.49% (95% CI: 1.56, 3.43) for all causes of illness and of 6.39% (95% CI: 4.38, 8.45) for respiratory causes, with a lag of 4 days.
Conclusions: There is an increased risk of respiratory disease associated with the increase in the maximum daily temperature during the warm period in the population of children in MC, controlling for O_3 and PM_{10}, pollutants associated with the increase in morbidity in this city.

SWEDISH ENVIRONMENTAL HEALTH QUESTIONNAIRE SURVEYS

Georgellis, Antonis, *Institute of environmental medicine, Karolinska Institutet, Sweden*
Bellander, Tom, *Institute of environmental medicine, Karolinska Institutet, Sweden*

Background and Aims: Environmental conditions, the general population's experience of these, and the level of knowledge throughout the community concerning the effect of environmental factors on public health are changing at an ever increasing rate. It is therefore important to regularly update the foundation of knowledge upon which decision making processes concerning environmental measures and priorities are dependent. The periodically published environmental health reports contribute significantly to such updates.
Methods: In Sweden, these reports are to a large extent based upon the National Environmental Health Surveys (MHE). The surveys have been conducted every 4th year since 1999, alternating between adults and children. The response rate has been between 60-73%. Bias in the sampling and the proportion of respondents in different groups has been adjusted for by calibration and hence, the responses are representative of the target population. The 4th is currently in progress and the invitation to respond has been sent to parents of about 80 000 children aged 6-10 months, 4, 8,12 and 16 years. The survey includes questions regarding children's health and annoyance in relation to various environmental factors.
Results: The results give an up to date describe of how the general population is exposed to risks caused by various environmental factors. Moreover, the results show differences between various sub-groups within the population, such as age, sex, and social class. Geographic differences both between but also within the different regions can be studied. Finally, time trends regarding exposures and annoyance related to various environmental factors can be followed. The surveys are also used for research purposes, and to evaluate the Swedish environmental quality objectives.
Conclusions: The periodical Environmental Health survey is an extremely important source of information in decision making processes that aim to promote awareness among citizens about the risks associated with environmental factors and to reduce the risk they pose to public health.

SHORT-TERM EFFECTS OF AIR POLLUTION IN A COHORT OF PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Annunziata Faustini *Department of Epidemiology, Regional Health Service of Lazio, Rome, Italy*
Massimo Stafoggia *Department of Epidemiology, Regional Health Service of Lazio, Rome, Italy*
Silvia Cascini *Department of Epidemiology, Regional Health Service of Lazio, Rome, Italy*
Francesco Troiano *Regional Environmental Protection Agency, Lazio Region, Rome, Italy*
Marina Davoli *Department of Epidemiology, Regional Health Service of Lazio, Rome, Italy*
Francesco Forastiere *Department of Epidemiology, Regional Health Service of Lazio, Rome, Italy*

Backgrounds and aims: It has been postulated that patients with chronic obstructive pulmonary disease (COPD) have a higher risk of emergency medical care and death after exposure to air pollution in comparison to the general population. Few observations are available where subjects with COPD have been compared with people without the disease. We designed a study to evaluate the daily air pollution effects in COPD and non-COPD sub-groups in Rome, Italy.
Methods: We identified a dynamic cohort of COPD patients resident in the city of Rome, Italy, using hospital admission data (1998-2009) and drug prescriptions data (2005-2009); subjects without COPD from the general population of the city were also defined. The follow-up for emergency hospitalisations and mortality lasted from 1st February 2005 to 31st December 2009. We carried-out a case-crossover analysis to estimate short-term effects of airborne pollutants (PM_{10}, $PM_{2.5}$, NO_2 and ozone) in the COPD cohort (analysis for the comparison cohort is on-going) .
Results: There were 49755 emergency hospitalisations and 16,683 deaths (18% out-of-hospital) in the cohort of 147,067 suffers from COPD as identified from hospital diagnoses (23%) or drugs prescriptions of respiratory drugs (77%). An increased risk of hospitalisation for respiratory diseases (3.88%; 95% Confidence Intervals, CI, 0.98-6.87) was observed for a 10• g/m^3 increase NO_2 (lag 0-5). The strongest effect was observed on respiratory mortality for $PM_{2.5}$ and NO_2 (10.66%; CI 1.86-20.23 and 7.17%; CI 0.89-13.85, respectively at lag 0-5). The effect on mortality was lower, but with similar pattern, for PM_{10}.
Conclusions: We confirmed a high risk of health effects due to air pollution in COPD patients. The strongest effect was for respiratory mortality in relation to $PM_{2.5}$ and NO_2. The estimates doubled respect those previously observed in Rome in the general population; however a more formal comparison will be done with the non-COPD population.

CAUSE SPECIFIC MORTALITY IN A COHORT OF PEOPLE LIVING CLOSE TO SIX MUNICIPAL SOLID WASTE LANDFILLS

Francesca Mataloni, *Department of Epidemiology Lazio Regional Health Service, Italy*
Carla Ancona, *Department of Epidemiology Lazio Regional Health Service, Italy*
Chiara Badaloni, *Department of Epidemiology Lazio Regional Health Service, Italy*
Simone Bucci, *Department of Epidemiology Lazio Regional Health Service, Italy*
Martina Nicole Golini, *Department of Epidemiology Lazio Regional Health Service, Italy*
Silvia Narduzzi, *Department of Epidemiology Lazio Regional Health Service, Italy*
Marina Davoli, *Department of Epidemiology Lazio Regional Health Service, Italy*
Francesco Forastiere, *Department of Epidemiology Lazio Regional Health Service, Italy*

Background and Aims: the risk perception at population level of possible adverse health effects of waste treatment and landfilling is strong, especially in Italy, although the scientific evidence is still limited We evaluated whether living close to a landfill is associated with an increased risk of cause specific mortality in Lazio, Italy.
Methods: we defined a cohort of residents within 5 km from six landfills during the period 1996-2008. Follow-up for vital status was done with the municipality of residence and mortality data were retrieved from a regional data base. Each participant's address was geocoded and assigned to a distance from each landfill on the basis of a GIS. Cause-specific mortality relative risks (RR, CI 95%), adjusted for age and socioeconomic status (area-based index) were calculated in 3 bands of increasing radius from landfills:0-2, 2-3, and 3-5 Km (reference group), using a Poisson regression model.
Results: the cohort consisted of 197.285 people, 2.7% of whom lived close (0-2 km) to the landfills; 43.6% of the residents at 0-2 km was of low socioeconomic status versus 28.2% observed in the reference group. No excess risk in mortality was observed when comparing people residents at 0-2 km with the reference group (3-5 km) (RR 1.03 CI 95% 0.93-1.14 men; RR 1.03, CI 95% 0.92-1.16 women). No distance related gradient was observed for cancer mortality (RR 0.92, CI 95% 0.77-1.10 and RR 0.95, CI 95% 0.76-1.20, men and women, respectively) or for several other causes analyzed.
Conclusions: subjects living close to landfills tend to be of lower socioeconomic status. In agreement with the available literature, our results indicate that after adjusting for socioeconomic status, there is no association between residence in areas with landfills and mortality.

HUMAN BIOMONITORING OF RESIDENTS LIVING IN THE VICINITY OF A MODERN SOLID WASTE INCINERATOR (SWI): A PILOT STUDY IN NORTHERN ITALY

Pier Alberto Bertazzi, *Department of Occupational and Environmental Medicine, University of Milan and Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*

Background and Aims: As part of IPPC related to the solid waste incinerator in Modena (Emilia-Romagna region, Italy), a human biomonitoring cross-sectional pilot study was carried out to investigate possible biomarkers of exposure related to incinerator emissions.
Methods: Between May and June 2010, 65 subjects living and working within 4 km from the incinerator for at least 3 years (exposed) and 103 referents living and working outside this area, within a 15 km distance from the incinerator for at least 3 years (not exposed) were recruited. Blood and urinary metals (Cd, Cu, Hg, Mn, Ni, Zn) and urinary polycyclic aromatic hydrocarbons (PAHs) were analysed. Information about lifestyle, anthropometric characteristics, residential history, and health status were collected by a self-administered questionnaire. A multivariate regression analysis was performed to investigate the different concentration of biomarkers in the two groups and the possible relationship between biomarkers and the distance of residence from the plant.
Results: Metals showed no difference between groups; their levels were within the Italian population reference values, with the exception of blood Zn and urinary Ni (possible sampling contamination). Metals showed association with age, gender, BMI, smoking habit, education, traffic, and diet, as expected.
As regard PAHs, 5 of them presented more than 50% of their values below the limit of quantification. The mean level of the remaining PAHs was: naphthalene 53.05±25.86ng/L, phenanthrene 9.27±5.52ng/L, fluorene 2.84±4.31ng/L, pyrene 1.56±0.71ng/L, and anthracene 0.73±0.62ng/L. The comparison between the two groups showed higher levels in the exposed subjects only for phenanthrene and anthracene ($p<0.01$).
Results of the multiple regression analysis showed that urinary phenanthrene, anthracene and Mn were inversely correlated to the distance of residence from the plant.
Conclusions: This study suggests that specific urinary PAHs and Mn may provide information about the exposure arising from SWI. Further analyses will investigate incinerator fallout maps.

COMPARATIVE ENVIRONMENTAL HEALTH RISK ASSESSMENT FOR USE IN POLICY-MAKING: THE VEGAS PROJECT

Reinhard Samson, *Bielefeld University, School of Public Health, Department 7 Environment & Health, Bielefeld, Germany*
Claudia Hornberg, *Bielefeld University, School of Public Health, Department 7 Environment & Health, Bielefeld, Germany*

Background and Aims:
Environmental stressors in Germany need to be examined regarding their health impact to develop suitable policies. The environmental burden of disease (EBD) concept combines aspects of morbidity and mortality of environmental stressors in the form of DALYs (disability-adjusted life years), which is useful for comparative risk assessment (CRA). The VegAS project [distribution-based analysis of health effects from environmental stressors] aims at providing a basis for policy-making.

Methods:
Seven environmental stressors – benzene, cadmium, noise, ozone, particulate matter, perfluorinated surfactants, and second-hand smoke – were considered because of their relevance to public health. Evidence levels of health effects were defined referring to international guidelines, reviews, meta-analyses, and epidemiological and toxicological studies. Exposure-response functions (ERFs) and population-based exposure data were evaluated to calculate the EBD. Parts of the DALY approach are discussed extensively and critically. Uncertainties are described and evaluated.

Results:
Up to ten health effects attributable to a single environmental stressor were identified with strong or moderate scientific evidence. Exemplary, cadmium causes different kinds of cancer, acute myeloid leukemia is attributable to benzene, and environmental noise induces myocardial infarction and sleep disturbance. Evidence differs strongly depending on the state of research of stressor and health outcome. Differences were also observed regarding availability (e.g., population-based registries, surveys), quality of ERFs and transferability to the general German population. Detailed uncertainty and sensitivity analyses are part of the project to enable reliable CRA results.

Conclusions:
Through high quality standards, the VegAS project will contribute to a realistic CRA by making use of the strengths of EBD analyses while carefully considering its limitations. A transparent application of the VegAS approach will substantially augment the options of policy-making. Final results are available in early 2012.

Funding by the German Federal Ministry of the Environment, Nature Conservation and Nuclear Safety is gratefully acknowledged.

DECREASING INFANT EXPOSURE TO PCDD/FS AND PCBS THROUGH BREAST MILK IN FINLAND

Riikka Airaksinen, *National Institute for Health and Welfare, Department of Environmental Health, Finland*
Panu Rantakokko, *National Institute for Health and Welfare, Department of Environmental Health, Finland*
Päivi Ruokojärvi, *National Institute for Health and Welfare, Department of Environmental Health, Finland*
Jouni T Tuomisto, *National Institute for Health and Welfare, Department of Environmental Health, Finland*
Hannu Kiviranta, *National Institute for Health and Welfare, Department of Environmental Health, Finland*

Background and Aims: PCDD/Fs and PCBs are environmental pollutants that are extremely persistent in the environment and accumulate in the human body. Because of their high lipophilicity, they are enriched in the fatty tissue. For women, lactation is the main route of elimination from the body. On a body weight basis, infants may be exposed to many orders of magnitude higher concentrations of these chemicals than adults. The main human health effects at current exposure levels are considered to be developmental effects in the foetus and children. In addition, these compounds are suspected to disturb the thyroid hormone system even at low exposure levels. The Finnish National Institute for Health and Welfare (THL) has monitored the levels of PCDD/Fs and PCBs in Finnish breast milk since 1987, and in 2000, PBDEs and DDT metabolites were added in the monitoring programme.
Methods: Sampling was conducted in 1987-88, 1993-94, 2000, and 2005. Another sampling round is currently on the way, and expected to yield results in 2011. The number of samples in each round was around 300, and samples were collected initially from two areas in southern Finland representing rural and urban areas. Later, northern areas were included in the studies. The samples were analysed for PCDD/Fs and PCBs, and from 2000 on also for PBDEs and DDTs. The samples have been stored for future needs.
Results: Between 1987 and 2005, the concentrations of PCDD/Fs and PCBs decreased significantly from 26.3 to 6.80 pg TEQ_{1998} g^{-1} fat (74.1%) and from 25.5 to 4.10 (83.9%), respectively. Based on the slope of the decrease, a further 10–15% decrease is expected between 2005–2011.
Conclusions: The study has shown a significant decrease in infant exposure to PCDD/Fs and PCBs. In 2011, information on current exposure will be obtained.

GREEN NEIGHBORHOOD QUALITY IS ASSOCIATED WITH PHYSICAL ACTIVITY BEHAVIOR AND SELF-RATED HEALTH STATUS IN SCANIA, SOUTHERN SWEDEN

Kim de Jong, Lund University, Lund, Sweden
Maria Albin, Lund University/ Lund University Hospital, Lund, Sweden
Erik Skärbäck, Swedish University of Agricultural Sciences, Alnarp, Sweden
Patrik Grahn, Swedish University of Agricultural Sciences, Alnarp, Sweden
John Wadbro, Swedish University of Agricultural Sciences, Alnarp, Sweden
Juan Merlo, Lund University, Malmö, Sweden
Jonas Björk, Lund University Hospital, Lund, Sweden

Background and aims: Various studies have shown positive associations between green environments and health or health-related behavior (de Vries et al, 2003, Groenewegen et al, 2006, Maas et al, 2006, Björk et al 2008, Sugiyama et al, 2008). However, neighborhood quality may not be equally important for each population subgroup (de Vries et al, 2003, Cummins et al, 2006). Our aim was to assess how quality of the green neighborhood environment is related to weekly level of physical activity, BMI and self-rated physical and mental health status and whether associations are modified by socio-demographic status.
Methods: We used self-assessments (N = 24,847) of five green qualities (culture, lush, serene, spacious and wild) and health status from a cross-sectional public health survey (2008). Area proportions of positive self-assessments for each quality were obtained from a multilevel model and used to create the area-aggregated Scania Green Score (SGS) (de Jong et al, 2011). Associations of the SGS and individual qualities with physical activity level, BMI and self-rated physical and mental health status were assessed in ordinal regression models, all adjusted for sex, age, educational level, economic status, country of origin, type of residence and as a sensitivity analysis for objectively assessed quality (GIS-based). We used the likelihood ratio test to investigate effect modification.
Results: Green neighborhood quality and health status were associated with socio-demographic status. SGS was associated with health status (OR 1.07: 1.03-1.21) and physical activity level (OR 1.16: 1.12-1.21), the latter association was modified by age (p=0.01) and educational level (p<0.001). SGS was not associated with BMI. The quality culture was clearly associated with all outcomes but for BMI only among tenants (OR 1.89: 1.19-3.01). Odds ratio's were 1.54 (1.19-1.99) and OR 1.43 (1.11-1.84) for physical activity and health status respectively. Effects for other qualities were ambiguous.
Conclusions: This study shows that green neighborhood quality can benefit health and health-related behavior, especially among specific subgroups, i.e. those most exposed to their neighborhood environment Notably these groups live in neighborhoods with least favorable green quality in Scania.

Background and aims. Several lines of evidence indicate that foetal exposures may be related with adult breast and prostate cancer. Anogenital distance is a sexually dimorphic phenotype that has been shown in animals to be related to foetal androgen action and that tracks through life. Anogenital distance has been scarcely used in human studies. A single study in adults found that shorter anogenital distance was a predictor of low sperm concentration. We evaluated the association of anogenital distance with breast and prostate cancer risk in a pilot study within a large population based case-control study in Spain (MCC-Sp).

Methods: Cases were identified at the Hospital del Mar, Barcelona and population controls were residents in the catchment area of the hospital. Anoclitoral (ACD: anus to clitoris) and anofourchetal distance (AFD: anus to fourchette) were measured in 46 breast cancers cases and 19 population controls. Anogenital distance (AGD: anus to upper penis), anoscrotal distance (ASD: anus to scrotum) were measured in 58 prostate cancer cases and 5 population controls. Odds ratios were adjusted for age, examiner, BMI (or weight and height) and parity (women).

Results: Anogenital distances were wider in males (mean AGD=120.7mm, SD=13.0; mean ASD = 35.8mm, SD=12.4) than females (mean ACD=102.5, SD=12.8; mean AFD=28.7, SD=6.6). No differences were observed for breast cancer (Odds Ratio (OR) for AGD=0.99, 95%CI 0.93-1.05; OR for AFD=1.09, 0.97-1.23). Shorter AGD (OR=0.85, 0.74-0.98) and ASD (OR=0.92, 0.84-1.01) were associated with a lower prostate cancer risk, although based on very small numbers.

Conclusions: This is the first study reporting anogenital measurements in adults in relation to cancer risk. Results are preliminary and, if confirmed, may indicate that prostate cancer is associated with lower levels of androgens in utero. The study is ongoing and results for a larger population sample will be presented.

Review on farm environment, genes and development of asthma and allergies

Dick Heederik, *Utrecht University, Institute for Risk Assessment Sciences, Utrecht, the Netherlands*

Background and Aims
Children growing up on farms are protected from asthma and atopy when compared to rural peers, yet the mechanisms underlying these effects are not exactly known. The review will summarize new findings mainly from two studies of the farming environment, i.e. PASTURE, a birth cohort and GABRIEL, a cross sectional study.
Methods
PASTURE has followed a birth cohort of 1063 children (half from farm families) from pregnancy up to age 6 yrs with extensive questionnaires, biological and environmental sampling and, immunological measurements. GABRIEL is a cross-sectional study of 9668 school-aged children, including 7606 with IgE measurements and 1708 with extensive genotyping data. Extensive environmental sampling was performed in about 800 children in one GABRIEL study area.
Results
Genome-wide interaction analysis for asthma and atopy and farm-related exposures in the GABRIEL study showed that the strong protective effect of a farm environment could not be attributed to the genetic make-up of the farming population nor to common genetic polymorphisms interacting with particular exposures. Exposure to a greater variety of environmental micro-organisms, however, was associated with a reduced risk of asthma (OR 0.86 (95%CI 0.75-0.99). Consumption of raw milk was inversely associated with asthma (aOR 0.59, 95% CI 0.46-0.74), atopy (0.77, 0.61-0.90) and hay fever (0.51, 0.37-0.69) independent of farming.
The longitudinal analyses of the PASTURE birth cohort showed that prenatal exposures modified atopic sensitization and cytokine patterns in cord blood and could influence the development of atopic dermatitis within the 2 first year of life. Gene expression of innate immunity receptors (TLR's) were decreased in children with atopic dermatitis.
Conclusions
The ongoing analyses of the cohort study will greatly enhance the understanding of the mechanisms underlying the protective effect of farm related exposures and hopefully open new avenues for prevention.

LUNG CANCER AND EXPOSURE TO MINERAL WOOLS: THE ICARE STUDY

Background and aims: In France, between 13 and 29% of lung cancers in men are estimated to be attributable to occupational factors. The aim of this work is to assess the risk of lung cancer associated with mineral wools (MW) currently used as a substitute for asbestos. They are suspected of increasing the risk of lung cancer because of their structure close to asbestos. Exposure to MW concerned around 15% of men in France.

Methods: ICARE is a large multicentre population-based case-control study conducted between 2001 and 2006 in 10 French *départements* with a general cancer registry. ICARE includes 2926 incident lung cancer cases and 3555 controls with 78% of men. A detailed description of lifetime occupational history was collected. The subjects' exposure to MW was first determined using a Job-Exposure Matrix (JEM) specific for MW. Then, individual exposure was assessed with an algorithm using specific questions on exposing tasks. We estimated odds ratios and 95% confidence intervals with unconditional logistic regression adjusted for age, department, number of job periods, lifelong cigarette smoking and exposure to asbestos (also assessed by a JEM and an algorithm).

Results: Analyses were conducted among men (2301 cases, 2780 controls) and concerned 27191 jobs. In the first analyses, we find significant associations between the risk of lung cancer and exposure to MW assessed with the JEM. They became nonsignificant and close to 1 when adjusting for exposure to asbestos. In contrast, a significant dose-response relation was found between exposure to asbestos and the risk of lung cancer, even when adjusted for exposure to MW.

Conclusions: These results need to be completed with the exposure assessment from the algorithm. This algorithm would help us disentangle individual levels of MW and asbestos exposure, which are closely related because of similar exposing jobs. Both results will be presented.

TRAFFIC DENSITY IN AREA OF RESIDENCE IS ASSOCIATED WITH PHYSICAL HEALTH-RELATED QUALITY OF LIFE IN WOMEN: THE COMMUNITY-BASED HORDALAND HEALTH STUDY

Hilde Gundersen, *Department of Public Health and Primary Health Care, University of Bergen, Norway*
Nils Magerøy, *Uni Health Bergen, Norway*
Bente E. Moen, *Department of Public Health and Primary Health Care, University of Bergen, Norway*
Magne Bråtveit, *Department of Public Health and Primary Health Care, University of Bergen, Norway*

Background and Aims: Vehicle traffic is increasing worldwide, and this is a major concern since traffic-related air pollution and noise may influence health. The aim of this study was to evaluate whether reduced health-related quality of life (HRQoL) among men and women is associated with increased vehicle traffic density in participants' area of residence.
Methods: A total of 16,410 individuals between the ages of 40 and 45 years from three municipalities in Hordaland County were asked to participate. The response rate was 55% for men and 66% for women. Vehicle traffic density in participants' area of residence was defined as low, moderate or high, with a maximum of 50,000 vehicles a day on the busiest roads. Using the SF-12 questionnaire, both physical and mental HRQoL were investigated in relation to vehicle traffic density.
Results: Linear regression analyses showed that women living in areas with high traffic density had significantly poorer physical HRQoL than women living in areas with moderate or low vehicle traffic density. There were no similar findings among men. Mental HRQoL was not associated with vehicle traffic density in the area of residence, neither for women nor for men.
Conclusion: There is an association between high vehicle traffic density in residential area and reduced HRQoL in women, but not in men.

AIRCRAFT NOISE EXPOSURE AND COGNITIVE PERFORMANCE IN CHILDREN LIVING NEAR THE CIAMPINO AIRPORT IN ROME

Background and Aims: chronic aircraft noise exposure has been associated with impairment of reading comprehension and long-term memory in the RANCH study. We evaluated the association between aircraft noise exposure and cognitive performance in children living around the Ciampino airport in Rome, Italy.
Methods: we investigated 555 children, aged 9-11 years, attending 13 schools located in the airport area. Aircraft noise Leq levels were measured for each school from 9.00 am to 1.00 pm. To estimate aircraft noise exposure at home, we defined three contours (Laeq,24h <60, 60-65, and >65-75 dB) using the Integrated Noise Model linked to each participant's address (a GIS system was employed). Children completed classroom-based tests on cognition, reading comprehension, recognition and clued recall, working memory, sustained attention, and auditory discrimination. Questionnaires were completed by parents to provide information about children's health status and socioeconomic context. The effects of airport noise on specific cognitive performance were analysed through adjusted logistic regression models (outcome variables: lowest decile of the distribution for each test) considering school clustering.
Results: in our sample, 40% of children was exposed at school at >65-75 dB, while 4.3% lived in homes exposed at >65-75dB. We found an association between aircraft noise levels at school and auditory discrimination ability (OR 1.7, 95% CI 0.9-3.1 when comparing >65-75 vs <60 dB), this impairment became statistically significant when children cognition was taken into account (OR 1.9, 95%CI 1.1-3.5). When we considered exposure at home, we found a borderline excess risk for impairment in cognition (OR 2.97, 95%CI 0.95-9.28) and a strong effect for auditory discrimination ability (OR 3.4, 95%CI 1.1-10.7). No association was found between exposure to aircraft noise and the other tests performed.
Conclusions: our findings indicate that chronic aircraft noise exposure plays a role in the cognitive development of children.

CLINICAL AND EPIDEMIOLOGICAL SURVEILLANCE OF A POPULATION CONTAMINATED BY BETA-HEXACHLOROCYCLOEXANE FROM AN ILLEGAL CHEMICAL DUMPING SITE

Fiorella Fantini, *Department of Prevention and Food Hygiene and Nutrition. Local Health Unit RMG, Italy*
Silvia Narduzzi, *Department of Epidemiology Lazio Regional Health Service, Italy*
Daniela Porta, *Department of Epidemiology Lazio Regional Health Service, Italy*
Francesco Blasetti, *Department of Prevention and Food Hygiene and Nutrition. Local Health Unit RMG, Italy*
Marina Davoli, *Department of Epidemiology Lazio Regional Health Service, Italy*
Francesco Forastiere, *Department of Epidemiology Lazio Regional Health Service, Italy*

Background and Aims: The health effects associated to Beta-hexachlorocycloexane (Beta-HCH), an organochlorine isomer of lindane, are still unclear. Potential effects on hormonal function, diabetes, cardiovascular, neurological, liver, renal, and reproductive disorders have been hypothesized. A population living close to the Sacco River Valley in central Italy has been exposed via food contamination from an illegal dumping site of a chemical industry producing pesticides. A programme of clinical and epidemiological surveillance has been going on since 2009. The objective of the study was to analyze the relationship between blood levels of Beta-HCH and some biochemical parameters.
Methods: A total of 495 people (48% of females), living within 1 km from the Sacco River, underwent an interview and a blood sampling for the detection of Beta-HCH and biochemical analyses (TSH, FT3, FT4, Cortisol, Transaminase, GammaGT, HDL-Cholesterol, Creatinine, Azotemia, Glycemia, Glycosylated Hemoglobin, Fibrinogen, FSH, LH, Prolactin, Testosterone). The association between Beta-HCH levels and each parameter was investigated using logistic regression (cut-off the 10^{th} or 90^{th} centile of the distribution) considering clustering within families. The analyses were done separately for gender, adjusting for age, educational level, breast-feeding (for women) and thyroid therapy (for TSH, FT3, FT4).
Results: The population had an average high level of Beta-HCH (geometric mean=80, GSD=1.2 ng/g lipids). In females, there was a clear association of Beta-HCH (per 100 ng/g lipids) with high TSH (OR: 1.38, 95%CI: 1.12-1.69), FT3 (OR: 1.25, 95%CI: 0.99-1.57), LH (OR: 1.31, 95%CI: 0.99-1.73), and low HDL (OR: 1.31, 95%CI: 1.08-1.58). In males, a no clear inverse association was found for FT3 (OR: 0.73, 95%CI: 0.54-0.99) and GammaGT (OR: 0.77, 95%CI: 0.59-0.99).
Conclusions: A clear effect of Beta-HCH on the thyroid regulation and function was suggested in females. The surveillance of the population is on-going and additional data will be available to confirm these results.

THE EFFECT OF PREVIOUS BREASTFEEDING ON THE BIRTH WEIGHT OF SUBSEQUENT CHILDREN

Merete Eggesbø, *NIPH, Norway*
Leda Chatzi, *University of Crete, Greece*
Monica Guxens, *CREAL, Spain*
Maria Vassilaki, *University of Crete, Greece*
Theano Roumeliotaki, *University of Crete, Greece*
Jordi Sunyer, *CREAL, Spain*
Manolis Kogevinas, *CREAL, Spain*

Background and Aims: Studies have shown that birth weight increases with parity, while breastfeeding lowers the maternal body burden of persistent environmental toxicants. We hypothesized that women with longer history of previous breastfeeding have a reduced risk of adverse birth outcomes in subsequent pregnancies due to the decreased exposure of the fetus to such toxicants.

Methods: We restricted our analysis to second gravida women with singleton births from the "Norwegian Human Milk Study" (HUMIS, n=806 mother-newborn pairs), the Spanish multi-center "INMA" study (n=737), and the Greek "Rhea" cohort (n=404). Breastfeeding duration in previous pregnancy (in months) was assessed by a questionnaire, and data on birth outcomes; birth weight, small for gestational age, large for gestation age, difference in birth weight between index and previous pregnancy, were obtained from the women's clinical records and questionnaires. Multivariable log-binomial and linear regression models were used, adjusting for several potential confounders.

Results: Breastfeeding duration in previous pregnancy is associated with a slightly reduced risk for small for gestational age neonates in index pregnancy, consistently in the three cohorts, though not statistically significant in any cohort. A per month increase in breastfeeding duration in Rhea cohort increased the birth weight in index pregnancy by 9.3 gr (b coefficient: 9.3; 95% CI: 2.5, 16.1), while smaller increases were observed in the INMA and HUMIS cohorts. Results will be presented on additional birth outcomes including large for gestational age, birth weight and the difference in birth weight between index and previous pregnancy.

Conclusions: This is the first time that this research hypothesis is being investigated. Results indicate that long duration of breastfeeding may slightly reduce the risk of adverse birth outcomes in subsequent pregnancies, although residual confounding of breastfeeding habits by socioeconomic-status is a challenge and cannot be fully eliminated.

IMPACT OF URBAN AIR POLLUTION ON INCIDENCE AND PROGNOSIS OF STROKE

Cesaroni G, *Department of Epidemiology, Lazio Regional Health Service, Italy*
Agabiti N, *Department of Epidemiology, Lazio Regional Health Service, Italy*
Davoli M, *Department of Epidemiology, Lazio Regional Health Service, Italy*
Forastiere F *Department of Epidemiology, Lazio Regional Health Service, Italy*

Background and aims: Few studies have evaluated the association between long-term exposure to air pollution and incidence or prognosis of stroke. We investigated the association between nitrogen dioxide (NO_2) exposure at residence and incidence of stroke (total and by subtype) and its prognosis within a large cohort study.
Methods: The Rome Longitudinal Study (RoLS) is a fixed cohort enrolled at the 2001 census. We selected subjects aged 45-80 years at the baseline who had not changed their address nor had a hospital admission for stroke in the previous five years (n=677,909). Incident cases of stroke occurred between October 2001 and December 2004 were selected from administrative databases. NO_2 exposure was estimated for residence's coordinates through a land use regression model (R^2=0.66). Subjects were followed till December 31st, 2006. We used Cox regression models to evaluate the association between NO_2 exposure and incidence of stroke and survival taking account of education, occupation, place of birth, and area-based socioeconomic position (SEP).
Results: During the period 2001-2004 there were 4455 new cases of stroke (76% ischemic) in the cohort . Average exposure of NO_2 was 44 (sd 8) µg/m^3. There was no evidence of association between NO_2 at residence and incidence of stroke in the study population, both for ischemic and hemorrhagic forms. Stroke incident cases in the highest quintile of exposure (>50.2µg/m^3) had 23% (95%CI:3%-47%) risk of dying for natural causes than those living in the lowest quintile (<35.7µg/m^3). After first stroke there was a 9% (95%CI:3%-17%) higher risk of dying for 10µg/m^3 increase of NO_2 at residence.
Conclusions: Although there was no evident association between air pollution exposure at residence and incidence of stroke, we found a strong evidence of association between NO_2 exposure and survival after first stroke.

INTEGRATED HEALTH IMPACT ASSESSMENT OF WASTE MANAGEMENT IN LAZIO (ITALY)

Carla Ancona, *Department of Epidemiology Lazio Regional Health Service, Italy*
Francesca Mataloni, *Department of Epidemiology Lazio Regional Health Service, Italy*
Chiara Badaloni, *Department of Epidemiology Lazio Regional Health Service, Italy*
Kees De Hoogh, *Department of Epidemiology and Biostatistics, Imperial College, London, United Kingdom*
Lubica Palkovicova, *Department of Environmental Medicine, Slovak Medical University, Bratislava, Slovakia*
Andrea Ranzi, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia Romagna, Modena, Italy*
Francesco Forastiere, *Department of Epidemiology Lazio Regional Health Service, Italy*

Background and Aims: the management of municipal solid waste (MSW) may entail health effects difficult to be quantified. We evaluated potential health impacts arising from MSW management under a 2008 baseline scenario (BS) and an alternative 2016 green scenario (GS) which includes decrease in waste production, increase in recycling, clean transportation, and no landfilling without pre-treatment.
Methods: we evaluated the population of the Lazio region in Italy (5.5 million inhabitants). Pollutants concentrations from transport, incineration, and combustion of landfills biogas were modelled using the ADMS-Urban model. Population-weighted exposure levels were calculated. Concentration-response functions were derived from systematic reviews of the literature. Cancer incidence (CI), low-birth weight (LBW) newborns, congenital anomalies (CA), respiratory symptoms (RS) and odour annoyance (OD), Years of Life Lost (YLL), and Disability Adjusted Life Years (DALYs) were estimated for the period 2016-2050.
Results: at the BS, 36,191 people lived nearby MSW facilities, while 14.606 were estimated under the GS. Waste transport health impact was estimated in 561 YLL at BS, 29 under the GS. For incinerators, CI was 7.5 (BS) and 2.5 (GS) cases. 10 YLLs were estimated at BS whereas 9.6 for GS. For landfills, LBW cumulative incidence was 8.3 cases (BS) and 2.8 (GS), respectively. The cumulative incidence of CA was 0.3 (BS) and 0.1 (GS) cases. The health impact as YLL was 17.9 (NO_2) at BS and 12.4 with GS. At the BS the prevalence of severe OD and RS were the same, 54 and 424, respectively while a decrease to 19 and 147 were predicted with the GS. About 3000 and 1600 DALYs were estimated under the two scenarios. The largest contribution to DALYs was from RS (about 90%) and OD.
Conclusions: although MSW management impact on health is moderate, a substantial improvement can be realized with a green waste policy.

ASSESSMENT OF HEALTH EFFECTS OF TRANSPORT POLICIES IN ROME: IMPACT ON SOCIO-ECONOMIC INEQUALITIES

Giulia Cesaroni, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Hanna Boogaard, *Institute for Risk Assessment Sciences, University of Utrecht, Utrecht, The Netherlands*
Sander Jonkers, *Netherlands Applied Research Organisation (TNO), TA Utrecht, The Netherlands*
Daniela Porta, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Chiara Badaloni, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Giorgio Cattani, *Italian Institute for Environmental Protection and Research (ISPRA), Rome, Italy*
Francesco Forastiere, *Department of Epidemiology, Lazio Regional Health Service, Rome, Italy*
Gerard Hoek, *Institute for Risk Assessment Sciences, University of Utrecht, Utrecht, The Netherlands*

Objectives and aims: To reduce traffic-related air pollution local councils usually introduce transportation policies, including congestion charges, environmental zoning, monetary subsidies to decrease the number of older cars on the road, and measures to promote public transport and cycling. Few studies have assessed the effects of these traffic policies. Our aim was to evaluate the impact, in terms of air quality and health effects, of the two low emission zones (Limited Traffic Zone and Railway Ring) implemented in Rome in the period 2001-2005, and to examine whether the impact was different according to socioeconomic position (SEP).
Methods: We evaluated the effects of the policy intervention on various stages in the full chain model, that is: pressures (number and age distribution of cars), emissions, PM10 and NO2 concentrations, population exposure, and years of life gained (YLG). The impact was evaluated according to a small-area indicator of SEP of the residents.
Results: In the period 2001-2005 there was a decrease in the total number of cars (-3.8%), of NO2 and PM10 emissions, of traffic-related concentrations (from 22.9 to 17.4 ug/m3 for NO2 and from 7.8 to 6.2 ug/m3 for PM10), and in the overall population exposure. The specific policy had an impact on concentrations in the two low emission zones (NO2: -4.13 and -2.99 ug/m3; PM10: -0.70 and -0.47 ug/m3). Overall, residents living along busy roads (264,522 subjects) gained 3.4 days per person (921 YLG per 100,000) for NO2 reduction; the gain was larger for people in the highest SEP group (1387 YLG per 100,000) than for residents in the lowest SEP group (340 YLG per 100,000).
Conclusions: The traffic policy in Rome was effective in reducing traffic-related air pollution, but because of the spatial distribution of SEP in the city, most of the health gains were found in well-off residents.

Indoor exposure of expecting mothers by VOC at home induce wheezing in young children

Ulrich Franck[a], Annegret Weller[a,d*], Stefan Röder[a], Uwe Schlink[a], Tibor Kohajda[b], Ulrike Rolle-Kampczyk[b], Michael Borte[e],Ulrike Diez[e], Irina Lehmann[c] , and the LiNA Study Group*

Helmholtz Centre for Environmental Research - UFZ, Leipzig, Germany; [a]Core Facility 'Studies',[b]Department 'Metabolomics', Leipzig, Germany ;and [c]Department 'Environmental Immunology', Leipzig, Germany; [d]University of Leipzig, Faculty of Medicine, Leipzig. Germany, [e]Children's Hospital, Municipal Hospital, Klinikum St. Georg gGmbH, Leipzig, Germany

Aims: To assess the effects of domestic exposure to volatile organic compounds during pregnancy and in the first year of life on respiratory diseases in young children.

Methods: A prospective cohort study was conducted in Leipzig, Germany, in expecting mothers and their children during the first year of life. Concentrations of volatile organic compounds were measured during these periods. Specific redecoration-associated VOCs have been identified. The health effects of these VOC were assessed for the exposure periods.

Results: We found VOC that were specifically associated to floor covering, floor covering with adhesives, and painting. Among respiratory health effects, wheezing that needed medical treatment was found to be most significantly associated to redecoration-related VOC exposures. Floor covering at home resulted in increased exposure levels of six specifically flooring-related VOC which induced significantly increased risks for treated wheezing. Among the specifically redecoration-associated VOCs, elevated styrene concentrations during pregnancy and during the first year of life, and methyl isobutyl ketone concentrations during the first year of life were identified to induce treated wheezing. For adhesive-related VOC we found significant adverse effects for ethylbenzene octane, 1-butanol, and o-xylene at elevated concentration levels during pregnancy. For painting-related VOC, we did not find significant risk increases.

Conclusions: VOC exposures during pregnancy have been identified to induce adverse effects of on children's respiratory health in the year after birth. We found these effects of exposure because of redecoration that recently mostly have been only accused to cause immediately respiratory effects in children.

Background and Aims: Subjects living in buildings located in volcanic areas may be exposed to H_2S and CO_2 emitted from the soil. Few studies have shown that geothermal emissions can cause fatalities from asphyxiation and increases in respiratory diseases. We studied the association between residence in a geothermal area and mortality and emergency room visits (ERVs) in Marino (Rome).
Methods: We enrolled the cohort of residents in Marino from 01/01/1996 to 31/12/2008. Each participant's address was geocoded and the mortality and ERVs follow-up was done using health databases. The cohort was divided in three zones, according to residence at baseline: the area close to the gas emission site (zone A), the surrounding area (zone B), and the rest of Marino (reference). We measured peaks of indoor CO_2 and H_2S up to 28% and >500 ppm in zone A and 11% and 54 ppm in zone B. We evaluated the risk of mortality and ERVs in zone A and B using a Poisson regression model adjusting for age and socio-economic status.
Results: 53.609 people were enrolled, 2.1% living in zone A and 5.4% in zone B. When we compared zone A with the reference, we found an increased risk of myocardial infarction mortality (RR 2.12, 95%CI 0.92-4.87) among men and increased number of ERVs both in men (RR 1.09, 95%CI 1.03-1.16) and in women (RR 1.15, 95% CI 1,08-1,22), in particular for intoxication (RR 2.70 95%CI 1.14-6.39) among men. In zone B, increased risks of ERV for dyspnoea (RR 1.50 95%CI 1.19-1.88 men; RR 1.41 95%CI 1.07-1.86 women) and chest pain (RR 1.42 95%CI 1.07-1.87 women) were found.
Conclusions: We found elevated mortality and ERVs rates consistent with high exposures to H_2S and CO_2. There is a need of epidemiological surveillance of populations living in high risk areas.

A CROSS SECTIONAL INVESTIGATION ON THE HEALTH STATUS IN A POPULATION EXPOSED TO 50Hz MAGNETIC FIELDS IN A DISTRICT OF ROME: HEMATOLOGICAL AND IMMUNOLOGICAL PARAMETERS

Caterina Bruno *Department of Environment and Primary Prevention, National Institute of Health, Rome , Italy*
Nicola Vanacore *National Centre for Epidemiology, Surveillance, and Health Promotion, National Institute of Health, Rome , Italy*

Robin Foà *Department of Cellular Biotechnologies and Hematology, Division of Hematology, "Sapienza" University, Rome, Italy*

Background and Aims: Extremely Low Frequency Magnetic fields are possible carcinogens and the question whether they cause biological effects is of special interests.
Aim of the study is to evaluate hematological and immunological parameters in the resident population of a district of Rome built in part under a 60 kV electric distribution line. In the same area two mortality and morbidity studies were previously performed.
Methods: Residential magnetic field levels based on current load, line characteristics and distance of the dwellings from the power line were estimated, and the study area was divided into sub-areas with differing magnetic field levels. Subjects living close to the line were contrasted with those resident in the more distant dwellings.
252 subjects had blood sample taken to investigate hematological parameters, including lymphocyte subsets. Lymphoproliferative response to mitogens and cytolytic activity of natural killer (NK) cells were tested.
A detailed questionnaire collected information on possible confounders.
Results: Preliminary results showed in "exposed" vs "unexposed" subjects:
a) increased platelet count and plateletocrit, and reduced basophilic granulocytes
b) reduced percentage of total CD3± T lymphocytes
c) reduced percentage of CD4± (helper inducer) T lymphocytes
d) reduction of CD4/CD8 ratio
e) increased percentage of NK cells
f) increased percentage of CD19 lymphocytes
Conclusions: Preliminary results showed some abnormalities in the hematological and immunological parameters of the exposed group which deserve further investigation.

Background and Aims: Acrylamide is a potential human carcinogen and neurotoxicant that crosses the human placenta. Some reproductive and developmental toxicity of acrylamide have been observed in rodents, yet evidence is limited and no human data exist. We examined the effects of hemoglobin adducts from acrylamide in cord blood, as well as its mutagenic and genotoxic metabolite glycidamide, on birth outcomes in the NewGeneris (Newborns and Genotoxic exposure risks) study population.
Methods: Included in this study were infants born to women with singleton pregnancies (N=1096) from Greece, Norway, Spain, Denmark and the United Kingdom. Cord blood adducts were simultaneously determined by the "adduct FIRE procedure" using liquid chromatography–tandem mass spectrometry (LC–MS/MS).
Results: Acrylamide exposure was associated with a significant decrease in birth weight. In linear regression models adjusted for gestational age and country of birth, the difference in mean birth weight for infants in the highest quartile of acrylamide adduct concentrations compared with that of infants in the lowest quartile was -127 gram (SE: -41; p=0.006, n=1096); this difference was similar in infants born to self-reported non-smokers (β: -115 gram; SE: -42; p=0.006, n=941) and for glycidamide adducts. No major changes in these associations were observed when self-reported maternal smoking, exposure to ETS, maternal age, pre-pregnancy BMI, and gender were included as additional covariates. High acrylamide exposure were also associated with increased odds ratios for small size for gestational age (birth weight <10th population centile taking into account week of gestation) and reduced head circumference.
Conclusions: This study is the first to evaluate the relationships between cord blood hemoglobin adducts from acrylamide and birth outcomes. As the associations between biomarkers of acrylamide exposure and reduced birth weight appeared in infants born to non-smokers, these results are likely to be associated to intake of less healthy food.

INCREASED PREVALENCE OF RESPIRATORY SYMPTOMS AMONG CHILDREN EXPOSED TO DAMPNESS AND MOULD AT SCHOOL

Background and Aims: Studies on respiratory health effects of dampness and mould among school-aged children have mainly focused on home environments. We studied the relationships between dampness and mould in school buildings and respiratory symptoms in children.
Methods: Primary schools in Finland, The Netherlands and Spain were selected according to the presence (n=29) or absence (n=28) of reported moisture damage (dampness and/or mould) that was confirmed by standardised building inspections. Parent-administered questionnaires among 9425 children aged 6-12 years included lower and upper respiratory tract symptoms in the last year (ISAAC) and potential determinants. Country-specific associations between building dampness problems and the prevalence of respiratory symptoms were assessed using logistic regression analyses adjusted for potential confounders including sex, age, educational level, and mould in the home, and were combined using random-effects meta-analyses.
Results: The prevalence of respiratory symptoms was higher in Finland than in the other two countries. Finnish children from exposed schools more often had respiratory symptoms in the last year including wheeze (Odds Ratio (OR) 1.35; 95% Confidence Interval (CI) 1.11-1.65), dry cough at night (OR 1.36; CI 1.13-1.64) and nasal symptoms (OR 1.33; CI 1.16-1.53). Associations for The Netherlands and Spain were not apparent. A significant interaction by country was found for wheeze (P for heterogeneity 0.003) and nasal symptoms (P=0.02). Controlling the analyses for mould or dampness at home did not change the results.
Conclusions: These preliminary analyses suggest that moisture damage in schools may have adverse respiratory health effects on the pupils. Finnish schoolchildren seem to be at higher risk, perhaps due to quantitative and/or qualitative differences in exposure characteristics. More complex analyses taking into account these differences as well as other spatial and temporal determinants of exposure related to climate and building use will be considered.

EFFECTS OF PRENATAL EXPOSURE TO AMBIENT AIR POLLUTION ON RESPIRATORY HEALTH IN EARLY LIFE – SOME METHODOLOGICAL CONSIDERATIONS BASED ON 'EDEN MOTHER-CHILD' COHORT

Background and Aims: The increasing availability of air pollution (e.g., dispersion) models with a fine spatial resolution in large areas offers opportunities to try better characterize the effects of prenatal exposure to air pollution on respiratory health in early-life. We aimed at evaluating this association and at illustrating some issues related to confounding and choice of study area that may impact on effect estimates.
Methods: We included 1082 mother-child pairs from EDEN cohort, living in rural and urban areas around Poitiers and Nancy, France. NO_2 and PM_{10} levels in the ambient air at the home addresses were estimated using ADMS dispersion model. Information on health outcomes until 1 year of age was obtained from questionnaires.
Results: Mean (sd) pregnancy exposure to NO_2 and PM_{10} were 20.9 (8.1) and 20.1 (4.3) $\mu g/m^3$, respectively. The adjusted odds-ratio (AOR) associated with a 10 $\mu g/m^3$ increase in NO_2 was 0.78 (95% confidence interval, 0.52-1.15) for doctor-diagnosed asthma, 0.81 (0.62-1.05) for wheeze and 0.95 (0.75-1.21) for bronchitis/bronchiolitis in the entire population. The AOR for doctor-diagnosed asthma was 1.15 (0.55-2.43) in Poitiers and 0.63 (0.38-1.04) in Nancy. Similar patterns, with no significant associations, were observed for PM_{10}. Maternal smoking habits, mode of transport, breastfeeding, daycare attendance differed significantly between both cities, urban and rural areas, and according to exposure levels..
Conclusions: Prenatal exposure to air pollutants was not significantly related to respiratory health in the first year of life; this may partly be explained by the low exposure levels and the early age of assessment of respiratory health. Additionally, exposure was strongly associated with area of residence and with many factors known to be associated with respiratory health. Given that these factors could not always be accurately assessed, there is potential for residual confounding. The potential for confounding may differ between urban and rural areas.

HEAVY METALS AND COUPLE FECUNDITY, THE LIFE STUDY

Zhen Chen, *NICHD, USA*
Sungduk Kim, *NICHD, USA*
Kathleen Caldwell, *CDC, USA*
Dana Boyd Barr, *Emory University, USA*

Background and Aims: Exposure to high concentrations of heavy metals has been associated with a spectrum of adverse reproductive outcomes in men and women. However, limited prospective study has focused on the relation between environmentally relevant concentrations and human fecundity serving as the impetus for the study.
Methods: Using population based sampling frameworks, we recruited 501 couples discontinuing contraception for the purpose of becoming pregnant in two geographic regions with reported exposure to persistent environmental pollutants including metals. Upon enrollment into the cohort, couples completed baseline interviews and anthropometric assessments and provided blood specimens for the quantification three metals (i.e., cadmium (ng/ml), mercury (ng/ml), lead (ug/dl)) using inductively coupled plasma mass spectrometry. Couples completed daily journals on intercourse and lifestyle behaviors along with menstruation and pregnancy test results for women. Couples were followed until an hCG pregnancy or 12 cycles without pregnancy. Fecundability odds ratios (FORs) and 95% confidence intervals (CIs) were estimated adjusting for maternal age, body mass index, cotinine, and serum lipids in relation to female then male exposures. FORs <1 reflect reduced fecundity or a longer time-to-pregnancy. Final models included both partners' metals concentrations along with relevant covariates.
Results: In adjusted models, cadmium was associated with reduced FORs for both female (0.82; 95% CI 0.69-0.99) and male (0.84; 95% CI 0.71-0.99) exposure. Lead was associated with a significant reduction in the FOR (0.86; 95% CI 0.75-0.98), but only for male exposure. In the joint analysis, male lead concentration significantly reduced the FOR (0.86; 95% CI 0.76-0.99). No association was observed for mercury and couple fecundity.
Conclusions: This prospective couple based cohort with longitudinal capture of time-to-pregnancy affirms the reproductive toxicity of cadmium and lead concentrations for environmentally relevant concentrations underscoring the importance of measuring both partner's exposures for coupled based reproductive outcomes.

PERFLUORINATED CHEMICALS AND SEMEN QUALITY, THE LIFE Study

Germaine Buck Louis, *NICHD, USA*
Steven Schrader, *NIOSH, USA*
Sungduk Kim, *NICHD, USA*
Anne Sweeney, *Texas A & M, USA*
Zhen Chen, *NICHD, USA*
Rajeshwari Sundaram, *NICHD, USA*
Enrique Schisterman, *NICHD, USA*
Rob Gore-Langton, *EMMES Corporation, USA*
Terry Turner, *NIOSH, USA*
Antonia Calafat, *CDC, USA*
Dana Boyd Barr, *CDC, USA*

Background and Aims: The relation between persistent environmental chemicals and semen quality is still evolving, given that much of the available evidence relies upon couples seeking infertility treatment. We assessed the relation between perfluorinated chemicals (PFCs) and semen quality in the context of lifestyle among male partners participating in a cohort of couples attempting to become pregnant without an infertility history.
Methods: We utilized population-based sampling strategies to recruit 501 couples discontinuing contraception for purposes of becoming pregnant from two geographic regions with reported environmental exposures to persistent pollutants. Upon enrollment into the cohort, couples completed baseline interviews and anthropometric assessments and provided blood for the quantification of 8 serum PFCs (perfluorosulfonates, perfluorocarboxylates and perfluorosulfonamides) using tandem mass spectrometry, 2005-2009. Men collected semen samples at home following two days of abstinence, and returned them by overnight mail to a central andrology laboratory. Linear regression analysis adjusting for age, urinary cotinine, serum lipids, and research site was used to estimate the effect of PFCs (ng/ml as categorized into quartiles) in relation to a spectrum of conventional semen quality measurements along with CASA and flow cytometry measures.
Results: Four PFCs (perfluorodecanoate [PFDeA], perfluorooctane sulfonamide [PFOSA], perfluorooctane sulfonate [PFOS], and perfluorooctanoate [PFOA]) were adversely associated with select semen quality endpoints, with effects seemingly concentrated with sperm head size. Men in the highest quartile of PFOA had significantly smaller sperm head length (-0.08; p=0.03), area (-0.26; p=0.03) and perimeter (-0.15; p=0.04) compared to men in the lowest quartile.
Conclusions: Select PFCs were associated with decrements in sperm head endpoints and may be indicative about possible modes of action, particularly in the absence of other adverse effects on other aspects of semen quality.

PERSISTENT ORGANIC POLLUTANTS AND ENDOMETRIOSIS: IMPORTANCE OF BIOLOGIC MEDIA FOR DEFINING EXPOSURE - THE ENDO STUDY

Germaine Buck Louis, *NICHD, USA*
C. Matthew Peterson, *University of Utah, USA*
Mary Croughan, *University of California, USA*
Zhen Chen, *NICHD, USA*
Rajeshwari Sundaram, *NICHD, USA*
Mary Hediger, *NICHD, USA*
Joseph Stanford, *University of Utah, USA*
Michael Varner, *University of Utah, USA*
Linda Giudice, *University of California, San Francisco*
Victor Fujimoto, *University of California, San Francisco*
Patrick Parsons, *Wadsworth Center, USA*
Kannan Kurunthachalam, *Wadsworth Center, USA*

Background and Aims: Persistent organic pollutants (POPs) have been associated with endometriosis, though with equivocal results possibly reflecting choice of biospecimen. We sought to assess this relation using omental fat as a measure of internal dose then compared findings with serum concentrations to assess the consistency.
Methods: We used a population-based matched exposure cohort design to establish an operative cohort of women aged 18-44 years undergoing laparoscopy from 14 clinical centers (n=495) for capture of incident endometriosis, and a similarly aged population cohort residing within 40 miles of the clinical centers who underwent pelvic magnetic resonance imaging (MRI) for the identification of incident endometriosis (n=131). All women completed baseline interviews, anthropometric assessment and provided blood and urine specimens, 2007-2009. Surgeons obtained visceral fat and completed standardized operative reports for gynecologic pathology and endometriosis staging. Two radiologists completed all standardized MRI. Using high-resolution mass spectometry, fat and serum concentrations were quantified for organochlorine pesticides (OCPs), polychlorinated biphenyls (PCBs) and polybrominated diphenyl ethers (PBDEs) in fat and serum. All chemical concentrations were log transformed prior to inclusion in logistic regression models when estimating odds ratios (OR) and 95% confidence intervals (CIs) for visually-diagnosed endometriosis adjusting for age, cotinine, body mass index, and a conditional parity-breastfeeding variable.
Results: Fat concentrations were higher than serum POP concentrations. In unadjusted models, significantly increased ORs for endometriosis were observed for hexachlorobenzene (HCB; OR=3.04), PBDE #183 (OR=1.3), PCB #28 (OR=1.64), PCB #151 (OR=15.01), and PCB #201 (OR=4.37), but only when using fat. HCB remained significant in adjusted models (OR=2.49; 95% CI 1.07-5.79). Further model exploration is underway, given the reduction conferred by cotinine (OR=0.88; 95% CI 0.79-0.99).
Conclusions: POPs were associated with endometriosis when using both the gold standard for internal dose (fat) and diagnosis (laparoscopy). Reliance on other biospecimen proxies may mask relations between lipophilic chemicals and endometriosis.

MORTALITY IMPACTS OF SULPHUR CONCENTRATIONS IN AIR IN 20 EUROPEAN CITIES IN THE APHEKOM PROJECT: A CASE-CROSSOVER DISTRIBUTED LAG APPROACH

Ariana Zeka, *Brunel University, Uxbridge, United Kingdom*
Susann Henschel, *Dublin Institute of Technology, Dublin, Ireland*
Patrick Goodman, *Dublin Institute of Technology, Dublin, Ireland*
Richard Atkinson, *St. George's, University of London, London, United Kingdom*
Antonis Analitis, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece*
Klea Katsouyanni, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Athens, Greece*
Alain Le Tertre, *French Institute for Public Health Surveillance, InVS, Paris, France*
Olivier Chanel, *French Institute for Public Health Surveillance, InVS, Paris, France*
Sylvia Medina, *French Institute for Public Health Surveillance, InVS, Paris, France*

Background and Aims: The implementation of three EU directives to reduce sulphur content in fuel was assessed for mortality impacts in 20 European cities, between 1990 and 2007 in the APHEKOM project. This specific study aimed to examine whether different lag structures apply to the relationships between cardiovascular and respiratory events and SO_2 concentrations, which will therefore result in differences in mortality impacts from regulation implementation. Prior evidence has shown that cardiovascular mortality is more likely to be affected by SO_2 concentrations on the same or the previous day of the event, while respiratory mortality more likely to show a delayed effect of exposure to the same pollutant.
Methods: City-specific data on SO_2 concentrations and all-cause and cause-specific mortality were obtained for 20 European cities. A city-specific distributed lag case-crossover design was implemented with two simultaneous lags in the model: average SO_2 concentration for lag 0 to 1 days (L01); and lag 2 to 5 days prior to the mortality event (L25). Pooled estimates of the city specific results were calculated using a random effects meta-analysis model.
Results: Pooled results showed a 1.17% (95% CI: 0.53%-1.80%) increase in all-cause mortality for every 10µg/m^3 change in SO_2 concentrations for L01, and no effect for L25. Respiratory mortality increased by 1.31% (95% CI: 0.04%-2.59%) with L25, and showed no effect with L01. Cardiovascular deaths showed a 0.94% (95% CI: 0.32%-1.57%) increase with L01 but not with L25. These associations were greater than those observed in no-lag models for both mortality causes.
Conclusion: The application of different lags in the association between cause-specific mortality and SO_2 concentrations showed stronger and more precise effect estimates than the no-lag approach. Considering the important decline in SO_2 concentration levels following regulation implementation, these lagged effects imply greater reductions in mortality than those suggested by no-lag models.

EXPOSURE VARIABILITY AND BEHAVIOUR OF INDOOR AND OUTDOOR AIR POLLUTANTS IN PRIMARY SCHOOLS IN THE UNITED KINGDOM

Ariana Zeka, *Brunel University, United Kingdom*
Benjamin J. Jones, *Brunel University, United Kingdom*
Yulia Anopa, *Brunel University, United Kingdom*
Anna Koulkova, *Karolinska Institutet, Sweden, and Brunel University, United Kingdom*

Background and Aims: Current evidence suggests that exposure to common indoor air pollutants is associated with adverse health effects in children. This study was conducted to examine air quality in four primary schools in southern England, in order to establish daily, weekly and seasonal variability of pollutant concentrations within and between the schools, and to understand the behaviour of common indoor and outdoor air pollutants.
Methods: Four primary schools were selected for the study, in urban, suburban and rural environments with diverse size and socioeconomic backgrounds. Air quality monitoring was conducted in three rounds (autumn, winter, summer) during the academic year 2009-2010. Each round involved monitoring continuously for one week in four locations of typical children's exposure: generally three indoors and one outdoors. Measurements were carried out for particulate matter count for size range 0.5-5.0μm ($PM_{0.5-5.0}$), carbon dioxide (CO_2), carbon monoxide (CO), and nitrogen dioxide (NO_2).
Results: Findings revealed great variability in $PM_{0.5-5.0}$ concentrations during the week and between rounds of measurements within each school, and between schools. CO concentrations were greatly variable for the suburban and rural schools. Little variability was seen for NO_2 concentrations. CO_2 levels differed during the day and between days and rounds in each school, and between schools, depending on the daily activity patterns of children and practice of ventilation. Linear regression models predicted indoor levels for $PM_{0.5-5.0}$, CO and NO_2, based on contribution of outdoor concentrations to the same pollutant, ventilation measured by CO_2 concentrations and weather variables.
Conclusions: Study findings showed variability in pollutant exposure levels between locations, days and seasons in each school, and between all four schools. These differences related to school building design and location, ventilation practices and children's daily activities. These findings support the need for developing methodology for personal exposure assessment to air pollutants among school children.

BRINGING THE GERMAN HUMAN BIOMONITORING SYSTEM INTO LINE WITH REACH - ARE GERMAN ENVIRONMENTAL SURVEY (GERES) AND ENVIRONMENTAL SPECIMEN BANK (ESB) APPROPRIATE TOOLS?

Marike Kolossa-Gehring, *Umweltbundesamt/ Federal Environment Agency, Germany*
Kerstin Becker, *Umweltbundesamt/ Federal Environment Agency, Germany*
Ulrike Fiddicke, *Umweltbundesamt/ Federal Environment Agency, Germany*
Christine Schulz, *Umweltbundesamt/ Federal Environment Agency, Germany*
André Conrad, *Umweltbundesamt/ Federal Environment Agency, Germany*
Christa Schröter-Kermani, *Umweltbundesamt/ Federal Environment Agency, Germany*
Margarete Seiwert, *Umweltbundesamt/ Federal Environment Agency, Germany*

Background and Aims
The German population is still substantially exposed to chemicals. This can be demonstrated for chemicals some of which have already been banned, restricted or cannot be further regulated because of their geogenic origin. Exposure levels, their sources and development over time are well documented by the German human biomonitoring (HBM) system consisting of the German Environmental Survey (GerES) and the Environmental Specimen Bank (ESB). While in the past outdoor air and drinking water were particularly important, today's exposure of the German population is mainly due to nutrition, indoor air, the broad variety of consumer products, body-care products, and cosmetics. Thus, not only the importance of the exposure pathways changed, but also the chemicals of concern. However, even if being banned decades ago, exposure levels of persistent chemicals like DDT or PCB as well as carcinogenic substances difficult to prevent emphasise the necessity of continuously monitoring persistent, accumulating or carcinogenic substances in humans and the environment.
Methods: Germany started a joint activity on enhancing HBM aiming at identifying and measuring current substances of possible concern regarding health impacts or potentially frequent occurrence in the population. Background, motivation, and status of this project will be presented.
Results: Three out of six chemicals to be banned from 2014 due to REACh regulations were identified as relevant chemicals by the German HBM system: As demonstrated by GerES data exposure to the phthalates DEHP, BBP and DBP exceeded tolerable daily intakes in a considerable fraction of children living in Germany. Musk fragrances, diaminodiphenylmethane (MDA), and flame retardant HBCDD are heading the project's elaborated priority-list for HBM methods to be developed.
Conclusions: The new HBM methods will help a) prioritizing substances of concern with regard to their occurrence in humans and the environment, b) following up efficiency of REACh as well as c) optimizing assessment requirements.

PRENATAL EXPOSURE TO RESIDENTIAL OUTDOOR AIR POLLUTION AND INFANT MENTAL DEVELOPMENT: MODULATION BY ANTIOXIDANTS AND DETOXIFICATION FACTORS

Background and Aims: Effects of air pollution on children's neurodevelopment have recently been suggested. We aimed to assess whether prenatal exposure to residential outdoor air pollution impaired infant's mental development, and whether antioxidant/detoxification factors modulate this association.
Methods: In the Spanish INMA (Environment and Childhood) Project, 2,644 pregnant women were recruited at 1st trimester. Nitrogen dioxide (NO_2) and benzene were measured with passive samplers covering the study areas. Land-use regression models were developed for each pollutant and applied to predict outdoor air pollution levels at each women address during the whole pregnancy. Information on parental socio-demographic, life-style, and child characteristics was obtained by questionnaire. Maternal diet was obtained in the 1st trimester through a validated food frequency questionnaire. Maternal circulating vitamin D in pregnancy were determined by radioimmunoadsorbant assay. Around 14 months, infant mental development was assessed using the Bayley Scales of Infant Development.
Results: Median exposure was 28.1µg/m^3 for NO_2 and 1.2µg/m^3 for benzene. Exposure to NO_2 and benzene showed a negative association with mental development, though not statistically significant, after adjusting for a large array of potential confounders (• (95%Confidence Interval) = -0.74 (-3,73;2,26) and -1.40 (-3,71;0,91), for a doubling in each compound, respectively). Stratifying by antioxidant/detoxification variables, a significant negative relation of both compounds in infants with low maternal intakes of fruits and vegetables during pregnancy was observed (-3.62 (-6,57;-0,68) and -3.56 (-6,12;-1,00), respectively) although interaction terms were only borderline significant ($p<0.10$). A negative non-significant association in non-breastfed infants and in infants with low maternal levels of vitamin D was also found.
Conclusions: This study supports the hypothesis that prenatal exposure to residential air pollutants may adversely affect infant mental development, and that these effects may be limited to infants whose mothers have low levels of antioxidant intakes and/or detoxification factors.

Evaluation of Statistical Weighting Approaches for a Meta-analysis of Occupational Acrylonitrile Exposure and Lung Cancer Mortality

Hien Q. Le, E. I. du Pont de Nemours and Company, United States
J. Morel Symons, E. I. du Pont de Nemours and Company, United States
Kim H. Kreckmann, E. I. du Pont de Nemours and Company, United States
Wayne M. Lednar, E. I. du Pont de Nemours and Company, United States

Background and Aims: Meta-analysis provides a useful quantitative summary for occupational mortality studies. We conduct a meta-analysis for lung cancer mortality and occupational acrylonitrile exposure comprising all available published studies through the end of the year 2010. In addition, we evaluate weighting methods typically applied by standard meta-analytic approaches for estimating summary standardized mortality ratios (SSMR).

Methods: Results were abstracted from mortality studies for eleven occupational cohorts. National comparisons were reported for eight cohorts while regional comparisons were reported for seven cohorts. The SSMR was calculated by pooled analysis, and by fixed and random effects models following heterogeneity assessment. The relative change in proportional weight for each study-specific SMR was evaluated.

Results: Pooled SSMRs were 0.93 (95%CI: 0.84, 1.02) and 0.84 (95%CI: 0.74, 0.94) for results from the national and regional comparisons, respectively. Due to significant evidence of heterogeneity in the results for both national comparisons (p=0.01) and regional comparisons (p=0.05), random effects SSMRs were estimated as 1.02 (95%CI: 0.85, 1.22) and 0.96 (95%CI: 0.77, 1.19), respectively. Standard statistical weighting approaches to meta-analysis increased the relative proportional weights assigned to studies reporting SMRs greater than 1.0 while those studies reporting SMRs less than 1.0 had decreased proportional weights.

Conclusions: Consistent with published qualitative reviews, occupational acrylonitrile exposure is not significantly associated with lung cancer mortality. The current meta-analysis weighting approach may introduce bias relative to summary estimates from pooled analyses. This is due to increased proportional weights assigned to studies reporting SMR greater than 1.0 without regard to cohort size or number of observed mortality outcomes.

TOOLS FOR ASSESSING HEALTH IMPACTS OF CLIMATE CHANGE: LESSONS LEARNT FROM MALTA AND TURKEY

Tanja Wolf, Climate change, green health services and sustainable development, WHO Regional Office for Europe, Rome
Bettina Menne, Climate change, green health services and sustainable development, WHO Regional Office for Europe, Rome

Background and Aims: Within the framework of the CIRCE project, training in assessing health effects of climate change was provided and assessments of past and future impacts on health were done in Turkey and Malta.
Methods: The training package and the pilot training were targeted for national public health experts appointed to co-ordinate the development of a climate change and health strategy. Various CIRCE partners contributed to the development and delivery of the training. The objective of the training was in particular to enable participants to assess health impacts and to develop a climate change and health strategy, emphasizing the health sector role in adaptation and mitigation. Assessments were done in Malta and Turkey so far.
Results: In Turkey, the assessment of health risks of climate change has an emphasis on infectious diseases. Risks of vector-borne, water- and food borne diseases are growing. Crimean-Congo Hemorrhagic Fever, Hantaviruses and phleboviruses infections were recently detected in Turkey, and all were described to be associated with climate changes.
In Malta, an increase in summer temperatures is of concern to human health, especially in the elderly. Also air pollution (particulate matter, ozone), thunderstorms and flash floods and infectious diseases (food- and vector-borne diseases) put health at risk . In the Maltese assessment risk perception was considered, finding that 84 % of the Maltese population is aware of climate change but that Maltese public perceives climate change “only somewhat” as a threat to human health.
Conclusions: Adaptation actions in the area of Public Health include to strengthen health, social and environmental systems and services to improve their capacity to prevent, prepare for, and cope with climate change. At the same time, any mitigation and adaptation measures should integrate health issues at all levels; raise awareness to encourage healthy mitigation and adaptation policies in all sectors; increase the health and environment sectors’ contribution to reducing greenhouse gas emissions; share best practices, research, data, information, technology and tools at all levels on climate change, environment and health and to identify research gaps.

INTEGRATED ASSESSMENT MODEL FOR ESTIMATING HEAT RELATED MORTALITY DUE TO GLOBAL CLIMATE CHANGE: RESULTS FROM THE INTARESE PROJECT

Francesca K. de'Donato, *Department of Epidemiology, Lazio Regional Health Service*
Sari Kovats, *London School of Hygiene & Tropical Medicine*
Maud Huynen, *International Centre for Integrated Assessment and Sustainable Development (ICIS), Maastricht University*
Patrizia Schifano, *Department of Epidemiology, Lazio Regional Health Service*
Paola Michelozzi, *Department of Epidemiology, Lazio Regional Health Service*

Background and Aim: The INTARESE project developed a framework for integrated environmental assessment. We report findings from WP 3.7 "Climate" that developed a method to quantify heat-related mortality in Helsinki (population=570 thousand), London (population= 7.5 million) and Rome (population= 2.7 million), under current and future climates.
Methods: Published European pooled temperature-mortality functions were used to estimate age-specific heat-related summer mortality. Future populations were derived from national estimates scaled to age specific projections for the study area. Climate scenario data from regional climate models were used to estimate heat-related deaths in 2030 and 2050. Age-specific death rates were assumed constant and a policy scenario (introduction of heat prevention plan), was included in the model (reduction in mortality of 46% derived from an Italian multi-city study).
Results: Under the current climate, heat-related deaths during an "average" summer: were 58 (95%CI 15,106) in Rome, 180 (95%CI 15, 369) in London and 8 (95%CI 1,16) in Helsinki; while during a "hot" summer estimates rose to 477 (95%CI 123,865), 1320 (95%CI 110,2649) and 79 (95%CI 6,163) respectively. By 2030, "average" summer heat-related deaths are projected to rise to 120 (95%CI 33,214) in Rome, 259 (95%CI 20, 510) in London and 14 (95%CI 1,28) in Helsinki. With the introduction of policy (heat prevention plans) by summer 2030, deaths will be reduced to 65 in Rome, 141 in London and 8 in Helsinki.
Conclusions: Integrated models of climate change impacts are able to consider both climate and population scenarios (growth and ageing). There is limited information on effect modifiers which may reduce future impacts due to acclimatization (autonomous adaptation) or policy measures (planned adaptation). Using available evidence, we found that intervention measures may contribute in reducing the impacts of climate change on health.

THE IMPACT OF HEAT AND HEAT-WAVE EPISODES IN EUROPEAN CITIES

Daniela D'Ippoliti, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Paola Michelozzi, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Claudia Marino, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Michela Leone, *Department of Epidemiology – Lazio Regional Health Service, Italy*
on behalf of the EU-funded EuroHeat Project

Background and aims: In recent years several EU projects (PHEWE, EuroHeat, CIRCE) investigated the impact of high temperatures and heat-waves producing a broad description of health effects in European cities. Since these projects used two different approaches, time-series and episode analyses, results are not easily comparable.
The EuroHeat project evaluated the impact of heat-waves on mortality during the 1990-2004 years in 9 European cities, comparing estimates with a standardized definition of heat-wave and results showed large heterogeneity of the effect among cities.
In this analysis an integrated approach is used to evaluate the increase in risk due to both the effect of daily temperatures and heat-waves in the EuroHeat cities.

Methods: The impact of high temperatures on mortality is investigated using distributed lag nonlinear functions of temperature (DLNM models) including an indicator term for heat-wave (defined as 2 or more consecutive days with maximum apparent and minimum temperature above the 90th monthly percentile). The effect is estimated as percent increase in daily mortality in the elderly (65+ years) and for different duration of heat-waves.

Results: Results of the EuroHeat study showed great geographical heterogeneity of the effect of heat-waves among cities. The increase in mortality was up to 3-times greater during heat-waves of long duration and high intensity. Results showed a greater impact in Mediterranean (+21.8% total mortality) than in North-Continental (+12.4%) cities, whereas the heat-wave impact was stronger in North-Continental cities in 2003. These results are compared with estimates decomposed in the two components of risk due to the effect of daily temperatures and heat-waves.

Conclusions: This additional analysis provides a more complete and comparable evaluation of the heat effect on mortality in European cities, jointly estimating the effect of daily temperatures and heat-waves. Furthermore, results allow comparisons for nonlinear delayed effects of temperatures and harvesting.

SHORT TERM EFFECT OF HIGH TEMPERATURES ON MORTALITY IN MEDITERRANEAN CITIES: RESULTS FROM THE EU-FUNDED CIRCE PROJECT (CLIMATE CHANGE AND IMPACT RESEARCH: THE MEDITERRANEAN ENVIRONMENT)

Michela Leone, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Daniela D'Ippoliti, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Claudia Marino, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Francesca de'Donato, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Antonis Analitis, *Department of Hygiene and Epidemiology - University of Athens, Greece*
Klea Katsouyanni, *Department of Hygiene and Epidemiology - University of Athens, Greece*
Tanja Wolf, *WHO Regional Office for Europe, Italy*
Bettina Menne, *WHO Regional Office for Europe, Italy*
Paola Michelozzi, *Department of Epidemiology – Lazio Regional Health Service, Italy*

Background and aims: Current scenarios indicate that the Mediterranean area will be especially vulnerable to future climate change. The effect of heat has been widely studied in Europe while to a less extent in North Africa and the Middle East. In the CIRCE project, we estimated the short-term effect of Maximum apparent temperature (Tappmax) on total and cause-specific mortality, (by gender and age groups) during summer (April-September) in 10 Mediterranean cities (Athens, Bari, Barcelona, Istanbul, Lisbon, Palermo, Rome, Telaviv, Tunis and Valencia). The presence of harvesting effect was also evaluated.
Methods: Two time series approaches were performed: a linear threshold model (GEE) and a distributed lag nonlinear model (DLNM) to overcome the assumption of linearity. The first model estimated the overall effect of Tappmax (lag0–3) above a city-specific threshold, while the second estimated the effect of 1°C step increases considering different time windows (up to 30 days).
Results: For most cities, J-shaped curves, with differences in the threshold and the impact of high temperatures were observed. The relationship was weak in the hottest cities (Telaviv, Tunis and Valencia). The greatest effect on total mortality was found in the 65+ age group. The second analysis shows a difference in the effect of Tappmax for 1°C step increases along the temperature and lag distribution. The harvesting effect was observed only in few cities.
Conclusions: The results show that the effect of heat and its temporal structure differs between cities. The weaker effect in North-African cities can be explained by the lower proportion of elderly and local population adaptation to heat. On the contrary, the progressive aging in European people will increase the fraction of susceptible population. Differences in local demographic characteristics may explain the heterogeneity of the harvesting effect.

CHARACTERIZATION OF GLOBAL DNA METHYLATION AT LINE-1 IN A COHORT OF URBAN ASTHMATIC CHILDREN WITH A GRADIENT OF EXPOSURE TO HIGHWAYS

Toby C. Lewis	University of Michigan, Ann Arbor, MI, USA
Laura Rozek	University of Michigan, Ann Arbor, MI, USA
Adrienne Van Zomeren-Dohm	University of Michigan, Ann Arbor, MI, USA
Bhramar Mukherjee	University of Michigan, Ann Arbor, MI, USA
Xiaodan Ren	University of Michigan, Ann Arbor, MI, USA
Graciela B. Mentz	University of Michigan, Ann Arbor, MI, USA
Thomas G. Robins	University of Michigan, Ann Arbor, MI, USA
Elizabeth Hughes	Arab Community Center for Economic and Social Services, Dearborn, MI USA
Community Action Against Asthma Steering Committee	Detroit, MI, USA

Background and Aims: Asthma is a complex chronic disease with heterogeneous clinical expression and waxing and waning activity over the life cycle. Epigenetic modifications may be a mechanism to explain clinical variability. However, the relationship between environmental exposures, epigenetic changes, and health outcomes is unclear, particularly in young vulnerable populations.

Methods: This study builds on an investigation of the impact of near-highway residence on the health of asthmatic children, "The Community Action Against Asthma (CAAA) Diesel Study." In this pilot study, we measured global DNA methylation in cells from saliva in a cohort of urban asthmatic children. Children aged 6-14 with asthma were recruited based on the proximity of their residence to highways. DNA was extracted from saliva samples from 79 children and assessed for degree of DNA methylation at four loci within LINE-1. We assessed the association between methylation and gender, age, and exposure to highways.

Results: Methylation of LINE-1 loci was heterogeneous and ranged from a mean of 66% at site 3, to 74% at site 2, with an overall mean of 70% across the four sites. Girls were hypomethylated at site 3 (65.64%) compared to boys (67.11%, p=0.048) and this difference remained significant after adjustment for gender, race, asthma severity, exposure to tobacco smoke, and highway exposure. Neither current highway exposure status nor asthma severity were significant independent predictors of methylation. However, changes in methylation pattern with age differed across exposure groups, showing a steeper declining gradient in the high diesel exposure group.

Conclusions: Differences in global methylation measured at LINE-1 are site-specific, present relatively early in life and may vary by exposure to roadway-associated air pollution. There may be important gender-specific differences in methylation. Expanded studies of the epigenome in exposed populations will help clarify the role of epigenetic modifications in asthma phenotype.

EXPOSURE ASSESMENT: PAST AND PRESENT

Dana Boyd Barr, Emory University, Atlanta, GA.

Background and Aims: Biomonitoring of exposure to short-lived chemicals is inherently complex. Furthermore, the multiple biomarkers that can be used for biomonitoring complicate the interpretation, compromise the specificity of the measurement and hinder our ability to link exposure to disease.
Methods: We have explored multiple markers of exposure to organophosphorus (OP) insecticides, their longitudinal variability, matrix stability and measurement error. Our evaluations have employed state- of- the- art mass spectrometry-based methods to understand the distribution of OP pesticide biomarkers in multiple matrices, their long term stability in various matrices, the contributions from non-toxic preformed environmental degradates, and their overall relation and measurement error.
Results: While serum/plasma measurements of the intact pesticide are more selective biomarkers of exposure, blood levels of these chemicals tend to be in the low pg/mL range, typically about 3 orders of magnitude lower than urinary metabolite levels. While urinary metabolite levels are typically significantly correlated ($r>0.5$, $p<0.001$), mass balance between exposures and metabolite levels can rarely be achieved. Significant contributions to urinary metabolite levels from preformed metabolites can occur. In fact, in many common food matrices, up to 30% of the pesticide residue can be converted to its preformed metabolite under normal storage conditions. Protein adduct measurements of OP pesticides allow retrospective and time-integrated exposure assessments but the measurements are cumbersome and costly. Although OP pesticides are not believed to appreciably bioaccumulate, certain OP pesticides can be deposited in adipose tissue.
Conclusions: While measuring the intact pesticide in biological matrices is the most selective measurement of OP pesticide exposures, this measurement can be hindered by analytical limitations. Creative, holistic approaches to assess OP pesticide exposure must be undertaken in order to fully understand their relation to disease.

OZONE AND CHILDREN'S HEALTH: TOWARD IMPROVING CONSIDERATION IN AIR QUALITY DECISIONS

Monica Silver, *ASPH Fellow at the U.S. Environmental Protection Agency- Office of Children's Health Protection, USA*
Brenda Foos, *U.S. Environmental Protection Agency- Office of Children's Health Protection, USA*

Background and Aims: Ozone, regulated by the U.S. Environmental Protection Agency (EPA) under the National Ambient Air Quality Standards, has been shown to have detrimental effects on human respiratory health, with some of the greatest effects seen in children and asthmatics. EPA must rely on the epidemiologic data to understand how ozone impacts susceptible populations, such as children. This work aimed to understand the current state of the science, identify data gaps and other important considerations, and propose ideas for filling the data gaps, in an effort to improve comparison across studies of the effects of ozone on children's respiratory health.
Methods: A literature search was conducted to identify peer-reviewed epidemiology studies with child subjects and ozone air pollution exposure; results were restricted to respiratory-related effects. A review of the studies was completed, comparing/contrasting methods including: exposures, outcomes, lags, co-pollutants, confounders and effect modifiers, and other variables. Data gaps were qualitatively analyzed, and the relative strengths and weaknesses of the studies were assessed.
Results: Over forty studies were identified, with varying subject ages, ozone exposure classification and measurement, co-pollutants, model types, confounders, and outcomes (ranging from expiratory measures to school absences). Data gaps were identified, including the need for data concerning the consequences of long-term ozone exposure and the lack of understanding of ozone effect(s) during gestation and early development.
Conclusions: There are inconsistencies in the methods and results of the ozone epidemiology literature focusing on children's health, which may hinder the ability of science decision-makers to incorporate all of the available research into policy recommendations. It is hoped that this analysis will enable key data gaps on the effects of ozone on children's respiratory health to be filled, and will aid the consideration of this research in future decisions regarding air quality improvement.

HAIR NICOTINE CONCENTRATION IN NON-SMOKING WORKERS EXPOSED TO SECONDHAND TOBACCO SMOKE

Verónica Iglesias, *School of Public Health, Faculty of Medicine, University of Chile, Chile*
Marcia Erazo, *Faculty of Medicine, University of Chile, Chile*
Andrea Droppelmann, *Laboratory of Occupational Health, Institute of Public Health, Chile*
Paulina Aceituno, *University of Chile, Chile*
Cecilia Orellana, *University of Chile, Chile*
Ana Navas-Acien, *Bloomberg School of Public Health, Johns Hopkins University, USA*

Background and Aim: Exposure to secondhand tobacco smoke (SHS) is a public health problem of high concern worldwide. Restaurants and nightclubs are the work environments with higher levels of exposure to SHS. Our aim was to assess personal exposure to SHS, measured by hair nicotine concentrations, and to identify its main determinants in non-smoking workers of bars and restaurants in Santiago, Chile.

Methods: A total of 79 non-smoking workers from 25 bars and restaurants were recruited in 2008 and completed a questionnaire, provided a hair sample to measure nicotine concentrations and used two passive personal samplers to measure airborne nicotine concentrations for 24 hours. One sampler was used during working hours and one sampler was used outside the workplace. Hair and passive sampler filters were analized at the Johns Hopkins Bloomberg School of Public Health. Multiple linear regression models were used to evaluate determinants related to hair nicotine concentrations.

Results: The median age was 30 years (interquartile range (IQR) 24-40). The proportion of men was 66%. The median number of days of work was 6 (IQR 5-6) and median number of hours worked per day was 9 (IQR 8-11). Comparing the hair nicotine concentrations by type of location, we found that workers in smoking venues had higher concentration (13.7 ± 5.5 ng/mg) than workers of non-smoking venue (3.5 ± 5.5 ng/mg) and mixed venue (3.7 ± 6.2 ng/mg). A change in 1 $\mu g/m^3$ in air nicotine concentrations in the workplace was associated with 0.42 ng/mg higher hair nicotine concentrations (95% CI 0.19, 0.65; R^2=0.13). Women had 0.64 ng/mg lower hair nicotine concentrations compared to men (95%CI -0.92, -0.36; R^2=0.20).

Conclusions: Results show that workers of bars and restaurants are unprotected against SHS exposure. Due to health risks associated with SHS exposure, a comprehensive smoke-free legislation is urgently needed in Chile.

PROFESSIONAL PESTICIDE EXPOSURE AND DEPRESSION

Marc G. Weisskopf, *Harvard School of Public Health, USA*
Frédéric Moisan, *INSERM and UPMC, Université de Paris, France*
Christophe Tzourio, *INSERM and UPMC, Université de Paris, France*
Alexis Elbaz, *INSERM and UPMC, Université de Paris, France*

Background and Aims: Limited evidence suggests a possible association between pesticide exposure and risk of depression. We explored this association within a Parkinson's disease (PD) case-control study among agricultural workers in France (1998-2000) characterized by a high prevalence of exposure.
Methods: Pesticide exposure was assessed among 177 PD cases and 567 controls all of whom were farmers or farm workers participating in Mutualité Sociale Agricole (France). Self-reported treatment or hospitalization for depression and year of first instance were reported. Exposure classification was based on occupational history, and detailed in-person and on-farm interviews by occupational physicians. Time-dependent exposures were determined on a year-by-year basis from year of first agricultural work to date of interview or year of first depression report, whichever occurred first. Hazard ratios (HR) for depression were estimated using Cox proportional hazards models, stratified by region, adjusted for PD status, age, sex, smoking, education, and history of head trauma. Multiple imputation was used to impute missing values of pesticide families. Analyses based on complete-data and imputed datasets were performed.
Results: Depression was reported by 83 subjects with a mean age of onset of 49 years (standard deviation=14; range=15-77). Ever exposure to herbicides was strongly associated with depression (HR: 2.83; 95% confidence interval [CI]: 1.15-6.97), but exposure to insecticides or fungicides were not. Results were similar when restricted to PD controls or men only. Compared to those never exposed to herbicides, the HR among those exposed for <137 hours (median) was 2.0 (95% CI: 0.8-5.2), and among those exposed ≥137 hours was 3.5 (95% CI: 1.3-9.9). Among specific herbicide families, only dinitrophenol herbicides were significantly associated with depression in both complete-data (HR: 3.35; 95% CI: 1.47-7.65) and imputed (HR: 2.36; 95% CI: 1.04-5.36) datasets.
Conclusions: Our results support an association between depression and professional pesticide exposure, in particular to herbicides.

THE INFANTS' ENVIRONMENTAL HEALTH (ISA) STUDY: A BIRTH-COHORT STUDY WITH AN ECOSYSTEM HEALTH APPROACH IN LIMÓN, COSTA RICA

Berna van Wendel de Joode, *Universidad Nacional, Costa Rica*
Ana María Mora, *Universidad Nacional, Costa Rica; University of California at Berkeley, USA*
Leonel Córdoba, *Universidad Nacional, Costa Rica*
Juan Camilo Cano, *Universidad Nacional, Costa Rica*
Rosario Quesada, *Universidad Nacional, Costa Rica*
Karla Solano, *Universidad Nacional, Costa Rica*
Clemens Ruepert, *Universidad Nacional, Costa Rica*
Brenda Eskenazi, *University of California at Berkeley, USA*
Catharina Wesseling, *Universidad Nacional, Costa Rica*
Christian Lindh, *Lund University, Sweden*

Background and Aims: In Costa Rica, pesticide use at large-scale banana plantations includes permanent use of chlorpyrifos-impregnated bags and weekly aerial spraying of mancozeb, an ethylene bisdithiocarbamate (EBDC) fungicide (Barraza et al., 2011). The ISA study aims to evaluate and reduce pesticide-related health risks in infants living in banana growing areas.
Methods: The study population includes 450 mother-child pairs from the Matina County, with intensive large-scale banana farming. To assess prenatal pesticide exposure, women's urine samples were collected during the first, second and third trimester of pregnancy. Also, environmental samples such as dust and soil samples were collected. To obtain information on sociodemographic characteristics, lifestyle habits, occupational history, and pesticide exposure, structured questionnaires have been administered to the women during pregnancy and postpartum. Infants' birth outcomes have been abstracted from the newborns' Official Cards of Health. The association between prenatal pesticide exposure and fetal growth will be examined using multiple linear regression models.
Results: To date, we have enrolled 370 mother-child pairs of whom about 100 women have delivered.
About 25% of the participants live less than 100 meters away from the banana plantations. To assess prenatal mancozeb, chlorpyrifos, and pyrethroid exposures, urine samples (n=468) of 257 pregnant women are being analyzed for the pesticide metabolites ethylenethiourea (ETU), 3,5,6-trichloro-2-pyridinol (TCPy) and phenoxybenzoic acid (PBA), respectively.
In 12 of the 40 villages, environmental exposure was measured on four different times using passive and active air sampling and recollecting dust and water samples and are being analyzed for ETU, chlorpyrifos, and pyrethroid concentrations.
Conclusion: We will compare environmental exposure and personal exposure estimates. We will present variability in infants' prenatal exposure levels over time. The results of the relationship between prenatal pesticide exposure to chlorpyrifos, mancozeb and pyrethroids in relation to birthweight, and length of gestation will be presented for approximately 250 children.

RELATION OF CHRONIC ENVIRONMENTAL LEAD EXPOSURE TO DEPRESSION AND ANXIETY SYMPTOMS IN OLDER WOMEN

Ki-Do Eum, *Harvard School of Public Health, USA*
Susan A. Korrick, *Brigham and Women's Hospital and Harvard Medical School, USA*
Jennifer Weuve, *Rush University Medical Center, USA*
Olivia Okereke, *Brigham and Women's Hospital and Harvard Medical School, USA*
Laura Kubzansky, *Harvard School of Public Health, USA*
Howard Hu, *University of Michigan School of Public Health, USA*
Marc G. Weisskopf, *Harvard School of Public Health, USA*

Background and Aims: Environmental lead exposure has been associated with adverse cardiovascular and cognitive outcomes, which are themselves correlated with psychological symptoms. Yet few studies have examined links between lead exposure and psychological symptoms. We explored the association between bone lead—a biomarker of cumulative lead exposure—and depression and anxiety symptoms among older women.
Methods: We measured patella and tibia bone lead by K-X-Ray-Fluorescence, and obtained repeated measures of depression and anxiety symptoms using the Mental Health Index 5-item subscale (MHI-5) and Crown-Crisp Index phobic anxiety scale (CCI) in 615 women in the Nurses Health Study. We analyzed MHI scores as a continuous variable using linear regression and estimated the odds of a CCI score ≥4 using generalized estimating equations, in both cases accounting for correlation between repeated outcomes (MHI: 3; CCI: 2) and adjusting for potential confounders.
Results: The average age of participants was 61 (sd=6) years at the time of bone lead measurement. While tibia lead was associated with moderately worse MHI-5 and CCI scores among all women, results were much stronger among women who, at bone lead measurement, were premenopausal or had been consistently on hormone replacement therapy (HRT) since menopause. In these analyses, women in the highest tibia lead tertile scored 8.16 points worse (95% CI: -11.60, -4.72; p-trend<0.0001) on the MHI-5 than women in the lowest tertile, and had increased odds of high phobic anxiety (CCI ≥4; OR=2.41; 95% CI: 1.06-5.50; p-trend=0.04). We found no relation of patella lead to depression and anxiety symptoms.
Conclusions: Our results support an association of cumulative environmental lead exposure with increased risk of depression and anxiety symptoms among older women. Weaker results when including women not consistently on HRT after menopause may be an artifact of increased error in estimating cumulative exposure with bone lead among these women.

CAN HEALTH IMPACT ASSESSMENT (HIA) BE A PLATFORM FOR SYNERGY BETWEEN ENVIRONMENT AND HEALTH? A CROSS-COUNTRY COMPARISON

Maya Negev, *Ben Gurion University of the Negev, Be'er Sheva, Israel*
Nadav Davidovitch, *Ben Gurion University of the Negev, Be'er Sheva, Israel*
Hagai Levine, *Ben Gurion University of the Negev, Be'er Sheva, Israel*
Rajiv Bhatia, *San Francisco Department of Public Health, University of California San Francisco, USA*
Jenny Mindell, *University College London, London, UK*

Background and aims: Natural and manmade physical environments are influential determinants of health. Sound public policy requires consideration of health, and working across diverse institutions; however, institutional fragmentation and inter-disciplinary specialization are potent barriers to this end. HIA practice is promoted internationally as a means of assessing health impacts of policies, plans and projects. We examine whether using HIA in decision-making has led to changes in inter-sectoral collaboration.

Methods: We utilize a case study approach, describing the evolution and outcomes of HIA initiatives in three countries. We examine whether HIA has led to procedural and substantive outcomes changes, including working relationships between environmental and health disciplines; inclusion of health in assessment and design practices; public and political understanding of the health-environment nexus; and policy, legislation, and regulations. We identify obstacles to inter-sectoral cooperation that HIA may trigger or expose.

Results: The country cases demonstrate diverse relationships, coalitions and disputes between environment and health professionals. In the USA, HIA has demonstrated the need for and feasibility of greater inclusion of health effects in the existing EIA process. It has been a catalyst for advancing health objectives with participation of economic development, transportation, and land-use planning institutions. In Israel, HIA exposed tensions between environment and health professionals, partially overcome in joint work to legislate HIA within EIA, stemming from realization of mutual interests. In the UK, HIA has often been undertaken in cases in which EIA is not conducted, such as policies and urban regeneration, developed and conducted by health practitioners independently of environmental practitioners.

Conclusions: The coalitions of health and environment experts recently formed around promoting HIA demonstrate it is a common ground for advancing mutual interests. While these interdisciplinary coalitions are complex and differences are hard to mitigate, they enable overcoming antagonism, and can serve as a platform for synergy.

ENHANCING THE MEDICATION SAFETY OF INFANTS AND CHILDREN

Shu-Hua Wu, *Chung Jen College of Nursing, Health Sciences and Management; CTUST, Taiwan*
Li-Feng Lin, *Central Taiwan University of Sciences and Technology, Taiwan*

Background and Purposes: The medication safety knowledge of main caregivers of infants and children directly or indirectly affect the infants/children's health. This study purpose was aimed to enhance the medication safety knowledge and ability of the main caretakers of infants/children, and help them to clearly describe the physical conditions of infants/children, understand the explanation of the usage of medicine bag, exactitude takes medicine, as well as to discuss with pharmacist when have medication problem or questions.
Methods: The subjects chosen from the main caregivers for infants and children while they take baby to received vaccination at a local health center in July 2010. Based on the medication safety need assessment found that the subjects lack of medication safety knowledge. Therefore, the researcher designed medication safety materials for medication safety education, including:(1) clearly describe the physical conditions of infants/children when go to medical clinic;(2) understand the explanation of the usage of medicine bag; (3) understand the medication usage and exactitude takes medicine; (4) to discuss with pharmacist or doctor when have medication problem or questions. To promote the main caregiver medication safety while the take care infants and children. After medication safety education, the closed end questionnaire was used to evaluate the effects of the medication safety educational program by telephone.
Results: After medication safety education for the main caregivers, the score of the medication safety knowledge of the main caregivers was increased from 79.22 to 98.15, show that the medication safety education was effective.
Conclusions: This study may be of impotence in Enhancing the Medication Safety of Infants and Children. As well as providing the community health workers with a better understanding of how to promote and enhance the medication safety of Infants and Children.

THE COMPLEXITY OF STAKEHOLDER PARTICIPATION IN HEALTH IMPACT ASSESSMENT (HIA)

Maya Negev, *Ben Gurion University of the Negev, Be'er Sheva, Israel*
Nadav Davidovitch, *Ben Gurion University of the Negev, Be'er Sheva, Israel*

Background and aims: Participation of stakeholders, both public members and professionals, is an integral part of HIA. Nevertheless, participatory HIA practices barely recognize or address the complexity which characterizes participation of diverse stakeholders. Our aim was to study participatory practices within HIA using a concrete case-study of multi-ethnic and multi-disciplinary HIA of a large metropolitan plan.

Methods: This research took place within the framework of an HIA regarding a metropolitan plan in the south of Israel that includes among other components a large industrial park and unrecognized Bedouin villages. The research included participant observation of the process, as well as in-depth interviews with the stakeholders and focus groups. The data was analyzed in qualitative methods.

Results: During the scoping stage of the HIA, the stakeholders scoped the environmental limitations zoning surrounding a hazardous industry and hazardous waste site. Process analysis revealed that stakeholders possess multiple types of knowledge, data and interests, often contradictory. These lead in turn to stakeholders speaking different languages and possessing different approaches to health, which may not be possible to mitigate within the framework of an HIA process. For example, the views of stakeholders regarding the required zoning surrounding the hazardous site ranged from 0 to 32km, based on diverse sets of data such as epidemiological studies, monitored emissions, modeling and local knowledge. Interests included employment, real estate, environmental quality and reputation alongside health.

Conclusions: Stakeholders in HIA are situated in different and often conflicting positions. The current frameworks of participation in HIA, and more widely the current culture of participation in decision-making, do not address this complexity. The presentation will include suggestions for modifying the current methods, taken from work on issues such as complexity and multiculturalism, in order to advance HIA towards meeting its goal to maximize health gain and minimize health inequality.

INDIGENOUS CHILDREN'S CHLORPYRIFOS EXPOSURE IN BANANA AND PLANTAIN COMMUNITIES IN TALAMANCA, COSTA RICA

Berna van Wendel de Joode, *Universidad Nacional, Heredia, Costa Rica*
Douglas Barraza, *Universidad Nacional, Heredia, Costa Rica; Wageningen University, The Netherlands.*
Clemens Ruepert, *Universidad Nacional, Heredia, Costa Rica*
Ana María Mora, *Universidad Nacional, Heredia, Costa Rica; University of California at Berkeley, USA*
Leonel Córdoba, *Universidad Nacional, Heredia, Costa Rica*
Catharina Wesseling, *Universidad Nacional, Heredia, Costa Rica*
Donna Mergler, *Université du Québec à Montréal, Canada*
Christian H. Lindh, *Lund University Hospital, Lund, Sweden*

Background and Aims: In Costa Rica, chlorpyrifos-treated plastic bags are used to protect the banana and plantain fruits from insects and to fulfil product standards. The aim of this study was to evaluate children's exposure to chlorpyrifos in communities situated nearby banana and plantain farms in Costa Rica.
Methods: The study was performed in three communities: in two, chlorpyrifos-treated bags were used in surrounding banana and plantain plantations whereas in the third community mostly not. In total, 140 children donated a urine sample of which forty on more than one occasion (n=207). TCPy levels were measured as a biomarker for chlorpyrifos exposure. Also environmental samples were taken.
Results: Children from the banana and plantain community had higher TCPy levels in urine than children from the organic community, GM=2.6; 2.2 and 1.3, respectively. In the plantain community boys had higher levels than girls, GM=2.9 versus 1.5 µg/g creatinine, p=0.01, whereas in the other communities levels were similar for both sexes. Children from the banana community were more homogenous exposed that children from the plantain community. In the banana and plantain community, chlorpyrifos was detected in several environmental media, including children's (n=12) hand and footwash samples. Median estimated values of the Absorbed Daily Dose of children from the banana and plantain community was five times the chronic US-EPA established reference doses (RfD).
Conclusions: Children living in the vicinity of plantations that use chlorpyrifos-treated bags are being exposed and at risk for overexposure. Measures are required to reduce this exposure.

HEALTH IMPACTS OF THE BUILT ENVIRONMENT: PHYSICAL INACTIVITY, EXPOSURE TO AIR POLLUTION, AND ISCHEMIC HEART DISEASE

Steve Hankey, *University of Minnesota, USA*
Julian D. Marshall, *University of Minnesota, USA*
Michael Brauer, *University of British Columbia, Vancouver, Canada*

Background: Physical inactivity and exposure to air pollution are important risks globally. Urban planning and the built environment may influence exposures to these risk factors in different ways and thus differentially impact the health of urban populations.
Aims: To investigate the built environment's influence on air pollution exposure and physical inactivity and subsequent health impacts.
Methods: We use a regional travel survey to estimate within-urban variability in physical inactivity and air pollution exposure ($PM_{2.5}$, NO_x, O_3) for ~30,000 individuals in Los Angeles. We then estimate the resulting risk for ischemic heart disease (IHD) using literature-derived dose-response values for the general public and for a sensitive subpopulation. We compare estimated IHD mortality risks between neighborhoods based on "walkability" scores, and conduct sensitivity analyses to explore robustness of our results.
Results: The proportion of non-sedentary individuals is ~2× larger in high- vs. low-walkability neighborhoods (24.9% vs. 12.5%); however, since a small share of the total population is physically active, between-neighborhood variability in estimated IHD mortality attributable to physical inactivity is modest (7 fewer IHD deaths per 100,000 in low- vs. high-walkability neighborhoods). Since spatial patterns differ for air pollutants, risks from air pollution exposure are similar between neighborhoods (9 fewer [13 more] IHD deaths per 100,000 for $PM_{2.5}$ [O_3] in low- vs. high-walkability neighborhoods). This suggests health benefits from increased physical activity may be realized in high-walkability neighborhoods only because of tradeoffs in air pollution exposure. Comparisons to data from other cities suggest our core conclusions are not unique to Los Angeles.
Conclusions: Accounting for exposure to air pollution is a critical aspect of planning for more clean and health-promoting cities.

THE EFFECTS OF HIGH IODINE INTAKE ON PERCHLORATE-RELATED DECREASES IN THYROID HORMONE, NHANES 2001-2

Lara Cushing
Allan H. Smith, PhD
Mark D. Miller, MD
Craig Steinmaus, MD

Background: Perchlorate is an oxidizing agent used to manufacture rocket fuel, munitions, and other products, and exposure in the U.S. is ubiquitous. Perchlorate inhibits iodide uptake into the thyroid and can decrease thyroid hormone production. Thyroid hormone is critical for proper neurodevelopment, and even small decreases in thyroid hormone during pregnancy have been linked with significant developmental effects in children. Recent evidence suggests that common environmental perchlorate exposures could decrease thyroid hormones in people with low iodine intake. This has led to the suggestion that all pregnant women should receive iodine supplementation. However, some data suggest that high iodine intake might also cause thyroid suppression.
Methods: Data from the 2001-2 National Health and Nutrition Examination Survey on serum thyroid hormones and urine perchlorate and iodine, and linear regression analyses, were used to assess whether previously observed perchlorate-related decreases in thyroid hormone might be greater in people with high iodine intakes.
Results: In women with urinary iodine <100 µg/L, a 10-fold increase in urinary perchlorate (about the 10^{th} to the 90^{th} percentile) was associated with an 11.4% decrease in serum thyroid hormone levels ($p<0.01$; $n=383$). In women with high urinary iodine (>95^{th} percentile of 600 µg/L) the effect was 3-times greater. That is, a 10-fold increase in urinary perchlorate was associated with a 34.7% decrease in serum thyroid hormone levels ($p=0.02$; $n=53$). No clear effect was seen in women with moderate urinary iodine levels (100-600 µg/L).
Conclusions: These data provide some indication that high iodine intake might worsen the thyroid effects of perchlorate. Although the sample size was small, the finding in the high iodine group is consistent with other studies in high iodine populations. These findings highlight the need to consider further research on the potential adverse effects of high iodine before new widespread iodine supplementation programs are begun.

ENVIRONMENT-FRIENDLY HABITS – WHO IS WILLING TO ADAPT?

A SURVEY IN A HEALTH CARE SETTING

Ralph Guggenheim, Tel Aviv University Faculty of Medicine, Sigal Rosenfeld, Dia Amiton

Hagalil St. 16, Netanya, Israel

Background and Aims

The health care setting is not a priori related to environment concerns. Even so, we assumed that while in a doctor's office, people may be willing to reflect about aspects of quality of life other than their health problems, such as environment issues. Effectively complying with the needs of the environment will require the cooperation of a large part of the population. Knowing the views of an unselected population, as encountered in a doctor's office, can be a first step in order to engage people to adapt to environment-conforming behavior. We inquired about awareness and interest in environment issues with visitors to a doctor's practice.

Methods

People visiting the practice were asked in consecutive order to fill out a 29 question survey, while they were sitting in the waiting room, before being seen by the physician.

The questions asked involved: the degree to which the environment was seen as endangered today and in the future, people's behavior relating to consumption and waste production, impact on the state of health as a result of environment influences, and willingness to make changes towards environment-friendly habits.

Results

129 questionnaires were filled out; the rate of participation was 59.7% of all visitors.

21 questions inquired about concern for environment issues; 73.8% of answers expressed concern. In 8 questions dealing with cooperation in favor of environment issues, 79.1% of answers expressed willingness to change environment behavior.

Conclusions

Participants in this survey showed significant interest in environment issues and willingness to contribute to their improvement, even though they were faced with the subject unexpectedly and with minimal preparation. It is clear that expression of concern is not equivalent to action. The results of the survey could serve as a stimulus to arouse discussion and facilitate changes in

behavior. It could be made more representative by applying it to additional settings, whether health institutions or other public settings.

GENETIC MODIFICATION OF THE ASSOCIATION BETWEEN DIOXIN EXPOSURE AND PUBERTAL ONSET IN A COHORT OF RUSSIAN BOYS

Mary M. Lee, *University of Massachusetts Medical School, Worcester, Massachusetts, USA*
Boris Revich, *Institute of Forecasting (RAS), Russia*
Russ Hauser, *Harvard School of Public Health, USA*

Background and Aims: Dioxins are environmental pollutants with various reproductive toxicities, possibly including delayed pubertal onset. Dioxin susceptibility varies widely between animal species, but it is unknown whether genetic polymorphisms affecsusceptibility in humans. In this prospective cohort of Russian boys, we assessed whether the observed associations betweenserum dioxin concentrations and pubertal onset differed by genotype.
Methods: 337 tagging single-nucleotide polymorphisms (SNPs) were selected from genes related either to dioxin metabolism or to pubertal development. Gene-environment interactions were assessed using two different statistical methods, considering both peripubertal and maternal serum dioxin concentrations, and pubertal onset defined both by testicular volume (TV) or genitalia staging (G2).
Results: The 408 boys were 8-9 years old at study entry, with a median serum TEQ of 21 pg/g lipid for boys and 25 pg/g lipid for their mothers. Using the first statistical method, in which SNPs are first screened for a significant marginal association with each outcome, two SNPs showed significant interactions with the sons' peripubertal serum dioxin concentration, after adjustment for multiple comparisons. One of the interactions was seen for TV pubertal onset, in the gene for estrogen receptor-α (ESR1). The other was for G2 pubertal onset in the SRC gene. Using the second method (i.e. including all SNPs regardless of marginal associations), significant interactions were seen for two SNPs in the glucocorticoid receptor (GR) after adjustment for multiple comparisons (both of them for G2 pubertal onset, with the sons' peripubertal serum dioxin concentration). No significant interactions were identified for maternal dioxin concentrations.
Conclusions: This is one of the first large studies to assess genetic susceptibility to dioxins. The findings suggest several genes which may modify the associations between dioxin and pubertal onset, although the results are sensitive to the choice of statistical method, and the method of assessment of pubertal onset.

ARSENIC AND T CELL FUNCTION IN AN ENVIRONMENT-MATERNAL INTERACTION STUDY (ARTEMIS)

Olivier Humblet, *Stanford University School of Medicine, Stanford, USA*
Susan A. Korrick, *Brigham and Women's Hospital and Harvard Medical School, Boston, USA*
Zhigang Li*, Dartmouth Medical School, Hanover, USA*
Margaret R. Karagas*, Dartmouth Medical School, Hanover, USA*
Kari C. Nadeau*, *Stanford University School of Medicine, Stanford, USA*

Background and Aims: Arsenic (As) is a common environmental toxicant to which millions of people are exposed via contaminated drinking water. Arsenic is linked to increased risk of infectious diseases and cancer, but its mechanism of action is uncertain. The immune system, especially T cell function (and specifically T regulatory cells (Treg), which play a critical role in suppressing inflammation), may be an important mediator of As toxicity.
Methods: The study will use prospectively collected data from a New Hampshire cohort of pregnant women and their infants to assess whether *in utero* As exposure (maternal pregnancy urine As) is associated with: 1) impaired T cell and Treg function in infant cord blood, and 2) decreased immune indicators of placental tolerance. We will 3) conduct exploratory analyses of cord blood T cell and Treg function as predictors of enhanced risk of childhood infections and atopic disorders, and 4) test the feasibility of assessing the relation of As with vaccine response, Treg numbers, and atopy (including IgE levels) in 1 year olds.
Preliminary Results: To date we have 213 cord blood and 162 placenta samples, with the goal of collecting at least 250 of each. The mean pregnancy urinary As concentration (excluding arsenobetaine) is 6.7 (range 0.4 – 288) ug/L. In preliminary analyses of cryopreserved cord blood lymphocytes from 16 newborns, the correlation between log(urine As) and T cell proliferation is 0.63 ($p=0.01$) and for Treg function is -0.33 ($p=0.21$).
Conclusions: Our preliminary findings support a potential role of *in utero* As exposure in altering newborn T cell, including Treg, function. With complete data, we will more fully address the impact of As on immune markers in cord blood and placenta to help inform whether As-related changes in these immune markers affect the risk of childhood infectious and allergic diseases.

AMBIENT AIR POLLUTION AND REGULATORY T-CELL FUNCTION IN ASTHMATIC CHILDREN

Olivier Humblet, *Stanford University School of Medicine, Stanford, USA*
Ira Tager, *School of Public Health, University of California, Berkeley*
Frederick W. Lurmann, *Sonoma Technology Inc., Petaluma, CA*
Kari C. Nadeau, *Stanford University School of Medicine, Stanford, USA*

Background: Exposure to ambient air pollution (AAP) is associated with increased severity and incidence of asthma, a disease characterized by increased inflammation. Regulatory T-cells (Treg) are newly discovered suppressors of immune response which are involved in asthma pathogenesis, and whose development and activity is regulated by the Foxp3 locus. We hypothesized that exposure to nitrogen dioxide (NO_2), ozone (O_3), and fine particulate matter ($PM_{2.5}$) would negatively affect function of Tregs.
Methods: Immune function was assessed in blood collected in early 2009 from 71 asthmatic children enrolled in a prospective cohort study in Fresno, CA. Treg cells ($CD4^+CD25^{hi}CD127^{lo}$) were purified by flow cytometry, then used in standard ^3H thymidine proliferation assays, flow cytometry, quantitative PCR, and chemotaxis assays. Daily AAP exposure for each child was estimated using a microenvironment model integrating data from multiple air monitoring sites. For this preliminary analysis, midway through participant recruitment, we assessed the associations of Jan. – Oct. 2008 daily average NO_2, O_3, and $PM_{2.5}$ concentrations with Treg function.
Results: Median age at blood draw was 14 years. Distribution of GINA asthma severity scores at baseline: 1 = 32%, 2 = 51%, 3 = 13%, 4 = 4%. Median AAP concentrations were 6.8 ppb for $N0_2$, 18 ppb for O_3, and 11 $\mu g/m^3$ for $PM_{2.5}$. No significant correlations were seen between any measures of immune function and exposure to NO_2, O_3, or $PM_{2.5}$. However, Foxp3 methylation was marginally-significantly inversely correlated with both O_3 ($r = -0.22$, $p = 0.06$) and NO_2 ($r = -0.18$, $p = 0.13$).
Conclusions: No significant associations were seen between AAP exposure and Treg function, possibly due to the small sample size of this preliminary analysis. Once recruitment is complete, this analysis will be re-done in the full population, with additional immune parameters.

MERCURY USE IN ARTISANAL SMALL-SCALE GOLD MINING IN ZIMBABWE: DISABILTY-ADJUSTED LIFE YEARS (DALYS) OF CHRONIC MERCURY INTOXICATION

Nadine Steckling, *Bielefeld University, School of Public Health, Department 7 Environment & Health, Bielefeld, Germany; Institute of Public Health, Medical Decision Making and Health Technology Assessment, Department of Public Health and Health Technology Assessment, UMIT - University for Health Sciences, Medical Informatics and Technology, Hall i.T., Austria*

Claudia Hornberg, *Bielefeld University, School of Public Health, Department 7 Environment & Health, Bielefeld, Germany*

Background and Aims: Artisanal small-scale gold mining (ASGM) is a poverty-driven activity in Zimbabwe and other developing countries. Mercury is used for extracting gold because it is readily available and effective. The environmental burden of disease method developed by the World Health Organization was used to estimate the impact of mercury use in ASGM on the health status of the Zimbabwean population.

Methods: Epidemiological and demographic information was collected on the Zimbabwean population (total, practicing ASGM, living in ASGM areas, chronic mercury intoxicated) through two field studies, international literature and official databases. Missing data were modeled using the software tool DisMod II. Disability-adjusted life years (DALYs) were calculated for 2004. Overestimation was avoided by estimating the lowest assumable DALY-scenario. The estimates were compared with disease burdens published in the recent *Global Burden of Disease* study.

Results: Chronic mercury intoxication attributable to the use of mercury in ASGM caused 4.24 DALYs per 1,000 inhabitants in Zimbabwe in 2004 (preliminary results), most of it attributable to male miners (65% of total DALYs). The total estimated burden of 52,932 DALYs calculated was comparable with the burden due to asthma in Zimbabwe. In Europe, the burden of road traffic accidents and hearing loss each also caused over 4 DALYs/1,000 inhabitants. Likewise comparable were cancer (except lung) in Hungary (highest country rate in the world, 4.1 DALYs), and cardiovascular diseases in Germany (3.9 DALYs), both attributable to indoors and outdoors air pollution, water, sanitation and hygiene.

Conclusions: The use of mercury in ASGM was identified as a serious public health issue. It is comparable with well-recognised international public health problems, although the lowest scenario was estimated. Interventions to reduce the burden are urgently needed. The analysis is limited by the data-scarcity. Refined analyses are currently in progress to improve the quality of the first estimates.

INDOOR AIR POLLUTION AND BLOOD PRESSURE IN ADULT WOMEN LIVING IN RURAL CHINA

Jonathan A. Patz, *Department of Population Health/Nelson Institute for Environmental Studies, University of Wisconsin-Madison, USA*
Leonelo E. Bautista, *Department of Population Health, University of Wisconsin-Madison, USA*

Background and Aims: Almost half the world's population is exposed to indoor air pollution (IAP) from use of coal and biomass fuels for domestic energy[1]. We investigated the association of IAP exposure with elevated blood pressure, which is an important risk factor for renal and cardiovascular disease.

Methods: We measured 24-hr personal integrated gravimetric exposure to particles less than 2.5 microns in aerodynamic diameter ($PM_{2.5}$) and systolic (SBP) and diastolic blood pressure (DBP) in the summer and winter among 280 women ≥25 years old living in rural households using biomass fuels in Yunnan, China. We investigated the association between $PM_{2.5}$ exposure and SBP/DBP using mixed-effects models with random intercepts to account for correlation among repeated measures.

Results: Personal 24-hr exposure to $PM_{2.5}$ ranged from 22 to 634 $\mu g/m^3$ in winter and 9 to 492 $\mu g/m^3$ in summer. A one log-$\mu g/m^3$ increase in $PM_{2.5}$ exposure was associated with 2.2 mmHg (95% CI: 0.8, 3.7; p=0.003) higher SBP and 0.5 mmHg (95% CI: -0.4, 1.3; p=0.31) higher DBP among all women, but the effect was dependent on age. Among women >50 years old, a one log-$\mu g/m^3$ increase in $PM_{2.5}$ exposure was associated with 4.1 mmHg (95% CI: 1.5, 6.6; p=0.002) higher SBP and 1.8 mmHg (95% CI: 0.4, 3.2; p=0.01) higher DBP. $PM_{2.5}$ exposure was positively associated with SBP among younger women, but the association was not statistically significant.

Conclusion: Our results suggest that $PM_{2.5}$ exposure from biomass combustion may be a risk factor for elevated blood pressure, and hence for cardiovascular diseases. Issues of energy and IAP should therefore be considered in the formulation of policies and interventions aimed at reducing the burden of cardiovascular disease in China and other countries where domestic biomass fuel use is common. Our findings should be confirmed in longitudinal studies.

Work stress and burnout among high tech shift workers in southern Taiwan

Chien-Yuan Huang[1,2] , How-Ran Guo[2,3]

[1]Tainan Science Park Clinic, Chi-Mei Medical Center, Tainan, Taiwan
[2]Department of Environmental and Occupational Health, National Cheng Kung University, Tainan, Taiwan
[3]Department of Occupational and Environmental Medicine, National Cheng Kung University Hospital, Tainan, Taiwan

Objective: Work stress, which might lead to the acculmulation of stress and in turn lead to various physical and mental illnesses, has become an important issue among workers in the high-tech industry. In recent years, there were many reports on the chronic fatigue associated with work stress, but few were from Taiwan. Therefore, we conducted a study to evaluate the associations between work stress and burnout among high tech workers.
Materials and Methods: We recruited workers working in a scientific park in southern Taiwan between October 1 and December 31, 2010. Information on demographic characteristics was collected through a self-administrated questionnaire. Participants also completed a job content questionnaire and reported habits of smoking and drinking.
Results: There were 774 workers participated in this study. We observed positive associations between work stress and age, marriage status, shift work, work position, perceived stress, economic stress, insomnia, depression, burnout for personal reasons, work-related burnout, over-commitment, and client-related burnout (all with $p < 0.05$). After adjusting for other factors, we found male gender (adjusted odds ratio [AOR] =2.09, 95% confidence interval [CI]: 1.26-3.49), shift work (AOR =1.93, 95% CI: 1.24-3.03), mild depression (AOR =1.69, 95% CI: 1.03-2.75), severe depression (AOR =5.35, 95% CI: 1.59-18.04), work related burnout (AOR =5.76, 95% CI: 2.00-16.59), and over-commitment (AOR =2.12, 95% CI: 1.07-4.18),were independent risk factors of work stress.
Conclusion: Among the high tech shift workers, work stress is associated with male gender, shift work, depression, work-related burnout and over-commitment. Therefore, intervention strategies for work stress should take into consideration these factors.

Key words: shift work, work stress, job content questionnaire and work fatigue.

RELATION BETWEEN COMMUTER AND EXPOSURE TO POLLUTION RELATED TO TRAFFIC IN BARCELONA.

Background and Aim: Travel microenvironments contribute to the highest non-occupational exposure levels encountered for many city-dwellers, due to proximity to the traffic source. Most travel exposure studies have been conducted in northern Europe. Barcelona, a city with amongst the highest car density in Europe, many street canyons, and bike lanes situated predominately on high traffic roads, presents an interesting field for assessing exposures across modes. We present results from a measurement campaign comparing travel by car, bus, bike, and on foot in Barcelona.
Methods: 86 trips were monitored between May and June of 2009 to measure five pollutants related to traffic: Black Carbon (BC) using a micro-aethalometer (Magee), Ultra Fines (UF) using CPC 3007 and P-TRAK, Carbon Monoxide (CO) and Carbon Dioxide (CO_2) using a Q-TRAK, Particular Mater of 2.5 • m ($PM_{2.5}$) using a Dust-Trak. At each of these trips there were different combinations of commuting (combining walking, bike, bus and car); route (two routes with two directions each one); and day period (four periods along the day).
Results: Car trips showed the highest exposure concentration for most pollutants (all except CO where bus riders showed the highest values), followed by bus riders, cyclist and pedestrians. Walking trips showed the lowest values of CO_2 (474 ppm) and UF (43986 • g/cm^3) and bike trips showed lowest values of CO (0.6 ppm). No differences were found between the routes followed, while differences by period of the day were found, except for CO. Using adjusted models to investigate the factors that could affect the levels of air pollution, we observed that temperature was associated to CO_2, and Wind Speed to UF measured by CPC.
Conclusions: In Barcelona, people using the car were the most exposed to traffic related air pollutants, while those walking were the least exposed.

SHORT-TERM IMPACT OF AMBIENT AIR POLLUTION ON BLOOD PRESSURE AMONG PREGNANT WOMEN: A LONGITUDINAL STUDY

Background and Aims. Epidemiological studies have reported inconsistent findings for the association between air pollution levels and blood pressure (BP), which has mainly been studied in elderly participants. Sort-term air pollution effects on BP have never been investigated in pregnant women, who may constitute a vulnerable population.
Methods. Between 2002 and 2006, 1,500 pregnant women from a mother-child cohort conducted in Nancy and Poitiers, France, underwent 11,220 repeated BP measurements (average, 7.5 measurements/woman). Nitrogen dioxide (NO_2), particulate matter with an aerodynamic diameter below 10µm (PM_{10}), and meteorological variables were measured on an hourly basis at permanent monitoring sites. Changes of BP in relation to short-term variations of air pollution were studied with mixed models adjusted for meteorology and personal characteristics.
Results. Elevated NO_2-levels 1 and 5 days and averaged over 7 days before the BP measurement were associated with reduced SBP. The strongest decrease was observed for the 7-day NO_2 average (percent change for a 10.7 µg/m³ increase in NO_2: -0.38%; 95%-confidence intervals: [0.62;-0.02%]). PM_{10} effects on SBP differed according to pregnancy trimester: 7-day averages of PM_{10} were associated with SBP increases during the first trimester (0.60% [0.09;1.11%]) and SBP decreases in the second (-0.55% [-0.91;-0.19%]) and third trimester (-0.35% [-0.69;-0.02%]) of pregnancy.
Conclusions. We observed NO_2 and PM_{10} effects on BP in pregnant women. Whether such changes in BP may have clinical implications remains to be investigated.

OZONE EFFECTS ON HEART RATE AND REPOLARIZATION PARAMETERS IN POTENTIALLY SUSCEPTIBLE INDIVIDUALS

Background and Aims. There is evidence for an association between elevated ozone levels and cardiovascular morbidity and mortality. However, knowledge about ozone effects on electrocardiogram (ECG) parameters is very limited. We investigated the effects of ozone on heart rate (HR) and repolarization parameters in potentially susceptible populations.
Methods. Between March 2007 and December 2008, 363 ECG recordings comprising more than 2000 1h-intervals were measured in 64 individuals with type 2 diabetes mellitus or impaired glucose tolerance and in 46 healthy individuals with a potential genetic predisposition on the detoxification pathways from Augsburg, Germany. Ambient ozone and meteorological data were acquired from a fixed monitoring site on an hourly basis. Associations between 1h-averages of ambient ozone and HR, Bazett-corrected QT-interval (QTc), T-wave amplitude (Tamp) and T-wave complexity (Tcomp) were analyzed using additive mixed models adjusted for long-term time-trend and meteorological variables. A variable indicating both the season and whereabouts of the participants during the 1h-ECG recordings (summer and outdoors vs. winter or indoors) was used to assess potential modification of the ozone effect.
Results. Increases in ozone by 20µg/m³ (≙10ppb) led to concurrent and 1h–4h delayed increases in HR by 0.5-0.7% in all participants. These effects were stronger (1.0-1.2%) when the participants were outdoors during summer. Furthermore, we detected in all participants a concurrent and 1h-lagged T-wave flattening of -1.31% [95%-confidence interval:-2.19;-0.42%] and -1.32% [-2.19;-0.45%], respectively. Correspondingly, 1h- and 2h-lagged increases in Tcomp by 2.12% [0.81;3.52] and 1.89% [0.55;3.26%] were associated with elevated ozone levels, respectively. However, no effects could be observed for QTc. In general, ozone effects were more pronounced in individuals with metabolic disorders.
Conclusion. Our observed findings might be a mechanistic link between elevated ozone levels and reported adverse cardiovascular outcomes.

SWIMMING POOL ATTENDANCE AND RESPIRATORY SYMPTOMS AT 1 YEAR: RESULTS FROM THE INMA BIRTH COHORT IN SPAIN

Background and Aims: Infant swimming pool attendance has been associated with increased respiratory diseases, but results are inconsistent. The aim was to assess the relationship between swimming pool attendance and several respiratory, atopic symptoms and infections during the first year of life.
Methods: Four birth cohorts from different regions in Spain taking part of the INMA project were used. Data was collected by standard questionnaire at 12-14 months of age on frequency of swimming (indoor and outdoor swimming pools in winter and summer) and having had the following symptoms: bronchiolitis, bronchitis, low respiratory track infection (LRTI), cough, wheezing, atopic eczema, otitis. Birth season, small for gestational age, breastfeeding, day care attendance, maternal age, education, social class and atopy were considered as potential confounders. Odds ratios and 95% confidence interval (OR 95%CI) were calculated by logistic regression.
Results: 2,644 children were included (855 from Valencia, 494 from Asturias, 638 from Guipuzcoa and 657 from Sabadell). Swimming pool attendance during the 1st year of age occurred among 42% of children, with a median cumulated duration of 720 minutes (Interquartile range = 210-1800). Swimming was more common among children in higher social classes with mid-aged mothers, day care attendants and those who breastfed or were born in autumn and winter. Prevalences of symptoms were 16% bronchiolitis, 14% bronchitis, 12% cough, 19% eczema, 33% LRTI, 32% wheezing and 31% otitis. Preliminary results showed no association between swimming pool attendance and symptoms. Compared to non-swimming pool attendants, children who attended swimming pools had the following adjusted OR (95%CI): bronchiolitis=1.04 (0.81-1.34), bronchitis=1.17 (0.91-1.51), wheezing=1.04 (0.86-1.25), respiratory infection=1.09 (0.91-1.32), cough=1.01 (0.78-1.31), eczema=1.03 (0.82-1.28), otitis=1.00 (0.83-1.21).
Conclusions: Results showed lack of association between swimming pool attendance and respiratory symptoms during the first year of life in Spain. Further analyses considering the type of swimming pool are planned.

A PILOT STUDY ON ELEMENTARY SCHOOL STUDENTS' PHYSICAL ACTIVITIES: FAMILY INVOLVEMENT BASE RESEARCH

Li-Feng Lin, *Institute of nursing, Central Taiwan University of Science and Technology,Taichung city ,Taiwan(ROC)*
Tzu-I Chiu,*School of Nursing, Central Taiwan University of Science and Technology, Taichung city ,Taiwan(ROC)*
Fu-Hui Lee,*Department of Nursing, Central Taiwan University of Science and Technology, Taichung city ,Taiwan(ROC)*
Su-chin Wu,*School Nurse,Central Taiwan University of Science and Technology Taichung city ,Taiwan(ROC)*

Background and Aims: The study purpose was to establish a family involvement base intervention program to promote parents and children's physical activities.
Method: The study subject was recruited from an elementary school at Taichung city in Taiwan the participants include elementary school children and their parents a total 66 people. Researcher applied SMART strategies (Specific; measurable; Acceptable; Realistic; Theoretical) and the "Physical Activity Pyramid" concepts suggests by ACSM to plan health education program, the study period from January, 2009 to December, 2009. A closed end questionnaires and physical fitness measurement was conduct to collect data for evaluate.
Result: The family participants can remind children to do physical activities, encourage children do exercise, and felt doing exercise with children was enjoyable and fun. Overall, children sat less and moved more. The light physical activity increased 40 minutes per week (from 170 min/week up to 210min/week), the moderate exercise increased 78 minutes per week (from 96 min/week up to 174min/week) and the vigorous physical exercise increased 41min per week (from 45 min/week up to 86min/week). total energy expenditure increased 252 calorie/day during weekdays, 339 calorie/day on Saturdays, After the family involvement base intervention program, about 70% of families expressed that they would like to keep participating in the parents'-children's physical activity project.
Conclusion: According to the results, this study may be of impotence in explaining by the family involvement base physical activity intervention program, As well as providing health educator t with a better understanding of how to promote school-children to be physical active.

RESULTS OF AN INTERVENTION STRATEGY TO REDUCE LEAD EXPOSURE IN SUSCEPTIBLE POPULATION GROUPS IN COPSA MICA AREA, ROMANIA

Eugen Gurzau, *Environmental Health Center and Babes-Bolyai University, Romania*

Iulia Neamtiu, *Environmental Health Center and Babes-Bolyai University, Romania*

Background and Aims: High levels of lead have entered the environment through human activities such as mining, industrial processes and burning fuels.
Studies conducted between 1991 and 2002 focused on lead exposure in children in Copsa Mica area where a primary smelter was processing zinc and lead from mining ores. The results showed an important exposure of the children to lead, impacting somatic development, heme synthesis and neuropsychological development. An intervention program was elaborated and implemented in 2002 in Copsa Mica and blood lead levels (BLL) in children aged 4-15 years were monitored over time to measure the progress along with the intervention.
Methods: Data on lead sources, risk factors (playing with soil, putting dirty toys in the mouth, hand washing, cleaning practices etc.), and socio-economic factors were collected using a questionnaire. BLL in children were measured by atomic absorption graphite furnace spectometry. A social marketing program have been implemented in the investigated area.
Results: The mean measured BLL decreased between 2002-2009 from 46 μg/dL in 2002 to 22 μg/dL in 2007 and to 16 μg/dL in 2009. Statistically significant correlations were found betwen blood lead levels in children and some behaviours/practices/ attitudes: dirty hands/toys to mouth behaviour, and the use of the vacuum cleaner to clean the house in 2009.
Conclusions: In spite of such a major decrease in BLL (three fold) during a relatively short period of time (2002-2009) and taking into account the huge amount of resources which have been allocated to the intervention program, there is still a great need for work to be done on formulating, elaborating and implementing additional measures along with specific indicators to measure the process and progress of intervention at individual level.

4-YEAR-OLD NEURODEVELOPMENT AND EARLY LIFE DETERMINANTS ARE LONGITUDINALLY ASSOCIATED TO 11-YEAR-OLD ATTENTION FUNCTION

Background and Aims: Previous studies have found association between cognitive development at 4 years old and several early life determinants such as maternal social class, maternal smoking during pregnancy, being first born, breastfeeding, cord blood DDT levels, indoor levels of NO2, and atopy. This study aimed to assess the association between child neurodevelopment at age 4 and the development of attention function at 11 years. We also aimed to assess the early life determinants related to attention functioning at age 11.
Methods: this study was based on a birth-cohort from Menorca, one of the Balearic Islands of the north-east coast of Spain. At 11 years old, 393 children were assessed with the Conners' Continuous Performance Test – Second Edition (CPT-II). This is a 14-minute computerized measure of inhibitory control, sustained attention, vigilance, reaction time, and response variability. The three outcomes analyzed of CPT-II were Omissions, Comissions and Hit Reaction Time. At 4 years old were assessed the child cognitive development (McCarthy Scales of Infant Development), social competence (California Preschool Social Competence Scale), and Attention Deficit and Hyperactivity Disorder (Diagnostic Criteria of DSM-IV).
Results: all the neurodevelopment outcomes at age 4 were significantly associated to Omissions and Comissions at 11 years. Omissions were associated to paternal education, being first born, atopy at age 4, and child's age, and male children. Paternal social class, child sex, breastfeeding, and DDT levels at age 4 were related with Comissions at 11 years. Finally, maternal social class, child's sex, breastfeeding and DDT levels at age 4 were related with Hit Reaction Time at 11 years.

Conclussions: neurodevelopment measurement during childhood is a good predictor of attention function in preadolescence period. Most of the early life determinants related with general cognition at age 4 were also related with the different components of attention at age 11.

INFLUENCE OF THE PRENATAL PCDD/F AND PCB EXPOSURE ON ADRENARCHE AND GENDER SPECIFIC ROLE BEHAVIOUR - RESULTS FROM THE DUISBURG BIRTH COHORT STUDY

Gerhard Binder, *Pediatric Endocrinology, University-Children's Hospital, Tubingen, Germany*
Michael Wilhelm, *Department of Hygiene, Social and Environmental Medicine, Ruhr-University Bochum, Bochum, Germany*

Background and aims: PCDD/F and PCBs have been described to interfere with the endocrine system. We examine if the prenatal exposure to these chemicals will influence the development of children during their childhood. The Duisburg Birth Cohort Study (Wilhelm et al., 2008, Mutat. Res. 659, 83-92) was initiated 2000-2002. Here we present data from examinations at 6-8 and 8-10 yrs after birth of the children.
Methods: PCDD/F and PCB concentrations in blood samples from mothers during pregnancy and in milk samples were measured using GC/HRMS. Blood serum samples were collected from 111/96 children aged 6-8 and 8-10 yrs, respectively, and were assayed for testosterone, estradiol and dihydroxyepiandrosterone sulphate (DHEA-S). Gender specific role behavior was measured using the Pre-School Activities Inventory (PSAI) at 6-8 yrs by scoring gender specific activities. Data analyses were performed by linear regression analysis using GEE to account for repeated measurements of the hormones.
Results: The average age of children was 6.6 and 8.5 yrs, respectively. PCDD/F and PCB levels were in the range of 4.3–97.3 (blood) and 3.0-78.7 (breast milk) pg WHO TEq/$g_{\text{lipid base}}$, respectively. Serum levels (geometric means) of DHEA-S at first examination were 144 and at second 282 ng/ml. Linear regression analysis showed a positive association between DHEA-S and breast milk WHO TEq (increase of 1.36, 95% CI 1.12-1.65 per doubling of WHO TEq). The total gender specific activity score ranged from -30 to +36. Means of activity scores were 20.4 (boys) and -9.5 (girls). The total activity scores significantly increased only in girls per doubling the prenatal exposure to ∑6 PCB and mono-ortho PCB (increase of: ∑6 PCB: 1.46, 95%-CI 1.04-1.88; mono-ortho PCB: 1.52, 95%-CI: 1.05-1.98).
Conclusion: Prenatal exposure to PCDD/F and PCB increases the levels of DHEA-S and also alters the gender specific role behaviour in girls.

Seafood consumption during pregnancy and child neurodevelopment in a population-based longitudinal study: the INMA cohorts

Michelle A. Mendez[1,2], Raquel Garcia-Esteban[1,2], Mónica Guxens[1,2], Ferran Ballester[2,3], Mario Murcia[2,3], Jesús Ibarluzea[2,4], Nerea Lerxundi[2,4], Anna Fernandez-Somoano[5], Adonina Tardon[2,5], Jordi Sunyer[1,2,6]

1 Centre for Research in Environmental Epidemiology (CREAL) and IMIM-Hospital del Mar, Spain;
2 CIBER Epidemiología y Salud Pública (CIBERESP), Spain
3 Unit of Environment and Health, Centre for Public Health Research (CSISP), Valencia, Spain
4 Public Health Division of Gipuzkoa, Basque Government, Spain
5 Department of Preventive Medicine. University of Oviedo, Asturias, Spain
6 Pompeu Fabra University, Spain

Background and Aims: Maternal seafood consumption during pregnancy has been associated with higher neurodevelopment scores in children. However, seafood is also an important source of contaminants associated with lower scores. As most studies to date have been conducted in populations with limited intakes, few have been able to examine how different seafood subtypes, which vary in content of both potentially beneficial fatty acids and neurotoxic contaminants, are associated with child development. This study, conducted in a sample with high seafood intakes, aims to address this gap.

Methods: The analysis included 1,895 women recruited during the first trimester of pregnancy as part of the multicenter Spanish INMA Childhood and Environment cohort in Asturias, Gipuzkoa, Sabadell, and Valencia. Trained psychologists assessed child neurodevelopment at approximately 14 months using the Bayley Scales of Infant Development, standardized for standardized for age in days at test administration. Multivariate linear regression was used to assess associations between test scores and maternal seafood intakes, classified as small fatty fish, large fatty fish, lean fish, and shellfish. Models adjusted for confounders including breastfeeding and parity; the effect of additionally adjustments and cord blood mercury and polychlorinated biphenyls and dichloro-diphenyldichloroethylene in 1st trimester maternal serum was examined.

Results: Mean seafood intakes were 4.5 times per week. First trimester intakes of small fatty fish ≥1 time/week, lean fish up to 3 times/week, and shellfish up to twice a week were positively and significantly associated with cognitive scores. Large fatty fish ≥1/week was associated with lower scores overall, though associations were heterogeneous across cohorts. Additionally adjusting for contaminants had no meaningful effect.

Conclusions: Results suggest maternal consumption of most types of seafood is largely beneficial for child neurodevelopment, but support current recommendations to limit intakes of large fatty fish species which may accumulate high levels of both mercury and lipophilic contaminants.

Limitations of Environmental Epidemiology for Guiding Environmental Policy

David Savitz, *Brown University, USA*

Background and Aims: Environmental epidemiologists aspire to generate research findings that provide an objective basis for the formulation of environmental policy. The ideal scenario in which epidemiologic research and policy are perfectly aligned is rarely realized, and efforts to force the epidemiologic evidence to fit sound policy can be detrimental to both.
Methods: I will examine illustrative current debates in environmental health policy in which the incremental, future contributions of epidemiology to their resolution appears to be limited: environmental tobacco smoke, drinking water treatment by-products, and electromagnetic fields. The past contributions and limits of further epidemiologic studies in these areas for guiding policy will be summarized.
Results: Sound policy decisions benefit from general guidance from epidemiology but also draw heavily on findings from toxicology and other contributory sciences, consideration of social and financial costs of alternative courses of action, and extrapolation of epidemiologic evidence. Epidemiologic research should be undertaken to inform policy in these areas when the capabilities of epidemiology match the needs of policy makers. In these examples, the inherent limitations in available epidemiologic methods (which could change with fundamental advances) suggest that additional studies offer little promise of contributing meaningfully to regulatory policy.
Conclusions: Recognizing that sound policy cannot and need not rely on definitive epidemiologic evidence would reduce the pressure to overstate certainty of epidemiologic findings, focus attention on identifying important policy questions that epidemiology is capable of addressing, and free policy makers of needing to invoke direct epidemiologic support for their decisions. Acknowledgment of the important but imperfect connection between environmental epidemiology and environmental policy would promote a more even-handed appraisal of the epidemiologic evidence and more strategically conceived epidemiologic studies, and potentially improve the quality of environmental policy.

AIR POLLUTION AND HEMATOTOXICITY – A POPULATION-BASED STUDY IN TAIWAN

Yu-Wen Chiu, *Department of Family Medicine, Ta-Tung Municipal Hospital,Department of Community Medicine, Kaohsiung Medical University Hospital, Taiwan Faculty of Medicine, Kaohsiung Medical University, Taiwan*
Hung-Yi Chuang, *Department of Community Medicine, Kaohsiung Medical University Hospital, Department of Public Health and Environmental Medicine, Kaohsiung Medical University, Taiwan*

Background and Aims: Kaohsiung City is one of the worst air quality cities in Taiwan because of many industries. Sequels of peripheral blood cells influenced by air pollutants exposure have been suggested in literature, yet the association is not clear and the evidence is not sufficient.
Methods: This population-based study recruited subjects from 4 out of 11 districts in Kaohsiung City between the year 2003 and 2004. Demographic data including habitual behaviours as well as blood counts were administered. Real-time measurements and hourly data of environmental pollutants included PM10, SO2, CO, NO2, O3, and PSI were collected from air quality monitoring stations. Air quality reports and blood exam data were merged for statistic analysis. Single-pollutant models and multiple-pollutants models were analyzed to realize the effects of pollutants exposure on white count series..
Results: Ten thousand one hundred and forty subjects (4,378 male) between the ages of 33–87 years were recruited. Carbon monoxide would increase white counts as well as neutrophils (regression coefficients 833.4), monocytes, and lymphocytes; whereas sulfur dioxide would decrease white counts as well as neutrophils and monocytes after short expose (within one week) toward air pollution. Gender, body mass index, and cigarette smoking would also contribute to white count elevation other than air pollution, though their effects are less than air pollutants.
Conclusions: Short exposure (within 7 days) toward air pollutants, carbon monoxide and sulfur dioxide in particular, has been supposed to be closely related with white counts alterations which would mediate to systemic inflammatory status.

Single nucleotide polymorphisms (5p15.33, 15q25.1, 6p22.1, 6q27 and 7p15.3) and lung cancer survival in European Prospective Investigation into Cancer and Nutrition (EPIC)

Wei W Xun, *Imperial College London, United Kingdom*
Paul Brennan, *International Agency for Research on Cancer (IARC), Lyon, France*
Paolo Vineis, *Imperial College London, United Kingdom*
Elio Riboli, *Imperial College London, United Kingdom*
EPIC collaborators*, various institutions*

Background and Aims: The single nucleotide polymorphisms (SNPs) rs402710 (5p15.33), rs16969968 and rs8034191 (15q25.1) have been identified by genome-wide association studies (GWAS) as significant predictors of lung cancer risk (McKay, J.D et. al, 2008; Hung, R.J et al, 2008), while rs4324798 (6p22.1) was previously found to influence survival time in small cell lung cancer (SCLC) patients (Yang et al, 2010).
Methods: Using the same population of one of the original GWAS, we investigated whether the selected SNPs and 31 others (also identified in GWAS) influence survival time in EPIC, assuming an additive model. The effect of each polymorphism on all cause survival was estimated in 1094 lung cancer patients, and lung cancer specific survival in 763 patients, using Cox regression adjusted for *a priori* confounders and competing causes of death where appropriate.
Results: After 1558 person-years of post-diagnostic follow-up, 874 deaths occurred from all causes, including 690 from lung cancer. In the lung cancer-specific survival analysis (1102 person-years), only rs7452888 (6q27) and rs2710994 (7p15.3) modified survival, with adjusted hazard ratios of 1.19 (P=0.009) and 1.32 (P=0.011) respectively, taking competing risks into account. Weak associations were identified in subgroup analysis for rs16969968 and rs8034191 (15q25.1) and rs4324798 (6p22.1) and survival in never-smokers, as well as for rs402710 in current smokers and SCLC patients.
Conclusions: rs402710 (5p15.33), rs16969968 and rs8034191 (both 15q25.1), and rs4324798 (6p22.1) were found to be unrelated to survival times in this large cohort of lung cancer patients, regardless of whether the cause of death was from lung cancer or not. However, rs7452888 (6q27) was identified as a possible candidate SNP to influence lung cancer survival, while stratified analysis had hinted at the possible roles of rs8034191, rs16969968 (15q25.1), and rs4324798 (6p22.1) in determining survival in lung cancer patients who were never-smokers, based on a small sample.

Manolis Kogevinas, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain and National School of Public Health, Athens, Greece*
Leda Chatzi, *Department of Social Medicine, Medical School, University of Crete, Heraklion, Greece*

Background and aims: Dioxins and dioxin-like compounds bioaccumulate through the food chain and act as endocrine disruptors. Diet during pregnancy is the main source of *in-utero* exposure to dioxins, with meat, fish, and milk intake as the main contributors. In animals, anogenital distance is used as an indicator of *in-utero* androgenic exposure. Only few human studies evaluated the association between *in-utero* exposure to environmental pollutants and anogenital distance in newborns, with inconsistent results. We examined the association between diet during pregnancy and anogenital distance in children in a population based mother child cohort in Crete (Rhea study).

Methods: We studied 492 mother-child pairs (mean age: 18 months, range: 4-36 months) from the Rhea study. Maternal dietary intake during pregnancy was assessed by a validated food frequency questionnaire. Daily frequencies were multiplied with portion sizes to estimate food intake in grams per day. Anogenital distance (AGD-anus to upper penis), anoscrotal distance (ASD-anus to scrotum) and penis width (PW) were measured for boys; anoclitoral (ACD-anus to clitoris) and anofourchetal distance for girls (AFD-anus to fourchete). Ratios of anogenital distances divided by body weight were calculated. Dietary intake was categorized in tertiles (using the lowest tertile as reference) and multivariate linear regression models were used.

Results: Higher meat and high-fat meat intake was associated with shorter anogenital distance especially for boys (p for trend<0.05 for ASD). Pregnant women in the highest tertile of high-fat meat intake (>70gr/day) gave birth to boys with shorter ASD (b coefficient -2.8; 95%CI: -5.16,-0.49), and ASD weight-ratio (b coefficient -0.24; 95%CI: -0.45,-0.02), in early childhood. No associations were found for fish and dairy intake.

Conclusions: The findings from this study suggest a potential association between high fat meat intake during pregnancy and shorter anogenital distance in male children, in Greece.

BRAIN CANCER ASSOCIATED WITH INCREASED MOBILE PHONE USERS: EVIDENCE FROM TAIWAN

Chia-Ying Lin, *China Medical University, Taiwan*

Yu-Jen Lin, *National Health Research Institutes, Taiwan*

Wen-Ru Yu, *Taipei City Hospital-Zhongxiao Branch, Taiwan*

Huei-Sheng Shiue, *China Medical University, Taiwan*

Trong-Neng Wu, *China Medical University, Taichung, National Health Research Institutes, Taiwan*

Background and Aims: Recent studies have shown that low-energy electromagnetic waves may affect human cognitive and brain function. However, evidence that mobile phone electromagnetic waves act as a carcinogen is still insufficient. Mobile phone was first introduced into Taiwan in 1989, its usage has reached 88.9% of the nation's population by 2007. Because use of mobile phones is different between cities and counties, the study aimed to investigate the numbers of mobile phone users in cities and counties and the corresponding trend in the brain cancer incidence from 1999 to 2007.

Methods: We used data on a total 22 cities and counties in Taiwan. Age-specific incidence rate (per 100,000 persons) of brain cancer from 1999 to 2007 were obtained from the cancer registry and standardized based on the 2000 WHO world standard population. Person-number and times of mobile phone usage were obtained from the Taiwan Directorate General of Budget, Accounting and Statistics.

Results: We used simple linear regression to compare trends (1999-2007) of standardized incidence rates between Taipei City (largest number of mobile phone users.) and Chiayi County (smallest number of mobile phone users.) (B=0.41, p=0.048). However, after adjustment for confounders (population density, average population served per physician, annual electricity consumption in the cities and counties, and the number of HIV infections), multiple regression results showed that the incidence of brain cancer and the number of mobile phone users had no significant correlation.

Conclusions: The results of this investigation did not support the hypothesis that the number of mobile phone users in Taiwan cities and counties had different brain cancer incidence.

Background and Aims: We have previously shown that several environmental contaminants are related to atherosclerosis. In real life however, we are exposed to a mixture of contaminants. Therefore, the present study aims to investigate whether mixtures of environmental contaminants are related to atherosclerosis in the elderly.
Methods: We used the grey scale of the intima-media complex, which is a measure of the lipid infiltration in the vascular wall, as the outcome variable in a sample of 1016 subjects aged 70 years. Predictions were generated from a linear model with 15 contaminants (4 PCBs, 4 plastic associated chemicals and 8 metals), their pair-wise interactions and the established risk factors cholesterol, BMI, blood pressure, smoking, sex and diabetes using the elastic net. These predictions were used as the outcome in a model which was simplified using a backwards step-down procedure until 95% of the variance in the predictions was accounted for. Each variable's partial R^2 statistic was used as a measure of that variable's relative importance in the final model. PCBs 170 and 209 were used as markers for high-chlorinated PCBs.
Results: The interaction between Mono-methyl phthalate (MMP) and Cadmium was the most important (rank 5, partial R^2 = 3.8%) followed by the interactions between high-chlorinated PCBs and Cadmium (rank 7, partial R^2 = 2.2%) and high-chlorinated PCBs and MMP (rank 10, partial R^2 = 1.2%). An interaction of lesser importance between MMP and Mercury could also be seen (rank 14, partial R^2 = 0.5%). All interaction effects affected the grayness of the intima-media complex and had p-values < 0.001.
Conclusions: The present study is amongst the first to investigate effects of mixtures of environmental contaminants on human health. The main finding is that MMP and Cadmium, highly chlorinated PCBs and MMP and Cadmium as well as MMP and Mercury may act in synergy to influence atherosclerosis development.

THE INFLUENCE OF ANTIOXIDANT VITAMINS INTAKE DURING PREGNANCY ON INFANT CORD BLOOD MERCURY CONCENTRATIONS

Hui Li, *Shanghai Key Laboratory of Children's Environmental Health, Shanghai Institute for Pediatric Research, Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, China*

Background and Aims: Antioxidant vitamins(Vitamins A, C, E) belong to the unenzyme antioxidant system, and play an important antioxidant effect in the human body. Many animal experiments suggested that vitamin supplements would affect the concentration of mercury in vivo. This research attempts to analyse the relationship between pregnancy antioxidant vitamins intake and cord blood mercury level. And to explore the protective effect of antioxidant vitamins to the injure of mercury.

Methods: One maternal and child health center or general hospital was selected in each geography district, China. About 200 pairs of mothers and full-term infants were recruited from October to December 2008 in each hospital. The umbilical cord blood was collected from each infant, then the concentration of total mercury was analysed. All mothers were asked to fill a questionnaire, and 1246 mother answered the questions about the vitamin A, C, E consumption during pregnancy.

Conclusions: The proportion of continued taking vitamins A, C, E were 12.0%, 13.3% and 12.8%, respectively. The proportion of intermittent taking were 29.8%, 34.3%, 32.0%, and the not taking were 58.2%, 52.3%, 55.2%. The difference of mercury concentrations between the discontinuous and continued taking was not statistically significant. The differences between the not taking and intermittent taking were statistically significant (*P* values were 0.019, 0.001, 0.026), The differences between the not taking and the continued taking were also statistically significant (*P* values were 0.001, 0.000, 0.000). But with the increase of antioxidant vitamins taking frequency, the mercury concentrations of umbilical cord blood elevated. There was no difference on babies' birth length or birth weight among different vitamins and different frequency consumption. And the influence on the head circumference of birth was statistically significant , *P* values were all <0.05. So Our study found that antioxidant vitamins intake during pregnancy couldn't lower the umbilical cord blood mercury level, but increase it. This may be related to mothers' living habits during pregnancy. Antioxidant vitamins intake during pregnancy was positively related to the baby's brain development.

Background and Aims: Anxiety has been expressed in regard to the danger of pregnant women eating seafood because of a reported danger to the fetal brain from mercury contained in seafood. However the studies that have shown this have been of populations where the seafood mainly consumed is high in the food chain, and includes pilot whale and tiger shark. This study aimed to assess the contribution of different components of the diet to the UK pregnant woman's blood mercury level in an area where the general consumption of fish is lower, and the species consumed are more often at the middle and lower ends of the food chain.

Methods: The study used information from 4484 pregnancies in the Avon Longitudinal Study of Parents and Children (ALSPAC), using blood collected in acid washed vacutainers when the women first reported for antenatal care. Information on the diet was collected from the women themselves using a detailed food frequency questionnaire. Statistical analysis used forward and backward stepwise regression with total mercury level as the outcome.

Results: The median of the total blood mercury distribution was 1.86µg/L, substantially higher than found in the pregnant women in the NHANES study in the US [0.89µg/L]. However the level of the 95th centile was significantly lower in ALSPAC than that of the US study (4.02 v. 5.98).

Altogether in ALSPAC the maternal diet was responsible for only 16.53% of the variation in total blood mercury. This included 6.95% of the variation due to consumption of seafood, i.e. 42% of the dietary variation. Other features of the UK diet positively associated with increased blood mercury levels included wine, herbal drinks and the use of "health foods".

Conclusions: Consumption of seafood in the UK is responsible for only a small proportion of the variance in blood mercury.

TRAFFIC-RELATED AIR POLLUTION, ASTHMA AND HAY FEVER AT THE AGE OF 11

Bert Brunekreef, *Institute for Risk Assessment Sciences, Utrecht University, The Netherlands - Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, The Netherlands*

Background and aim: In the PIAMA-study, we found positive associations between residential exposure to traffic-related air pollution and the incidence and prevalence of asthma and asthma symptoms until age 8. Puberty is an important milestone for the development of asthma and allergy. We therefore extended our previous analyses with three years of follow-up and studied the association between residential exposure to traffic-related air pollution and asthma and hay fever at age 11 years.

Methods: We estimated exposure to NO_2, fine particulate matter, and soot at the birth address by land-use regression models. Associations of exposure to air pollution with questionnaire-reports of diagnoses and symptoms of asthma and hay fever and were explored by multiple logistic regression analysis in approximately 2600 children. Effects were first estimated for all children and then for boys and girls separately by adding a gender-air pollution interaction term to the model.

Results: The participants' median age was 11.3 years (range 10.1-12.8). Overall, air pollution was (marginally) significantly associated with shortness of breath [adjusted odds ratio (95% confidence interval) 1.36 (1.05-1.77) per 3.5 $\mu g/m^3$ (interquartile range) change in $PM_{2.5}$] and nocturnal dry cough [1.30 (0.99-1.69)]; doctor-diagnosed hay fever [1.43 (1.03-1.97)], and symptoms of allergic rhinitis [1.25 (0.96-1.63)] during the past 12 months. Associations between $PM_{2.5}$ and these symptoms of asthma were largely limited to girls, while associations with hay fever were found in boys and girls. However, effects of air were not significantly different between boys and girls. Air pollution was associated with doctor-diagnosed asthma in girls [1.72 (1.00-2.96)], but not in boys [0.83 (0.50-1.35)], p-value interaction < 0.05].

Conclusions: Exposure to traffic-related air pollution is positively associated with symptoms of asthma, hay fever and related symptoms at age 11 years. The association with asthma may be stronger in girls than in boys.

WOMEN AND WATERPIPE SMOKING: LIBERAL SYMBOL OR SEXUAL ALLURE?

Fouad M. Fouad, *Syrian Center for Tobacco Studies, Syria*

Background and Aims: Despite emerging evidence on its adverse health effects, waterpipe tobacco smoking (WTS) is becoming more prevalent than that of cigarettes among women and girls in Syria. In the face of a strong taboo against female smoking, adult family members appear to be more permissive towards women smoking waterpipe than cigarettes. The aim of this paper is to assess whether seductive images and sexual allure themes are present in women and men discourses about waterpipe.
Methods: Nineteen focus group discussions (FGDs) and eleven in-depth interviews were conducted in Aleppo, Syria in 2008. Men and women, waterpipe smokers and non-smokers were recruited from both urban and rural areas. Separate FGDs were conducted by gender, age group, and waterpipe smoking status. The discussions were thematically analyzed. The main themes were the image of women smoking waterpipe and men's attraction to these women. Moreover, the sexual allure conveyed through waterpipe smoking, as well as WTS as a symbol of emancipation, were illustrated.
Results: Focus group participants stated that women smoke waterpipe to draw the attention of men, that women smoking waterpipe are attractive, and described the specific communication used to convey sex appeal while smoking waterpipe. Smoking waterpipe is a sign of strength and power for 'liberal women', and a way to prove themselves. Women smoked waterpipe as a way to express their emancipation and waterpipe smoking is one step forward toward gender equalization.
Conclusions: In-depth exploration of the social aspects of WTS in a specific context is crucial to understanding WTS behavior. This has significant implications on future interventions curbing the use of WTS.

Background and Aims: Antenatal passive exposure to tobacco smoke could influence early steps of leukemogenesis. This study aimed to explore the effect of maternal smoking during pregnancy on childhood acute leukemia (AL), accounting for genetic polymorphisms that modulate metabolite production.
Methods: Data are drawn from the national population-based study ESCALE, which included 764 AL and 1681 controls in 2003-2004. Mothers of cases and controls were interviewed by telephone on their tobacco consumption during pregnancy, using a standardized questionnaire. A sub-sample of 493 cases (433 lymphoblastic (ALL) and 51 myeloblastic (AML)) and 549 controls, with European ancestry from at least 2 grandparents, was genotyped on Illumina high throughput platforms. Genotype imputation was used to complete the data for untyped polymorphisms. Candidate alleles were *CYP1A1*2A/2B* (rs4646903), *CYP2E1*5* (rs2031920, rs3813867), *NQO1*2* (rs1800566), *NAT2*5* (rs1801280) and *EPHX1* polymorphisms in exons 3 (rs1051740) and 4 (rs2234922). Logistic regression models were adjusted on the gender*age quota sampling variable used for the selection of controls, birth order, breastfeeding and socioeconomic parental situation. Gene-environment interactions were also assessed by case-only analyses.
Results: ALL and AML were associated neither with maternal smoking during pregnancy, nor with candidate polymorphisms in *CYP1A1*, *CYP2E1, EPHX1* and *NQO1.* The presence of two slow *NAT2*5* alleles was significantly associated with ALL (OR=1.7 [1.2-2.6]). Analyses suggested an interaction borderline of significance between the slow *EPHX1* phenotype (rs1051740 CT or CC, rs2234922 AA) and the slow *NAT2* phenotype (rs1801280 CC). There was no interaction between any of the polymorphisms under study and maternal smoking.
Conclusions: The ESCALE study did not evidence the interaction between maternal smoking and *CYP1A1*2A/2B* suggested previously (Clavel et al., 2005). The association with NAT2 slow phenotype is compatible with the only previous study reporting on this phenotype in childhood ALL (Krajinovic et al., 2000). The interaction *EPHX1-NAT2* needs replication.

John E. Vena, PhD, *Cancer Epidemiology, Prevention and Control Program, Georgia Cancer Center and Department of Epidemiology and Biostatistics, College of Public Health, University of Georgia*

Background. Radon is a lung carcinogen exhibiting complex interrelationships with its geologic origins and potential exposure routes. Georgia (GA) has high concentrations of naturally occurring radon and no analytic studies have assessed the impact of exposure on cancer risk in the state.

Methods. A geographic information system was used to evaluate relationships between radon and cancer incidence using GA Comprehensive Cancer Registry (2000-2007) data. Lung (N=43,910), female breast (N=41,515), colorectal (N=29,251), bladder (N=5,607), leukemia (N=24,003), and kidney (N=8,143) cancer cases were obtained at the individual-level. Because it is unlikely to be related to radiation exposure, cervical cancer cases (N=2,893) were also obtained from the registry for use as controls. Radon data for GA were obtained from the University of GA Cooperative Extension and Florida Department of Health. Kriging was used to smooth exposure data. Based on the final kriging model, a predicted radon concentration was assigned to each cancer case or control based on their latitude and longitude of residence at diagnosis. Spatial and non-spatial logistic regressions were used to evaluate the relationship between log-transformed predicted radon concentrations and cancer incidence.

Results. There were 25,237 radon (mean=5.5±425 pCi/L; max=67,487 pCi/L) measurements in GA. In unadjusted models, there was a significantly increased odds of exposure to radon for bladder (odds ratio: 1.10; 95% confidence interval: 1.02, 1.18), colorectal (1.08; 1.02, 1.15), breast (1.25; 1.17, 1.32), leukemia (1.15; 1.08, 1.23), and kidney cancer (1.13; 1.05, 1.20) cases. A positive, though non-significant, relationship was detected for lung cancer (1.04; 0.98, 1.10). After adjustment for race, age at diagnosis, cancer stage, and county-level median household income, a significant relationship persisted for breast cancer (1.11; 1.04, 1.19).

Conclusions. Preliminary relationships were detected between elevated radon exposure and cancer incidence, especially breast cancer. Detailed analyses including spatial regression and cluster modeling at the individual-level are underway.

Pamela Ohman-Strickland, *UMDNJ-School of Public Health, USA*
Howard M Kipen, *UMDNJ-Robert Wood Johnson Medical School, USA*

Background: Associations between traffic-related air pollutants (TRAPs) and acute cardiopulmonary outcomes may be confounded by psychological stress, noise, and other exposures. Laboratory-based exposure studies of the health effects of vehicle emissions can control these factors, but may differ in important ways from 'real-world' conditions. We compared two methods for controlling exposure to particulate TRAPs among volunteers during car rides simulating a rush-hour commute.
Methods: A total of 47 adult subjects were passengers during two 2-hr car rides, at least 1 week apart, in a Ford Taurus sedan. The route was primarily on the New Jersey Turnpike, a major highway with heavy diesel truck traffic. Twenty subjects had one ride with the external air intake vent open, and one ride with the vent closed. Twenty-seven subjects wore a powered air-purifying respirator (PAPR) with the vent open during both rides, but with a high-efficiency particulate air (HEPA) filter in place in the PAPR during only one of the car rides. All subjects were blinded to the exposure conditions, which were administered in random order. Measurements in the vehicle and inside the respirator facepiece included total particle count and particulate matter less than 2.5 μm ($PM_{2.5}$). Subjects reported levels of stress by questionnaire before, during, and after the rides.
Results: Closing the vent reduced in-vehicle mean particle number and $PM_{2.5}$ concentrations by 53% and 29%, respectively. In contrast, the PAPR with filter in place reduced mean particle number and $PM_{2.5}$ inside the respirator facepiece by greater than 99.9% and 83%, respectively. Changes in stress levels were similar comparing subjects under the PAPR filter/no-filter conditions to subjects under the vent open/closed conditions.
Conclusions: The PAPR was an efficient, well-tolerated, and cost-effective method for controlling particle exposure in blinded, crossover studies of acute health effects of exposure to particulate TRAPs.

THE RELATIONSHIP OF ENVIRONMENTAL EXPOSURE TO POLYCHLORINATED BIPHENYLS AND P,P'-DDE WITH HUMAN SPERM SEX-CHROMOSOME DISOMY

Megan McAuliffe, *Harvard School of Public Health, United States*
Paige Williams, *Harvard School of Public Health, United States*
Susan Korrick, *Channing Laboratory, Brigham and Women's Hospital, Harvard Medical School, United States*
Larisa Altshul, *Harvard School of Public Health, United States*
Melissa Perry, *George Washington University School of Public Health and Health Services, Harvard School of Public Health, United States*

Background and Aims: Chromosomal abnormalities contribute substantially to reproductive problems, yet environmental risk factors have not been well investigated. We evaluated associations between PCBs and p,p'-DDE exposure with sperm sex-chromosome disomy.
Methods: We conducted a cross-sectional study of 192 men from subfertile couples. Multiprobe fluorescence in situ hybridization (FISH) for chromosomes X, Y, and 18 was used to determine XX, YY, XY, and total sex chromosome disomy in sperm, using a semi-automated scoring method. Serum was analyzed for concentrations of 57 PCB congeners and p,p'-DDE. Poisson regression models were used to calculate incidence rate ratios (IRRs) for disomy by exposure quartiles controlling for potential confounders and semen parameters.
Results: The median percent disomy was 0.3 for XX and YY, 0.9 for XY, and 1.6 for total sex chromosome disomy. After adjustment, total sex chromosome disomy IRR for the highest vs. lowest quartile of serum DDE exposure was 1.27 (95% CI: 1.22-1.33). IRRs showed significantly increasing trends for increasing quartiles of p,p'-DDE in XX, XY, and total sex chromosome disomy. There was a significant increase in IRRs of YY, XY, and total sex chromosome disomy for increasing quartiles of the ∑4prevalent PCBs (118, 138, 156, and 180) and ∑estrogenic PCBs (44, 49, 52, 101, 187, 174, 177, 157/201). There was also an increase in XY and total sex chromosome disomy for increasing quartiles of ∑dioxin-like PCBs (95/66, 74, 77/110, 105/141, 118, 156, 167, 128, 138, 170). For XX disomy, however, IRRs decreased significantly with increasing quartiles for all PCB summary measures examined (∑4prevalent, ∑estrogenic, and ∑dioxin-like).
Conclusions: Our findings suggest DDE may be associated with increased XX, XY and total sex chromosome disomy, while PCB exposures may be associated with increased YY, XY and total sex chromosome disomy, but decreased XX disomy. These findings require confirmation in further studies.

PUBLIC PERCEPTION OF CLIMATE-CHANGE AS A HEATLH RISK IN SEOUL, KOREA

Hyunjin Han, *Graduate School of Public Health, Seoul National University, Korea*
Ho Kim, *Graduate School of Public Health, Seoul National University, Korea*
Soonman Kwon, *Graduate School of Public Health, Seoul National University, Korea*

Background and Aims: "Risk Society" is the terminology used in order to define modern society owing to the manners that it organizes in response to the risks and growing environmental concerns. Moreover, environmental and public health policies related to the issues should be considered on the basis of the public risk perception in order to provoke the better public willingness to adapt them. Although the importance of climate-change adaptation has been consensus, there have been relatively little climate-change health risk perception concerns. Therefore, this study aims to identify public risk perceptions on climate-change health impacts while analyzing the influencing factors benefitting the climate-change adaptation policy implementation.
Methods: The survey was conducted in a form of telephone interviews in December 2008 with probability-proportional-to-size-samples of 1,200 adults in Seoul by trained interviewers. Logistic regressions were performed using STATA/SE 10.01 and spatial analysis was assisted with ArcGIS 10.
Results: Most of the respondents believe that global climate-change is serious (93.25%), health risk of the climate-change is hazardous (81.33%), and general climate-change risk awareness dramatically increases health risk recognition (OR: 16.15, 95%CI: 9.20 to 28.37, p=0.000). Age square, day time residence area and low income are significant factors influencing the risk perception, but their impacts or confidence intervals are limited. There is no clear spatial clustering of the risk perception, and former exposures to the environmental risk communication regarding ozone, heat wave and fine dust warning have no impact on it. However, the regional differences on the risk perception and exposure levels of the risk communication exist.
Conclusions: In this paper, we attempted to address the climate-change related health risk perception while comparing the regional variation. Although there are limited variables available, the results have some important implications regarding general climate-change risk awareness, socio-economic status to health risk, and regional disparity of risk communication.

Background: Large multi-city studies conducted in the United States and in Europe have demonstrated that short-term exposure to airborne particulate matter is associated with an increase in daily mortality and hospital admissions for cardiovascular diseases**.** Several sub-group of the population are recognised to be more vulnerable, specifically disadvantaged groups.
Objectives: To evaluate whether socioeconomic status (SES) modified the short-term association between PM_{10} and onset of myocardial infarction (MI) in France.
Methods: The study population comprised all MI events (*n* = 2140) occurring among adults aged 35-74 years in Strasbourg (France) during years 2000-2007. SES was estimated at French census block level using a deprivation index classified into five categories. Hourly PM_{10} concentrations were modeled using the ADMS-Urban air dispersion model. A time-stratified case-crossover analysis was performed to estimate the associations between daily PM_{10} concentrations and MI events, stratifying by neighborhood deprivation category. Different exposure lags were tested for PM_{10} concentrations: lag01, average of the same and previous day, lag02, average of the same and 2 previous days and lag03 or the same and 3 previous days.
Results:A significant influence of neighborhood SES was found with a greater PM_{10} effect among subjects living in the most deprived neighborhoods. The relative excess of MI risk per 10-µg/m^3 increase in PM_{10} ranges between 15% for lag01 (95%IC [1,1%;30.8%]) and 18% ([3.1 to 37.1) for lag02, but only in the most deprived census blocks (p ,for heterogeneity between neighborhoods SES categories ranges from 0.04 to 0.07 across lags).
Conclusion:These findings suggest a strong differential susceptibility according to SES related factors. This might be due to pre-existing health conditions that render people living in more deprived areas more frail, to exposure in other microenvironments that add to the stress due to ambient air (e.g. poor housing, workplace pollution, commuting time) or to other unknown vulnerability factors.

Key words: air pollution; coronary heart disease; neighborhood; socioeconomic status; small-area analysis

ESTIMATING PERSONAL EXPOSURE TO INDOOR AND OUTDOOR AIR POLLUTANTS DURING SCHOOL DAY IN PRIMARY SCHOOLS

Ariana Zeka, *Brunel University, United Kingdom*
Benjamin J. Jones, *Brunel University, United Kingdom*
Yulia Anopa, *Brunel University, United Kingdom*

Background and Aims: Studies that characterize personal exposure to indoor and outdoor air quality of school children have been limited. This study aimed to extend the knowledge of air quality in schools, develop methodology for estimating personal exposure to air pollutants during school day, and contribute to the current international need for further research in indoor air quality.
Methods: Four primary schools in southern England were selected for the study, in urban, suburban and rural environments. Air quality monitoring was conducted in three rounds (autumn, winter, summer) during the academic year 2009-2010. Each round involved monitoring for one week in four locations typical of children's exposure. Measurements were carried out for particulate matter count of size range 0.5-5.0μm ($PM_{0.5-5.0}$), carbon dioxide (CO_2), carbon monoxide (CO), nitrogen dioxide (NO_2), formaldehyde (HCHO), and total volatile organic compounds (tVOC). Time-activity patterns of children in schools were recorded, and used to create a representative personal exposure matrix for each child according to time spent in different environments. Statistical testing compared estimated personal exposure and measured concentrations in school classrooms.
Results: We found important differences between personal exposure and measured concentrations during the summer round in all schools, in particular for CO (t-test p-value range: 0.004-0.11), NO_2 (<0.001-0.13), HCHO in two schools (0.001-0.15), and $PM_{0.5-5.0}$ for one school (0.08-0.11). We observed no significant differences during autumn and winter rounds. Results, however, suggested an increase in the weekly variability of greater than 50% in pollutant levels for $PM_{0.5-5.0}$, NO_2, and tVOC in three of the four schools, comparing personal exposure to measured concentrations.
Conclusions: These findings show the importance of characterization of personal exposure to indoor and outdoor air pollutants in schools. The findings provide useful methodology that will lead to better quantification of environmental exposures in children, thus strengthening the estimation of the exposure-risk association.

SERUM PFOA AND PFOS LEVELS AND LIVER FUNCTION BIOMARKERS IN THE C8 SCIENCE PANEL STUDY

Valentina Gallo, *London School of Hygiene & Tropical Medicine, United Kingdom*
Maria-Jose Lopez-Espinosa, *London School of Hygiene & Tropical Medicine, United Kingdom*
Nicola Fitz-Simon, *London School of Hygiene & Tropical Medicine, United Kingdom*
Debapriya Mondal, *London School of Hygiene & Tropical Medicine, United Kingdom*
Giovanni Leonardi, *London School of Hygiene & Tropical Medicine, United Kingdom*
Ben Armstrong, *London School of Hygiene & Tropical Medicine, United Kingdom*
Tony Fletcher, London School of Hygiene & Tropical Medicine, United Kingdom

Background and Aims: Perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS) have been found in relatively higher concentration in liver; in rats, they have been associated with hepatocellular adenomas. Some studies in humans have reported non consistent associations between PFOA and liver enzymes. The aim of this study is to examine the cross-sectional association between serum levels of PFOA and PFOS with markers of liver function in adults.
Methods: In the C8 Science Panel Study in the Mid Ohio Valley, associations between liver markers and PFCs have been investigated in 47,092 eligible adults. We studied alanine transaminase (ALT), gamma-glutamyltransferase (GGT), and total bilirubin as markers of liver function. Linear and logistic regression models (using high enzyme levels as endpoint) were fitted adding potential confounders (age, physical activity, Body Mass Index, ethnicity, alcohol consumption, socio-economic status, fasting status, month of blood sample, and insulin resistance).
Results: Ln-transformed values of ALT are significantly associated with ln-PFOS in linear regression models (beta 0.020, SE=0.003, $p<0.001$), and in logistic regression models with a steady increase in the OR estimates across deciles (p-value for trend across deciles <0.001), and a significant OR for ln-unit of PFOS (OR=1.13, 95% C.I. 1.07-1.18, $p<0.001$). No association was observed between GGT and PFOS; linear regression models show a positive association between bilirubin total and PFOS (beta 0.051, SE 0.003, $p<0.001$). Findings for PFOA will also be presented but must first be presented to the local community.
Conclusions: This study includes a large population exposed to higher than background levels of PFOA and typical levels of PFOS. The association of ALT with PFOS confirms previous findings, while the association of bilirubin total was in the opposite direction than previously observed.

THE USE OF INSTRUMENTAL VARIABLES TO REDUCE CONFOUNDING AND REVERSE-CAUSATION BIAS IN A CROSS-SECTIONAL STUDY FOR PFOA IN RELATION TO CHOLESTEROL

Nicola Fitz-Simon *London School of Hygiene and Tropical Medicine, UK*
Ben Armstrong *London School of Hygiene and Tropical Medicine, UK*
Tony Fletcher *London School of Hygiene and Tropical Medicine, UK*

Background and Aims: Studies of association between an exposure and response in cross-sectional studies may give biased estimates due to unmeasured confounding or reverse causality. However, if we can identify a variable that is (1) associated with the exposure (2) conditionally independent of the response given the exposure; and there is an association between this "instrumental" variable and the response, we may infer a causal relationship between the exposure and the response and derive an unbiased estimate of this relationship. This is illustrated by application to the relationship between serum PFOA and cholesterol.
Methods: The C8 Science Panel Study in the Mid Ohio Valley comprises studies on various outcomes, including cholesterol, in relation to exposure to PFOA in drinking water. Our analyses are based on 56,544 people aged over 18, who had lived in six contaminated water districts, and participated in the survey in 2005-6. Water district was strongly associated with serum PFOA, and thus is a good instrument if the populations of each water district have similar distributions of unmeasured risk factors for cholesterol. We assess the use of water district and alternatives as an instrument for measured serum PFOA, to estimate the association between PFOA and cholesterol.
Results: Water district was strongly associated with serum PFOA (Cragg-Donald F statistic = 3699, R^2=0.43). The IV estimated coefficient for association of log serum PFOA with log LDL cholesterol was 0.0072(se= 0.0017). In comparison, a simple linear regression estimate, adjusted as was the IV estimate for age, gender, BMI and medication was 0.015 (se=0.001).
Conclusions: While some types of confounding are avoided by the IV estimate, differences in unmeasured risk factors across water districts may cause bias. In this case both the conventional and IV estimates show an association, which strengthens previous conclusions about the relationship between serum PFOA and cholesterol.

TRANSPORTION, AIR POLLUTION AND PHYSICAL ACTIVITIES (TAPAS), A 6-CITY INTEGRATED HEALTH RISK ASSESSMENT PROGRAM OF ACTIVE TRAVEL POLICIES: THE PARIS CASE STUDY

Hala Nassif, *Institut de Recherche bioMédicale et d'Epidémiologie du Sport, INSEP, Paris, France Université Paris-Descartes, Paris, France*

Hélène Desqueyroux, *ADEME - Département surveillance de la qualité de l'air, Paris, France*

Maxime Chombart, *ADEME - Département surveillance de la qualité de l'air, Paris, France*

Gérard Missonnier, *ADEME - Département surveillance de la qualité de l'air, Paris, France*

Jean-François Toussaint, *Institut de Recherche bioMédicale et d'Epidémiologie du Sport, INSEP, Paris, France Université Paris-Descartes, Paris, France*

Audrey de Nazelle, *Centre for Research in Environmental Epidemiology (CREAL) Barcelona, SPAIN*

Background and Aims: Active transportation helps in decreasing the burden of rising chronic diseases, the epidemic of obesity and air pollution emissions. Within the general program developed by the TAPAS consortium we present here the Paris case study.

Methods: We collected data from national or private surveys. Indicators collected are: demographic/geographical characteristics of the city, prevalence and type of active transportation, accident rates, and exposition to pollutants. In addition, we conducted a pilot study using heart rate monitors and specific indicators measured within a trip to measure the energy expenditure (EE) in different transportation modes. Second, we are developing a systematic approach to address and involve stake holders in the active travel initiative.

Results: Paris has 2.2 million inhabitants. The number of people that declare practicing a leisure time physical activity for at least 20 minutes (min) per day is 55.4% and the average daily air pollution (with the suburbs) is 20.9 $\mu g/m^3$ for PM10, 13.5 $\mu g/m^3$ for PM2,5 , 79.7 $\mu g/m^3$ for O_3 According to a recent national survey (2000-2008) the number of trips by foot constitutes 46.63% of the total transportation modes with an average time of 14.33 min; the bike represents 2.69% for an average duration of 20.69 min per trip. The public transportation and the car represent 33.52% and 12.12% respectively. Cycling accidents in 2008 were 567 with 5 reported deaths. The pilot study for EE revealed that for a same itinerary a 70 kg male subject increases his EE (kcal/hr) without significantly increasing the time spent commuting (e.g.173 kcal/hr for the subway *vs* 495 kcal/hr for cycling). Finally, on-going meetings with several stake holders are arising great interest in the TAPAS initiative leading to valuable collaborations.

Conclusion: The following on-going research offers valuable proof and insight to the development of possible further future policies that would promote the use of active transportation.

ETHICAL CHALLENGES IN EPIDEMIOLOGIC STUDIES ON AIR POLLUTION AND HEALTH

Jouni J.K. Jaakkola, *Center for Environmental and Respiratory Health Research, University of Oulu*

The importance of clean air for healthy life was recognised already in the Hippocratic corpus in 5th century BCE. (*On Airs, Waters, and Places*). Epidemiologic studies continue to play an important role in providing evidence about adverse effects of ambient air pollution during different periods of life on respiratory, cardiovascular, carcinogenic diseases and adverse pregnancy outcomes. These studies support air pollution regulations; although recent epidemiologic evidence suggests that air pollution levels below current standards increase health risks. Epidemiologist conducting studies may face ethical challenges at different phases from design and conduct to interpretation and reporting of results.

Typically large populations are exposed to varying levels of air pollution. Often the average increase in the risk of adverse effects is from low to moderate, but the population health impact on common diseases can be substantial. Our design features or analytical approaches may be critical in indentifying susceptible groups, such as pregnant women, infants, senior citizens or individuals with chronic illnesses.

Air pollution exposure is often higher in socioeconomically deprived populations and low socioeconomic status may be related to susceptibility to adverse effect of air pollution. Choices of study design and analytical approach may either emphasize elimination of confounding due socioeconomic factors or elaboration of environmental inequity.

Production of air pollution can be linked to strong economic and political interests and therefore epidemiologists may feel pressure in publishing the results. What is the role of scientific community in supporting the epidemiologists?

Air pollution and green house gas productions are often linked, but there may be situations where alternative choices of energy production weaken green house gas emissions but strengthen ambient air pollutant emissions (e.g. gasoline or diesel engines).

This session provides a forum for identification of and discussion on ethical issues related to studies on air pollution epidemiology.

EFFECTS OF AIR POLLUTION AND TEMPERATURE ON VASCULAR FUNCTION IN PEOPLE WITH DIABETES

Yongsheng Li, *Joslin Diabetes Center*
Diane R Gold, *Harvard School of Public Health, Department of Environmental Health, Boston, MA, USA.and Channing Laboratory, Brigham and Women's Hospital, Department of Medicine, Harvard Medical School, Boston, Massachusetts, USA.*

Background and Aims: Diabetes is associated with impaired vascular function, and people with diabetes may be vulnerable to air pollution and temperature effects on cardiovascular morbidity and mortality. In people with diabetes, we investigated how changes in pollution and temperature influenced changes in brachial artery diameter that may reflect biologic mechanisms through which pollution influences the risk of clinical cardiovascular events.
Methods: The complete study population consisted of 49- to 85-year old Boston residents (N=64) with type 2 diabetes, observed up to 5 repeated times. Baseline brachial artery diameter (BAD), and flow- and nitroglycerin-mediated dilation were measured by ultrasound at each visit. Air pollutant exposures for black carbon (BC), organic carbon (OC), nitrogen dioxide (NO_2), $PM_{2.5}$, particle number (PN), sulfates (SO_4) and particulate mass components (nickel and zinc) were measured at our stationary ambient monitoring site. We applied linear models with fixed effect for subjects, adjusting for temperature, date and season. Effect estimates were scaled by the interquartile pollutant range (IQR).
Results: Smaller diameter was associated with increases in the means of the one- to four- day levels of pollution. For example, decreases in BAD occurred with increases in the mean 4-day levels of BC (-0.04 mm, 95% C.I.: -0.07 - -0.002 for an IQR=0.3 $\mu g/m^3$), OC (-0.07 mm, 95% C.I.: -0.11- -0.03), $PM_{2.5}$, NO_2, and CO. In contrast, diameter was larger by 0.13 mm (95% C.I.: 0.075 - 0.19) for an increase of 10 degrees C in the previous 24h mean temperature. FMD responses were less consistent, with a suggestion of positive associations mostly in subjects with smaller BAD (female).
Conclusion: The pollution- and temperature- associated changes in brachial artery diameter that we observed may reflect biologic mechanisms through which pollution increases cardiovascular risk in people with diabetes.

TEMPERATURE VARIABILITY AND LONG-TERM SURVIVAL

Antonella Zanobetti, Department *of Environmental Health, Harvard School of Public Health, Boston, USA*
Marie S. O'Neill, *Departments of Environmental Health Sciences and Epidemiology, University of Michigan School of Public Health, Ann Arbor, MI*
Carina J. Gronlund, *Departments of Environmental Health Sciences and Epidemiology, University of Michigan School of Public Health, Ann Arbor, MI*
Joel Schwartz, Department *of Environmental Health, Harvard School of Public Health, Boston, USA*

Background and Aims: Time series studies show that cold and hot temperatures, and their extremes, are associated with increased death rates. Few if any studies have evaluated longer-term temperature associations with deaths. Because there is evidence of adaptation to usual temperature, but higher deaths at unusual temperatures, we hypothesized that a long-term exposure relevant to mortality might be temperature variability.
We investigated whether the variance of summer (June-August) and winter (December-February) temperatures were associated with survival in four cohorts of persons with predisposing diseases in 135 US cities. Rather than modeling exposure cross-sectionally, as typical in cohort studies, we treated temperature variance as a time varying exposure.
Methods: We used Medicare data (1985-2006), and constructed cohorts of persons hospitalized with: chronic obstructive pulmonary disease (COPD), diabetes, congestive heart failure (CHF), and myocardial infarction (MI). Yearly summer and winter temperature variance were linked to the individuals during follow up in each city. We applied Cox's proportional hazard model for each cohort within each city, adjusting for individual risk factors, and long term trends, and pooled results across cities.
Results: Significant summer hazard ratios for mortality, ranged from 1.038 (95% Confidence Interval (CI): 1.024, 1.052) per an IQR increase in summer variance for persons with CHF, to 1.055 (95% CI: 1.035, 1.076) for persons with an MI. Associations during winter were also significant, with a hazard ratio of 1.017 (95% CI: 1.009, 1.025) for CHF, and 1.018 (95% CI: 1.008, 1.028) for persons with MI, per IQR increase in winter variance. Associations were higher in the elderly and lower in cities with a higher percent of green space.
Conclusions: Increases in temperature variability in the cold and warm seasons were associated with increased mortality of the elderly. Some adaptation measures, such as green space, may ameliorate this effect.

MOBILE PHONE USE AND HEALTH: INNOVATION IN RECRUITMENT TO THE UK COSMOS COHORT STUDY

Mireille B.Toledano, *MRC-HPA Centre for Environment and Health, Department of Epidemiology & Biostatistics, School of Public Health, Imperial College London, London, UK*
Rachel B. Smith, *MRC-HPA Centre for Environment and Health, Department of Epidemiology & Biostatistics, School of Public Health, Imperial College London, London, UK*
James E. Bennett, *MRC-HPA Centre for Environment and Health, Department of Epidemiology & Biostatistics, School of Public Health, Imperial College London, London, UK*
James Brook, *MRC-HPA Centre for Environment and Health, Department of Epidemiology & Biostatistics, School of Public Health, Imperial College London, London, UK*
Paul Elliott, *MRC-HPA Centre for Environment and Health, Department of Epidemiology & Biostatistics, School of Public Health, Imperial College London, London, UK*

Background: UK COSMOS is a new cohort, contributing to the international COSMOS study on mobile phone use and health. A 2009 UK pre-test study which used paper and online questionnaires, showed that paper-based recruitment procedures were too costly for large-scale recruitment. Ethical approval was granted to conduct the whole recruitment procedure online – consent, participant registration and questionnaire. To our knowledge this is the first UK health study to collect consent online.
Methods: The main recruitment campaign launched in April 2010, with postal invitations to almost 2.4 million UK mobile users via their network operator. Respondents logged into a secure website to consent and register, before completing the baseline questionnaire on mobile usage, lifestyle and health. Participants could log in/out to complete the questionnaire in their own time. We used e-mail and SMS to remind participants to complete the questionnaire if they did not do so in one session.
Results: To date, 67,988 people have joined the cohort (pre-test = 246, main launch = 67,742). The overall recruitment rate across both phases was 2.83%. 99.6% of the cohort completed the recruitment process online. The cohort comprises 46% males, 54% females, with median age of 48. Age distribution is similar by sex. Distribution of mobile call usage is similar by sex (by design the cohort was stratified by mobile phone usage), but varies by age. Preliminary analysis of e-mail/SMS reminders suggests SMS may be more effective than e-mail in promoting questionnaire completion.
Conclusions: We have demonstrated use of online e-consent and data collection in epidemiological research. Future large-scale epidemiological studies may benefit from the cost-savings and streamlining inherent in this approach. During 2011, we will continue our innovative use of new technologies by piloting recruitment via SMS invitation (ethical approval already obtained) to boost the cohort size and potentially improve response rates.

THE VICIOUS CYCLE OF WATER- PARASITE, IS THE FIRST PROBLEM OF CHILDREN'S ENVIRONMENTAL HEALTH AS A FACTOR IN MALNUTRITION AND INFECTION IN CHRONIC DEGENERATIVE EMERGING ECOSYSTEMS

Cuitláhuac Alfonso Rovirosa Madrazo *D.Sc, EMS*, *CEBMMC A.C, CONACYT cuitlahuacrovirosa@exalumno.unam.mx*
Atieel Flores Morales *M.D.' Centro de Estudios Superiores de Tepeaca, Puebla*

Background and Aims: The problem of environmental sanitation of the water in *emerging countries* such as the case of **México** is already an alarming problem. Infections from parasites, bacteria, viruses and protozoa produce malnutrition, intestinal infections and serious injury in child populations. Vectoring caused by the mixture of wastewater (WW) flowing water bodies used by marginalized populations is still a problem exceeded for intestinal infection levels in children 8 months to 5 years. The study of sampling 100 children in **Coahuixco** in communities, state of **Puebla**, **Mexico**, we throw the result that the strategy based on post-infection parasite established by the government is inefficient, expensive and only reveals that there are adequate controls in the relationship: *Downloads WW-Infiltration Reusable Water Bodies* used by the communities.
Objectives: Propose as to reduce intestinal infections in children in high poverty communities with diagnostic methods for rapid response.
Methods: We used GIS techniques Stool, fresh *in situ* fixation $(CH_2O)n$ the characterization with high resolution microscopy and differentiation sex parasites in ♀ **-** ♂ to reduce reinfection.
Results: We found the following species: *C. mesnili*, *E. Coli*, *E. histolytica*, *G. lamblia* and *A. lumbricoides*. He threw 29% positive (+), we proposed solutions downloads (WW) with chlorine tablets (Cloralex-MX) in toilets to inactivate upstream WW and type bag filter housings for drinking water (Pentair's water supply-USA). **Conclusions:** We must change the policy to combat the environmental prevention parasitemias by a WW controlling discharges and water supply otherwise the infant mortality will not decline.

URBAN SPRAWL AND BODY MASS INDEX: A FIXED-EFFECTS ANALYSIS IN TWO COHORTS OF OLDER WOMEN IN THE UNITED STATES

Peter James, *Harvard School of Public Health, USA*
Jaime E. Hart, *Harvard School of Public Health, USA*
Philip J. Troped, *Purdue University, USA*
Francine Laden, *Harvard School of Public Health, USA*

Background and Aims: Growing research has highlighted how dense neighborhoods with connected street networks may influence body mass index (BMI) by providing opportunities for walking or bicycling. We aim to study whether this relationship exists prospectively in individuals who change neighborhoods.
Methods: This study examines the effect of changes in the county sprawl index, a measure of residential density and street accessibility, and changes in BMI in a sample of Nurses' Health Studies (NHS and NHSII) participants throughout 831 counties across the continental United States who moved at least once between 1986 and 2005 (n=10,519 nurses with 14,326 moves for NHS and n=11,560 nurses with 17,414 moves in NHSII).
Results: For NHS, the mean change in the county sprawl index from pre-move to post-move address was -9.3 (standard deviation 34.7), while for NHSII, the mean change in the county sprawl index was -10.8 (standard deviation 44.2). The mean change in BMI was 0.2 kg/m^2 (standard deviation 1.6) for NHS and 1.2 kg/m^2 (standard deviation 2.3) for NHSII. At first move, the average age of NHS participants was 60.3 years (range 39-83), and 40.1 years (range 26-57) for NHSII. In fixed-effects analyses adjusting for age, smoking status, race, and husband's education, moving to a county with a one standard deviation decrease (37.6) in the county sprawl index (indicating a move to a less dense, less compact county) was associated with a two-year change in BMI of 0.005 kg/m^2 (95% CI -0.024, 0.035) in NHS and -0.004 kg/m^2 (95% CI -0.037, 0.030) in NHSII. We found no evidence of effect modification by age, smoking status, race, or husband's education.
Conclusions: None of the associations examined in this study were statistically significant, indicating that moving less dense, less compact county is not associated in our study with change in BMI within two years.

PILOT TESTING OF HEALTH-RELATED INDICATORS OF CLIMATE CHANGE IN EUROPE

Andrey Egorov, *WHO European Centre for Environment and Health, Bonn, Germany*
Dafina Dalbokova, *WHO European Centre for Environment and Health, Bonn, Germany*
Christian Gapp, *WHO European Centre for Environment and Health, Bonn, Germany*
Anna Paldy, *National Institute of Environmental Health, Budapest, Hungary*
Janos Bobvos, *National Institute of Environmental Health, Budapest, Hungary*
Michal Krzyzanowski, *WHO European Centre for Environment and Health, Bonn, Germany*

Background and Aims: The WHO European Centre for Environment and Health has completed the Climate, Environment and Health Action Plan and Information System (CEHAPIS) project involving the specification of health-related indicators of climate change. These indicators will be integrated in the Environment and Health Information System (ENHIS) to monitor climate change-related environmental health issues and public health benefits of adaptation and mitigation policies.
Methods: Pilot testing of seven indicators was conducted using data from CEHAPIS project partners and international databases. Methodologies were finalized and recommendations developed for improving data availability.
Results: Population-weighted exposure to ground level ozone across Europe was estimated using compiled datafrom the European Environment Agency. Surveys of policies to prevent heat-related health effects in France, Hungary and Spain demonstrated substantial between-country variation, and utility of the proposed indicator. Daily data from Budapest, Hungary was used to demonstrate a methodology of heat wave exposure assessment. An easy-to-use excess mortality estimation method was shown to be sufficiently sensitive only for high intensity heat waves. Population exposure to ragweed pollen in Hungary was unusually low during the dry hot summer of 2007, which matched expectations. Information on pollen exposure in other countries was not readily available. In Ireland, unusually high and early seasonal peaks of Salmonellosis and Cryptosporidiosis were also observed in 2007. The temporal resolution of the European Centre for Disease Prevention and Control infection surveillance data was insufficient for assessing the effects of climate variability in most countries.
Conclusions: Exposure to ozone and policies to reduce health effects of heat are indicators ready for implementation in ENHIS. Necessary actions concerning surveillance, data accessibility, legislation, and institutional infrastructure were recommended to the European Commission in order to advance the implementation of the CEHAPIS indicators and monitor health-related aspects of climate change.

A CONCEPTUAL FRAMEWORK FOR SUSTAINABLE FOOD PRODUCTION: THE ENVIRONMENTAL NUTRITION MODEL

Sabaté J[1], Sranacharoenpong K[1], Hilton J[1], Soret S[2]

[1]Loma Linda University, Department of Nutrition, [2]Loma Linda University, Department of Environmental and Occupational Health

Background and Aims

Climate change is emerging as a major challenge of the 21st century. Agriculture both affects and is affected by climate change, yet agriculture and food production has been largely overlooked in discussions on climate change policy. A new paradigm is needed for sustainable food system development and climate change mitigation. Central to this new paradigm is a comprehensive understanding of how food systems shape and are shaped by biological, social and environmental relationships and interactions.

Methods

Research was conducted along several consecutive strands: 1) Current food production practices; 2) Life cycle analysis on multiple foods of plant and animal origin; 3) Quantification of food systems waste generation, including greenhouse gas emissions; 4) Determinants of food consumer demand; and 5) Population food eating patterns. These and other lines of inquiry established the need for a framework and led to the development of the Environmental Nutrition Model.

Results

The Environmental Nutrition Model is a graphic conceptual framework that encompasses the multifaceted associations of the food system with the physical and social worlds, and its intended and undesirable consequences in the environment and in the health of populations. It delineates the inputs and outputs of the food system, showing desirable (food) and undesirable (waste) products. The lifecycle of foods, determined by the processing, transportation, storage, retail and waste disposal practices are defined and affected by consumer demands in a given society.

Conclusions

This Environmental Nutrition Model will be a useful didactic and research tool to explain, understand and ultimately contribute to the necessary modifications and changes of the current food systems to achieve more sustainable practices. The graphic model will be presented.

AMBIENT AIR POLLUTION AND CARDIOVASCULAR MORBIDITY AMONG POTENTIALLY SUSCEPTIBLE GROUPS

Maggie L. Clark, *Department of Environmental and Radiological Health Sciences, Colorado State University, USA*

Background and Aims: Evidence suggests that risks associated with exposure to ambient air pollutants are not uniform across individuals; however, there is considerable uncertainty in estimates for susceptible populations.
Methods: We conducted a five-year study (2003-07) examining the association of fine particulate matter ($PM_{2.5}$) and gases with cardiovascular hospital admissions in Denver, Colorado. We investigated the relationships between daily counts of cardiovascular disease admissions and same-day concentrations of ambient air pollutants ($PM_{2.5}$ mass, elemental carbon [EC], organic carbon [OC], sulfate, nitrate, source-apportioned PM, gases) among potentially susceptible subgroups defined by comorbid illness (using secondary diagnoses, e.g. hypertension, diabetes), age, race, sex, and payment type.
Results: The mean daily concentration of $PM_{2.5}$ mass was 8.0• g/m^3 (standard deviation 5.1• g/m^3). We observed increases in cardiovascular disease hospital admissions, particularly for ischemic heart disease, in relation to increases in $PM_{2.5}$ mass, EC, and OC concentrations as well as several of the PM source factors. For the PM species, the associations were strongest for EC (relative risk [RR per interquartile range] = 1.019; 95% confidence interval [CI] 1.010-1.028 per 0.33• g/m^3 increase) and OC (RR=1.017; 95%CI 1.006-1.028 per 1.7• g/m^3 increase). We did not observe consistent evidence of heterogeneity of these associations by subgroups. Some indication of stronger effects among patients with comorbid ischemic heart disease (IHD), including coronary atherosclerosis, compared to patients without comorbid IHD and among non-white patients compared to white patients was observed, although confidence intervals were wide and overlapping.
Conclusions: Although associations were detected among the total population at relatively low PM mass and component concentrations, we did not observe strong evidence of effect modification by potentially susceptible subgroups. The use of secondary diagnoses may have limited our ability to detect comorbid illness.

FOOD PRODUCTION, POPULATION DIETARY PATTERNS AND CLIMATE CHANGE

Sam Soret ,*Loma Linda University, Department of Environmental and Occupational Health*
Kitti Sranacharoenpong ,*Loma Linda University, Department of Nutrition*
Janice Hilton, *Loma Linda University, Department of Nutrition*
Joan Sabaté, *Loma Linda University, Department of Nutrition*

Background and Aims: Substantial evidence exists linking food production and environmental degradation. Often overlooked is the interconnection between food consumption patterns at the population level and climate change. The aim of this study was to compare the greenhouse gas (GHG) emissions (CO_2, CH_4, and N_2O) from current agricultural operations to produce the foods actually consumed by a health-oriented population of vegetarians and nonvegetarians.
Methods: Food consumption patterns of vegetarians were compared with nonvegetarians by using data from the Adventist Health Study, a cohort of 34,000 California Adventists, of which 45% were vegetarians. Consumption of 10 foods of a 50 food-item questionnaire were significantly different between the two dietary groups. Using primary agricultural data from California and published emission factors, we estimated CO_2 emissions associated with three production inputs: primary energy, pesticides, and fertilizers, utilized to produce each of the ten foods, including the production of the feed given to animals. We also quantified emissions for CH_4 from ruminant digestion and manure handling and storage, and N_2O from crop N fertilization and animal waste management.
Results: Production of the plant foods consumed by the average vegetarian results in greater emissions compared to nonvegetarians: 35 versus 27 Kg of CO_2-eq/yr. Conversely, the per capita consumption of animal foods by vegetarians results in much less emissions compared to nonvegetarians: 19 versus 475 Kg of CO_2-eq/yr. Overall, the per capita difference in annual emissions is 449 Kg of CO_2-eq greater for the nonvegetarian diet.
Conclusions: These findings support the hypothesis that plant-based diets have markedly lower GHG emissions and thus less global warming potential than meat-based diets, although exceptions may occur in relation to some agricultural practices, transportation and processing. Daily food choices of large segments of the population may ultimately result in major impacts on the environment and have public health consequences.

ACUTE EFFECTS OF WOODSMOKE EXPOSURE AS MEASURED BY PERSONAL CARBON MONOXIDE ON HEART RATE VARIABILTY IN GUATEMALA

John P. McCracken, *Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA - Center for Health Studies, University of the Valley, Guatemala City, Guatemala*
Joel Schwartz, *Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA*
Anaité Díaz, *Center for Health Studies, University of the Valley, Guatemala City, Guatemala*
Kirk R. Smith, *Environmental Health Sciences, University of California, Berkeley, CA, USA*

Background and Aims: Evidence suggests that fine particulate air pollution is a cause of cardiovascular disease, but little is known about the effects of indoor air pollution from household solid fuel use in developing countries. In the RESPIRE randomized trial of a chimney woodstove, we examine short-term associations between personal carbon monoxide (CO), as a proxy for woodsdmoke, and heart rate variability (HRV).
Methods: Electrocardiogram sessions lasting 20 hours were repeated up to three times among 49 intervention (chimney stove) and 70 control (open fire) women 38 to 84 years of age. HRV values (SDNN, RMSSD, HF, LF, VLF) were recorded for each 30-minute period. Continuous personal CO exposures were measured starting 24 hours before and during each electrocardiogram. Linear mixed effects models with random intercept for subject, random intercept for study day nested within subject, and a first-order autoregressive term within subject-day were used to estimate the association between natural log transformed 30-min HRV and CO (1-hour, 4-hour, and 8-hour moving averages), adjusting for hour of day (dummy variable for each hour), age, body mass index , asset index, ever smoking, secondhand tobacco smoke, wood-fired sauna use, season, ambient temperature, and rainfall.
Results: The means of 30-min average personal CO levels were 2.6 (n=4265, SD=2.5, range=0.2-20.6) and 1.0 (n=4426, SD=1.3, range=0.2-9.3) ppm in the open fire and chimney stove groups, respectively. All models we ran suggest HRV increases with personal CO. Each 1 ppm increase in 4-hour moving average CO was associated with a 4.6% (95% CI: 1.2, 8.2) increase in LF and a 2.4% (95% CI: 0.3, 4.6) increase in VLF. Associations with 8-hour moving average CO were similar and were significant for LF, VLF, and RMSSD.
Conclusions: Personal exposure to woodsmoke was associated with increased HRV, particularly the low frequency components, suggesting that woodsmoke exposure has acute effects on the autonomic control of the heart.

PREVALENCE OF INFECTIOUS DIARRHEA CAUSED BY *SALMONELLA SPP.* IN SLOVAKIA (SR)

Janka Poracova, *Presov University in Presov, Excellence Centre of Human and Animal Ecology, Slovakia*;
Tatiana Kimakova, *Pavol Jozef Safarik University in Kosice, Faculty of Medicine, Department of Public Health, Slovakia*
Marta Blascakova, *Presov University in Presov, Excellence Centre of Human and Animal Ecology, Slovakia*
Lucia Frankova, *Presov University in Presov, Faculty of Humanities and Natural Sciences, Department of Biology, Slovakia*

Background: Salmonella infections are caused by non-typhoid salmonellas which are transmitted from animals to human with typical clinical symptoms including severe diarrhea with fever, etc. (Bálint et al., 2000). They are Salmonellas primarily adapted to animals causing zoonoses. Apart from other characteristics of pathogenicity and virulence factors common also for typhoid salmonellas they increasingly produce enterotoxin which is similar to enterotoxic *E. coli*. Together with cytotoxin of other invasive enteropathogens they cause inflammatory type of diarrhea. The source of infection include warm-blooded and cold-blooded vertebrates (Rovný et al., 1995).
Material and methods: The diagnosis of salmonellosis is confirmed by the clinical picture testing stool, urine, hemocultivation, cultivation of pus or other liquid, obtained by puncturing.
Results: During years 2000 - 2006 salmonellosis mostly occurred in Slovakia in months May -September with the highest incidence of 2886 cases (June 2000), 2819 (July 2001), 2449 (June 2002), 2265 (June 2003), 2086 (September 2004) and 1879 (September 2005). In October no occurence of salmonellosis was monitored during the whole period. The increase was recorded in months November - December (1675-1438, 2000; 1535-1552 in year 2001; 962-1118 in year 2002; 947-1213 in year 2003; 1126-1127 in year 2004; 1071-734 in year 2005). The most frequent causes of salmonellosis included infected households (28% of cases), public supply (25%) school meals (20%), catering (8%), hospitals (5%), social institutions (2%), import (2%), other (4%).
Conclusion: Sustainability of good health is the main objective of the European Union and the organizations which through their activities are involved in processes to improve public health, disease prevention, and identifying sources of health hazards.

Anthony J. Hedley, School of Public Health, The University of Hong Kong, Hong Kong, China

Chit–Ming Wong, School of Public Health, The University of Hong Kong, Hong Kong, China

Background and Aims: A wide body of epidemiological evidence demonstrated consistent associations between temperature and daily mortality mainly from ecological time series studies. But few studies have examined these associations in a cohort.

Methods: We used a matched case-control design with time-dependent covariates to assess short-term effects of apparent temperature (AT) on mortality in a cohort of 66,820 persons aged 65 years or older, with a total of 14,446 deaths after about 10 years of follow up. The cases and controls were matched by duration of exposure with adjustment for particulate matter of aero-diameter ≤ 10μm (PM_{10}) and potential confounding factors. We examined the associations of mortality with mean AT, defined by moving averages of AT at current day up to the previous 13 days for cool season (≤20.8 ^{o}C) and up to 7 days for warm season (≥28.3 ^{o}C).

Results: In the cool season, a 1^{o}C decrease of AT in moving average of current day up to previous 6 days was associated with 3.1 % (95% confidence interval:1.9%, 4.3%), 3.5% (1.4%, 5.6%) and 3.9% (0.1%, 5.9%) increase for all-cause, cardiovascular and respiratory mortality, respectively. In the warm season, a 1^{o}C increase of AT in moving average of current and previous one day was associated with 1.1 % (–1.0%, 3.2%), –0.8 % (–4.6%, 3.2%) and 2.2 % (–0.3%, 7.7%) change for the corresponding mortality categories.

Conclusions: In the cool season apparent temperature was associated with increased risks of all-cause and cardiorespiratory mortality. But in the warm season the associations were not observed in the sub-tropical city where air conditioners are commonly used.

IMPACT OF EMISSIONS FROM ALUMINUM ELECTROLYSIS PLANTS ON AMBIENT AIR POLLUTION AND PREGNANCY OUTCOMES AND NEWBORN'S HEALTH

Vladimir B. Gurvich, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*
Dmitriy V. Kuzmin, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*
Vladimir V. Ryzhov, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*
Nina P. Makarenko, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*

Background and Aims: We studied two aluminum-producing plants located in the cities of Kamensk-Uralskiy and Krasnoturyinsk (Middle Urals) emitting pollutants creating multicomponent environmental contamination. The change from Soderberg to prebaked anodes implemented early this century for some of the electrolyzers in Kamensk-Uralskiy has allowed total atmospheric emissions to be reduced 3.5 times. The purpose of our study was investigated the possible adverse effects of ambient air pollution on pregnancy and birth outcomes, exposed to such pollution in these towns.
Methods: We studied ambient air pollution with fluorides, benzo(a)pyrene, alkali and sulfur dioxide during the warm and cold seasons of 2004 at a distance of up to 3 kilometers from the aluminum plants. Information on the health status of pregnant woman and newborn dwelling in the same areas was obtained from official medical documentation for the same period. The association of health with ambient air pollution was analyzed using linear multiple regression models.
Results: The maximum daily average concentrations in Krasnoturyinsk and Kamensk-Uralskiy were (in mg/m^3) respectively, 0.0166-0.0806 and 0.008867-0.0433 for HF, 0.024-0.124 and 0.014-0.064 for low soluble fluorides, 0.000011-0.00005 and 0.000013-0.000067 for benzo(a)pyrene, 0.0144-0.0622 and 0.0047-0.0152 for NaOH, 0.075-0.125 and 0.01-0.0425 for SO_2.
There was not found any association of the pregnant women's health outcomes with ambient air pollution. The incidence of illness in newborn was higher in Krasnoturyinsk than in Kamensk-Uralsky, including intrauterine growth retardation (IUGR), 128,0‰ vs. 37,0‰ and low birth weight (LBW; < 2,500 g) - 70,0‰ vs. 42,0‰, respectively. IUGR was associated with concentrations of low soluble fluorides (B=176.423±60.445) and SO_2 (B=194.015±46.297), and also LBW with benzo(a)pyrene (B=8582.681±2478.736) and NaOH (B=11.860±4.605).
Conclusions: Industrial emissions from aluminum electrolysis plants contaminate the environment of adjoining residential areas (particularly where the use of Soderberg anodes continues) demonstrating association with considerable impairment to newborn's health.

COPHES GUIDELINES TO MEASURE EXPOSURE OF CHILDREN AND THEIR MOTHERS: SELECTION OF PARTICIPANTS, RECRUITMENT AND FIELD WORK IN DEMOCOPHES

Milena Horvat, *Jožef Stefan Institute, Ljubljana, Slovenia*
Louis Bloemen, *Environmental Health Science International, Amsterdam, The Netherlands*
Marike Kolossa-Gehring, *Federal Environment Agency, Berlin, Germany*

Background and Aims: In support of the European Environment and Health Action Plan, European scientists have started to define, organize and manage a coherent human biomonitoring (HBM) approach. COPHES (Consortium to Perform HBM on a European Scale) provides the scientific and conceptual background. DEMOCOPHES, the respective pilot study, will work on the hypothesis that HBM can be performed in a coherent and harmonized way throughout Europe.
Methods: Commonly developed protocols, strategies and scientific tools serve as the basis to measure exposure of 120 mother and child pairs to mercury, cadmium, cotinine and phthalates in 17 participating countries. To develop a common protocol for recruitment and fieldwork was a challenging task. Selecting participants from inhabitant registries is the optimum strategy, but due to country-specific restrictions a second option, the selection of participants via schools, is offered. Participants are chosen from two sampling locations: one area with low and another with a high degree of urbanization. A written consent, questionnaires, a protocol sheet, urine and hair samples and individual letters of the results for the participating families are the common fundamental fieldwork instruments.
Results: The essential elements for quality control of field work were identified and will be applied according to the developed SOPs: fieldwork manuals are being prepared, interviewers will be trained and check-lists for internal and external quality control will be used.
Conclusions: On the basis of a well reasoned fieldwork concept and SOPs for all steps of the study including chemical analyses and statistical data treatment, evaluation of DEMOCOPHES will help COPHES to establish harmonized procedures for HBM in Europe. HBM can support policy in a multitude of ways, inter alia, as a tool to support REACh, to identify exposed subgroups and to help evaluate policy actions for exposure reduction.

COPHES and DEMOCOPHES are funded by the EU (FP7 grant agreement 244237 and LIFE09 ENV/BE/000410). Thanks to the COPHES consortium for the support. www.eu-hbm.info

European NO2 land use regression incorporating satellite- and ground-based measurements

Danielle Vienneau, *MRC-HPA Centre for Environment and Health, Department of Epidemiology and Biostatistics, Imperial College London, United Kingdom*

Dylan B. Millet, *Department of Civil Engineering, University of Minnesota, Minneapolis, USA*
Julian D. Marshall, *Department of Civil Engineering, University of Minnesota, Minneapolis, USA*

Background and Aims: Land use regression (LUR) models have increasingly been applied to assess air pollution exposures typically at the city level. Fewer examples at the continental scale exist. With recent improvements in data quality and availability, including pollutant measurements from satellites such as Ozone Monitoring Instrument (OMI), modelling over larger areas at finer spatial resolutions is possible.
Methods: Land use regression was used to model ambient NO2 using ca. 2000 monitoring sites across Western Europe from the Airbase network. The network includes sites located in background, industrial and traffic environments. Characteristics of land use in buffers from 100 to 10,000m included high and low density residential, industrial, ports, urban green space, total built up, and natural areas. Major, secondary and local roads, derived from a 1:5,000 road network for Europe, were extracted in buffers up to 1000m. Information on altitude, population density and distance to sea were also available. LUR models with and without satellite-derived (OMI) NO2 concentrations were explored for years 2005-2007 for all sites combined.
Results: Preliminary results for year 2007 indicate a model performance of R2 = 0.49, with a SEE of 0.452 based on annual-mean concentrations (natural log) at monitoring sites. Inclusion of satellite data improves model performance (R2: 0.44 without satellite data, 0.49 with satellite data). Current refinements to the model are expected to improve performance. Preliminary models include satellite measurements, proportion of built up land, local roads and major roads as the most important independent variables. LUR models for 2005 and 2006 will also be presented.
Conclusions: Preliminary results support the potential to build a Europe-wide LUR models for NO2 using readily available data. Satellite-derived measures of ground-level NO2 appear to improve model performance. Our results will be used to construct high resolution (~100m) maps of NO2 concentrations across Western Europe.

ASSESSMENT OF HEALTH COSTS AND BENEFITS FOR ACTIVE TRANSPORT

Ari Rabl, *CEP, ARMINES/Ecole des Mines de Paris, 6 av. Faidherbe, 91440 Bures sur Yvette, France, ari.rabl@gmail.com*
Audrey de Nazelle, *Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain.*

Backround: There is a growing awareness that significant health and environmental benefits could be achieved by reducing car use and shifting instead to active transport. We estimate health impacts due to a shift from car to bicycling or walking.
Methods: We evaluate four effects: changes in exposure to ambient air pollution for individuals who change their transportation mode, their health benefit, health benefit for the general population due to reduced pollution, and risk of accidents. We consider only mortality in detail. For the dispersion of air pollution from cars we use results of the Transport phase of the ExternE project series and derive general results that can be applied in different regions. We calculate physical activity health benefits of bicycling and walking based on the most recent review by the World Health Organization.
Results: For a driver who switches to bicycling for a commute of 5 km (one way) 5 days/week 46 weeks/yr health benefits from physical activity are worth about 1300 €/yr, and in a large city (>500,000) the value of the associated reduction of air pollution is around 30 €/yr. For individuals who makes the switch, changes in air pollution exposure and dose implies a loss of about 20 €/yr under our standard scenario but that is highly variable and could even have the opposite sign. The results for walking are similar. Increased accident risk for bicyclists implies a loss that is an order of magnitude smaller than health benefits of physical activity. Uncertainty analyses show the order of magnitude of these estimates is robust.
Conclusion: Despite large uncertainties it can be concluded that health benefits due to physical activity is by far the most important item. We illustrate results comparing costs and benefits of the Vélib bicycle sharing program of Paris.

ASSOCIATION BETWEEN PARENTAL ALCOHOL-RELATED BEHAVIORS AND CHILDREN'S DRINKING

Background and Aims. Many researches have evidenced a high prevalence of youthful use of alcohol. Aim of this study was to acquire information about the pupil's alcohol-related behaviors and parent's use of and attitudes toward alcohol in order to assess the presence of early risk behaviors in pupils.
Methods. The data were collected using a questionnaire anonymous, semi-structured and self-administered. A total of 281 pupils resident in Catania (Males: 49.8% Females: 50.2%), aged between 6 -12 years have joined the survey .
Results. 42.3% of the pupils have already tasted alcohol (M: 49.3% F: 35.5%, $p < 0.025$), in particular the 29.9% the wine (M: 35.0% F: 24.8%), the 30.6% the beer (M: 40.7% F: 20.6%, $p < 0.0005$) and 12.8% the strong drinks (M: 16.4%, F: 9.2%). 40.2% of the pupils (ages 6-12) drink alcohol (M: 44.3% F: 36.2%). Overall, 60.5% of pupils live with families who use alcohol at the meal (M: 63.6% F: 57.4%) and the fathers drinking are more frequent than mothers drinking (M: 63.7% F: 24.9%, $p < 0.0005$). The pupils that had tasted alcohol and live with parents drinker (52.9%) are significantly more numerous ($p < 0.0005$) than those living with parents non-drinker (21.6%). At the end, the percentage of pupils drinker (54.1%) living with parents drinker was significantly higher ($p < 0.0005$) than that living with parents non-drinker (18.0%).
Conclusions. Results highlight an early/widespread alcohol use and an elevated prevalence of pupils who use alcohol. Moreover the findings suggest that living with parents drinkers favor the initiation and use of alcoholic beverages.

Background and Aims: Within the TAPAS research program, quantitative assessments are developed for six case study cities in Europe, linking determinants of active travel to potential co-benefits and co-risks of modal shifts from motorized to non-motorized modes of travel. We describe here the Barcelona case study.
Methods: We identified local sources of information from government agencies describing active travel and environmental conditions. We aimed at selecting policies of local and international interest, with quantifiable or demonstrated effectiveness. We reviewed local and regional governmental policy documents; met individually with agency representatives, elected officials, and others; and organized a local stakeholder workshop. We are also conducting experimental work generating new data to help fill research gaps in current framework.
Results: Barcelona, capital of the Catalan region of Spain, has 1.6 million inhabitants. Only 60% of Catalans reach recommended levels of physical activity, 20% are entirely sedentary. With a low 2% of trips made cycling, Barcelona and its mild Mediterranean climate (average 17.3 degrees Celsius, 74 day of rain) has high potential to increase cycling. Within the city, 45% of trips are made on foot, 30% by public transport, 10% by car. Due to the greatest car density in Europe (6.1 cars/km^2), Barcelona is highly polluted, with, on average: 40$\mu g/m^3$ PM10 , 19$\mu g/m^3$ PM2.5, and 50$\mu g/m^3$ NO_2 concentrations in 2009. Each year 1500 pedestrians are injured, 100 seriously and 15 die. Cyclists account for 300 injuries and about 2 deaths per year. Relevant policies we are considering for assessment include 1) Bike sharing system (Bicing), 2) bike lane network; 3) intermodality; 4) traffic calming. We have piloted successfully the experimental study of commuter exposure-health relationships and the survey of active travel determinants.
Conclusion: Barcelona is an interesting case for assessing potentials to increase physical activity while addressing challenging environmental conditions to mitigate risks.

Background and Aims: The estrogenic insecticide chlordecone was extensively used from 1973 to 1993 in French West Indies, to control banana root borer. Its persistence in soils has lead to the widespread pollution of the environment including tap water sources and crops. Foetal exposure to endocrine disrupting chemicals may increase obesity risk. The effect of prenatal chlordecone on infant's growth is unknown. Our objective was to study the association between prenatal chlordecone on infant's growth at birth and 3 months.
Methods: 1042 pregnant women have been enrolled in a prospective cohort study in Guadeloupe between 2004 and 2007. A sub-cohort has been followed at 3, 7 and 18 months with weight and height collected in 303 term newborns at birth and in 248 infants at 3 months. Chlordecone has been assessed in 253 maternal blood samples at delivery and in 211 cord blood samples (detection limit =0.06 ng/L).
Results: Chlordecone has been detected in 55.9% of cord blood samples and in 89.7% of maternal samples. When detected, the median value for chlordecone was 0.30 ng/ml in cord blood and 0.39 ng/ml in maternal blood. Newborns with chlordecone in cord blood higher than the median presented smaller length at birth than newborns with chlordecone below the median or not detected values (p-trend=.02) after adjustment, but no difference in ponderal index, birthweight, or head circumference. Infants with chlordecone level in cord blood higher than the median had higher ponderal index at 3 months (p-trend=.07). Associations were found between chlordecone in maternal blood and ponderal index (p-trend=.04), weight (p-trend=.003) and weight gain at 3 months (p-trend=.007) after adjustment for maternal age, infant's age, maternal BMI, smoking, alcohol, diabetes, infant's gender, breastfeeding, and lipids.
Conclusion: Chlordecone at birth was associated with a decreased length at birth and increased ponderal index at 3 months.

EXPOSURE TO PARENTAL SMOKING AND THE RISK OF SMOKING UPTAKE IN PUPILS

Margherita Ferrante, *Department "GF Ingrassia", Sector of Hygiene and Public Health, Catania University, Catania, Italy*

Background and Aims. There is increasing evidence that contact with other smokers, particularly in the family, is a strong determinant of risk of smoking uptake. Aim of the study was to acquire information about the pupil's smoking habits and parent's use of and attitudes toward tobacco in order to assess the presence of early risk behaviors in pupils.
Methods. Population data, initiation and smoking behavior of pupils, smoking habits of cohabiting family were collected by an anonymous and semi-structured self-administered questionnaire. The research involved 281 pupils (M: 49.8% F: 50.2%) of a primary school in Catania between 6-12 years of age.
Results. The 6.0% of the pupils had already tried to smoke tobacco, males (10.7%) significantly more numerous than females (1.4%), aged between 7-12 years (M: 9.1a; F: 10.0A). The 2.1% of pupils were occasional smoker, usual smokers are only males (M: 6.0%, F: 0.0%), aged between 7-12 years. The 47.7% of pupils living with family smoking, 21.7% of households only the father smoker (M: 20.7% F: 22.7%), and in the 7.5% only the mother (M : 9.3%, F: 5.7%), while in the 17.1% smoked both parents (M: 18.6% F: 15.6%). Pupils who have tried smoking and living in households where the parents smoking (10.6%) were significantly more numerous compared to peers who had already had the same experience (2.0%) but living with family Non-smoking. Finally, the students who live with smokers smoking family amounted to 4.5%, while non-smokers who live with family are the 1 .3%.
Conclusions. We note, with concern, that the smoker initiation involved a significant percentage of school children - part of which says smoking - half of which is exposed "to smoke" in a familiar environment. Still, the smoking habits of family members seem to favor the smoker testing of pupils being however an entirely avoidable health risk.

ORGANOCHLORINE PESTICIDES AND PCBs IN NEWBORNS IN A GENERAL POPULATION OF A STRONGLY INDUSTRIALIZED AREA

Berit Glomstad, *Institute for environment assessment and water research (IDAEA-CSIC), Barcelona, Catalonia, Spain*
Esther Vizcaino, *Institute for environment assessment and water research (IDAEA-CSIC), Barcelona, Catalonia, Spain; Universitary Institute of Oncology, University of Oviedo, Oviedo, Asturias, Spain*
Joan O. Grimalt, *Institute for environment assessment and water research (IDAEA-CSIC), Barcelona, Catalonia, Spain*
Adonina Tardon, *Universitary Institute of Oncology, University of Oviedo, Oviedo, Asturias, Spain*

Background and Aims: During pregnancy, organochlorine pollutants (OCs) are transferred from mother to fetus through the placenta (Vizcaino et al. 2011). Prenatal exposure may be related to future health problems of infants (Gladen et al. 1988). The body burden of compounds arriving to fetus depends on the environmental conditions in which the mothers live. In the present study prenatal exposure to OCs in a strongly industrialized area (Asturias, Spain) is investigated.
Methods: As part of the INMA (Environment and childhood) project (Ribas-Fito et al. 2006), 226 cord serum samples from the cohort of Asturias were analysed for OCs, including pentachlorobenzene (PeCB), hexaclorobenzene (HCB), 7 polychlorobiphenyl congeners (PCBs), 4 hexachlorocyclohexane isomers (HCHs) and dichlorodiphenyltrichloroethane (DDT) and its metabolites. The analyses were performed using liquid-liquid extraction, followed by gas chromatography electron capture detection (GC-ECD).
Results: 4,4'-DDE was the most abundant compound (median concentration of 0.51 ng/ml), and was detected in 99 % of the samples, while 4,4'-DDT (0.07 ng/ml) was found in 68 % of the samples. PCB congeners 118, 138, 153 and 180 were detected in more than 90 % of the samples, with PCB153 as the most abundant congener (0.14 ng/ml). HCB (0.14 ng/ml) and • -HCH (0.05 ng/ml) could be detected in respectively 96 and 86 % of the samples.
Conclusions: Prenatal exposure to OCs and PCBs is also occurring in Asturias. Comparing with other previously published INMA cohorts the observed concentrations are lower than those in samples from Menorca, but similar to those found in Valencia (Vizcaino et al. 2011).

LEAD EXPOSURE ALTERS NEURAL MECHANISMS OF LEARNING: A PILOT STUDY OF FEAR-POTENTIATED STARTLE IN ELDERLY MEN

Rachel Grashow, *Harvard School of Public Health, Boston, USA*
Linda H. Nie, *School of Health Science, Purdue University, West Lafayette, USA*
David Sparrow, *VA Boston Healthcare System, Boston, USA*
Howard Hu, *University of Michigan School of Public Health, Ann Arbor, USA*
Marc Weisskopf, *Harvard School of Public Health, Boston, USA*

Background and Aims: Physiologically-based indicators of neurological function could provide mechanistic insight into toxicant actions on the brain, and perhaps prove a more objective and sensitive measure of such effects than other methods. We explored the effects of lead exposure on classical conditioning of the acoustic startle reflex (ASR)—a simple form of learning in the brain—in a population of elderly men.
Methods: Fifty-one men from the Normative Aging Study (NAS) with patella and tibia bone lead measurements made with K-X-Ray-Fluorescence participated in a fear-conditioning protocol. One of two visual conditioned stimuli (CS) on a computer was paired with a mild finger shock. Eye-blink responses (electromyogram) to a loud noise burst were recorded with surface electrodes. Conditioning was indexed as the difference in z-scored eye-blink responses to noise bursts delivered in the presence of the paired and non-paired CS after the pairing process—when no shocks were delivered.
Results: The mean age of the men was 76 years (standard deviation [sd]=5.9) and mean patella lead concentration was 22.4µg/g bone (sd=12.2; range=5-63). In unadjusted analyses among 37 men with valid eyeblink responses at the end of the protocol, conditioning was 0.56sd less (95% CI:-1.02, -0.11; p=0.02) per 20 µg/g patella lead (the interquartile range of the parent NAS population). Tibia results were similar. Adjusting for age weakened associations only slightly, but there was no association between age itself and conditioning. Baseline startle amplitude was associated with age (β=-26.577µV per year; 95% CI:-47.67, -5.48; p=0.0137), but not with conditioning.
Conclusions: In elderly men patella bone lead concentrations, a marker of cumulative lead exposure, predicted learning in a fear-conditioning startle paradigm. While the data are taken from a relatively small sample, this initial exploration offers the possibility that the ASR may provide a new paradigm to explore the effects of neurotoxicant exposure.

EXPOSURE TO SECONDHAND SMOKE AND REPRODUCTIVE OUTCOMES BY MATERNAL HISTORY OF ASTHMA

Background and Aims: Cigarette smoking in women is highly prevalent in South European countries. Multiple studies confirm that tobacco consumption is associated with reduced birthweight. Less clear is the reproductive effects of secondhand smoke (SHS) exposure. An issue that has not been clarified is the reproductive effect of these exposures among subgroups, and particularly the potential higher risk among mothers with a history of asthma. We assessed the role of pre-natal maternal tobacco use and SHS on reproductive outcomes and assessed the interaction with maternal history of asthma.
Methods: Data was collected from two birth cohorts, the INMA study, established in Spain and the Rhea study in Crete, Greece. Given that decreased birthweight is determined mostly by exposure to smoking during the later half of pregnancy we measured cotinine at the 32 weeks of pregnancy in 2219 and 510 women, respectively.
Results: All women had detectable levels of cotinine. Only 35% and 3% reported not being exposed to SHS or active smoking in the INMA and Rhea cohorts, respectively. Active smoking (cotinine>100ng/mL) was related to a 150g decrease in birthweight and a relative risk of 2 for small for gestational age and fetal growth restriction only in the INMA cohort. Among those exposed to SHS (cotinine:20-100ng/mL) the decrease in birthweight was 20 and 26g, respectively, but these differences could be due to chance. These results were not modified by maternal asthma. Household exposure to SHS was associated with lower birthweight, but only in the Greek cohort.
Conclusions: In countries with high prevalence of smoking and SHS exposure, cotinine levels compatible with no active smoking during the third trimester of pregnancy had a non-significant decrease in birthweight or impaired reproductive outcomes, perhaps due to the lack of unexposed women. Maternal history of asthma did not modify the results.

ARE SEVERE HEAT WAVE EPISODES STILL AFFECTING MORTALITY IN ITALIAN CITIES?

Manuela De Sario *Department of Epidemiology, Lazio Regional Health Service, Italy*
Bargagli Anna Maria *Department of Epidemiology, Lazio Regional Health Service, Italy*
Michela Leone *Department of Epidemiology, Lazio Regional Health Service, Italy*
Martina Ventura *Department of Epidemiology, Lazio Regional Health Service, Italy*
Francesca de' Donato *Department of Epidemiology, Lazio Regional Health Service, Italy*
Adele Lallo *Department of Epidemiology, Lazio Regional Health Service, Italy*
Michelozzi Paola *Department of Epidemiology, Lazio Regional Health Service, Italy*

Background and Aims: In July 2010 the North and Centre of Italy were affected by severe heat-wave episodes. In most Italian cities an operational program for the prevention of heat-health effects is ongoing since 2004, based on city-specific Heat Health Watch Warning Systems (HHWWS). The objective is to evaluate the impact of 2010 heat-wave in Italian cities and to discuss possible public health implications.
Methods: Mortality data for all natural causes in subjects aged 65+ was retrieved from the national mortality surveillance system. The impact of the 2010 heat-wave was first explored computing excess mortality during high-risk warning days (HHWWS: level 2 and 3), as difference between observed and expected mortality from historical time series data.
A time-series approach (GEE) was then used to estimate the increase in mortality during heatwave days compared to non heat-wave days in a reference period (2007-2010) Heat-wave was defined as 2 or more consecutive days with maximum apparent and minimum temperature above the 90th monthly percentile.
Results: During the July heat-wave (between 1-24 July), a significant excess in mortality was observed in 11 cities (+854 deaths, around +30% increase). Results from the GEE model showed a significant increase during heat-wave days compared with non heat-wave days in several cities (+31.3% in Torino, +36.3% in Genova, +21.4% in Rome).
Conclusions: Although other analysis suggest a temporal reduction in the impact of heat on elderly mortality in Italian cities due to the introduction of heat-response plans, these results show that in 2010 heat wave episodes still have a significant impact on mortality. The evaluation of prevention measures to identify the most effective in coping with heat-waves should become a public health priority.

HOW TO IDENTIFY HIGH RISK POPULATION SUBGROUPS FOR HEAT PREVENTION PROGRAMS: AN INDICATOR OF SUSCEPTIBILITY BASED ON ADMINISTRATIVE DATA

Schifano Patrizia *Department of Epidemiology, Lazio Regional Health Service, Italy*

Cappai Giovanna *Department of Epidemiology, Lazio Regional Health Service, Italy*

Bargagli Anna Maria *Department of Epidemiology, Lazio Regional Health Service, Italy*

Manuela De Sario *Department of Epidemiology, Lazio Regional Health Service, Italy*

Michelozzi Paola *Department of Epidemiology, Lazio Regional Health Service, Italy*

Background and Aims

A key component of heat prevention programs is the identification of high-risk population. This study presents an indicator of susceptibility to heat based on data from current informative systems and developed within the Italian Heat Health Prevention Plan.

Methods

We analysed the cohort of residents in Rome 65+ years in the period 2005-2007 (N=624,561). Variables considered were age, gender, civil-status and socio-economic position, and a list of diseases associated to heat extracted from the hospital information system. Vital status was retrieved from the Regional-Mortality-Registry. We used a Poisson generalised linear model to predict the probability of dying during days of heat wave (HWd) and no HWd for each combination of the above risk factors, separately for the 65-74 and 75+ years old. Two indicators were tested: the absolute (AD) and relative difference (RD) of the predicted probabilities. The observed relative risk (RR) of dying during HWd and no HWd were computed for increasing values of the indicator, both in the studied and a validation population.

Results

The RD indicator for the 65-74 yrs-old and AD for the 75+ were chosen. Indicators discriminate well those with the highest RR of dying in HWd vs no HWd, as well as those who seem to be protected during HWd. Among the 65-74 yrs-old, subjects in the highest 5% of the score distribution have at least a chronic pathology associated to heat and the 90% have COPD. While among the 75+ yrs group, 60% have at least three chronic diseases, 80% are women, and 90% are not married. Socio-economic-position doesn't differ according to susceptibility levels.

Discussion

The indicator might represent a valid standardized approach for the selection of subjects to be targeted to prevention programs. However its performance should be enhanced taking into account other sources of data, as the pharmaceutical registry.

PRENATAL EXPOSURE TO ORGANOCHLORINE COMPOUNDS AND ULTRASOUND MEASURES OF FETAL GROWTH

Maria-Jose Lopez-Espinosa, *Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain. London School of Hygiene and Tropical Medicine, United Kingdom*
Mario Murcia, *Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain. Center for Public Health Research, Spain*

Ferran Ballester, *University of Valencia, Spain. Center for Public Health Research, Spain. Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain*

Background and Aims: Prenatal exposure to some organochlorine compounds (OCs) has been associated with adverse pregnancy outcomes but no study has assessed OC exposure effects by using ultrasound measurements. To investigate the possible association between fetal growth and maternal (n=485) and cord (n=490) concentrations of some OCs, including *4,4´*-DDT, *4,4´*-DDE, hexachlorobenzene (HCB), β-hexachlorocyclohexane (β-HCH), 4 polychlorinated biphenyl (PCB) congeners (118, 138, 153 and 180), and their sum (ΣPCBs) in a mother-infant birth cohort in Valencia, Spain.
Methods: We fit linear mixed models to estimate longitudinal growth curves for estimated fetal weight (EFW), abdominal circumference (AC), femur length (FL), and biparietal diameter (BPD) in each trimester of pregnancy. Standard deviation (SD) scores were calculated from longitudinal growth curves, adjusted for gestational age and potential growth determinants. Size at 12, 20, and 32 weeks was assessed by unconditional SD scores. We studied the association between fetal growth and maternal and cord OC concentrations by multivariate regression analyses.
Results: We found statistically significant inverse associations between EFW, FL and cord serum *4,4'*-DDE concentrations at mid-pregnancy, and between EFW, AC and cord serum HCB or β-HCH concentrations at end-pregnancy. We found statistically significant inverse associations of FL and BPD with PCB 138 concentrations at the beginning of pregnancy and between AC, FL and PCB 153, 180 and ΣPCBs at mid- and end-pregnancy. The range of decrease for the four fetal parameters was between -5 and -14% for each 10-fold increase in the OC concentrations.
Conclusions: These results suggest that prenatal exposure to some OCs may impair fetal growth. This effect is mainly demonstrated during mid- and end-pregnancy, and OC measures in cord serum are, in general, a better biomarker of exposure to detect impairment of fetal growth. Ultrasound measures constitute a promising way to examine how early prenatal OC exposure affects fetal growth.

ASSESSING HEALTH IMPACTS OF CHANGES IN INDOOR PARTICLE CONCENTRATIONS FROM CHANGES IN ENERGY EFFICIENCY: METHODOLOGICAL CONSIDERATIONS

James Milner, *London School of Hygiene & Tropical Medicine, UK*
Paul Wilkinson, *London School of Hygiene & Tropical Medicine, UK*
Ben Armstrong, *London School of Hygiene & Tropical Medicine, UK*
Zaid Chalabi, *London School of Hygiene & Tropical Medicine, UK*
Sotiris Vardoulakis, *London School of Hygiene & Tropical Medicine, UK*
Michael Davies, *University College London, UK*

Background and Aims: Major changes to the energy efficiency of dwellings are planned in pursuit of greenhouse gas mitigation targets. This has renewed interest in the potential health impact of such changes, specifically the degree to which reduced ventilation may affect exposure to particles derived from outdoor sources. However, for health impact calculations, theoretical considerations suggest that exposure-response coefficients derived from studies of outdoor air pollution need to be adjusted to account for time-activity patterns and the relationship between outdoor concentrations and indoor particles from outdoor sources.
Methods: Our starting point is the use of $PM_{2.5}$-mortality coefficients from published sources, specifically the American Cancer Society. Using evidence on the relationship between indoor and outdoor concentrations, combined with estimates of time-activity patterns, we derive an adjusted coefficient for use in health impact studies. Two key assumptions are: (i) indoor $PM_{2.5}$ of outdoor origin is directly proportional to outdoor concentrations; (ii) indoor $PM_{2.5}$ of indoor origin is independent of outdoor concentration.
Results: Building physics models and empirical data provide sets of estimates for the relationship between outdoor levels of $PM_{2.5}$ and those in the indoor environment derived from outdoor sources. These distributions of estimates suggest that the relative risk suitable for health impact calculations of changes in indoor $PM_{2.5}$ exposures should be up to 50% greater than the published coefficients from semi-ecological cohort studies. Different parameters may be applied to obtain the increment in mortality per unit exposure in different conditions.
Conclusions: For health impact calculations of the effect of changes in dwelling-related air exchange rates on exposure to particles from outdoor sources, it is important to adjust the coefficients of exposure-response relationships derived from published epidemiological studies based on outdoor measurements. This scaling implies the burden of mortality associated with indoor air pollution exposures is appreciably greater than previously estimated.

CHILDHOOD LEUKEMIA AND MATERNAL OCCUPATIONAL EXPOSURES TO ORGANIC SOLVENTS IN COSTA RICA

Patricia Monge[(1)], Freddy Briceño [(1)] , Timo Partanen[(1]

Background and aims

Parental occupational exposures to organic solvents are being suggested as risk factors for childhood leukemias, although evidence is inconsistence. We report results from a case-control study of parental occupational exposures to organic solvents and its association with childhood leukemia.

Methods

Incident cases during 1995-2000 were identified from the National Tumor Registry (N= 300), with 579 population controls.

Evaluation of retrospective occupational exposures of parents to 12 organic solvents was performed combining data from (1)exposure matrix (JEM), and (2)interview individual data. JEM estimates three intensity levels of exposure to 12 agents, 25 occupations, 40 uses and 21 years. The questionnaire includes information on type of substance; use; period; frequency and duration of exposure; occupation; and PPE.

Results

Risks for benzene, toluene, xylene and turpentine were analyzed individually and also combined. Models were performed using data on exposed versus (vs) unexposed; high vs low exposures and high vs unexposed. Risks were higher for **high vs unexposed** for benzene before and during pregnancy (OR=2.61 95%CI 1.20-5.65, number of cases [NC] 16; and OR=2.56 95%CI 1.13-5.75, NC 14 respectively); toluene (OR=2.27 95%CI 1.1-5-0, NC 27); xylene (OR=2.6 95%CI 1.20-5.6; NC16); and turpentine (OR=2.3 95%CI 1.1-5.0; NC 14). **High vs low** exposures before pregnancy, were significantly elevated for benzene (OR=4.54; 95CI% 1.10-18.78), NC 16/8); xylene (OR=4.95; 95CI% 1.10-22.26, NC 16/7). For the four substances combined (OR=4.82 95%CI 1.13-20.7, NC 16/8), and

exposed vs unexposed (OR=1.32 95%CI 1.1-1.71, NC 46), and high vs low exposures (OR=2.77 95%CI 1.0-7.7, NC 29).
All models were adjusted for maternal exposure to pesticides and urban/rural residency. ORs and/or NCs were low for other solvents.

Conclusions

Maternal exposures to aromatic substances seem to be associated with the outcome. There is correlation between the exposures to aromatic solvents. Dose-response analysis is suggested for benzene, xylene before pregnancy and exposures to aromatics combined before and during pregnancy.

A MULTISTATE LIFE TABLE MODEL INCLUDING DISEASE RECOVERY FOR ASSESSING THE HEALTH IMPACTS OF CHRONIC ENVIRONMENTAL EXPOSURES

James Milner, *London School of Hygiene & Tropical Medicine, UK*
Zaid Chalabi, *London School of Hygiene & Tropical Medicine, UK*
Paul Wilkinson, *London School of Hygiene & Tropical Medicine, UK*
Sotiris Vardoulakis, *London School of Hygiene & Tropical Medicine, UK*
Michael Davies, *University College London, UK*

Background and Aims: Multistate life tables, which model the movement of individuals within a population over time between various health states, provide benefits over standard life tables since they account for the many chronic health conditions associated with environmental exposures. However, these models have not previously included disease recovery. This is an important omission for certain conditions, such as asthma, from which people may recover during their lifetime. As such, this work aims to develop and apply a tool capable of including disease recovery for use in environmental risk assessment.
Methods: We present details of a new multistate life table model. The starting point for the method is age- and disease-specific mortality, disease prevalence and incidence rates. Individuals within the population may move between good health, several disease states, a recovered state and, ultimately, death. Time spent with disease is weighted for reduced quality-of-life. The model estimates quality-adjusted life expectancy (QALE) and can be used to study patterns of mortality and morbidity over time in response to changes in environmental exposures.
Results: We describe illustrative examples of the application of the model for health impact assessments of housing interventions in England and Wales. In particular, we show that a relatively modest decrease (3 $\mu g\ m^{-3}$) in average indoor $PM_{2.5}$ exposure results in an increase in QALE at birth of around two months, with ~600 fewer new diagnoses of asthma in children under 15 and ~3,000 fewer new cases of coronary heart disease per year.
Conclusions: The new model provides substantial benefits for performing environmental health impact assessments. Including disease recovery is an important step towards modelling the effects on population health of complex actions and interventions in a comprehensive manner. The model will provide useful information for policy-makers, helping them to more effectively determine the health impacts of environmental policies.

ALTERNATIVE EXPOSURE ASSESSMENT METHODS FOR RESIDENTS NEAR INCINERATORS: A SIMULATION STUDY

Anna Freni Sterrantino, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy; Department of Statistics, University of Bologna, Italy*

Paolo Lauriola, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy*
Francesco Forastiere, *Department of Epidemiology, Regional Health Service, Lazio, Italy*

Background and Aims: A multisite project on health effects of exposure to incinerators (Moniter Project) was undertaken in Emilia-Romagna region (Italy). A retrospective cohort of residents (period 1995-2006) was enrolled to study mortality and morbidity effects. Residential exposure to incinerators was estimated from a dispersion model using emission data at enrolment (1995). Individual residential exposure was assigned to the cohort (about 250.000 subjects). A successive categorization (quintiles) was made for epidemiological analyses. Cumulative exposure could not be calculated for all cohort members. We have conducted a simulation study, using a sub-sample of the cohort with complete cumulative exposure data, to evaluate the consequences of possible misclassification of this exposure assessment method.
Methods: For a sub-cohort (about 30.000 subjects), information about residential history from the start of the plant (1980) was available, and cumulative exposure (period 1980-1995) for each subject was calculated using two different dispersion maps over time, and residential mobility. A validation study was performed to estimate possible misclassification of exposure at enrolment, calculated as for the whole cohort. A simulation procedure was used with 1000 datasets with a mean incidence rate ratio (IRR)=1.5 between the highest and the lowest exposure class of cumulative exposure and a statistical significant trend.
Results: When we compared categories of prevalent exposure at baseline with cumulative exposure, 73.5% of subjects remained in the same class and 5.2% move to nonadjacent categories. Extreme classes (lowest and highest) showed higher concordance (81.7% and 84.50%). Overall weighted kappa was 85.3%. The simulation study provided a median value of 1.414 for the IRRs between extreme categories [range:1.06-2.04] with 29.2% of the simulations overestimating the IRR. The positive trend remain significant in 63.9% of simulations.
Conclusions: We found a moderate agreement between baseline and cumulative exposure. However, in case of nondifferential misclassification between nonadjacent categories, caution regarding estimation has to be considered.

As, Hg AND Ni LEVELS IN SERUM AND SEMINAL PLASMA AND MALE INFERTILITY

Background/Aims: An increasing number of studies suggest that chemical and physical agents in the environment, introduced and spread by human activity, may affect male fertility in humans.
We investigated the relationships between exposure to heavy metals (Arsenic, Lead, Nickel) in the serum and in seminal plasma and the presence of possible alterations of sperm parameters of male exposed to air pollution of an area of high environmental crisis.

Methods: A case–control study was conducted. The cases (87) were recruited from Melilli, the controls (13) were recruited by Regalbuto, a rural area. The heavy metals concentrations were detected by a Perkin Elmer Elan DRC-e ICP-MS. The progressive motility (a+b) of spermatozoa was evaluated.

Results: Lead, arsenic and nickel showed higher concentrations in cases than controls in both serum and seminal plasma. The samples showed a motility reduction from 45% to 23 % (50% reduction). In both volunteers, sperm density and morphology were into the reference limit of WHO parameters, whereas a slight decrease was detected in progressive motility in male volunteers living in the study area.

Conclusion: Our results suggest that the presence of Lead, Nickel and Arsenic in the reproductive tract of men may be related to a moderate alteration of motility of spermatozoa. This study suggest that heavy metals may have adverse impacts on male reproductive health.

Erik Melén, *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden - Astrid Lindgren Children's Hospital, Karolinska University Hospital, Stockholm,*
Sweden
Tom Bellander, *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*

Background and Aims: Epidemiological studies of the association between traffic-related air pollution and long-term effects on the development of childhood airway disease have shown inconsistent results. We aimed to assess the development of allergic and non-allergic asthma in children up to 8 years of age, in relation to exposure to residential outdoor air pollution from traffic during the 1st year of life.
Methods: The spatial distribution of nitrogen oxides from traffic (traffic-NO_x) and inhalable particulate matter from traffic (traffic-PM_{10}) in the study area was assessed using emission inventories and dispersion models. Estimated levels were used to assign first-year exposure levels for children in prospective birth cohort BAMSE (n=4089), by linking to geocoded home addresses. Children were followed with questionnaires at 0, 1, 2, 4 and 8 years, and blood samples were taken at 4 and 8 years. Asthma was defined as ≥4 episodes of wheeze in the last 12 months or 1 episode in combination with inhaled corticosteroids. *Asthma* at 4 and 8 years was subdivided in *allergic* or *non-allergic* according to presence of sensitization to inhalant allergens. The association between air pollution and asthma was analyzed using multiple logistic regression.
Results: Air pollution exposure during the first year of life was associated with non-allergic asthma (OR for 47 μg/m³ traffic-NO_x corresponding to the 5^{th}–95^{th} percentile difference in the cohort =2.4; 95% CI=1.0 – 5.6 at 4 years, and 2.6; 0.9 – 8.1 at 8 years). No association with allergic asthma was found (OR = 1.5; 95% CI=0.4 – 5.1 at 4 years and 0.8; 0.2 – 2.4 at 8 years). Results were similar using traffic-PM_{10}, which was highly correlated to traffic-NO_x (r=0.95).
Conclusions: Exposure to moderate levels of locally emitted air pollution from traffic during infancy appears to increase the risk of non-allergic asthma in children up to 8 years of age.

MODELING OF INDOOR CONCENTRATIONS AND TOXICOLOGICAL ASSESSMENT OF CANDLE BURNING EMISSIONS

Nicola Tecce, *Università dell'Insubria, Italy*

Andrea Cattaneo, *Università degli Studi di Milano, Italy*

Marco Derudi, *Politecnico di Milano, Italy*

Giuseppe Nano, *Politecnico di Milano, Italy*

Domenicio Maria Cavallo, *Università dell'Insubria, Italy*

Background and Aims: the burning of candles is one of the most important indoor sources in terms of direct emission of airborne pollutants. The aim of this study is to determine and quantify the toxicological impact of some selected chemical products emitted from the burning process of candles.
Methods: the work investigated different types of candles selected on the basis of fragrances (bark, frangipane, opium, rhubarb, aloe) and raw materials (paraffin, slack wax, and 'intermediate' wax).
The analysed products of combustion were: BTEX, formaldehyde, acetaldehyde, acrolein, PAHs, CO, SO2, NO2 and particulate matter. The design and development of a combustion chamber enabled the standardization of the 'combustion system' with its several variables.
Exposure limits for each studied substance were selected analysing data in scientific literature and international guidelines.
Indoor concentrations were predicted by ConsExpo 4.0 model. The construction of exposure scenarios was focused on the worst-case conditions: 4 candles burned for 4 hours, minimum volume for an indoor environment (25 m3) and minimum ventilation (0.1 ach).
Results: estimated indoor airborne concentrations generated by the combustion of candles charged with fragrance oils exceeded only the acrolein exposure limit by an order of magnitude. However, the predicted indoor concentrations of acrolein were an order of magnitude lower than usual indoor background levels measured in urban areas.
As regards raw materials, slack wax showed concentrations an order of magnitude higher than particulate matter, SO2 and NO2 exposure limits. Moreover, benzo(a)pyrene concentrations were equal to the relative exposure limit.
Conclusion: the different chemical composition of candles and related raw materials significantly affects the emission factors and estimated indoor concentrations of the selected airborne pollutants.
The slack wax was characterized by some critical points in terms of possible health risks, owing to the differences in terms of oil percentage in raw materials.

CADMIUM TOXICITY: A POSSIBLE CAUSE OF MALE INFERTILITY.

Background/Aims: Human, animal and in vitro studies suggest that heavy metals may have adverse impacts on male reproductive health, even at relatively low-level exposures. Epidemiological studies provided equivocal results concerning the effects of cadmium (Cd) on hormone concentration, male infertility and sperm parameters. Very few human observational studies have analyzed the relationship between male reproductive function and heavy metal concentrations in diverse biological fluids.
A case–control study was conducted to examine relationships between environmental exposures, particularly to Cd, with male infertility.

Methods: A case–control study was conducted. The cases (87) were recruited from Melilli, the controls (13) were recruited by Regalbuto, a rural area. The Cd concentrations were detected by a Perkin Elmer Elan DRC-e ICP-MS in seminal plasma. The progressive motility (a+b) of spermatozoa was evaluated.

Results: Cd showed higher concentrations in in seminal plasma of cases (1.67 µg/l) while in controls is lower (0.55 µg/l).
In both volunteers, sperm density and morphology were into the reference limit of WHO parameters, whereas the cases samples showed a motility reduction from 45% to 23 % (50% reduction).

Conclusion: Our results indicate that the males exposed to environmental Cd showed a deleterious effect on fertility.

META-ANALYSIS OF THE EFFECTS OF FORMALDEHYDE EXPOSURE ON THE RISK OF SPONTANEOUS ABORTION

Thomas F. Bateson, *U.S. Environmental Protection Agency, Washington, DC, USA*
Barbara Glenn, *U.S. Environmental Protection Agency, Washington, DC, USA*
David Bayliss, *U.S. Environmental Protection Agency, Washington, DC, USA*
Dihua Xu, *University of Maryland, Baltimore County, MD, USA*
Bimal Sinha, *University of Maryland, Baltimore County, MD, USA*

Background and Aims: We reviewed the evidence supporting an association between formaldehyde exposure and increased risks of spontaneous abortion or miscarriage. Several reports of adverse reproductive effects have been associated with formaldehyde exposure in humans and animals. An earlier meta-analysis reported non-significant increased summary risks based on maternal and paternal exposures (Collins et al., 2001). The aim of the current meta-analysis is to update the earlier effort with focus solely on maternal exposures.
Methods: We systematically reviewed the epidemiologic literature on the relationship between formaldehyde exposures and spontaneous abortions in humans. We selected to review six research articles concerning 3,233 women (528 with spontaneous abortion) which contain information suitable for meta-regression analysis. Pooled ORs and 95% CIs were obtained using fixed-effects and random-effects models with inverse variance weights. We tested heterogeneity using Cochrane's homogeneity statistic and quantified with the Q statistic. The potential for publication bias was assessed using the p-values from each of the included studies to compute the number of potentially unpublished studies with non-significant findings which would be necessary to change the meta-regression conclusions.
Results: While there was some heterogeneity in the reported results, it was not statistically significant (Q=10.95; p=0.0523). A fixed-effects model, which did not account for variation among the 6 studies, indicated the OR value of 1.95 for exposed women compared to unexposed (95%CI: 1.43-2.65). A random-effects model, which did account for variation among the studies, indicated the OR value of 1.91 for exposed women compared to unexposed (95%CI: 1.18-3.10).
Conclusions: Our updated meta-analysis supports the conclusion that formaldehyde exposure may increase the risk of spontaneous abortion among women. We computed that more than 25 additional unpublished studies with non-significant results would be necessary to change this conclusion.

INDIVIDUALIZED VS ECOLOGICAL AIR POLLUTION TIME SERIES: A COMPARATIVE STUDY OF MODELLING SPATIOTEMPORAL VARIABILITY

Konstantina Dimakopoulou, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Xanthi Pedeli, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Alexandros Gryparis, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*
Klea Katsouyanni, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National and Kapodistrian University of Athens, Greece*

Background and Aims: Studies of air pollution effects on health are often based on ecological measurements covering a large area with a few fixed monitoring sites. Recently several attempts are made to produce individualized exposure assessment appropriate for large scale use. We used a land use regression (LUR) model to assess daily exposure to NO_2 and PM_{10} for 50 addresses spread within the Greater Athens Area. This individualized exposure assessment was compared to a time-series of ecological measurements, based on the daily average from fixed monitoring sites that has been used in the past, in order to estimate exposure for all subjects.
Methods: We used semiparametric regression for modelling the spatiotemporal NO_2 and PM_{10} variability for geocoded addresses, using traffic load in a 100m radius buffer as well as daily meteorological variables. We evaluated the geographical variability introduced by the individualized time-series of NO_2 and PM_{10} concentrations in the study area using linear mixed models. We also assessed the validity of the individual series by comparing with the 2010 fixed site monitoring air pollution data which were not included in our model building process.
Results: We calculated the differences between the ecological and each individualized series. The mean difference (SD) was -3.26 (11.844) • g/m^3 ranging from -64.7 to 74.8 • g/m3. Thus the individualized series were on the average higher compared to the ecological series. The differences between ecological and each individualized series were higher in the summer by 5.26 (95%CI 4.86,5.65) • g/m^3 compared to the winter period and their median correlation was 0.67 (range 0.66-0.68). The model showed good validity with the 2010 data.
Conclusions: Our LUR model introduces substantial geographical variability and is well correlated with the ecological measurement on the time scale. It represents a substantial improvement over the ecological measurement for a more personalized exposure assessment.

QUANTIFICATION OF FREE AND CONJUGATED BISPHENOL A IN HUMAN FETAL LIVER TISSUE

Muna Nahar, *University of Michigan, USA*
Chunyang Liao, *Wadsworth Center, USA*
Kurunthachalam Kannan, *Wadsworth Center, USA*
Laura Rozek, *University of Michigan, USA*
Dana Dolinoy, *University of Michigan, USA*

Background and Aims: The high production monomer, bisphenol A (BPA), is incorporated into polycarbonate plastic and epoxy resin for use in a variety of consumer products. Human biomonitoring studies of urine and serum BPA levels indicate continuous exposure that varies with age, race, gender, and diet. Animal studies have linked BPA to adverse health effects, ranging from reproductive to neuroendocrine dysfunction; however, the relevance of toxicological exposure levels to circulating human levels remains less characterized.
Methods: Here, we use high-performance liquid chromatography (HPLC) coupled with API 2000 electrospray triple-quadrupole mass spectrometer (ESI-MS/MS) to quantify BPA levels in fetal human liver tissue obtained from normal subjects from the University of Washington Laboratory of Developmental Biology (n=10).
Results: Total and free BPA were detected in 100% of the samples. Total BPA, a measure of free plus glucoronide conjugated BPA, ranged from 4.24 to 96.8 ng/g, with a mean value of 33.7 ng/g and a median value of 30.3 ng/g. Free BPA concentration ranged from 3.63 to 47.2 ng/g (mean: 22.4 ng/g and median: 21.3 ng/g). Fetal tissue samples exhibited a high ratio of free BPA to glucoronide conjugated BPA, ranging from 0.92 to 6.70, with a mean ratio of 3.48. Neither free, glucoronide conjugated, nor total BPA was associated with sex ($p>0.48$).
Conclusions: Our results suggest that the developing fetus may have reduced capacity to detoxify BPA. Quantification of internal doses of both free and conjugated BPA provides an opportunity to better understand the ontogeny of xenobiotic metabolism and its contribution to toxicity in sensitive populations. Furthermore, comparison of human tissue levels of BPA with levels measured in dosed laboratory animals will allow for more sophisticated interpretation of the relevance of toxicological studies.
This study was supported by ES017524 and T32 ES07062.

Background and Aims: Given the large costs and the lack of light measurement devices to measure individual exposure to certain pollutants, it is very common in epidemiology to estimate the exposure to pollution using models based on ambient measurements. This estimation does not usually take account of uncertainties that may lead to attenuation of the effect, bias and loss of power. The aim of this study was to compare the results of a traditional analysis with those obtained when using a model that incorporates the uncertainty of all modelling steps.
Methods: The INMA birth cohort study in Sabadell includes 657 pregnant women from whom information from questionnaires is collected at 12 and 32 weeks of pregnancy and at delivery. NO_2 measurements used to develop a land use regression (LUR) model are made at 57 sites in the city, and are supplemented by personal, home-indoor and home-outdoor measurements for 57 cohort subjects. We developed linear regression model of personal exposures to NO_2 for all women. We first modelled subjects' home-outdoor concentrations as a function of the LUR outputs, and home-indoor as a function of information provided by questionnaires (gas cooking, ventilation, etc.). These two predictions then fed into the personal exposure model. We compare a frequentist approach to a Bayesian modelling approach accounting for uncertainty.
Results: Estimations obtained for personal NO_2 for both methods were similar. The only observed differences between both approaches were observed at the standard deviation of the coefficients estimates. Higher values were obtained through the bayesian model (0.43 and 0.66 for outdoor and indoor NO_2, respectively) than for the linear model (0.27 and 0.53).
Conclusions: Although no good predictive models were obtained for either of the two methods, the bayesian approach seemed to better incorporate the uncertainty associated to the various modelling steps.

A MODEL-BASED APPROACH TO LIMIT OF DETECTION IN STUDYING ENVIRONMENTAL CHEMICAL EXPOSURES AND TIME TO PREGNANCY

Sungduk Kim, *NICHD, USA*

Zhen Chen, *NICHD, USA*

Neil J. Perkins, *NICHD, USA*

Enrique F. Schisterman, *NICHD, USA*

Rajeshwari Sundaram, *NICHD, USA*

Germaine Buck Louis, *NICHD, USA*

Background: Human exposure to persistent environmental pollutants often results in a range of exposures with a proportion of concentrations below laboratory detection limits. Growing evidence supports that inadequate handling of concentrations that are below the limit of detection (LOD) may bias health effects in relation to chemical exposures. We sought to quantify such bias in day specific probability of conception during the fertile window, and propose a model-based approach to reduce the biases.

Methods: We assumed a flexible multivariate skewed generalized *t* distribution constrained by LODs, which realistically represents the underlying shape of the chemical exposures. Correlations in the multivariate distribution provided information across chemicals. Simulating 1000 datasets with three chemicals exposures having 40-60% below LODs, we compared results from the proposed approach to those from naïve substitution by LOD/$\sqrt{2}$ for concentrations below LODs. We further applied the proposed approach to data from the Longitudinal Investigation of Fertility and the Environment (LIFE) Study adjusting for age, parity, daily usage of cigarettes and alcohol.

Results: Simulations revealed relative biases 25%, 94%, and 96%, respectively for the three chemicals using substitution, while the proposed approach results are 8%, 9%, and 5%. In LIFE data, polychlorinated biphenyl (PCB) #105, #209, perfluorooctane sulfonamid (PFSA), and cadmium had 26%, 77%, 91% and 43%, respectively, below the LODs. Posterior means (95% credible intervals) for these chemicals are 0.073(-0.303,0.457), 0.240(-0.132,0.604), -0.25(-0.690,0.124), and -0.120(-0.559,0.299) using substitution and -0.015(-0.397,0.407), 0.137(-0.193,0.477), -1.179(-1.929,-0.491), and -0.169(-0.746,0.380) using proposed approach. Substitution yields no significant chemical effects, where the proposed approach shows PFSA is significant and negatively associated with fecundity.

Conclusions: In estimating effects of chemical exposures on conception probabilities, the substitution can lead to biased estimates while the proposed method yields more accurate estimates. In LIFE study data, we found a statistically significant negative association between PFSA and day specific conception probabilities.

DETERMINATION OF RISPERIDONE IN BLOOD AND HAIR BY LC-ESI-MS-MS-TQD.

Background/Aims: Mental illnesses produce some of the most health problems faced by society. Scientists have long known that these mental illnesses arise from combinations of genes and environmental factors. Now the role of the environment in the etiology of mental illness has become more clear.

The antipsychotic drugs are commonly used for the treatment of schizophrenia and anxiety disorders. Although hair analysis has become a test widely used to detect the use/abuse of many toxic and therapeutic substances, very few data are available regarding hair testing for antipsychotic drugs. The risperidone (RSP) is one of the less investigated substances.

The possibility to identify and quantify antipsychotic drugs in human hair could be an interesting epidemiological, clinical and forensic tool in therapeutic drug monitoring. The aim of the present pilot study was to develop and validate a method for the quantitative determination of RSP in blood and hair samples by LC-ESI-MS-MS.

Methods: study was carried out on blood and hair samples collected from psychiatric patients treated with risperidone. Each patient gave informed consent. Hair samples were washed, decontaminated, pulverized, incubated in 1 ml of HCl 0.1N and extracted with chloroform:isopropanol (80:20; v/v) at pH 7, pH 9 and pH 11. Blood specimens were extracted with 1-chlorobutane after alkalinization with sodium borate (pH to 12). Bupivacaine was used as internal standard. Hair and blood extracts were analyzed by LC-ESI-MS-MS-TQD using Varian 320MS. Validation experiments (specificity, interferences, interday and intraday precision and accuracy, LOD, extraction yield, interferences and ion suppression) were performed.

Results: Our preliminary results showed that this method allows to detect and quantify risperidone in hair and blood of the patients chronically treated with doses ranging from 1 to 8 mg/daily.

Conclusion: Hair testing can be used in monitoring of chronic antipsychotics intake; however, further studies are required to improve its epidemiological applications

Background and aims: Methylmercury, a worldwide contaminant found in fish and seafood, can have serious adverse effects on the developing nervous system. However, essential nutrients such as the long-chain n-3 polyunsaturated fatty acids, including docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) in fish provide beneficial effects on brain development. Underestimation of the effects of both mercury toxicity and fish benefits may occur from the lack of mutual adjustment. We examined these effects in regard to neurodevelopment in176 children in a Faroese singleton birth cohort.
Methods: We determined the cord blood mercury concentration and the relative concentrations of cord serum phospholipid fatty acids. Maternal hair mercury at parturition was also measured. Neuropsychological performance in verbal, motor, attention, spatial, and memory functions was assessed at 7 and 10 years of age. The sum of DHA and EPA represented the total n-3 fatty acid concentration (correlation=0.98, $p<0.001$) and was included as the nutrient adjustment. Multiple regression and structural equation models (SEMs) were carried out to determine the confounder-adjusted effect of methylmercury exposure.
Results: Indicators of prenatal methylmercury exposure were significantly associated with naming, verbal learning, and spatial performance. The association strengthened after adjustment by fatty acids. Taking into account correlations among related measures to derive latent exposure and response variables in SEMs, we found significant associations of mercury exposure with deficits in verbal and memory performance at 7 years and 10 years of age, and also in spatial function at 10 years.
Conclusions: Prenatal exposure to methylmercury was associated with deficits at school age in domains known to be sensitive to this neurotoxicant. This effect was strengthened after nutrient adjustment. These findings suggest that essential fatty acid information needs to be included or modeled in analyses of similar studies to avoid underestimation of the methylmercury effects.

COMPARISON OF EFFECTS INDUCED BY FORMALDEHYDE EXPOSURE ON ALVEOLAR AND BRONCHIAL EPITHELIAL CELLS IN VITRO

Charles Persoz, *Université Paris Descartes, France*
Sophie Achard, *Université Paris Descartes, France*
Véronique Vitry, *Université Paris Descartes, France*
Ali Mekbeul, *Université Paris Descartes, France*
Isabelle Momas, *Université Paris Descartes, France*
Nathalie Seta, *Université Paris Descartes, France*

Background and Aims Exposure to formaldehyde (FA) at environmental concentrations is suspected to be associated to asthma and respiratory disorders. Nevertheless, the physiopathology of this relation is still unclear and experimental data are needed. In vitro experimentation is complementary to epidemiological studies. However experimental procedure parameters need to be adapted, such as the choice of target cells of respiratory tract. The aim of this study was to compare the inflammatory response of FA exposure at environmental level on alveolar and bronchial epithelial cells.

Methods
Human alveolar (A549) and bronchial (BEAS-2B) epithelial cells were exposed at the air-liquid interface in a Vitrocell exposure module to FA (50 µg/m3) (or air for control) during 30 min. After 24h post-incubation, cellular viability was assessed using LDH release. Two chemokines (IL-8, MCP-1) were assayed in the apical supernatant by ELISA. In addition, to modulate inflammatory response, pre-sensitization was performed using LPS (5 µg/mL) (to mimic a bacterian activation), TNFα (1 ng/mL) or macrophages conditioned media (to mimic the macrophages/epithelial cells cooperation) during 16h before exposure.

Results
Whatever the cell type, cell viability was unaffected by air or FA exposure compared to cells not exposed at the air-liquid interface. Without presensitization or after LPS presensitization, FA had not effect on A549 or BEAS-2B, compared to air-exposed cells. FA exposure, after TNFα presensitization, resulted in an inflammatory response, an increase of IL-8 production by A549 cells; after macrophage conditioned media presensitization, an increase of IL-8 production by A549 cells, and decrease of MCP-1 production by BEAS-2B cells was observed.

Conclusions
After presensitization FA exposure at environmental levels provokes an inflammatory response in epithelial cells of the respiratory tract. Moreover, this response is differently modulated depending on the level of the cells in the respiratory tract.

Theme: Exposure assessment, methods.

Background and aims: Particle size distribution is important for human exposure and risk assessment, as well as for understanding the mechanisms of atmospheric processes. In the present study, the toxicity of particulate matter (PM10) was determined using a rapid and cost-effective bioluminescence assay, the Microtox bioassay. However the ecotoxicological effects of the particulate matter, has not been investigated, thus the current study is a preliminary effort to correlate physicochemical properties of particulate matter to biological impact.
Methods: Samples were collected in an heavy industrialized area of Sicily (Italy). Dust emissions seem to be the most serious problem in the area, as the measured ambient concentrations of suspended particles are at high levels and exceed local and international standards. The air quality control around the area is monitored by a measurement stations network, which has been installed by the CIPA. The ecotoxicological test was based on the measurement of bio luminescence inhibition of the marine bacteria *Vibrio fischeri* within a short exposure time. The % bioluminescence inhibition or the EC50 value (the % of sample concentration that causes 50 % effect on the test organism) of a sample was calculated as an end point. The light emitted from the control sample and the samples have been measured using the Microtox model 500 analyzer after 5,15 and 30 min exposure of the bacteria.
Results: Were tested 20 filters containing PM10, the result EC50 was corrected for the toxicity of white filters. The average EC50 results after 5 minutes of exposure is 26.50%, is 49.48% after 15 and after 30 is 53.07%.
Conclusions: This assay shows good correlations to detect toxicity across a wide spectrum of toxicants. The effect of pollutants on *Vibrio fischeri* is known in the literature for water and sludge, further studies will be able to relate additional information concerning the air.

AN EXPLORATORY STUDY OF QUALITY OF LIFE AND PERCEPTION OF ENVIRONMENTAL POLLUTION IN TARANTO, ITALY

Maria Angela Vigotti, University of Pisa,Italy
Palmira Scalamandrè, Liceo scientifico di Stato "G. Battaglini",Taranto,Italy
Zeynep Dörtbudak, Koç University, Istanbul, Turkey
Davide SimoneRusso, Liceo scientifico di Stato "G. Battaglini",Taranto,Italy
Francesco Candelli, Liceo scientifico di Stato "G. Battaglini",Taranto,Italy
Federica Bruno, Liceo scientifico di Stato "G. Battaglini",Taranto,Italy
Federica Loiacono, Liceo scientifico di Stato "G. Battaglini",Taranto,Italy
Pierluigi Massimilla, Liceo scientifico di Stato "G. Battaglini",Taranto,Italy

Background and Aims: WHO has defined the city of Taranto (Apulia, South-Eastern Italy) as a high environmental crisis risk area with excess total and cancer mortality[1]. Since the late '60's, heavy industries (steel & cement plants, oil refinery) have been located very near residential areas. There are no studies investigating residents' perception of environmental pollution in Taranto [2-4].

Methods: We used qualitative and quantitative methods to assess perception of environmental quality, pollution and quality of life (QOL) in a convenience sample of high-school parents (N=118). A survey questionnaire for assessing demographics, perception of environmental quality via visual analogue scales (VAS) and the Italian version of WHOQOL-BREF were used [5].We also conducted qualitative interviews with 27 subjects to further illustrate residents' perception of their environment.

Results: The subjects' (50 men, 67 women), mean age was 47.25±13.41. Majority were married (71.8%), had a high-school diploma or above (87%), lived with others (92.8%), were employed with regular (93.0%) low-to-middle income (<=2000 €, 68.6%). Subjects' mean rating of components of the environment in Taranto (VAS) were 22.7% air, 41.94% drinking water, 44.96 % sea water, 38.37 % other water, 37.76 % soil, 47.95% meat, 44.33% poultry, 55.72 % shellfish, 58.74% fish and 45.83% produce. Mean WHOQOL-BREF scores for the physical (71.39±14.56), psychological (59.40±9.26) and environmental (52.68±13.84) domains were significantly lower than Italian population norms (t_{phy}=5.48, , p<.001; t_{psy}=10.27, p<.001, t_{env}=5.47, p<.001; df=494) but not social relationships (70.47±16.47)[6]. Qualitative analysis revealed main themes of discourse as: difficulty breathing mornings and evenings, noxious air, ability to tell refinery and steel factory emissions apart by smell, reminiscence of childhood with cleaner environment, expression of helplessness regarding environmental pollution.

Conclusions: The results of our study show lower QOL, grim perception of the environment in a sample of Taranto residents; indicating a need for large scale, population-based studies investigating QOL effects of environmental pollution in the region.

Background and Aims: Formaldehyde is ubiquitous in ambient and indoor air. Human exposure primarily results from off-gassing of processed wood products and as a combustion by-product. Evidence of carcinogenicity beyond nasopharyngeal cancer (NPC) includes other site-specific relationships in the upper respiratory tract (URT).
Methods: We systematically evaluated the epidemiologic literature on the relationship between formaldehyde exposures and URT cancers.
Results: The National Cancer Institute cohort study of 25,619 workers exposed to formaldehyde reported increased NPC mortality risk (SMR=2.1, 95% CI: 1.05-4.21) and demonstrated exposure-response relationships with cumulative exposure to formaldehyde (*p-trend*=0.025) and peak exposure to formaldehyde (*p-trend*<0.001). These results were substantiated by a robust collection of exposure-response results from case-control studies. Luce et al. (2002) pooled standardized data from 12 separate studies of sinonasal cancer providing the strongest evidence that formaldehyde is associated with sinonasal cancer. Together with the NPC findings in the neighboring tissue of the URT, this is evidence of a causal association of formaldehyde exposure with sinonasal cancer. The evidence for a specific effect on the risks of buccal, oropharyngeal, hypopharyngeal, and laryngeal cancers is slight when examining each of these extremely rare URT endpoints individually. However, the large NCI study showed a statistically significantly increased risk for URT cancers as a group and for buccal cavity cancers. Further evidence includes a nearly 4-fold increased risk of hypopharyngeal cancer (Laforest et al., 2006) and the demonstration of an exposure-response relationship for duration of formaldehyde exposure and risk of laryngeal cancer (Shangina et al., 2006).
Conclusions: We conclude that there is causal evidence for NPC and sinonasal cancer in neighboring tissues of the URT and the other sites of first contact with inhaled exposure to formaldehyde and these collective results support a broader pattern of carcinogenicity within the URT.

Flemming Nielsen, University of Southern Denmark, Odense, Denmark
Pal Weihe, Faroese Hospital System, Torshavn, Faroe Islands

Background and Aims: Certain persistent pollutants, such as PCBs and DDTs, are thought to cause endocrine disruption. We examined the serum hormone profile in boys at puberty age in regard to their prenatal pollutant exposures.

Methods: In 1986-1987 cord blood was sampled from a Faroese birth cohort and kept frozen. In 2000-2001, birth cohort members were invited for clinical examinations at age 14 years and underwent Tanner staging and, finger length measurement, and serum hormone assessment. Of 436 boys participating (85%), complete data were available for 361 boys (71%). The cord blood has now been analyzed for the persistent pollutants. Associations between exposures and endocrine outcomes were explored by regression analysis after confounder adjustment.

Results: Prenatal exposure to PCBs and DDTs showed a negative association with serum concentrations of testosterone and luteinizing hormone and a positive association with sex-hormone-binding globulin. No association was seen with inhibin B and follicle-stimulating hormone, and the same was true in regard to Tanner stage and testicular size. Results were similar for the different PCBs and DDTs, which correlated closely among themselves.

Conclusions: These results suggest that an antiandrogenic effect of persistent pollutants may be mediated centrally, rather than through direct testicular toxicity.

Community Perceptions of Living Next to a Major Railyard: The ENRRICH Project.

Caroline Youssef, Rhonda Spencer-Hwang, Susanne Montgomery, SamSoret and Megan Brown

BACKGROUND:
The BNSF San Bernardino Railyard (SBR) is a major trade gateway in the United States and one of the busiest facilities of its kind in California. Local community and air pollution control agencies have identified SBR as a significant public health and environmental justice issue. The Environmental Railyard Research Impacting Community Health (ENRRICH) project has aims to examine potential health effects associated with residential proximity to this railyard. As part of a qualitative preparatory phase we explored community members perceived environmental health risks and their thoughts about possible changes in their environment. We see this input as essential to the conduct of respectful health research that will include mitigation foundation development.

METHODS:
Community-based participatory research (CBPR) strategies were utilized to engage the community residents living in close proximity to the railyard. Semi-structured key informant interviews (n=12) and five focus groups (n=53) were conducted in English and Spanish. Following Grounded Theory methodology, interviews and focus groups were recorded, transcribed verbatim, translated, thematically coded for recurrent themes and organized into overarching categories.

RESULTS:
Five over arching themes were found: perception of health consequences, perceived factors influencing health, community infrastructure and challenges, community relationship with SBR, and desired changes for the community. Residents understand the threat of outdoor air pollution and associated risks, but barriers including lack of community infrastructure, violence and the economic downturn hinder their motivation and ability to act. While seen as a nuisance and somewhat recognized for its inherent risks, residents often chose not to engage in thoughts about health consequences since air pollution was not an immediate visible and pressing concern as they battle with the impacts of the economic downturn and poverty to survive.

CONCLUSION:
Resident perspective is critical to inform the health research and risk reduction mitigation plans, adding complexity to the planned health outcomes research.

CHILDREN'S BURDEN OF DISEASE CAUSED BY LEAD EXPOSURE IN CHINA

Mingyu Ding, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Background and Aims: To explore Chinese children's disease burden of mild mental retardation (MMR) caused by lead exposure

Methods: Articles on children blood lead levels (BLLs) published from 1994 to 2008 were collected through Chinese Biomedical Disk, Chinese Journal Full-test Database and other ways according to formulated criteria. The children's incidence rate of MMR (IMMR) and disease burden (DALYs) due to lead exposure were estimated using the methods recommended by WHO.

Results: The study showed that the mean BLLs of urban and rural children were 7.26μg/dl, 7.88μg/dl, and the IMMR were 18.1‰, 19.5‰, both of that were higher than the average level of Western Pacific Region with 7.7‰. The DALYs of children in city due to lead exposure were 39.4 (DALYs per 1000 children), while the DALYs in rural area were 43.2. Before the leaded gasoline banned in China, the urban children's mean BLLs were 9.33μg/dl, IMMR was 21.8‰ and the loss of DALYs were 47.8; while those dropped to 7.04μg/dl, 17.5‰ and 38.2, respectively after the ban. For rural children, the mean BLLs were 8.22μg/dl, IMMR was 20.2‰ and DALYs were 44.0 before the ban, while those dropped to 7.70μg/dl, 19.6‰ and 42.7, respectively after.

Conclusions: We can conclude that ban of leaded gasoline reduced the BLLs of children, and then reduced the disease burden caused by lead-induced MMR, yet that in rural areas decreased relatively by less; the incidence rate of MMR was still in the high level. It was urgent and necessary that we should prevent and control the children's lead exposure to reduce the economical loss and social effect.

LUNG CANCER MORTALITY RISK AMONG AN OCCUPATIONAL COHORT EXPOSED TO A MIXTURE OF COMMERCIAL AND NON-COMMERCIAL AMPHIBOLE ASBESTOS FROM VERMICULITE MINING OPERATIONS IN LIBBY, MONTANA

Thomas F. Bateson, *U.S. Environmental Protection Agency, Washington, DC, USA*
Leonid Kopylev, *U.S. Environmental Protection Agency, Washington, DC, USA*

Background and Aims: Vermiculite mining and milling in Libby, MT supplied the majority of North American demand for vermiculite during the 20th century. Libby vermiculite is contaminated with amphibole asbestos, including, winchite, richterite and tremolite. Libby workers and residents in the community were exposed to this mixture of largely non-commercial asbestos fibers for decades. Several million homes in North America may have vermiculite attic insulation from the Libby, MT mine.
Methods: Our analysis is based on 880 workers hired after 1959 when fiber concentrations were lower and possibly more consistent with potential environmental exposure. We used Cox proportional hazards models with time-dependent covariates to assess the effects of Libby amphibole asbestos on lung cancer mortality. Multiple exposure metrics including cumulative exposure, residency-time weighted exposure, and metrics mathematically allowing for effects of fiber clearance or translocation were evaluated. We compared lung cancer potency results using slopes and their corresponding risks with the slopes and risks from other investigations of the Libby worker cohort.
Results: There are four researchers who have recently published lung cancer potency results for the Libby amphibole asbestos worker cohort: Sullivan (2007), Berman and Crump (2008), Larson et al. (2010) and Moolgavkar et al. (2010). The adjusted lung cancer mortality slopes per calendar year from these four studies ranged from 1.6x10E-3 to 4.2 x10E-3 per fiber/cc-year. Risks derived through life tables based on age-specific cancer mortality rates from these four studies ranged from 0.01 to 0.08 per fiber/cc. Uncertainties in the application of these epidemiologic data are discussed.
Conclusions: Libby amphibole asbestos, a mixture composed primarily of non-commercial amphibole asbestos, has repeatedly been shown to be associated with lung cancer mortality by different investigators using varying definitions of this occupational cohort.

INTERACTIONS BETWEEN PARTICULATE AND TEMPERATURE ON MORTALITY OF CIRCULATORY SYSTEM DISEASES IN BEIJING, CHINA

Jinliang Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Yun Zhou *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Ling Liu, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Yanzhen Wu, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Background and Aims: To explore the interaction between particulate matter (TSP and PM_{10}) and temperature on mortality caused by circulatory system disease in different genders.

Methods: A Poisson semi-parametric generalized additive models (GAM) was used to examine whether there is interactive effects of particulate matter and temperature on mortality of circulatory system disease. The split point of low, medium, high temperature layer was determined based on the sensitivity tests. The interaction between atmospheric particulate matter (TSP and PM_{10}) and daily average temperature on daily mortality caused by circulatory system disease was analyzed through comparing the effects of atmospheric particulate matter in high/low and medium temperature layer.

Results: A 10μg/m^3 increase in TSP and PM_{10} with an increase of 0.055%(P=0.160) and 0.268%(P=0.002)in mortality cause by circulatory system disease. According to the results of sensitivity tests, P_{20}/P_{80} and P_{25}/P_{75} were determined as the split point of low, medium, high temperature layer. In the model with P_{20}/P_{80} split point as the temperature stratification, a 10μg/m^3 increase in TSP was associated with an increase of 0.244%(P=0.088), 0.015%(P=0.0180) and 0.437(P<0.001) in mortality cause by circulatory system disease at high, medium and low temperature, while in the model with P_{25}/P_{75} split point as the temperature stratification, the increased percentage were 0.196%(P=0.126), 0.016%(P=0.733) and 0.116%(P=0.054). With the 10μg/m^3 PM_{10} increase, the percentage of mortality will in crease 0.408%(P=0.066), 0.240%(P=0.011) and 0.342%(P=0.072) in high, medium and low temperature when P_{20}/P_{80} as the split point of temperature, 0.602%(P=0.007), 0.209%(P=0.030) and 0.340%(P=0.047) when P_{25}/P_{75} as the split point of temperature.

Conclusions: All results suggested that both particulate matter and daily average temperature may effect on daily mortality caused by circulatory system diseases independently. Forthmore, there was interaction on the mortality caused by circulatory system diseases between TSP, PM_{10} and high/low temperature.

ABSTRACT

Background and aims: Long-term exposure to traffic-related noise may increase blood pressure levels and induce hypertension, especially at night-time; however the evidence is still heterogeneous. Besides, long-term exposure to traffic-related air pollution has been also associated with cardiovascular health and it may confound the effects of road traffic noise on common cardiovascular endpoints. We evaluated the association between traffic-related noise and hypertension, adjusting for traffic-related air pollution in the city of Girona, north-eastern Spain within the REGICOR-AIR project.

Methods: We evaluated 3480 baseline participants (35-83 years old) corresponding to the population-based HERMES cohort (years 2003-2005) with blood pressure measurements and with socio-demographic, dietary and physical activity information. Outdoor residential road traffic noise levels for night ($L_{Aeq,night,9pm-7am}$) and 24 hours ($L_{Aeq,24h}$), and outdoor residential nitrogen dioxide (NO_2) levels were derived with a validated city-specific noise model (Environmental Noise Directive 2002/49/EC) and a land-use regression model, respectively. Logistic regression models were performed for hypertension (defined as systolic blood pressure ≥140mmHg or diastolic blood pressure ≥90mmHg or hypertension treatment) and traffic-related noise, adjusting for relevant confounders.

Results: A non-significant association was found between long-term exposure to road traffic noise and hypertension for an increase in 10dB(A) in $L_{Aeq,night}$ (OR=1.02; 95%CI 0.86-1.20) and in $L_{Aeq,24h}$ (OR=1.04; 95%CI 0.88-1.22). This association remained unchanged after adjusting for NO_2. No significant associations were observed in the stratified analyses by gender or age groups.

Conclusions: The overall non-significant positive effect estimates are in line with some previous epidemiological studies. However, we could not confirm some of the reported significant effects observed in previous studies by gender or age groups. Further analyses will include the evaluation of coping behaviour against noise and sensitivity analyses on the noise exposure assessment. Furthermore, we will also study the association between blood pressure and road traffic noise.

INTERACTIONS BETWEEN PARTICULATE AND TEMPERATURE ON NON-ACCIDENTAL DEATHS OF DIFFERENT GENDERS IN BEIJING, CHINA

Ling Liu, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Jinliang Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Yanzhen Wu, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Background and Aims To explore the interaction between particulate matter (TSP and PM_{10}) and temperature on non-accidental deaths of different genders.

Methods A Poisson semi-parametric generalized additive models (GAM) was used to examine whether there is interactive effects of particulate matter and temperature on non-accidental deaths. The split point of low, medium, high temperature layer was determined based on the sensitivity tests.

Results According to the results of sensitivity tests, P_{20}/P_{80} and P_{25}/P_{75} were determined as the split point of low, medium, high temperature layer. In the model with P_{20}/P_{80} split point, a 10μg/m^3 increase in TSP was associated with an increase of 0.308%, 0.042% and 0.498% in non-accidental deaths of women at high, medium and low temperature, while were higher than the increase of 0.046%, 0.002%and 0.338% of men. In the model with P_{25}/P_{75} split point as the temperature stratification, the increased percentage of women were 0.318% and 0.171% respectively in high and low temperature layer, were higher than men -0.062% and 0.064%. The percentage increase of non-accidental deaths in women was closed to men in medium temperature layer. With the 10μg/m^3 PM_{10} increase, the percentage of mortality of women will increase 0.814%, 0.219% and 0.638% in high, medium and low temperature when P_{20}/P_{80} as the split point, while mortality of men will increase -0.057%, 0.085% and 0.263%.In the model with P_{25}/P_{75} split point, the increased percentage of women were 1.160%, 0.194% and 0.452% in high, medium and low temperature layer, were also higher than men0.058%, 0.083% and 0.154%.

Conclusion The interaction on daily non-accidental deaths between atmospheric particles matter and daily average temperature in different gender was different. The impact on women was more than men.

SURVEY ON THE LEVEL OF BLOOD LEAD AND OTHER HEAVY METAL ELEMENTS IN CHILDREN AROUND COPPER SMELTER AREA

Bing Wang, *1, Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

2, Peking University Health Science Center, Beijing, China

Yanshen Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Xiaoyan Zou, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Jinliang Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Background and Aims: To describe the impact of copper smelter on blood lead and other heavy metal elements concentrations of children living around.

Methods: Eighty children at the age of 6-11 from 4 schools which located within 5 km, between 5-10km, over 10km away from the copper smelter were chosen, respectively. The children's venous blood were collected by purple-cap tube and measured by ICP-MS to detect the levels of lead, zinc, iron, copper, selenium, nickel, mercury, cadmium, chromium and manganese. Arithmetic mean was used to describe the normal distribution measurements, geometric mean (GM) for those geometric normal distribution, and median for other distributions.

Results: The GM of blood lead was 28.53μg/L (15.28~53.83μg/L), much lower than reported Chinese children's average level of 76.71μg/L; the GM of blood copper was 926.67μg/L (729.07~1305.90μg/L), nearly equal to the level of 910μg/L of children 6-13 years old reported by Changli Zhang; and the mean of zinc with 5.23 mg/L (3.64~7.60 mg/L) was also nearly equal to Zhang's study. Meanwhile, the mean of selenium was 131.78μg/L, the GM of cadmium and manganese were 0.16μg/L and 17.19μg/L, the median of iron, nickel, mercury, and chromium were 69.98 mg/L, 2.38μg/L, 0.55μg/L and 1.73μg/L, respectively. The results of stratified analysis showed that (1) There was no dose-response relationship between the distance from the cooper smelter and the concentrations of blood heavy metals; (2) The boys' blood levels of lead, iron and zinc were significantly higher than girls' ($P<0.05$), while other heavy metals without gender difference; (3) There was no significant correlation between age of children and the levels of blood heavy metals.

Conclusions: The concentrations of heavy metal elements of children investigated were largely in the range of healthy children's blood heavy metal levels reported; there was no significant correlation between children's residences and their heavy metal levels.

CORDBLOOD ACRYLAMIDE LEVELS AND GENE EXPRESSION IN NEWBORN EXPOSED DURING PREGNANCY

Fabio Gallo, *National Cancer Research Institute, Genoa, Italy*
Marcello Ceppi, *National Cancer Research Institute, Genoa, Italy*
Hans Gmuender, *Genedata, Basel, Switzerland*
Hans von Stedingk, *Stockholm University, Stockholm, Sweden*
Margareta Törnqvist, *Stockholm University, Stockholm, Sweden*
Sarah Fleming, *University of Leeds, Leeds, United Kingdom*
Joost van Delft, *Maastricht University, Maastricht, The Netherlands*
Kevin Hochstenbach, *Maastricht University, Maastricht, The Netherlands*
Domenico Franco Merlo, *National Cancer Research Institute, Genoa, Italy*

Background and Aims: Hemoglobin acrylamide adducts (HbAA) are biomarkers of exposure to acrylamide (AA). The highest AA concentrations are found in potato chips and french fries. Concerns about AA exposure *in utero* and the risk of adverse health effects are justified by AA potential carcinogenicity. Aim of this study was to investigate the association between exposure to AA in newborn during pregnancy and expression levels of 43 genes indicative of genotoxic and immunotoxic events.
Methods: The study included newborns from Greece, Norway, Spain, Denmark, and the United Kingdom (No=1151) whose mother gave informed consent at the time of recruitment in the EU funded Integrated Project NewGeneris (Newborns and Genotoxic exposure risks). HbAA were measured by the "adduct FIRE procedure" using LC-tandem mass spectrometry and gene expression by RT-PCR techniques. Mean ratios were computed to estimate the effect of each gene expression on HbAA level. The relationships between Hb-AA (log transformed) and genes expressions were investigated within each country by using the log-linear and in all newborns by fitting the mixed-effects linear regression model adjusting for selected covariates (child gender, ethnic group, gestational age, smoking during pregnancy). Multiple comparisons was accounted by the false discovery rate (FDR) correction and adjusted p-value < 0.05 were considered significant.
Results: Two genes were found to be associated with Hb-AA levels among newborns from all countries: HS00427977_M1_ERH_GTX_ITX (MR=0.79; 95%CI:0.71-0.89), and HS00925195_M1_PRKCA_GTX (MR=0.93; 95%CI: 0.88-0.98). The association with the former gene was observed in newborns from UK (MR=0.70; 95% CI:0.57-0.87) and Spain (MR=0.66; 95% CI: 0.54-0.82) where some other genes showed a statistically significant relationship with Hb-AA. The analysis of newborns from Greece revealed a significant correlation between HS00925195_M1_PRKCA_GTX (MR=0.91; 95%CI: 0.86-0.98) and Hb-AA. Further associations detected in other countries will be presented.
Conclusions: The results suggest that an increased expression of the above-mentioned genes, both involved in cell cycle regulation, is associated with a decreased level of Hb-AA in newborns possibly due to acrylamide exposure via maternal food intake during pregnancy.

SURVEY ON LIVING ENVIRONMENT OF FAMERS IN CENTRAL PLAIN CHINA

Guoliang Chen, *1, Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

2, School of Public Health, Hebei Medical University, Shijiazhuang, Hebei, China

Ling Liu, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Jinliang Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Background and Aims: To describe the farmers' living environment in investigation area. And to provide information and basis for formulating environmental comprehensive management plans.

Methods: We have chosen 560 farmer households as the subjects of household-spot observation and inquiring survey. The study was implemented by trained observers according to formulated observation outline.

Results: (1) Hygiene conditions: the households surveyed were generally in good hygiene conditions, except 20.9% of them. Less than 20% of households deposited chemical fertilizer, pesticide, farm tools and grains together; about 50% of households discarded their garbage and sewage randomly; 60% kept free-roaming poultry and poultry droppings could be found in 30% of them. (2) Kitchens: 96.4% of households owned separate kitchens. The availability of clean fuel was low, and firewood and coal were still the main cooking fuel, accounting for 60.7% and 40.8%; tightness of kitchen chimney in 24.6% of households were in poor conditions. (3) Drinking water: 66.4% of the households used shallow groundwater in distributed supply, among them 78.4% used manual-operating well and 21.6% open well. There were also some risk factors of drinking water safety, for example, 6.7% of the wells located within 20m away from the toilets and 56.5% of households used water containers. (4) Toilet: the households hardly had sanitary latrines. Although most of toilet had roof-toilet, 46.1% of the toilets were in poor hygiene conditions. (5) Village environment: 81.1% of villagers showed their approval about the living condition, and 18.9% dissatisfied with it; 69.8% of them considered the poor river water did adverse effect on daily life, 56% believed that usage of river water had being influenced and 32.9% believed it might contaminate groundwater.

Conclusion It was necessary to improve the living environment, such as promoting the use of clean fuel, providing safety drinking water and protect the river pollution.

EXPOSURE TO PM2.5 AND CAUSE-SPECIFIC MORTALITY RISK IN ADDITIONAL FOLLOW-UP OF THE HARVARD SIX CITIES STUDY: IDENTIFICATION OF SUSCEPTIBLE SUB-POPULATIONS

Francine Laden, *Harvard School of Public Health, USA*
Jaime E Hart, *Harvard School of Public Health, USA*
Robin C Puett, *Arnold School of Public Health, University of South Carolina, USA*
Joel Schwartz, *Harvard School of Public Health, USA*
Frank E Speizer, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School, USA*
Douglas W Dockery, *Harvard School of Public Health, USA*

Background and Aims: Long-term exposures to particulate matter < 2.5 microns ($PM_{2.5}$) have consistently been associated with increased mortality. Effect modification by gender, socioeconomic status, obesity and smoking has been suggested in many studies. We assessed effect modification of the $PM_{2.5}$ and cause-specific mortality associations in the Harvard Six Cities Study.
Methods: The Harvard Six Cities adult cohort study consists of 8,111 white adults recruited 1974 to 1978. Participants completed a questionnaire at enrollment with information on personal characteristics. Vital status and cause of death have been updated through 2006 using the National Death Index. Annual $PM_{2.5}$ was measured by study or USEPA monitors depending on the calendar year. We used Cox proportional hazards regression models to estimate hazard ratios (HR) and 95% confidence intervals (CIs). Effect modification by gender, smoking status, education, obesity, and occupational dust and fume exposure was examined in stratified models and with interaction terms.
Results: With 196,547.25 total person-years of follow-up, there were 4,044 deaths, including 1,680 and 318 from cardiovascular disease and lung cancer, respectively. For each 10 µg/m3 increase in $PM_{2.5}$ in the year of death, the HR for cardiovascular and lung cancer mortality was 1.24 (95%CI 1.12-1.36) and 1.36 (95%CI 1.07-1.69) in models adjusted for BMI, smoking, gender, age, calendar time and education. We observed little evidence of effect modification for cardiovascular mortality. For lung cancer, effects were strongest for participants with less than a high school education (HR=1.83), ever smokers (HR=1.44) and those with dust/fume exposure (HR=1.64). However, none of the interaction terms were statistically significant.
Conclusions: In this continued follow-up of the Harvard Six Cities Cohort, $PM_{2.5}$ is associated with increased risk of mortality from cardiovascular disease and lung cancer. Unlike other investigations, no effect modification for cardiovascular mortality was observed and modifiers of the lung cancer association were modest.

Lung Cancer Effect Modification			
High School	HS or greater	1.08 (0.78-1.48)	0.14
	< HS	1.83 (1.26-2.67)	
Smoking	Ever smoker	1.44 (1.13-1.84)	0.94
	Never smoker	1.11 (0.49-2.55)	
Obesity	Obese	1.29 (0.41-4.06)	
	Not obese	1.37 (1.08-1.73)	
Gender	Male	1.47 (1.11-1.95)	0.30
	Female	1.13 (0.75-1.70)	
Dust or Fumes	No	1.07 (0.72-1.59)	0.07
	yes	1.64 (1.20-2.24)	

Cumulative Exposure to Lead is associated with Increased Risk of Type-2 Diabetes: the VA Normative Aging Study (NAS)

Siying Huang *Department of Environmental Health Sciences, University of Michigan School of Public Health, USA*
Sung Kyun Park *Department of Epidemiology, University of Michigan School of Public Health, USA*
Bhramar Mukherjee *Department of Biostatistics, University of Michigan School of Public Health, USA*
Huiling Nie *School of Health Sciences, Purdue University, West Lafayette, IN, USA*
David Sparrow *VA Normative Aging Study, Veterans Affairs Boston Healthcare System, Boston, MA, USA*
Howard Hu *Department of Environmental Health Sciences, University of Michigan School of Public Health, USA*

Background:

There is limited evidence of the effect of lead exposure ontype-2 diabetes. Lead has high affinity for osteocalcin, and suppresses the mRNA expression of osteocalcin, which causes insulin resistance and reduced adiponectin expression. The aim of this study is to explore the potential role of cumulative lead exposure as measured in cortical bone (tibia) by K-X-ray fluorescence in the etiology of type-2 diabetes.

Method:

We examined 878 subjects who participated in the bone lead sub-study of the Normative Aging Study between 1991 and 1996. Given the decades-long half-life of tibia bone lead, we investigated development of type-2 diabetes from the baseline of the original cohort (1962-1969) through 2007 (person-years= 55,667). Diabetes status was determined from physician diagnosis, anti-diabetic medication use, fasting glucose≥126 mg/dl, or two-hour glucose tolerance test≥200 mg/dl. Age-adjusted tibia lead levels were categorized into high and low groups at median. Log rank test and proportional hazards (PH) model were used to examine the difference of diabetes onset age between high and low lead groups.

Result:

Of the 878 subjects at baseline, 278 subjects developed diabetes. Tibia lead levels were slightly higher in diabetics (22.9 vs. 21.1 μg/g, p=0.07). Log-rank test showed a significant difference in survival functions between high and low tibia lead groups (p=0.007). The average onset ages were 74.7 (SE=0.52) in high lead group and 80.8 (0.64) in low lead group. After controlling for age at first bone lead measurement, education, and smoking status, the PH model showed that compared to the low tibia group, the high tibia group had a 1.33 (95%CI: 1.03, 1.71) times the risk to develop type-2 diabetes.

Conclusion:

The results suggest that cumulative exposure to lead facilitates the development of type-2 diabetes. Additional research in this area is needed.

DECREASED VACCINATION RESPONSES IN CHILDREN WITH PRENATAL AND POSTNATAL EXPOSURES TO IMMUNOTOXICANTS

Philippe Grandjean, University of Southern Denmark, Odense, Denmark, and Harvard School of Public Health, Boston, USA
Elisabeth Wreford Andersen, University of Copenhagen, Denmark
Esben Budtz-Joergensen, University of Copenhagen, Denmark
Pal Weihe, Faroese Hospital System, Torshavn, Faroe Islands
Flemming Nielsen, University of Southern Denmark, Odense, Denmark
Carsten Heilmann, National University Hospital, Copenhagen, Denmark

Background and Aims: Polychlorinated biphenyls (PCBs), perfluorinated compounds (PFCs), and methylmercury may cause immunotoxic effects, but the human health significance of this potential is unknown. We assessed the possible adverse effects on serum concentrations of specific antibodies against childhood vaccines.
Methods: Within a cohort of 656 singleton births formed in the Faroe Islands during 1999-2001, we measured serum antibody concentrations against tetanus and diphtheria at ages 5 years (before and after a booster vaccination) and at 7 years. We analyzed PCBs, PFCs, and mercury concentrations in blood samples from pregnancy and the child at ages 5 and 7 years. The results were analyzed by regression analysis and structural equation models.
Results: A total of 587 children participated in the examinations at ages 5 and/or 7 years. Both PCBs and PFCs revealed negative associations with antibody concentrations. The strongest associations suggested a decrease in the antibody concentration by about 20% for each doubling in PCB exposure and up to 50% for a doubling in PFC exposure. The risk of having an antibody concentration below a clinically protective level of 0.1 IU/L increased with the exposures.
Conclusions: Immunotoxicant exposure in children affects their serum concentrations of specific antibodies against vaccination toxoids, thereby counteracting the intended protection offered by childhood vaccinations. These observations may potentially reflect a more general immune system dysfunction, which could have wider implications.

TRITIUM: RELATIVE BIOLOGICAL EFFECTIVENESS AND CANCER RISK

Ghassan Hamra, *UNC-Chapel Hill School of Public Health*
David Richardson, *UNC-Chapel Hill School of Public Health*
Richard MacLehose, *University of Minnesota, School of Public Health*

Background and Aims: The relationship between exposure to tritium, a source of beta radiation, and risk of cancer has received little attention in the epidemiological literature. For radiation protection purposes, and for radiation risk assessments, tritium dose and gamma radiation doses are often combined. This is done under the assumption that the biological effectiveness of the absorbed dose of tritium relative to the absorbed dose of gamma radiation, or RBE, is 1. In this paper, we utilize Bayesian methods in order to evaluate the excess relative rate (ERR) of leukemia and leukemia excluding CLL per unit of absorbed dose of tritium as well as its RBE compared to absorbed dose of gamma radiation.
Methods: In order to conduct this analysis, we utilize an incidence density sampling procedure to select cases and controls from the Savannah River Site occupational cohort of workers employed from 1951-1999. Markov chain Monte Carlo methods are used for the analysis in order to incorporate informative priors.
Results: The ERR/10mGy and associated 90% highest posterior density (HPD) of leukemia and leukemia excluding CLL are 0.272 (0.024, 0.660) and 0.304 (0.044, 0.753), while the RBEs are 8.36 and 5.36, respectively.
Conclusions: This is the first empirical estimate of tritium's relationship to cancer risk based on epidemiological data.

CHARACTERIZING PERSONAL INDOOR AND OUTDOOR AIR POLLUTION EXPOSURE OF PREGNANT WOMEN POPULATION

Background and Aims: Recently there has been an increasing interest in investigating the ambient air pollution effect on pregnancy and foetus development. An important issue is to improve the exposure assessment approach. Barcelona has one of the highest levels of traffic related air pollution in Europe. We aimed to characterize the relationship between personal, indoor and outdoor exposure to air pollution during pregnancy.
Methods: Personal, indoor and outdoor air pollution monitoring for $PM_{2.5}$ mass and absorbance, NO and NO_2 was simultaneously conducted in a sample of 54 pregnant women resident in Barcelona for 2 and 7 days respectively, from November 2008 to November 2009.
Results: Geometric mean exposure of outdoor samples were relatively high: (GM (GSD)) $PM_{2.5}$=18 µg m^{-3} (1.6), 'soot' as filter absorbance=2.70 $10^{-5}m^{-1}$ (1.8), NO=23 µg m^{-3} (2.5) and NO_2 =35 µg m^{-3} (1.3). The $PM_{2.5}$ personal and indoor exposure levels were higher than the outdoor levels and showed good correlation (personal vs indoor ρ=0.81, personal vs outdoor ρ=0.39 and indoor vs outdoor ρ=0.63). A similar pattern was observed for the levels of 'soot' and NO for which we observed a higher correlation between personal and outdoor levels ρ=0.57 and ρ=0.76 respectively. Personal NO_2 mean values were lower than indoor levels, 33 µg m^{-3} (1.4) and 36 µg m^{-3} (1.4) but well correlated. Preliminary results are showed for NO_2 and NO.
Conclusions: This is the first study in Barcelona evaluating exposure levels, variation and correlation between personal indoor and outdoor air pollution exposures values in pregnant women. The differences in the personal and outdoor values indicate the need to evaluate the measurement error when performing an exposure assessment.

John J. Godleski, *Harvard School of Public Health, Department of Environmental Health, Boston MA, USA*

Background and Aims: Epidemiologic evidence suggests that chronic stress may alter susceptibility to air pollution. Persistent spatial confounding between these exposures, however, limits the utility of epidemiologic methods alone to disentangle these effects, and it can not identify physiologic mechanisms.
Methods: Using a rat model of social stress, we examine continuous respiratory and cardiovascular responses to concentrated fine ambient particles (CAPs). Twenty-four 12-week old male Sprague-Dawley rats are randomly assigned to four groups (Stress/CAPs; Stress/Filtered Air (FA); Non-stress/CAPs; Non-stress/FA). Stress group animals are individually introduced into a dominant male's home cage twice weekly. Blood drawn at sacrifice is analyzed for immune and inflammatory markers.
CAPs are generated using the Harvard fine particle concentrator, which enriches real-time urban ambient fine particles by approximately a factor of 30. CAPs/FA exposures are delivered in single-animal plethysmographs, 5 hours/day on 10 days, with respiratory function continuously monitored using a Buxco system during CAPs exposures. Cardiovascular measures are collected via telemetry during CAPs and stress exposures. Lungs, hearts, and adrenals are fixed at constant pressure and random slices obtained for histology.
Results: We previously reported that stressed animals display higher average CRP, TNF-alpha, and white blood cell counts. In response to CAPs, stressed animals display increased respiratory frequency, lower flows and volumes -- suggesting rapid, shallow breathing patterns. Preliminary cardiovascular data indicate elevated heart rate (HR), systolic and diastolic blood pressures (SBP, DBP) during stress exposures.
Conclusions: Our findings suggest that chronic stress may alter respiratory and cardiovascular responses to air pollution in animals. Higher CAPs exposures were associated with a rapid shallow breathing pattern, only under chronic stress. Stress exposures also induce increases in HR, SBP, DBP, and temperature. Blood measures point to possible inflammatory pathways. Preliminary analyses suggest stress-related alterations in CAPs response; further investigation is needed to identify possible physiologic pathways for differential susceptibilities.

THE COOKING USING DIFFERENT FUELS AND THE LEVEL OF INDOOR AIR PAHS

Background and Aims: To understand the impact of cooking by daily fuels on the levels of indoor air polycyclic aromatic hydrocarbons (PAHs).

Methods: Four households with similar house structure and economic conditions were chosen in a village of North Jiangsu province. Fuels (including straw, coal and liquefied petroleum gas (LPG)) were used to cook the same foods in each kitchen. Indoor air PAHs (including those adsorbed on PM_{10} and in gaseous state) were collected and detected during cooking.

Results: The majority of PAHs (including PAHs adsorbed on PM_{10} and in gaseous state) in indoor air produced by all 3 fuels burning was those under 4-ring and gaseous PAHs. The median percentages of PAHs under 4-ring and in gaseous state accounting for total PAHs were 93.86% (93.63% ~ 94.52%) and 94.20% (81.36% ~ 94.34%), respectively. The levels of total PAHs in kitchen air produced by straw, coal and LPG burning were 4.70μg/m^3, 3.91μg/m^3 and 3.65μg/m^3, respectively. The levels of gaseous PAHs in kitchen air brought by all 3 fuels combustion were higher than those adsorbed on PM_{10}. The median difference between gaseous and adsorbed on PM_{10} was 3.05μg/m^3 (2.49μg/m^3 ~ 3.29μg/m^3). The levels of PAHs adsorbed on PM_{10} in kitchen air produced by straw, coal and LPG burning were 0.738μg/m^3, 0.204μg/m^3 and 0.198μg/m^3 respectively, while the levels of gaseous PAHs were 3.97μg/m^3, 3.70μg/m^3 and 3.45μg/m^3 respectively. PAHs under 4-ring adsorbed on PM_{10} accounted for 64.22% (63.13%~82.52%). PAHs under 4-ring dominated gaseous PAHs and received 95% (95.49% ~ 96.41%) as well.

Conclusions: The majority of PAHs in indoor air brought by all 3 fuels combustion was PAHs under 4-ring and in gaseous state. Straw burning produced the maximum PAHs, coal finished the second, and LPG got the minimum.

VALIDATED MEASURES OF CHRONIC OCCUPATIONAL NOISE ON HYPERTENSION DIAGNOSIS

Background and Aims

Studies report positive associations between occupational noise and cardiovascular illness, although several potential casual pathways exist. Noise may directly affect auditory function as a physical exposure, or as a chronic stressor. Noise effects may also be confounded by work-related physical hazards, including heat and chemical agents. Finally, accurate ascertainment of true occupational noise exposures is complicated, due to more vigilant use of hearing protection (HP) in noisier environments.

Methods

We use a unique dataset of in-ear (past HP) noise dose measurements to adjust ambient noise measurements. We then perform multivariate logistic regression analyses predicting hypertension onset, using each of three alternative noise metrics: (1) ambient noise, (2) HP-adjusted ambient noise, (3) hearing loss (an indicator of chronic noise exposure from all sources).

Cohort data is derived from company records and health claims files for aluminum manufacturing employees in eight U.S. states. The dataset includes noise measures on 14,807 employees, with sufficient detail at the individual, job, and plant levels to examine multiple workplace factors affecting cardiovascular health.

Results

Preliminary analyses reveal significant variability, within and across plants, in noise exposures and hypertension outcomes. Analyses using ambient noise display consistent *inverse* associations with hypertension, which may be due to exposure misclassification or healthy worker effects. Preliminary analyses using hearing loss suggest non-significant positive associations with hypertension onset overall, though a subset of

plants demonstrate significant risks predicted by hearing loss.

Conclusions

Just as pathways for chronic noise exposures on cardiovascular health remain unclear, it remains unknown whether hearing protection can modify hypertension risk. If more refined analyses of HP-adjusted noise exposures better predict hypertension, this suggests that HP interventions may effectively reduce cardiovascular risk.

TRAFFIC-RELATED AIR POLLUTION AND RISK OF CONGENITAL ANOMALIES IN BARCELONA

Background and aim: There is a growing number of studies on ambient air pollution and risk of congenital anomalies. In a recent meta-analysis, NO_2 and SO_2 exposures were related to increases in risk of coarctation of the aorta and tetralogy of Fallot, and PM_{10} exposure to an increased risk of atrial septal defects. So far no refined spatial exposure models have been used in this field. We conduct a study of traffic-related air pollution exposure estimated by land-use regression models and risk of congenital anomalies in Barcelona.
Method: Cases with congenital anomalies and control births are selected from the population-based Barcelona Birth Defects Register (REDCB) between 1995 and 2006. In Barcelona, traffic related air-pollution levels have been measured and refined exposure modelling techniques are employed to develop a detailed spatial land-use regression (LUR) model, within the framework of ESCAPE Project. The geocode of the maternal residence at birth will be linked to the exposure estimates for PM_{10}, $PM_{2.5}$, NOx and NO_2. Logistic regression models will analyse the risk of congenital anomaly groups and air pollution exposures.
Results: A total number of 3129 cases have been registered, the most frequent groups are congenital heart defects (34%), urinary tract defects (19%), limb reduction defects (13%), and central nervous system defects (13%), 25% of cases had a chromosomal anomaly. The mean maternal age was 32 years both for cases and controls. Control mothers were higher educated (43% vs 39% in cases had completed the university) and lived in less deprived areas. The Barcelona LUR models explained 72% of intraurban NO_2 variability, 79% of $PM_{2.5}$ variability. Findings on the association between exposure to traffic-related air pollutants and risk of specific congenital anomalies will be presented.
Conclusion:
This study will allow corroboration of the findings of previous studies, using more refined spatial models of air pollution.

THE EFFECTS OF DAILY FUELS COMBUSTION ON INDOOR AIR QUALITY IN RURAL CHINA

Background and Aims: To understand the influence of daily fuels (including biogas, straw, coal, and liquefied petroleum gas (LPG)) in rural China on the levels of indoor air SO_2, NO_2 and CO.

Methods: In rural northern Anhui province, we chosen 20 households, with the same house structure and completely separated kitchens which had very similar size, ventilation and stoves location. Of them, biogas, straw, coal, or (LPG) were used as the daily fuel in each 5 households respectively. Successively 48h SO_2 and NO_2 in kitchens and bedrooms were collected by Radiello passive diffusion tubes and 48h CO successively measurements were taken using EL-USB-CO (Lascar, UK).

Results: Among the 4 daily fuels, there was no any difference in levels of SO_2, NO_2 and CO in bedroom air, which were much lower than those in kitchen air. The levels of 3 indoor air pollutants in the kitchen air produced by coal combustion were significantly higher than those produced by other fuels. The geometric mean of SO_2 and NO_2 were 3196.48μg/m^3 and 67.90μg/m^3, respectively. And means of the top 3 peak concentrations of CO were 633.9ppm, 510.27ppm and 408.80ppm, respectively. In addition, straw had a relatively large effect on indoor air quality (IAQ). The levels of NO_2 and CO in kitchen air from straw combustion were higher than those from LPG and biogas. The geometric mean concentration of NO_2 was 25.40μg/m3, and means of the top 3 peak concentrations of CO were 75.11ppm, 42.98ppm, 31.07ppm, respectively. LPG and biogas showed less influence on 3 kitchen air pollutants.

Conclusion: IAQs in kitchen air were mainly influenced by daily fuels in study area, while those in bedroom air were barely influenced. Coal burning brought the most serious indoor air pollution, and LPG and biogas were relatively clean.

THE LEVEL AND DISTRIBUTION OF POLYCYCLIC AROMATIC HYDROCARBONS IN SEDIMENTS OF THE HUAIHE RIVER AND THEIR ECOLOGICAL RISK

Objective Describing the levels and distributions of 16 PAHs in the sediments of the Huaihe River.

Method Searching and collecting articles on the PAHs in the sediments of the Huaihe River from year 1980 to 2010, integrating and analyzing the levels and distributions of 16 kinds PAHs in the 35 reported sections of the sediments in Huaihe River basin and evaluating the potential ecological risk.

Result (1) The average content of the PAHs in the sediments of the Huaihe River was 143.1ng/g, which was lower than those in other rivers basin in China, such as Yangtze River in Nanjing, Yellow River and Pearl River. (2) The level of the PAHs in the sediments showed great surge along the stem of the Huaihe River. The level of PAHs was 1293.0ng/g at the Fengtai Bridge (Huainan, 2007), 1278.0ng/g at the Luo River Power Plant (Huainan, 2007) and 1007.7ng/g at the Pingwei (Huainan, 2006), while 5.4ng/g at Han Ying (Bengbu, 2007) and 6.7ng/g at the Pier One (Bengbu, 2007). (3) Based on Long's method of Effort Range Low and Medium (ERL/ERM) calculated potential ecological risk of PAHs in the sediments was less than 10%. The level of Dibenzo (a,h) anthracene was 156.5ng/g and its ecological risk was between 10% and 50%. (4) Benzo (b/k) fluoranthene, indeno (1,2,3-cd) pyrene and benzo (ghi) perylene and so on were detected in 31 of 35 sections, which imply there were the biological toxic side effects in sediments of huaihe River.

Conclusion Compared with other river basin, the contents of the PAHs in the sediments of the Huaihe River were lower in the overall situation and the potential ecological risk was on the relative low level. However, attention should be pay to the detected PAHs with no minimum safe value in some sections.

URINARY BIOMARKERS OF EXPOSURE TO GLYCOL ETHERS AND ADVERSE PREGNANCY OUTCOMES

Background and aims : Glycol ethers (GE) are widely used solvents present in various products such as paints, cleaning agents or cosmetics. GEs toxic effects are attributed to the production of alkoxycarboxylic acids, some of them are known developmental toxicants (MAA and EAA) or embryotoxic (BAA) in animals. The aim of our study was to test the association between levels of alkoxycarboxylic acids and the occurrence of adverse pregnancy outcomes.

Methods : The PELAGIE birth cohort included 3,421 pregnant women before 19 weeks of gestation between 2002 and 2006. At inclusion, women provided a urine sample. Urinary levels of 8 alkoxycarboxylic acids were assessed by chromatography (LOD=0.05mg/L) in a nested case-control study comparing 174 cases of fetal growth restriction, 111 preterm births, and 505 controls, odds ratios (OR) were estimated using logistic models adjusted for potential confounders. The study of the association with birth weight and gestation length was restricted to controls using linear regression models.

Results : The percentage of samples in which alkoxycarboxylic acids were identified ranged from 4.4% for EAA to 71.5% for BAA (metabolite of EGBE, present in cleaning products) and 91.3% for PhAA (metabolite of EGPhE, present in cosmetics). Frequently detected BAA and PhAA were not asssociated with fetal growth. EEA was the only metabolite showing an association with fetal growth restriction (OR =2.17 95% CI : 1.0-4.8) and birth weight decrease (b= - 193.1 g; p=0.02). No association was seen with preterm birth or gestation length.

Conclusions : Frequently detected alkoxycarboxylic acids in pregnant women (BAA and PhAA) are not associated with growth restriction. EAA, a known developmental toxicant in animals, is the only GE metabolite associated with fetal growth restriction in our study.

GREEN SPACE, HEALTH INEQUALITY, AND PREGNANCY

Mark J. Nieuwenhuijsen, *Centre for Research in Environmental Epidemiology (CREAL), Spain*

Background and Aims: Green spaces have been suggested to improve both perceived and objective physical and mental health and well-being; however, there is no available evidence on the impact of green spaces on pregnancy. The aim of this study was to investigate the impact of surrounding greenness and proximity to major green spaces on birth weight (BW) and gestational age at delivery (GA) and to describe the effect of socioeconomic status (SES) on this relationship.
Methods: This study was based on a cohort of births (N=8246) that occurred in a major university hospital in Barcelona during 2001-2005. We determined surrounding greenness as average of Normalized Difference Vegetation Index (NDVI) (Landsat ETM+ at 30mx30m resolution) in a buffer of 100m around each maternal place of residence. To address proximity to major green spaces, a binary variable was created indicating whether maternal residential address falls within a buffer of 500m from boundaries of a major green space, according to the *Ecologic Map of Barcelona*. SES data at both individual (ethnicity, occupation, and education) and area (MEDEA index at census tract level) was obtained for each participant. For each indicator of green exposure, linear regression models were constructed to estimate change in BW and GA adjusted for relevant covariates.
Results: None of the indicators of green exposure were associated with BW and GA. After stratifying the analysis according to education level, we detected an increase in BW (grams) among lowest education level group (N=164) who were either living close to a major green space (Regression coefficient (95% confidence Interval (CI)) of 189.8 (23.9, 355.7) or had higher surrounding NDVI (Regression coefficient (95% CI) of 436.3 (43.1, 829.5)). This finding was not observed for GA.
Conclusions: Our study suggests a beneficial effect of exposure to green spaces on birth weight among lower SES groups.

LAG STRUCTURE AND HARVESTING EFFECTS OF AIR POLLUTION ON DAILY OUTPATIENT VISITS

Yanshen Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Jinliang Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Ling Liu, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Yu Wu, *Department of Internal Medicine, Henan Provincial People's Hospital, Zhengzhou 450003, China*

Background and Aims: To explore whether there is harvesting effect between air pollutants and daily outpatient visits in Zhengzhou.

Methods: We collected air quality data, weather data and daily outpatient visits for the department of respiratory medicine, cardiovascular internal medicine and neurology from December 1, 2008 to November 30, 2009 in Zhengzhou, and then used generalized linear distributed lag models to explore the relationship between air pollutants and daily outpatient visits, after adjusting confounding effects of long-term and seasonal trend, daily temperature and relative humidity.

Results: PM_{10} and NO_2 were significantly associated with daily outpatient visits for the department of cardiovascular internal medicine. An increase of 10 μg/m^3 in PM_{10} was associated with an ER of 3.55% (95% CI: 0.28%~6.93%) outpatient visits for the department of cardiovascular internal medicine. And an increase of 10 μg/m^3 in NO_2 was associated with an ER of 17.72% (95% CI: 2.84%~13.48%) outpatient visits for the department of cardiovascular internal medicine. We didn't observe harvesting effects between PM_{10} and NO_2, and daily outpatient visits for the department of cardiovascular internal medicine. PM_{10}, SO_2 and NO_2 were not significantly associated with daily outpatient visits for the respiratory internal medicine and neurological internal medicine. Also, SO_2 was not significantly associated with daily outpatient visits for the department of cardiovascular internal medicine.

Conclusion: Daily PM_{10} and NO_2 concentration were positively associated with daily outpatient visits for the department of cardiovascular internal medicine in Zhengzhou, and there is no harvesting effect.

EVALUATION OF THE FREQUENCY OF CONSUMPTION OF FOODS CONTAINING GENOTOXIC COMPOUNDS IN A COHORT OF MEXICAN PREGNANT WOMEN

Marisol Castillo-Castrejón, *Universidad Nacional Autonoma de Mexico, Mexico City, Mexico*
Alejandra Migoya-Graue, *Universidad Nacional Autonoma de Mexico, Mexico City, Mexico*
Adriana Castañón-Figueroa, *Universidad Nacional Autonoma de Mexico, Mexico City, Mexico*
Noemi Meraz-Cruz, *Universidad Nacional Autonoma de Mexico, Mexico City, Mexico*
Marie S. O'Neill, *University of Michigan, Ann Arbor, MI, USA*
Felipe Vadillo-Ortega, *Universidad Nacional Autonoma de Mexico, Mexico City, Mexico*

Background and Aims
Prenatal exposure to polycyclic aromatic hydrocarbons (PAHs) and heterocyclic aromatic amines (HCAs) are associated with increased risk for adverse birth outcomes. In addition to air pollution, foods may contribute to PAH/HCA exposures, which form depending on cooking methods. To evaluate the contribution of ambient pollution exposures to pregnancy outcomes, we are following a cohort of low-socioeconomic status pregnant women in Mexico City. The aim of this preliminary study was to assess the frequency of dietary PAH/HCA intake and consumption habits in our cohort.

Methods
A food frequency test and a 24-hour dietary recall were applied to participants at different times during prenatal follow-up. This questionnaire includes foods with a high content of PAHs/HCAs. Additionally, we are collecting information on participants' air pollutant exposure, medical, obstetrical and nutritional variables.

Results
Data from 300 women were analyzed. Total energy intake was 1954 ± 421.9 (mean±SD) calories per day. Dietary distribution of macronutrients was 15.4% proteins, 54.7% carbohydrates and 29.6% lipids. Homemade breaded fried chicken, deep-fried tacos and cooked pork skin were an important source of PAHs/HCAs. Other foods such as grilled tomato sauce, toasted bread, grilled cactus and toasted tortilla were also consumed on daily basis. Women consumed more dietary PAH/HCAs from cooked cereals and vegetables than from meat sources.

Conclusions
Main foods contributing to PAH/HCA intake in a Mexican urban pregnant population were identified. This pattern of consumption reflects the frequent intake of low-cost homemade foods with high PAH/HCA content. No quantitative studies of PAHs/HCAs are available for Mexican foods. Future plans include determining the relative contributions of dietary PAHs/HCAs, air pollution, and tobacco smoke exposures to DNA damage during pregnancy by correlating these exposures to PAH/HCA DNA adducts in mother's and umbilical cord blood. We will also evaluate associations between DNA damage and pregnancy outcomes.

EXPOSURE TO PERFLUOROOCTANOIC ACID THROUGH CONSUMPTION OF OHIO RIVER WATER

Susan M. Pinney, *University of Cincinnati College of Medicine, Dept. of Environmental Health, Cincinnati, OH, USA*
Robert L. Herrick, *University of Cincinnati College of Medicine, Dept. of Environmental Health, Cincinnati, OH, USA*
Robert Bornschein, *University of Cincinnati College of Medicine, Dept. of Environmental Health, Cincinnati, OH, USA*
Antonia M. Calafat, *Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA, USA*
Kayoko Kato, *Division of Laboratory Sciences, National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA, USA*
Frank M. Biro, *University of Cincinnati College of Medicine, Dept. of Pediatrics and Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA*
Paul Succop, *University of Cincinnati College of Medicine, Dept. of Environmental Health, Cincinnati, OH, USA*

Background and Aims: Perfluorooctanoic acid (PFOA) is used in the production of stain and grease-resistant coatings; the human health effects of PFOA exposure are not well understood. An industrial plant in Parkersburg, WV discharged PFOA and other polyfluroalkyl compounds (PFCs) into the Ohio River from 1980 to 2004. Residents of communities near Parkersburg and girls living in the Greater Cincinnati area have serum PFOA concentrations higher than general population levels. This study examined PFOA exposure in communities along the Ohio River between Parkersburg and Cincinnati.
Methods: Participants recruited from Huntington, WV, Portsmouth, OH and Fort Thomas, KY in 2009 and 2010 provided 15-mL blood samples to measure PFC concentrations and clinical parameters and answered questions about water consumption, health effects, and residential history. Drinking water sources were identified for each community through records searches and meetings with utilities. Associations between serum PFOA concentration and recruitment site, cumulative years drinking Ohio River water, self-reported daily tap water consumption, age and gender were analyzed using ANCOVA.
Results: Serum has been analyzed for 193 participants from Huntington, WV (N=74), Portsmouth, OH (N=90), and Fort Thomas, KY (N=29); 61 additional samples are currently being analyzed. PFOA concentrations range from 0.4ng/mL to 62.7ng/mL (median 9.7ng/mL). Median serum PFOA concentrations for each site were greater than the 2007-2008 NHANES median (4.30 ng/mL). Preliminary analysis indicated a significant correlation between serum PFOA concentration and the cumulative number of years the participant used Ohio River water; residents with two or more years consuming Ohio River water had higher serum PFOA concentrations than residents who used other water sources.
Conclusions: These findings suggest that communities along the Ohio River between Parkersburg and Cincinnati are exposed to PFOA and the major source is drinking water drawn from the Ohio River.

The findings and conclusions in this poster have not been formally disseminated by the Centers for Disease Control and Prevention and should not be construed to represent any agency determination or policy.

EXPOSURE OF LAKE MÖHNE ANGLERS TO PERFLUORINATED COMPOUNDS - ONE YEAR FOLLOW UP

Jürgen Hölzer, *Department of Hygiene, Social and Environmental Medicine, Ruhr-University Bochum, Germany*

Johannes Müller, *Institute and Outpatient Clinic of Occup., Social a. Environ. Medicine, University Erlangen-Nürnberg, Germany*
Paul Just, *Staatliches Veterinäruntersuchungsamt, Arnsberg, Germany*
Knut Rauchfuss, *North Rhine-Westphalia State Agency for Nature, Environ. a. Consumer Protection, Recklinghausen, Germany*
Martin Kraft, *North Rhine-Westphalia State Agency for Nature, Environ. a. Consumer Protection, Recklinghausen, Germany*
Michael Wilhelm, *Department of Hygiene, Social and Environmental Medicine, Ruhr-University Bochum, Germany*

Background and Aims: In 2008, a cross-sectional study was performed at Lake Möhne, Germany, to assess the PFC body burden of 105 anglers (Hölzer et al. 2008). The contamination of Lake Möhne fish occurred mainly by application of polluted soil conditioner on agricultural lands, which drained into tributaries of the river Möhne. North-Rhine-Westfalian Ministry for Environment recommended limiting fish consumption from Lake Möhne to three times a month at most. The fish advisory is based on a provisional tolerable daily intake of 100 ng PFOS/kg_{bw}. Here we report for the first time on the results of the follow up study, which was performed more than one year after the first study.
Methods: Lifestyle factors, fish and drinking water consumption habits were assessed by questionnaire and interview. Perfluorooctanoate (PFOA), perfluorooctanesulfonate (PFOS), perfluorohexanoate (PFHxA), perfluorohexanesulfonate (PFHxS), perfluoropentanoate (PFPA) and perfluorobutanesulfonate (PFBS) in blood plasma and PFOA/PFOS in fish and drinking water samples were measured by solid phase extraction, HPLC and MS/MS detection.
Results: PFOS concentrations in perches ranged between 22 and 160, in pikes between 15 and 73 ng/$g_{fresh\ weight}$. 84 anglers (80 %) participated in the follow up study. Median interval between the two blood samples was 420 days. 12 percent of all participants stopped angling and eating fish from Lake Möhne after the first study 2008. Among those anglers, who stopped angling and eating fish from Lake Möhne, PFOS-concentrations in blood plasma decreased by 4 and 33 % (geometric mean: 17 %).
Conclusions: The observed decline of PFOS-concentrations in anglers seems to reflect both the discontinued intake by the anglers and the decrease of PFOS in the general population.

Françoise Clavel-Chapelon, National Institute of Health and Medical Research, (Inserm), France; Paris-South University 11, France.
Judith Garcia-Aymerich, Centre for Research in Environmental Epidemiology (CREAL), Spain; Municipal Institute of Medical Research (IMIM-Hospital del Mar), Spain; CIBER Epidemiologia y Salud Pública (CIBERESP), Spain; Department of Experimental and Health Sciences, Universitat Pompeu Fabra, Doctor Aiguader 88, 08003 Barcelona, Spain.

Background and Aims: Potential benefit of physical activity in asthma incidence is scarce and controversial. We aimed to assess the association between regular physical activity and adult-onset asthma.
Methods: We included 51,080 women from a French cohort study, and followed them from 1993 to 2003. Physical activity at baseline was defined as time spent in household and leisure time physical activity, converted to metabolic equivalents (METs), and categorised in tertiles. Adult-onset asthma during follow-up was defined according to the American Thoracic Society criteria.
Results: Mean age at baseline was 53 years, 13% of women were current smokers, 19% were overweight or obese, and 56% were postmenopausal; 512 (1%) developed asthma. No association was found between physical activity and asthma incidence in the crude or in the adjusted Cox regression model (adjusted HR 1.03 and 1.01 for the 2nd and 3rd tertiles compared to the 1st tertile, p-for-trend=0.979).
Conclusions: Physical activity is not related to adult-onset asthma in this cohort of French middle-aged women.

NOISE ASSESSMENT IN EPIDEMIOLOGICAL STUDIES

Danny Houthuijs, *National Institute for Public Health and the Environment (RIVM), The Netherlands*
Wolfgang Babisch, *Federal Environment Agency (UBA), Germany*
Wim Swart, *National Institute for Public Health and the Environment (RIVM), The Netherlands*

Background and Aims: In studies on noise and health different exposure indicators are used varying from the presence of a noise source, measurements at specific locations and modelling of noise at different facades of home addresses. The use of different exposure assessment methods was explored.
Methods: The impact of road noise on use of antihypertensive drugs was studied in The Netherlands with registered data for about 1 million patients from pharmacies. The exposure was derived from noise maps and aggregated at postal code area, the level for which medication data was available. In a study among 1048 German children information on the road traffic exposure at home was collected in an interview (Babisch et al 2009). This was validated with short-term noise measurements. Blood pressure was measured at clinical study centres.
Results: In the Netherlands an association was observed between road traffic noise and antihypertensive use although there was substantial exposure misclassification. The RR per 5 dB was 1.17 [95% CI: 1.02-1.33] for a threshold of 60 dB and 1.03 [1.00-1.07] for a threshold of 50 dB. In Germany the lowest blood pressure was found among children whose room was facing a 'low traffic' street. The difference with children with a room facing a street with a 'high or extremely high traffic' volume was on average 1.8 mmHg for systolic blood pressure; 0.48 mmHg [0.15-0.81] per 5 dB.
Conclusions: The results indicate that different exposure assessment methods are capable of identifying risks of road traffic noise exposure in health studies. The pro and cons of different approaches will be discussed.

AUTOMATIC TIME-ACTIVITY CLASSIFICATION BASED ON GLOBAL POSITIONING DATA

Jun Wu, University of California, Irvine, USA
Chengsheng Jiang, University of California, Irvine, USA
Douglas Houston, University of California, Irvine, USA
Ralph Delfino, University of California, Irvine, USA
Dean Baker, University of California, Irvine, USA

Background and Aims: Air pollution epidemiological studies are increasingly using global positioning system (GPS) to collect time-location data. However, remarkable uncertainties in GPS data create challenges for reliably characterizing time-activity patterns from the raw GPS data. We aimed to develop models to classify people's major time-activity patterns directly from the GPS tracking.

Methods: We collected 131 person-days of GPS time-activity data in 2008 for 47 residents in Southern California. Time-activity patterns were coded for each subject based on GPS recordings, time-activity diary logs, and follow-up interviews. Using similar methods, 7-day validation data were collected from three research staff in 2010. We developed, evaluated, and compared two models for extracting time-activity patterns (i.e. indoor static, outdoor static, outdoor walking, and in-vehicle travel) from the GPS data. A rule-based model developed user-defined rules based on time, speed, and spatial relationship of the GPS points, while a logistic model trees (LMT) model required minimal user-input by using existing software that combined a tree structure with logistic regression.

Results: Indoor static, outdoor static, outdoor walking and in-vehicle travel accounted for 82.7%, 6.1%, 3.2% and 7.2% of the points in the main dataset, respectively. Both the rule-based and the LMT models correctly classified more than 90% of reported indoor static points and more than 70% of reported in-vehicle travel points, with Type 1 error (over-estimation) and Type 2 error (underestimation) <9% for indoor static classification and <29% for in-vehicle travel classification. Both models performed the worst in identifying outdoor static points. The performance of the LMT model improved significantly when using training data from the 7-day validation dataset likely because of more accurate diary data.

Conclusion: Our models can successfully identify static and in-vehicle travel points from raw GPS data. It is more challenging to separate outdoor static from indoor static points.

Variation in Genes Regulating Male Reproductive Development In Relation to Anogenital Distance Measurements, Potential Markers of In Utero Androgenization

Sathyanarayana S[1,2], Swan, SH[3], Farin FM[4], Wilkerson HW[4], Grady R[5], Zhou C[1,2], Schwartz SM[6,7]

1. Department of Pediatrics, University of Washington
2. Center for Child Health, Behavior, and Development, Seattle Children's Research Institute 3. Department of Obstetrics and Gynecology, University of Rochester Medical Center
4. Department of Environmental and Occupational Health Sciences, University of Washington
5. Division of Pediatric Urology, Children's Regional Hospital & Medical Center
6. Department of Epidemiology, University of Washington
7. Epidemiology Program, Fred Hutchinson Cancer Research Center

Purpose: Single nucleotide polymorphisms (SNPs) in genes regulating male reproductive tract development have been associated with male genitourinary abnormalities, but no studies have examined the relationship between SNPs and novel anogenital measurements such as anogenital distance (AGD), anoscrotal distance (ASD), and penile width (PW).

Methods: We examined whether common variation in 34 SNPs within genes regulating male genital development (AR, ESR1, ESR2, CTGF, CYR61, INSL3, RXFP2, ATF3) is associated with AGD, ASD, and PW in 106 healthy male infants (ages 2-34 months) from the multi-center Study for Future Families. DNA was extracted from buccal smears, and we used linear regression models to assess the relationship between anogenital measurements and SNP genotypes with adjustment for covariates.

Results: We found that the rs2077647 G allele, located in a coding region of *ESR1*, was associated with a shorter AGD (-7.3mm, 95% CI -11.6 to -3.1). In addition, the rs10475 T allele, located in the 3' untranslated region of *ATF3*, was associated with a shorter ASD (-4.3mm, 95% CI -7.2, -1.4). We observed no association between PW and any SNPs examined.

Conclusions: We found that minor alleles for two SNPs within genes that are involved in estrogen mediated male genital development were associated with AGD and ASD. These results are preliminary but suggest that these measures may be intermediate phenotypes that form within the same developmental pathway as other abnormalities such as hypospadias and cryptorchidism. Future studies are needed to functionally validate that ESR1 and ATF3 are involved in the development of intermediate male phenotypes.

INTERACTION OF ENVIRONMENTAL FACTORS AND SEX ON THE PREVALENCE OF CONGENITAL ANOMALIES

Louis Goffe, *School of Biology, Newcastle University, UK*
Judith Rankin, *Institute of Health and Society, Newcastle University, UK*
Roy Sanderson, *School of Biology, Newcastle University, UK*
Dilhani Samarasekera, *Institute of Health and Society, Newcastle University, UK*
Tanja Pless-Mulloli, *Institute of Health and Society, Newcastle University, UK*

Background and Aims: The exact aetiology of many congenital anomalies (CA) is unclear. Genetic and environmental factors have been suggested. Using 10,311 cases notified to the Northern Congenital Abnormality Survey (1985-2003) we reported sex ratios for a range of CAs[1]. Here we explore interactions between environmental factors and sex ratio.
Methods:A range of environmental and socio-economic variables were extracted for the 10,311 CA records, including; landscape composition (land cover, road networks and topology), population density and measures from the Index of Multiple Deprivation 2004 (IMD). Specific CAs were selected (hydrocephalus, ventricular septal defect (VSD), oesophageal atresia, upper limb reduction, other trisomy and DiGeorge syndrome (DGS)), that had shown non-significant sex-bias to avoid analysing those CAs known to be prevalent in one sex. These data were analysed, with birth weight, gestation age and year of birth, where the response variable was sex, using a logistic model to test the null hypothesis that the proportion of males and females associated with a given CA was unaffected by environmental factors. Multi-model inference (MMI) was used to check the relative weighting of significant predictors.
Results: Hydrocephalus showed measures of landscape composition and abundance of motorway/primary roads as significant factors in the sex ratio of cases.
Upper limb reduction showed a significant effect of both IMD score and land cover. IMD shows a strong association (est=0.027; P=0.009), implying a bias towards male births with higher IMD scores (more deprived).
No variable in the analysis of VSD, oesophageal atresia or other trisomy and DGS was significant.
Conclusion: There is a variation between the results for these CAs. While not all displayed an association between environmental factors and the sex ratio, some showed a significant relationship. This study indicates a need for further investigation with more CAs and environmental variables with application of more sophisticated analysis.

ASSESSMENT OF RADON ASSOCIATED LIFETIME RISK IN SUPPORT TO RADIATION PROTECTION

Dominique Laurier, *Institut de Radioprotection et de Sûreté Nucléaire (IRSN), France*
Ladislav Tomasek, *National Radiation Protection Institute (SURO), Czech Republic*
Margot Tirmarche, *Institut de Radioprotection et de Sûreté Nucléaire (IRSN), France*

Background and aims: Quantification of radon associated lung cancer risk is a major public health issue. Many epidemiological studies provided results on the exposure-risk relationship in miners or in the general population. Nevertheless, due to variations in the study designs, in the characteristics of the studied populations and in factors that modify the exposure-risk relationship, it is difficult to verify the coherence of published results. We present here calculations of lifetime excess absolute risks (LEAR) to compare the results of models derived from different populations when applied to the same scenario of exposure.
Methods: Models derived from pooled miner studies and pooled indoor studies were applied. Background rates were those proposed by the International Commission for Radiation Protection (ICRP). Different scenarios of chronic low rate exposure were considered. A sensitivity analysis was performed to evaluate the impact of methodological choices (model, background rate, lifetime duration…).
Results: Based on the BEIR VI model and the Czech-French model, a LEAR of about 5 10^{-4} per Working Level Month (WLM) was derived. This estimate has to be compared with the value of 2.8 10^{-4} per WLM published in 1993 in the ICRP Publication 65. The sensitivity analysis showed that the estimated LEAR vary from 3 to 7 10^{-4} per WLM according to the model used. Calculations also illustrated the sensitivity of LEAR estimates to background rates. When applied to adapted scenarios, LEAR estimates obtained from miners and from indoor studies were different for less than 30%.
Conclusions: LEAR estimates based on recent models derived from pooled analyses of miner data are higher than the one previously considered by the ICRP. Calculations demonstrate a good consistency between lung cancer risk estimates obtained from miners or indoor studies. These results provide support to the elaboration of radiation protection measures regarding radon exposure.

SHORT HISTORY AND RATIONALE FOR REVISED ETHICS GUIDELINES

Colin L. Soskolne, *University of Alberta, Canada*

In 1999, the International Society for Environmental Epidemiology (ISEE) adopted its Ethics Guidelines. Guidelines articulate our professional collective values and the principles according to which we are held both professionally and publicly accountable. They provide a basis for deciding actions in both our research and practice realms. Finally, they provide insight to students to help in their socialization as professional environmental epidemiologists.

Because social values, technological advancements, and legal contexts within which environmental epidemiologists work change over time, a subcommittee was formed at the 2009 annual ISEE conference to review and update our 1996 Guidelines. Its goals were, among others, to (a) include current ethical and philosophical challenges; (b) re-craft recommendations for professional conduct; and (c) provide case studies to enhance the relevance of the Guidelines and stimulate discussion about solutions.

The subcommittee has been working on the revision over the past two years. The process involved a core writing group which expanded halfway into the project. Once agreement was reached by the slightly enlarged writing group, the broader Ethics and Philosophy Committee was invited to provide critique.

The current draft is now being brought to all ISEE members to solicit feedback. In the process, we are expecting more environmental epidemiologists to become aware not only of the guidelines, but also of their content. Through the recent ISEE-member survey, many members are not aware of the Guidelines despite the critical need for principles to avoid unethical practice in our discipline.

The Guidelines apply to all conducting and applying environmental epidemiology research, including individual researchers, institutions, private sponsors, and governmental agencies. Through these guidelines, the ISEE seeks to ensure the highest possible standard of transparent and accountable ethical practice, not only for those environmental epidemiologists in research, but also for those in public health practice.

IMPACT OF AIR POLLUTION ON THE RESPIRATORY HEALTH OF CHILDREN WITH SICKLE CELL ANEMIA IN ATLANTA, GEORGIA USA

Fuyuen Yip, *Centers for Disease Control and Prevention, USA*
Jeremy Sarnat, *Emory University, USA*
Fernando Holguin, *University of Pittsburgh, USA*

Background and Aims: Children with sickle cell disease (SCD) comprise a potentially susceptible, yet largely unstudied, sub-group. SCD is an inherited, autosomal recessive blood disorder and is one of the most prevalent genetic disorders in the United States. The aim of this study is to determine if elevated concentrations of exposures to air pollutants are associated with adverse respiratory health effects in children with SCD. To our knowledge, this is the first U.S. study examining these potential associations in this population.
Methods: We conducted a panel study of seven homozygous children with SCD in Atlanta, GA from 2008–2009. Repeated measurements of 24-hour integrated personal exposures to fine particulate matter ($PM_{2.5}$) and nitrogen dioxide (NO_2) were collected for two seasons. Concurrent assessments of the children's pulmonary inflammatory response and lung function were also conducted. We used a linear mixed-effects model with random intercept to examine the relationship between the children's air pollution exposures and specific health outcomes.
Results: The children's mean age was nine years (range: 7–12 years). Preliminary 24h median personal $PM_{2.5}$ and NO_2 exposure concentrations were 11.3 ug/m^3 (range: 1.3-31.9 ug/m^3) and 15.0 ppb (range: 5.9 – 99.7 ppb), respectively. Exhaled nitric oxide (eNO) measurements for all children ranged from <5 to 57.5 ppb. The median percentage of predicted Forced Expiratory Volume at 1% (FEV_1) was 83.7% (range: 57.9%-99.4%) and FEV_{25-75} was 1.6% (range: 0.2%-4.1%). While not significant, a standard deviation increase in NO_2 was associated in a 0.54 ppb reduction in eNO after controlling for season, day of week, and demographic characteristics.
Conclusions: The initial findings were suggestive of an association between children's eNO levels and exposures to NO_2. Other markers of airway inflammation and lung function will also be presented to help elucidate the variability and strength of this association among the children.

ASSOCIATIONS OF PRENATAL EXPOSURE TO ORGANOHPOSPHATE PESTICIDES WITH BIRTHWEIGHT AND GESTATIONAL LENGTH, AND MODIFICATION BY *PON1* GENOYTPE

Stephen A. Rauch, *BC Children's Hospital, Canada*
Joe M. Braun, *Harvard University, United States*
Dana Boyd Barr, *Emory University, United States*
Jane Khoury, *Cincinnati Children's Hospital Medical Center, United States*
Kim Yolton, *Cincinnati Children's Hospital Medical Center, United States*
Antonia M. Calafat, *Centers for Disease Control, United States*
Angela Montesano, *Centers for Disease Control, United States*
Bruce Lanphear, *BC Children's Hospital, Canada; Simon Fraser University, Canada*

Background and Aims: Prenatal exposure to organophosphate (OP) pesticides, a widely-used class of insecticides, may decrease birthweight and shorten gestational length. *PON1*, a gene coding for paraoxanase (PON), an OP-detoxifying enzyme, may mediate susceptibility. We examined relationships of prenatal OP exposure with birthweight and gestational length. We also assessed interactions by infant *PON1* genotype, using two previously-identified polymorphisms, $PON1_{192}$ and $PON1_{-108}$.
Methods: We collected two spot-urine samples around 16 and 26-weeks gestation from 334 pregnant mothers enrolled in the HOME Study, a prospective birth cohort study. We measured six dialkyl phosphate (DAP) metabolites of OP pesticides and used multivariable regression to examine relationships between DAP concentrations and birthweight and gestational length. We examined whether functional polymorphisms of $PON1_{192}$ and $PON1_{-108}$ mediated susceptibility.
Results: In multivariable analyses, each 10-fold increase in total DAP concentration was associated with a 0.5 week decrease in gestation (95% confidence interval [CI]: -0.8, -0.1), and a -151g decrease in birthweight (95% CI: -287, -16). Associations between birthweight and OP pesticides were primarily the result of shortened gestation. Race modified these associations; Black mothers showed a greater decrease in birthweight than White mothers (Black: β=-188g, 95% CI: -395, 19; White: β=-118g, 95% CI: -296, 60; p-value for interaction =0.46), but only White mothers showed an association between OP exposure and gestational length (Black: β=-0.1 weeks, 95% CI: -0.9, 0.6; White: β=-0.7 weeks, 95% CI: -1.1, -0.3; interaction p=0.10). In *PON1*-stratified models, associations with perinatal outcomes were strongest in infants who were heterozygous for $PON1_{192}$ and $PON1_{-108}$.
Conclusions: Prenatal OP exposure was associated with shortened gestation and reduced birthweight, but the effects differed by race. The *PON1* polymorphisms did not show the expected pattern, possibly due to differences in the underlying population substructure or in pesticide-specific exposures not captured by DAP metabolites.

GSTO AND AS3MT GENE POLYMORPHISMS AND DIFFERENCES IN URINARY ARSENIC CONCENTRATIONS AMONG RESIDENTS IN BANGLADESH

Ema Rodrigues, Harvard School of Public Health, USA
Molly Kile, Harvard School of Public Health, USA
Elaine Hoffman, Harvard School of Public Health, USA
Quazi Quamruzzaman, Dhaka Community Hospital, Bangladesh
Mahmuder Rahman, Dhaka Community Hospital, Bangladesh
Golam Mahiuddin, Dhaka Community Hospital, Bangladesh
Yumei Hsueh, Taipei Medical University, Taiwan
David Christiani, Harvard School of Public Health, USA

Background and Aims: The main objective of this paper is to determine whether single nucleotide polymorphisms (SNPs) in the glutathione S-transferase omega (*GSTO*) and arsenic(III)methyltransferase (*AS3MT*) genes are associated with the concentrations of urinary arsenic among individuals without arsenic-induced skin lesions.

Methods: A case-control study (N=900 cases; 900 controls) was conducted in rural Bangladesh to investigate the environmental and genetic risk factors associated with skin lesions. This analysis was limited to the controls in order to eliminate any possible confounding by disease status. Water and urine samples were collected and analyzed for arsenic concentrations using inductively coupled plasma-mass spectrometry (ICP-MS), and the following SNPs were detected in DNA extracted from whole blood: *GSTO1* rs4925*, GSTO2* rs156697*, GSTO2* rs2297235, and *AS3MT* rs11191439. The arsenic species measured in urine included arsenite (As^{V}), arsenate (As^{III}), monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA). We performed linear regression for each urinary metabolite using the dominant genetic model while controlling for water arsenic levels, age, sex, body mass index (BMI), education, and urinary creatinine levels. Additionally, a pathway analysis was used to simultaneously evaluate the associations among drinking water arsenic levels, urinary arsenic metabolites and SNPs in the *GSTO* and *AS3MT* genes using PROC CALIS in SAS.

Results: The variant genotype in the *GSTO* genes were associated with lower urinary arsenic concentrations, specifically MMA, DMA, and total As, indicating an overall decrease in urinary arsenic excretion. Conversely, the variant genotype, Met287Thr, in the *AS3MT* gene had higher urinary arsenic concentrations, specifically As^{III} and MMA, compared to the wild type.

Conclusions: Among healthy individuals, genetic polymorphisms in the glutathione-s transferase omega genes and arsenic methyltransferase genes potentially modify arsenic metabolism as evidenced by altered urinary arsenic excretion. The linear regression models and pathway analysis resulted in similar findings.

INDOOR AND OUTDOOR CONCENTRATION OF PARTICULATE MATTER, ELEMENTAL CARBON AND ORGANIC CARBON AT HOMES IN FRESNO (FACES STUDY).

Maria J. Lopez[1], Elizabeth M. Noth[2], SK Hammond[2].

[1] Public Healht Agency of Barcelona. Lesseps, 1. 08023. Barcelona (Spain), mjlopez@aspb.cat

[2] School of Public Health, University of California. Berkeley (California).

Background and aims
The Fresno Asthmatic Children's Environment Study (FACES) was an eight-year epidemiological study focused on the determination of the effects of air pollution on the natural history of asthma in children who reside in Fresno, California. The objective of this work is to describe the indoor and outdoor home concentrations of particulate matter (PM), elemental carbon (EC) and organic carbon (OC).

Methods
Between February 2002 and February 2003, a home-intensive exposure assessment was carried out at a subset of homes. 24-hr integrated samples of PM2.5, PM10, EC and OC were collected inside and outside 84 homes over 5 days during two weeks (28 homes were sampled twice). Variables related to activities at home such as candles burned or fireplace used were also recorded at the same period. A descriptive analysis including median, interquartile ranges and indoor/outdoor ratios was assessed. Correlation between indoor and outdoor concentration was assessed using Spearman's correlation.

Results
The number of indoor/outdoor paired samples included in the study were 502 for PM2.5, 507 for PM10, 243 for EC and 243 for OC. The indoor/outdoor median ratios in summer for PM2.5, PM10, EC and OC were 0.80, 0.72, 0.86 and 1.34 respectively. The indoor/outdoor median ratio in winter were 0.63, 0.91, 0.80 and 1.21 respectively. The correlation between indoor and outdoor concentration was positive and statistically significant for all the pollutants in both seasons. Higher concentration of different pollutants were found in homes with presence of some of the indoor activities studied.

Conclusions
The indoor/outdoor correlation found for all the pollutants studied suggests that ambient pollution is one of the main sources for these indoor pollutants. However, the differences found in indoor concentration according to the presence of indoor activities highlight the importance of other indoor potential sources of indoor pollution.

G-ESTIMATION USING A TRICHOTOMOUS EXPOSURE MEASURE

Sally Picciotto, *University of California, Berkeley, USA*
Jonathan Chevrier, *University of California, Berkeley, USA*
Ellen A. Eisen, *University of California, Berkeley, USA*

Background and aims: The healthy worker survivor effect is a ubiquitous source of bias in occupational studies. Correcting for it requires causal methods, of which g-estimation is the best choice if follow-up is long and continues past the end of employment, when exposure can no longer occur. Previous applications of g-estimation have used a binary measure of exposure. Our ultimate aim is to apply g-estimation to a quantitative exposure measure; we begin by considering three categories instead of two.
Methods: We generalize a structural accelerated failure time model suitable for harmful exposures in order to examine the effect of exposure to oil-based metalworking fluids on survival time to heart disease death in a cohort of autoworkers. Confounding and censoring adjustments consider age, race, sex, plant, prior exposures to oil-based and other metalworking fluids, and temporary time off work. This last variable acts as a proxy for health status in order to prevent healthy worker survivor bias. G-estimation requires an exposure model; here we use linear regression. The observed distribution of annual exposure in this cohort is skewed: exposure is 0 for most of the observations, but some annual exposures exceed 9mg/m3. We define annual exposure in 3 categories (0, low, and high), with 0.1mg/m3 as the cutoff between low and high exposure, and assign the median within each category as the exposure.
Results: G-estimation produces an effect estimate of 1.038, representing the ratio of median survival time if no one were ever exposed to that under the observed exposures. (The ratio exceeds 1 because survival time is longer if unexposed.) This corresponds to a hazard ratio of 1.029 per mg/m3-year of exposure.
Conclusions: Methods that correct for the healthy worker survivor effect are more difficult to implement with a multi-level exposure measure, but success is critical for occupational epidemiology.

SERUM DDT IN MOTHERS AND EARLY MENOPAUSE IN DAUGHTERS : A FIFTY YEAR FOLLOW- UP OF THE CHILD HEALTH AND DEVELOPMENT STUDIES PREGNANCY COHORT

Barbara A. Cohn, *Public Health Institute, USA*
Piera M. Cirillo, *Public Health Institute, USA*
Nickilou Y. Krigbaum, *Public Health Institute, USA*
Julie D. Flom, *Columbia University, USA*
Heba Tawfik, *Columbia University, USA*
Mary Beth Terry, *Columbia University, USA*

Background and Aims: We report on the relation of DDT compounds measured in mothers' serum samples collected in the early postpartum to the menopause experience of 567 daughters an average of 43 years later.
Methods: Women were born between 1959 and 1967 near Oakland, California, USA, to mothers enrolled in the Child Health and Development Studies pregnancy cohort. Daughters completed an interview during 2005-2008 when they were ages 39-48 years (median age 43 years). We examined whether DDT exposure measured in serum samples collected from their mothers in the early postpartum predicted daughters' menopausal status at age 45 or younger, using a generalized linear model (logit link function), to account for siblings in the sample, adjusted for age at interview and birth year.
Results: Most women (73%) were pre-menopausal at the interview, 16% were peri-menopausal, 10% reported surgical menopause, 1% reported natural menopause, and 4% were unclassified. We observed higher risk of early menopause or peri-menopause in association with higher levels of *o, p'*-DDT in maternal serum (Relative Risk (RR) = 2.0, 95% Confidence Interval (CI)=1.3, 3.3, for 4th quartile vs. 1st quartile of maternal serum *o ,p'*-DDT). In contrast, *p, p'*-DDT was protective (RR=0.5, 95%CI=0.3, 0.9, for the 4th quartile vs. the 1st quartile of maternal serum *p, p'*-DDT). Linear trends for each compound were significant ($p<0.02$).
Conclusions: Findings suggest that intrauterine life is a window of susceptibility for environmental influences on ovarian aging in humans. *o, p'*-DDT may be a protective risk factor for breast cancer via early ovarian senescence and *p, p'*-DDT may be a deleterious risk factor via later age at menopause. Findings are consistent with breast cancer associations that we previously reported for DDT compounds and mothers' risk of breast cancer in this cohort (Cohn et. al. 2007).
References: Cohn BA, Wolff MS, Cirillo P, Sholtz RI. DDT and Breast Cancer in Young Women: New Data on the Significance of Age at Exposure. *Environ Health Perspect.* October, 2007;115(10):1406-1414.

PRENATAL PHTHALATE EXPOSURE AND NEURODEVELOPMENT AT 3 YEARS OF AGE (PILOT STUDY)

Martha M. Téllez-Rojo, *Center for Evaluation Research andSurveys, National Institute of Public Health, Cuernavaca, Morelos, Mexico*
Alejandra Cantoral, *Center for Evaluation Research and Surveys, National Institute of Public Health, Cuernavaca, Morelos, Mexico*
David E. Cantonwine, *Department of Environmental Health Sciences, University of Michigan School of Public Health*
Lourdes Schnaas, *Department of Developmental Neurobiology, Instituto Nacional de Perinatologia, Mexico City, Mexico*
Adriana Mercado, *Center for Evaluation Research and Surveys, National Institute of Public Health, Cuernavaca, Morelos, Mexico*
Howard Hu, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, MI USA*
John D. Meeker, *Department of Environmental Health Sciences, University of Michigan School of Public Health*

Background and Aims: Prenatal exposure to phthalates has been negatively associated with neurodevelopment in the limited studies conducted to date, possibly due to their connection with altered thyroid signaling or other mechanisms. Different associations have been reported between boys and girls. The aim of this pilot study is to investigate the relationship between maternal urinary phthalate concentrations during pregnancy and children's neurodevelopment at 36 months of age.
Methods: Urinary phthalate metabolites (MEHP, MBzP, MEP, MBP, MCPP, DEHP) and bisphenol a (BPA) were measured in 45 pregnant women at the third trimester of pregnancy; children's neurodevelopment was assessed using the mental development scores (MDI) from the Bayley Scales of Infant Development-II at 36 months of age (20 boys and 25 girls). The relationship between specific gravity-corrected prenatal phthalate concentrations and MDI was estimated using adjusted linear regression models stratified by sex.
Results: After the correction for urinary dilution and adjustment for potential confounders, an increase in $\log_e$ concentrations of MEHP and MBzP were associated with lower MDI scores in girls: MEHP: -5.53 (95%CI: -10.35, -0.71), MBzP:, -5.11 (95%CI: -9.38,-0.84). The remaining phthalate metabolites and BPA were inversely associated with MDI but not statistically significant. There were no statistically significant associations between MDI and prenatal phthalate concentrations among boys.
Conclusions: A differential effect of prenatal phthalates exposure by gender was documented in this study in relation to neurodevelopment. MEHP and MBzP, high-molecular weight phthalates, were associated with a lower MDI in girls at 36 months of life. Further studies are needed with larger sample sizes to confirm these results.

DAILY MORTALITY AND OFFICIAL THRESHODLS FOR HEAT WAVES IN SPAIN

Aurelio Tobías, *Institute of Environmental Assessment and Water Research, Spanish Council for Scientific Research, Spain*
Ben Armstrong, *London School of Hygiene and Tropical Medicine, UK*
Antonio Gasparrini, *London School of Hygiene and Tropical Medicine, UK*
Julio Díaz, *National School of Public Health, Instituto de Salud Carlos III, Spain*

Background and Aims: After the 2003 heat wave the Spanish Ministry of Health developed a heat health watch warning systems based on simultaneous exceeding of city-specific thresholds for minimum and maximum daily temperatures. The aim of this study is to quantify the effects of heat waves, based on official thresholds, on total daily mortality.
Methods: Total daily mortality and minimum and maximum temperatures for the 51 capital cities were collected from June to September for the period 1995-2004. Data was analysed using GEE for Poisson regression. Relative Risk (RR) of total daily mortality was quantified for the current and previous day of official threshold exceeded.
Results: The number of days in which the thresholds were exceeded show great inconsistency, with provinces with great number of exceeded days adjacent to provinces that did not exceed or rarely exceeded. Highest effects of extreme hot days were more frequent in lag one than for the current day, ranging from 11 to 56%. Only in the largest cities like Madrid, Barcelona and Seville were short-term effects for both lags were also statistically significant.
Conclusions: Thresholds for the Spanish heat health watch warning system do not reflect well the impact of heat on mortality. Criterion for the choice of thresholds must be based on epidemiological instead of only on meteorological basis.

TWO-PHASE CASE-CONTROL STUDY DESIGN FOR BIOMARKER MEASUREMENTS IN GENE-ENVIRONMENT INTERACTIONS STUDIES

Duncan C. Thomas, *University of Southern California, USA*
Sandrah Eckel, *University of Southern California, USA*
Kiros Berhane, *University of Southern California, USA*

Background and Aims: Two-phase case-control designs have emerged as a cost-efficient way of obtaining additional data by subsampling jointly on exposure and disease, combining the main and substudy data in the analysis. We consider the optimal design of studies of gene-environmental (GxE) interactions mediated through a latent biological process for which a surrogate biomarker is available. In the Southern California Children's Health Study (CHS), air pollution and maternal smoking have been shown to interact with genes in the nitrosative stress pathway (e.g., nitric oxide synthase, *NOS2A*), leading to inflammation and downstream sequellae like asthma. We have measured exhaled nitric oxide (eNO), a marker of the underlying inflammatory process, longitudinally on all CHS participants.
Methods: By theoretical calculations, we derived the optimal sampling fractions for biomarker measurements for a substudy stratified jointly by exposure, genotype, and disease status. For simple environment, genotype, and disease variables, the full likelihood can be used; more generally, semi-parametric maximum likelihood or Horwitz-Thompson estimating equations approaches are needed to avoid estimating many nuisance parameters. We illustrate the approach on CHS data by comparing the asymptotic relative cost-efficiency (ARCE) of analyses of the complete eNO data with those obtained by subsampling.
Results: The optimal design for estimating the GxE interaction term typically entails sampling all exposed carrier cases, some of the other cases, and only a few controls; when biomarker costs are 16x enrollment, exposure, and genotyping costs, the optimal choice yields a 4-fold ARCE compared to measuring all subjects. Similar comparisons for main effects, for continuous biomarker measurements, and a range of model parameters will be shown. For the CHS data, subsampling 37.5% of the subjects jointly on disease and exposure only increased the standard errors by 33%.
Conclusions: Two-phase designs can potentially greatly improve the cost-efficiency of GxE studies involving biomarker measurements.

SPATIO-TEMPORAL MODELING OF AIR POLLUTION INCORPORATING TIME-VARYING METEOROLOGY

Duncan C. Thomas, *, University of Southern California, USA*
Meredith Franklin, *, University of Southern California, USA*
W. James Gauderman*, University of Southern California, USA*

Background and Aims: In the Southern California Children's Health Study (CHS), we have measured ozone and oxides of nitrogen in 942 locations in 12 communities in two seasons for two weeks each, and particulate elemental and organic carbon at 217 locations for two 4-week periods in 8 of these communities. These measurements have been used in combination with various traffic-related predictors to build spatial models for pollution concentrations for all CHS subjects. However, wind patterns and regional pollution levels vary considerably over time and should be taken into account when assigning annual-average exposure levels.

Methods: A theoretical form of the covariance in exposures at different locations as a function of spatial separation and wind can be derived by partial differential equations. We developed a statistical spatio-temporal modeling framework that incorporates the distribution of wind speeds and directions over time and estimates the exposure at unmeasured locations over time, based on concurrent measurements at other locations, the central site measurements, and a line source dispersion model for traffic (CALINE). These estimates are then integrated over time to obtain annual average exposures.

Results: A model that included traffic-related covariates achieved cross-validated R^2s of 0.60–0.79 for nitrogen oxides, with the major contributor being CALINE; incorporation of residual spatial correlation structure significantly improved model fit. Predictions of particulate EC were much poorer, (R^2 < 0.3), indicating that traffic predictors alone are not suitable for all pollutants. Associations with lung function were significantly stronger for spatially modeled NO_x pollution (p<.005) than with CALINE predictions or other traffic variables.

Conclusions: Meteorological information, particularly wind speed and direction, improve the predictions of air pollution exposures. Novel ways of incorporating the functional form of winds into the spatial covariance structure of our prediction model are presented.

A STATISTICAL FRAMEWORK FOR ENVIRONMENTAL EPIGENETICS

Duncan C. Thomas, *University of Southern California, USA*
Carrie Breton, *University of Southern California, USA*
Mohammed T. Salam, *University of Southern California, USA*
Talat Islam, *University of Southern California, USA*
Frank Gilliland, *University of Southern California, USA*

Background and Aims: Several lines of evidence—experimental and environmental—suggest that epigenetic mechanisms such as DNA methylation may play a role in mediating exposure-response relationships, including possible transgenerational effects. For example, in the Southern California Children's Health Study (CHS), we have previously reported an effect of grandmaternal smoking during pregnancy on asthma risk in the second generation, which could be mediated epigenetically.
Methods: We propose a latent variable modeling framework for investigating such phenomena, fitted using Markov chain Monte Carlo methods. The model is specified in terms of components for (1) the risk of disease given exposure, genotype, and methylation, (2) the level of acquired methylation given exposure and inherited methylation, (3) the inherited methylation given parental methylation, and (4) the error structure of methylation measurements.
Results: In simulation studies, we have shown that all parameters of the model are estimable, provided the model is correctly specified. In a sample size of 1000 3-generation pedigrees, a RR of 3.2 for the mediating effect of methylation on exposure-response relationships is detectable with 90% power (comparing 0 vs. 100% methylation; estimated mean differences in methylation were 24% by subjects' own exposure, 12% per exposed parent, and 7% per exposed grandparent). Coefficients of variation for other parameter estimates were 1.8% for the exposure effect and 3.2% for the methylation effect in submodel (2), and 6.7% for the transmission effect in submodel (3).
Conclusions: We have previously shown associations of PM and ozone with DNA methylation of inducible nitric oxide synthase (iNOS), modified by a common promoter haplotype in the gene *NOS2A*, and a 3-way interaction between PM exposure, *NOS2A*, and iNOS methylation on exhaled NO measurements. This presentation will provide a unifying framework for synthesizing such observations.

Title: DEVELOPMENT OF AN ONLINE DATABASE OF LABORATORIES FOR MEASUREMENT OF EXPOSURE BIOMARKERS (MEB-Lab)

Susan M. Pinney, *University of Cincinnati College of Medicine, Dept. of Environmental Health, Cincinnati, OH, USA*
Aleksey Porollo, *University of Cincinnati College of Medicine, Dept. of Environmental Health, Cincinnati, OH, USA*

Background and Objective: Environmental epidemiology is a rapidly expanding field, fostered by the ever-increasing capacity to measure internal exposure to environmental chemicals. Researchers are often frustrated in their search for the best laboratory for their analyses of these chemicals in blood or urine. We have developed a Web-based database of laboratories capable of measuring exposure biomarkers (MEB-Lab database) and offer it as a resource to the community of environmental scientists.

Methods: Information for the database was initially gathered from the websites and other printed materials of relevant laboratories across the USA. To augment this information, we contacted these laboratories asking for additional details. Data elements requested include the laboratory location, contact information, website url, chemical biomarkers measured, analytic technique, limits of detection specific to the biologic media, and laboratory publications.

The backend of the system was developed using a MySQL platform, and the frontend interface was developed using HTML, Javascript and Perl. After an iterative process of user needs assessment by local experts, we designed the web interface to enable users of the system to invoke simple standard queries. Queries generate information about laboratories capable of measuring a specified environmental biomarker or class of biomarkers, or information about the biomarkers measured by a specified laboratory.

Results: The MEB-Lab database currently contains detailed information from 42 laboratories, each linked to 154 environmental biomarkers within 13 chemical classes. Initial testing indicates that the system functions as intended. The database can be accessed through the University of Cincinnati Center for Environmental Genetics website http://www.eh.uc.edu/ceg/.

Conclusions: The MEB-Labs online database is a first-of-its kind, openly accessible resource that addresses a need of the environmental epidemiology community. Ongoing work includes continued communication with laboratories and the addition of an online evaluation module that prompts users to provide feedback to improve future versions of the system.

Support for this project provided by the National Institute of Environmental Health Sciences to the University of Cincinnati Center for Environmental Genetics (P30-ES06096).

MATERNAL AND FETAL DIFFERENCES IN BISPHENOL A EXPOSURE DURING PREGNANCY-REVIEWING THE EVIDENCE

Tracey J. Woodruff, *Program on Reproductive Health & the Environment, University of California San Francisco, 1330 Broadway Street, Suite 1100, Oakland, CA, 94612*, WoodruffT@obgyn.ucsf.edu

Carrie Dickenson, University of California San Francisco, USA

Jackie Schwartz, University of California San Francisco, USA

Julia A. Taylor, University of Missouri, USA

Victor Y. Fujimoto, University of California San Francisco, USA

Patricia Hunt, Washington State University, Pullman, WA, USA

Background and Aims: Bisphenol A (BPA) is widely used products including: plastic bottles, food can linings and carbonless paper receipts is found in over 95% of the US general population and pregnant women, and is of concern for potential developmental effects. The fetus has less capacity to conjugate BPA, thus potentially leading to higher exposures of unconjugated BPA, the more biologically active compound, potentially leading to greater risks. We compare maternal and fetal levels of BPA using maternal serum and amniotic fluid from 2nd trimester pregnant women and discuss how it compares to existing data.

Methods: We are collecting maternal serum and amniotic fluids from 100 2nd trimester pregnant women undergoing elective pregnancy terminations at San Francisco General Hospital. Women are interviewed about dietary intake of potentially BPA contaminated foods and beverages. Samples are collected in BPA-free containers and stored at -70C. We have conducted preliminary analysis on 26 samples for unconjugated, conjugated, and total BPA using high performance liquid chromatography with an ESA CoulArray 5600 detector (limit of detection 0.25 ng/mL).

Results: Preliminary results indicate 93% of participants eat food from metal cans; 42% regularly touch receipts; and 22% drink water from, hard plastic bottle. All women had detectable levels of BPA, similar to findings among the US population. Among the 26 paired samples, median levels of total BPA in amniotic fluid was 7.9 ng/mL compared to 1.2 ng/mL in maternal serum. Higher levels of unconjugated BPA compared to conjugated BPA was also found in amniotic fluid (median (IQR) ratio 2.8 (1.0-7.2)). Further results from the study population will be presented at the symposium and compared to other similar studies.

Conclusions: Data suggest greater fetal exposure to total and unconjugated BPA, consistent with studies suggesting the fetus has decreased capacity to metabolize BPA and may be at higher risk from BPA.

RISK ASSESSMENT AROUND THE LANDFILL OF CUAUTLA MORELOS MEXICO. SITE CHARACTERIZATION

Margarita Sánchez-Arias, *Instituto Nacional de Salud Pública, México*
María Alejandra Terrazas-Meraz, *Universidad Autónoma del Estado de Morelos, México*
Horacio Riojas-Rodríguez, *Instituto Nacional de Salud Pública, México*
Irma Rosas-Pérez, *Universidad Nacional Autónoma de México, México.*
Christina Siebe-Grabach, *Universidad Nacional Autónoma de México, México*
Ana Cecilia Espinosa-García, *Universidad Nacional Autónoma de México, México*
René Santos-Luna, *Instituto Nacional de Salud Pública, México*

Background and Aims: In Mexico only 58% of generated solid waste is deposited in landfills. Information on improper waste handling and its possible health risk is limited. The main aim is to characterize biological agents and chemical concentrations in air, water, soil and leachate from the landfill as possible pathways to human exposure, "La Perseverancia" in the State of Morelos.
Methods: The characterization was developed in two stages: 1) an exploratory sampling at the landfill in order to detect microbiological and chemical pollution indicators. Airborne viable particles and nonviable (PM_{10}) were sampled, metals in air were analysed by X ray fluorescence. In soil samplings, physicochemical parameters were measured: pH, electrical conductivity and metal concentrations (Fe, Cu, Mn, Zn, Pb, Ni, Cr, Cd). Microbiological indicators of fecal contamination were quantified in groundwater and leachate sampling 2) For the selection of sampling sites, a geographic information system was developed and a meteorological station was installed; we selected 2 areas for aerobiological sampling into the closest neighborhood as well as 23 extraction wells and 16 points along 2 rivers for sampling groundwater and surface water.
Results: Preliminary mean PM_{10} concentration was 68.6 $\mu g/m^3$ (rain season 33.1 and dry season 99.0 $\mu g/m^3$); 39% of particles were metals in a subsample (n=11), Mn and Ni exceed the recommended inhalation reference dose. Mean electrical conductivity values in leachate samples were 21.81 mS/cm. *Pseudomonas stutzeri and Proteus* sp. were isolated for viable particles and *Pseudomonas*, *Proteus* and *Escherichia coli* were the mainly genera identified for leachate sampling. With the results obtained of electrical conductivity, 5 of the 23 extraction wells were selected to monitor for the next 8 months.
Conclusions: Water seems to be a possible media for biological contamination while particle contain both biological and metal concentrations relevant for people living close to the landfill.

SYMPOSIUM LEAD INTRODUCTION PAPER

TITLE:

UBIQUITOUS SENSING FOR EXPOSURE ASSESSMENT IN ENVIRONMENTAL EPIDEMIOLOGY

Background and Aims

Exposure assessment has and continues to be a major weakness in Environmental Epidemiology. Due to the financial and logistical cost of personal monitoring, most epidemiologic studies have relied on surrogate estimates of exposure, usually assigned to the home location of study subjects. The errors in these exposure assignments probably bias results toward the null. This paper aims to supply a commentary and conjecture on the impact that ubiquitous sensing will have on exposure assessment in Environmental Epidemiology.

Methods

I rely on reviews of the literature undertaken from 2007 to the present. Specifically, I review novel developments in ubiquitous sensing that will lead to much greater ability to estimate the dose, rather than just the proxies for exposure to environmental contaminants or hazards.

Results

Many of the important opportunities that will guide exposure assessment for Environmental Epidemiology in the 21st century arise from innovations in related science and technology. Cell-phone technologies increasingly contribute to improving diagnostics and patient care through telemedicine. The major societal investments occurring in telemedicine will have beneficial spin offs for exposure assessment in epidemiological studies. Innovations from telemedicine are now spurring fields known as "ubiquitous", "embedded" and "participatory" sensing. Working prototypes based on cell-phone technologies have already demonstrated capacity to measure physical activity, geographic position, lung function, and pollution exposures. Such technologies can also be woven into social networking systems to voluntarily capture and share data on environmental conditions and the human response while in the exposure field.

Discussion

Ubiquitous sensing offers tremendous promise for improved exposure assessment. Protection of personal privacy, analysis of the voluminous data generated by the sensors, and integration with other emerging methods from molecular epidemiology represent critical areas for research and development.

Michael Jerrett, PhD, University of California, Berkeley, USA

THE ADDED HEAT WAVE EFFECT IN THE ASSOCIATION BETWEEN TEMPERATURE AND HOSPITAL ADMISSIONS AMONG THE ELDERLY IN 129 U.S. CITIES

Carina J. Gronlund, *University of Michigan School of Public Health, Ann Arbor, MI, USA*
Marie S. O'Neill, *University of Michigan School of Public Health, Ann Arbor, MI, USA*
Antonella Zanobetti, *Harvard School of Public Health, Boston, MA, USA*
Greg A. Wellenius, *Brown University School of Medicine, Providence, RI, USA*
Joel Schwartz, *Harvard School of Public Health, Boston, MA, USA*

Background and Aims: With climate change, heat waves will become more severe, and understanding the association between heat waves (HWs) and morbidity outcomes in vulnerable populations can inform heat adaptation strategies. We aimed to determine the association between heat waves and hospital admissions controlling for daily temperature.
Methods: We used a case-crossover analysis to evaluate associations between elderly (Medicare-covered) hospital admissions, regional airport weather data and ozone data (1992-2006) for 129 U.S. cities. HWs were defined as daily mean, minimum or maximum apparent temperatures (ATs) above the 90^{th}, 95^{th} or 99^{th} percentile of summer (May-September) temperatures for at least two days. Admissions by primary discharge diagnoses were regressed on the day in the HW using a time-stratified case-crossover design, stratified by month, controlling for AT and ozone averaged over lags 0-1, and an AT moving average for lags 2-5. Results were pooled by climate region (based on cooling- and heating-degree-days).
Results: The added HW effect depended on the region, the hospital discharge diagnosis and the definition of the HW. At a higher percentile threshold, the magnitude of the association was greater but the 95% confidence interval wider. An added HW effect was seen in colder regions but not warmer regions (e.g., in the coldest region, all-cause admissions increased by 5.9% (0.50%, 12%) on days the mean AT was above the 99^{th} percentile for at least 2 days). An added HW effect was seen for respiratory, renal and heat-related discharge diagnoses. HWs were inversely associated with cardiovascular admissions.
Conclusions: Consistent with other studies of the association between HWs and mortality, results vary by climate, outcome and HW definition. Nevertheless, a small added HW effect was observed in colder climates. Future research will address comorbidities, effect modification by ozone and individual characteristics, and explanations for the regional differences.

LAND USE REGRESSION METHOD TO EVALUATE THE ASSOCIATION BETWEEN PRENATAL EXPOSURE TO PARTICULATE MATTER AND NEONATAL NEUROBEHAVIORAL PERFORMANCE

Dr. Guang-Wen Lien, Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University College of Public Health, Taipei, Taiwan

Prof. Suh-Fang Jeng, School and Institute of Physical Therapy, National Taiwan University College of Medicine, Taipei, Taiwan

Prof. Wu-Shiun Hsieh, Department of Pediatrics, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan

Prof. Pan-Chung Chen, Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University College of Public Health, Taipei, Taiwan

Background and Aims: Traffic-related air pollutants, such as PAH, PM_{10}, and NO_2, have been reported to cause adverse effects on children's neurobehavioral functions. However, little is known about the effect of prenatal exposure to these pollutants on subsequent neonatal neurobehavioral development. This study aimed at using land-use regression (LUR) model to evaluate residential PM_{10} exposure levels during different trimesters of each pregnant woman, and investigate its association with neonatal neurobehavioral performances.

Methods: The study subjects were selected from the Taiwan Birth Panel Study which enrolled 442 infant-mother pairs between May 2004 and February 2005. Basic characteristics and living environmental factors were retrieved by professional interviewers using structured questionnaires within 3 days of infant delivery. In the meantime, the physiotherapist evaluated the neonatal neurobehavioral performances using the Chinese-version of Neonatal Neurobehavioral Examination (NNE). Monthly mean PM_{10} data were retrieved from 17 Air Quality Monitoring Stations and residential PM_{10} concentrations were predicted using LUR model. Candidate predicting variables for LUR model included local land use, population density, road type, and road length. The association between prenatal PM_{10} exposure and NNE was evaluated using multiple linear regression model.

Results: A total of 141 infants have completed the NNE. The mean (SD) score for tone and motor patterns was 23.16 (1.71), primitive reflexes was 22.31 (1.76), behavioral responses was 24.67 (1.73), and total NNE was 70.17 (3.30). The predicted median (IQR) PM_{10} concentration during first, second, and third trimester were 56.35 (13.7), 46.36 (18.9), and 53.43 (8.5) $\mu g/m^3$, respectively. The results showed significant negative association between PM_{10} levels at third trimester and primitive reflexes score (β= -0.089, 95%CI= -0.123 ~ -0.055) and total NNE score (β= -0.132, 95%CI= -0.198 ~ -0.066).

Conclusions: Our study provides the first epidemiological data supporting the adverse effect of gestational PM_{10} exposure on neonatal neurobehavioral development.

$PM_{2.5}$ COMPONENTS EXPOSURES AND CARDIAC AUTONOMIC FUNCTION: A PANEL STUDY OF TAXI DRIVERS

Shaowei Wu, *Department of Occupational and Environmental Health Sciences, Peking University School of Public Health, 38 Xueyuan Road, Beijing 100191, China, E-mail: wswmytnihao@bjmu.edu.cn*

Furong Deng, *Department of Occupational and Environmental Health Sciences, Peking University School of Public Health, Beijing, China*

Jie Niu, *Department of Heart Medicine, Peking University Third Hospital, Beijing, China*

Youcheng Liu, *Department of Environmental and Occupational Health Sciences, School of Public Health, University of North Texas Health Science Center, Fort Worth, Texas, United States*

Xinbiao Guo, *Department of Occupational and Environmental Health Sciences, Peking University School of Public Health, Beijing, China*

Background and Aims: Carbonaceous and metallic components of particles have been shown to play a role in particles' effects on cardiac autonomic function as measured by heart rate variability (HRV). We previously reported the association of HRV with marked changes in traffic-related particulate air pollution around the Beijing 2008 Olympic Games in a panel of taxi drivers (Wu et al., 2010). We further investigated the relationship between exposures to the carbonaceous and metallic components of traffic-related particles and HRV in the same population.

Methods: Repeated measurements of in-car exposures to particulate matter ⩽2.5 μm in aerodynamic diameter ($PM_{2.5}$) and carbon monoxide were conducted in a group of 14 taxi drivers for one work shift in four study periods around the Beijing 2008 Olympics. The quantities of organic/elemental carbons and 27 elements of the traffic-related $PM_{2.5}$ mass were determined laboratorially. Linear mixed-effects models were used to evaluate the impact of exposures to different $PM_{2.5}$ components on HRV while controlling for potential confounders.

Results: Taxi drivers' exposures to traffic-related $PM_{2.5}$ components showed dramatic changes across the four study periods around the Beijing 2008 Olympics. Differences in associations of traffic-related $PM_{2.5}$ components with HRV were found. An interquartile range (IQR: 917.9 ng/m3) increase in calcium was associated with a 5.48 milliseconds [95% confidence interval (CI): 0.71, 10.24] increase in standard deviations of normal-to-normal (SDNN) intervals, whereas an IQR (4.1 ng/m3) increase in nickel was associated with a 1.53 milliseconds (95% CI: 0.14, 2.92) increase in SDNN index. Additionally, a decline of 8.11 milliseconds (95% CI: -15.26, -0.97) in SDNN per IQR (481.4 ng/m3) increase in iron was also found.

Conclusions: Our results support associations of $PM_{2.5}$ metallic components with cardiac autonomic function in the study population. Future studies are needed to clarify the interaction among different $PM_{2.5}$ components or the role of $PM_{2.5}$ mixtures.

A CASE-CROSSOVER ANALYSIS EXAMINING TEMPERATURE AND EMERGENCY ROOM VISITS IN CALIFORNIA

Rupa Basu, PhD, MPH, *Office of Environmental Health Hazard Assessment, Oakland, CA, USA*
Dharshani Pearson, BA, *School of Public Health, University of California, Berkeley, CA, USA*
Brian Malig, MPH, *Office of Environmental Health Hazard Assessment, Oakland, CA, USA*
Rachel Broadwin, MPH, *Office of Environmental Health Hazard Assessment, Oakland, CA, USA*
Shelley Green, PhD, *Office of Environmental Health Hazard Assessment, Oakland, CA, USA*

Background and Aims: The association between temperature and mortality has been widely researched over the past decade. Temperature and morbidity outcomes, however, have been far less studied. We examined the association between mean daily apparent temperature and emergency room (ER) visits in California.
Methods: We used a time-stratified case-crossover design for data analysis during the warm season of May through September 2005 to 2008 in all 16 climate zones in California. The study population included only cases residing within 10 kilometers of meteorologic monitors. Conditional logistic regression models with apparent temperature were applied by climate zone, and these estimates were combined in meta-analyses to create overall estimates. Our analyses considered the effects of various disease subgroups, race/ethnic groups, and age groups, and air pollutants (nitrogen dioxide, ozone, carbon monoxide, and sulfur dioxide). The California Irrigation Management System and U.S. Environmental Protection Agency provided the meteorologic and air pollution data, while the California Office of Statewide Health Planning and Development supplied the ER data.
Results: Our study population included nearly one million ER visits. Significant ($p < 0.05$) positive associations were found for same-day apparent temperature and ischemic heart disease (excess risk per 10F = 1.7%), ischemic stroke (2.8%), cardiac dysrhythmia (2.8%), hypotension (12.7%), diabetes (4.3%), intestinal infection (6.1%), dehydration (25.6%), acute renal failure (15.9%), and heat stroke (393.3%). Hemorrhagic stroke and hypertension had significant negative associations. These estimates remained robust to the adjustment for air pollutants. Hispanics exhibited greater risks than Whites for many outcomes, including ischemic stroke, ischemic heart disease, diabetes, and dehydration. Risks were generally higher among the elderly. Some outcomes had strong disparities between coastal and non-coastal regions.
Conclusions: To prevent heat-related ER visits, persons with pre-existing CVD disease, the elderly, and racial minorities should be targeted. Mitigation strategies should be region-specific, and require an immediate response.

RISKS ASSOCIATED WITH ACTIVE TRAVEL IN PARK-ADJACENT NEIGHBORHOODS IN LOS ANGELES, USA

Jason G. Su, *Environmental Health Sciences, School of Public Health, University of California, Berkeley, California 94720.*
Michael Jerrett, *Environmental Health Sciences, School of Public Health, University of California, Berkeley, 94720.*
Audrey de Nazelle, *Centre for Research in Environmental Epidemiology (CREAL), Parc de Recerca Biomèdica de Barcelona, Spain.*
Jennifer Wolch, *College of Environmental Design, University of California, Berkeley, 94720.*

Background and Aims: Poor and minority neighborhoods have limited access to parks, open space and recreational programming. This lack of access is associated with reduced physical activity and with increased risk of obesity. The access may be even worse if the environments people must travel through to parks are unsafe. In this research, we investigated whether active transportation to parks was more dangerous as a result of increased risk of traffic crashes and higher air pollution exposure for persons living in socially disadvantaged neighborhoods.
Methods: The study was conducted in the Green Visions Plan area in Southern California, an area over 5.5 million acres (>22,000 km^2) spanning four municipalities in Los Angeles. A quarter-mile (~0.4 km) buffer distance to public parks was used to define park-adjacent neighborhoods. Socioeconomic and racial-ethnic characteristics in park-adjacent neighborhoods were estimated using a proportion algorithm by intersecting the corresponding year 2010 U.S. Census tract level statistics. The Southern California travel survey data were used to derive active mode split estimates and then used to impute to all park-adjacent neighborhoods. Data on traffic crashes were acquired from the Statewide Integrated Traffic Records System (SWITRS) for 1999 – 2008. The total number of traffic crashes within each park-adjacent neighborhood was summed. The socioeconomic and racial-ethnic characteristics were modeled against traffic crashes, traffic-related air pollution and their cumulative impacts.
Results: We identified that higher proportions of African Americans, Latinos, families in poverty, and areas of low education were significantly correlated to higher rates of active travel. Those disadvantaged groups also experienced greater air pollution, higher rates of traffic crashes and larger cumulative impacts.
Conclusions: Active transportation to parks is more dangerous for persons living in neighborhoods with high proportions of socially disadvantaged people. Traffic safety and air quality improvements in disadvantaged neighborhoods will enhance access to parks in neighborhoods where residents are at high risk.

INEQUALITIES IN ENVIRONMENTAL BURDENS ACROSS THREE MAJOR METROPOLITAN AREAS IN CALIFORNIA

Jason G. Su, *Environmental Health Sciences, School of Public Health, University of California, Berkeley, California 94720-7360.*
Michael Jerrett, *Environmental Health Sciences, School of Public Health, University of California, Berkeley, California 94720-7360.*
Rachel Morello-Frosch, *Department of Environmental Science, Policy and Management and School of Public Health, University of California, Berkeley, California 94720.*
Bill M. Jesdale, *Department of Environmental Science, Policy and Management, University of California, Berkeley, California 94720.*
Amy D. Kyle, *Environmental Health Sciences, School of Public Health, University of California, Berkeley, California 94720-7360.*

Background and Aims: Communities of color and low income are affected by multiple environmental hazards that can magnify risks to human health. In earlier research we developed an index of inequalities in environmental hazards to assess the cumulative impacts from air pollution. Here we extended the this index to compare inequalities to air pollution and heat stress for groups of different socioeconomic composition and racial-ethnic status among three large metropolitan areas in California: Alameda County (San Francisco East Bay Area), San Diego and Los Angeles.
Methods: The index used the cumulative proportion of the population — ranked by area-based racial-ethnic composition or socioeconomic strata, starting from the most disadvantaged — against metrics that represented cumulative environmental hazards. Two main cumulative inequality indices were investigated: one with the cumulative impacts from nitrogen dioxide (NO_2), fine particulate ($PM_{2.5}$) and diesel PM, and another with the cumulative impacts from air pollution and heat stress.
Results: Results indicate that, for the three air pollutants, the inequality was greatest for diesel particulate matter, followed by NO_2 and $PM_{2.5}$. Inequalities for the cumulative burden of these three air pollutants were greater than those for single pollutants. Though inequalities differed significantly for exposure to most of the three environmental hazards within and between regions, their cumulative inequalities did not differ between any two regions. Inequalities in heat stress showed that communities with greater proportions of whites had greater impact from heat for Alameda and San Diego, but the relationship was reversed for Los Angeles with minority population having higher impact. Adding heat stress worsened the cumulative impacts from air pollution for Los Angeles, but decreased the inequalities for Alameda and San Diego.
Conclusions: The results provide a useful policy tool to address inequalities between regions and within a region between various environmental factors.

THE CASUALTIES OF EXCESSIVE SPEED: INNOVATION AND RESEARCH QUALITY ARE VICTIMS OF SHORT-TERM FUNDING OF RESEARCH

Remy Slama, *Inserm, Team of Environmental Epidemiology, U823, Grenoble University, Institut Albert Bonniot, France*
Cécile Chevrier, *Inserm, U625, GERHM, Rennes University, France*
Tony Fletcher, *London School of Hygiene and Tropical Medicine, UK*

Background and Aims: Assessing the impact of environmental exposures on human health is a long and complex pluridisciplinary task. Between population recruitment and the first statistical analyses, 3 to 5 years can typically elapse, sometimes many more for cohort studies. This is hardly compatible with funding bodies limiting research projects to 3-4 years in some countries. In addition, evaluation of researchers' work relies a lot on measures more related to publications quantity than quality. Our aim is here to discuss the consequences of this time pressure and to discuss the interest of developing a concept of *slow science* in environmental epidemiology, inspired from the *slow food* movement initiated in gastronomy in reaction to the fast-food culture.

Results: Consequences of short-term funding and of focusing evaluations on publications quantity include researchers slicing research projects into small pieces, spending too little time on crucial steps of projects such as statistical analysis and too much on administrative issues…Suggestions to develop a *slow science* approach in epidemiology might imply giving more support for feasibility studies; making it clear that statistical analysis is not a brief and minor task (by formalizing quality controls steps, having detailed analysis plans being defined prior to analysis…); and encouraging institutions to offer a palette of funding proposals of various durations and to promote research quality rather than quantity, as stated e.g. by DFG, the German Research Foundation (by making the evaluation of research groups relying more on an in-depth analysis of a few key publications than on a superficial automated summing of the impact factors of *all* publications).

Conclusions: Moving towards *slow science* should not be seen as implying less science but more sound results and increased innovation, efficiency and diversity in our research field. Achieving this requires increased dialogue between researchers and the 'consumers' of epidemiological science.

RESULTS OF MONITORING CAMPAIGN ABOUT THE IMPACT OF NO-TRAFFIC SUNDAYS ON ATHMOSPHERIC POLLUTION: A SCIENTIFIC BREAKING NEWS FOR THE CITY OF MILAN

Ario A. Ruprecht, *LARS, Environmental Research Laboratory SIMG-Italian College GPS*

Background and Aims: To evaluate the efficacy in atmospheric pollution reduction during Sunday traffic limitation within the Milan City Municipality borders measuring the Black Carbon (BC) content in Particulate Matter (PM).
Methods: Analyzers: One precalibrated analysers (Aerocet 531, MetOne) were used to record mass of PM_{10} and BC with one micro Aethalometers AE51 (Magee). **Procedure:** everyday in a selected high traffic street of Milan and from Friday 4th until Sunday 6th February the instruments measured the PM and BC at the same hours. During the Sunday they also measured the concentration before and after the cessation of the traffic restrictions. Traffic density was also measured.

Results: From Friday to Sunday the mean (SD) concentrations of PM_{10} were 89.8(10.6), 78.3(15.9) and 120.6(42.23) ⌠g/m^3 and of BC were 9.5(3.0), 11.4(3.7) and **8.1(1.8)** respectively. The percent of BC in PM_{10} was 10.6, 14.6 and **6.6** percent respectively. Traffic density was 1,600/2,000 vehicles per hour (including motorcycles and buses) during no restrictions time and 350/400 on Sunday. The BC in PM_{10} percent increased from 6.6 to 12.4 one hour after the cessation of traffic restrictions on Sunday.
Conclusions: Despite the considerable increase in PM_{10} on Sunday as compared with Saturday, probably due to meteorological changes, the BC concentrations were lower both in absolute values and in percent in PM_{10} indicating a lower toxicity. No-traffic Sunday's bring immediate benefits in air quality regardless the absolute values of PM concentrations but only within the interested area and the benefits disappears after less than one hour after traffic start.

THE ETHICAL DIMENSIONS OF A CHANGING CLIMATE

Colin Soskolne, *University of Alberta, Canada*

Global warming is causing more frequent and severe extremes in weather. Sea-levels are rising with island states poised to vanish. Over time, these trends are expected to worsen. If some predictions materialize, a sixth major extinction awaits us. What could be more important for environmental epidemiologists than to help inform policies that might avert such catastrophic harms? *En route* to possible extinction, as global average heating continues, local habitats will change thereby exposing local populations to environmental harms through exposure to challenges not before seen in such communities. Studying potential harms is prerequisite to health planning. Despite the ethical imperative to pursue research to help with adaptation, access to funds for research is less likely in a context of ideologically driven policy that denies climate change. Countries contributing both to denial and to greenhouse gas emissions are the more affluent in the world where wealth allows them a buffer against extremes in weather. Meanwhile, the poorer countries, not contributing to the accumulation of emissions, do not have buffering capacity and are suffering the greatest negative impacts from weather changes. These phenomena are leading to a widening of the 90:10 gap where 90% of the world's research funding goes into the study of problems affecting only 10% of the global population. This session will reflect on the Polluter Pays and the Post-Cautionary Principles. The hardships resulting in the countries where land is being bought by rich countries with the sole ambition of feeding their local populations will also be addressed. The presentation aims to engage the audience and provide the opportunity for discussion by identifying, among others, the principles noted above in each of this session's presented papers.

DETECTION AND ATTRIBUTION OF HEALTH EFFECTS TO GLOBAL CLIMATE CHANGE

Kristie L Ebi, *Carnegie Institution for Science, Stanford, US.*
R Sari Kovats, *London School of Hygiene & Tropical Medicine, UK*

Background and Aims: There are frequent claims that climate change is already affecting human health. Attribution of health effects to environmental exposures is a standard part of environmental epidemiology. With respect to global climate change, the IPCC defines attribution as the evaluation of the relative contribution of causes to a change in a system affected by climate. We describe robust criteria for the attribution of health effects to observed climate change.
Methods: Published peer reviewed studies that claimed to quantify current health effects attributable to observed climate change were identified and reviewed. Studies were classified according to categories described in the IPCC Guidance Paper on Detection and Attribution and whether they met our criteria.
Results: Very few of the published studies met our criteria. Due to the complexity of the causation of disease patterns over time, it is unlikely that climate change attribution can be made with high confidence in the near term. Special caution should be made for claims regarding the health effects of individual extreme events.
Conclusions: At present, the attribution of changes in population health to observed climate change is dependent on the validity of two or three step attribution along a complex causal chain. Human forcing of the climate is only detectable on large spatial and temporal scales (at least 30 years) for which datasets on disease distribution are often not available, and the comparison of multiple studies (as has been done in the biological sciences) is not possible for health. However, we argue that robust associations between health and climate factors can be used to indirectly estimate the current attributable burden of observed global climate change.

ENVIRONMENTAL LEAD EXPOSURE AND ODDS OF EARLIER PUBERTAL ONSET

Background and Aims: Evidence for associations between lead (Pb) and late onset of puberty have come primarily from cross-sectional studies. Earlylife exposure to lead may be important for puberty onset because of the long-term effects of lead on the endocrine system. We examined the association of maternal bone Pb, a marker of cumulative prenatal Pb exposure, with odds of earlier pubertal onset.
Methods: Maternal bone Pb was assessed at 1-month postpartum using in vivo K-X-ray fluorescence (K-XRF). Multivariable logistic regression was used to investigate the association of prenatal Pb levels with onset of puberty as assessed by self-reported Tanner stage greater or equal than 2 for genitalia (G2 among boys), breast (B2 among girls) and pubic hair development (P2 for each sex), adjusting for child's age and maternal education.
Results: There were 69 girls and 59 boys aged 6 to 15 years with Tanner staging and prenatal Pb measures. Among girls, mean age at study visit was 8.9 years (SD= 2.1); 39% were at stage B2 or above and 16% at stage P2 or above. Mean age at menarche was 10.6 years (SD= 1.7). Among boys, mean age was 9.1 years (SD= 2.2); 66% were at stage G2 or above, and 17% at stage P2 or above. Associations were primarily null between maternal bone Pb and odds for earlier or later onset of puberty, though slightly higher odds for later puberty onset with increased Pb levels was detected (for example for boy's pubic hair OR=1.09, 95% CI= 0.94 to 1.27).
Conclusion: These results suggest that prenatal Pb levels are not associated with odds of earlier or later pubertal onset in a longitudinal cohort study in Mexico, but interpretation is limited by small sample size. Investigation of this association in a larger study sample is warranted.

ENVIROGENOMARKERS: A EUROPEAN MOLECULAR EPIDEMIOLOGY PROJECT ON THE DEVELOPMENT OF BIOMARKERS OF ENVIRONMENTAL HEALTH BY *-OMICS.

Roel Vermeulen, University of Utrecht
Jos Kleinjans, Maastricht University
Paolo Vineis, Imperial College
Ingvar A. Bergdahl, Umeå University
Domenico Palli, Istituto per lo Studio e la Prevenzione Oncologica
Euripides G. Stephanou, University of Crete
Pietro Comba, Istituto Superiore di Sanita
Hannu Kiviranta, National Institute for Health and Welfare
Mark S. Gilthorpe, University of Leeds
Bo A. Jonsson, Lund University
Soterios A. Kyrtopoulos, National Hellenic Research Foundation

Background and Aims: EnviroGenomarkers is a project aiming at the development of a new generation of biomarkers to study the role of environmental agents in human disease through the large-scale application of a range of –omics technologies (*-OMICS). Breast cancer and lymphoma related biomarkers will be developed using a case-control design nested within two prospective adult cohorts. Biomarkers of neurodevelopmental effects during early childhood will be studied within a prospective child cohort.
Methods: Prospectively collected biosamples are being analysed with high-density screens, including plasma metabonomics using HPLC/MS/MS, epigenomics using CpG island microarrays, gene expression using whole-genome microarrays and targeted proteomics using multi-analyte profiling arrays, in combination with advanced bioinformatics. Exposures of interest (PCBs, PAHs, cadmium, phthalates and brominated flame retardants - PBDEs) are evaluated using validated biomarkers of exposure.
Results: Methodological studies were performed to mimic the range of conditions likely to have been encountered during the processing and storage of the biobank samples. These studies showed an effect of prolonged bench time > 8hrs on all OMIC platforms. Furthermore, an effect of anticoagulants was found for several OMIC-technologies. Using only samples from the biobanks with a bench time less than 8hrs indeed showed that high quality data could be obtained from stored biobank samples for 80-100% of the samples depending on the technology applied.
Conclusions: It is concluded that samples from long-term storage in existing biobanks can be successfully analysed using omics technologies provided they are selected to satisfy identified criteria regarding their handling history. Based on this, the project has recently moved on to its next phase involving the application of the high-density technologies on biobank samples from the study cohorts to identify markers of environmental risk factors of breast cancer and lymphoma.
Acknowledgement: EnviroGenomarkers is funded by the European Union (Grant Agreement No. 226756)

DO STATINS MITIGATE THE EFFECTS OF PM_{10}? A CASE-ONLY ANALYSIS ON HOSPITAL ADMISSIONS FROM REGIONAL GOVERNMENT ADMINISTRATIVE DATABASES

Background and Aims: While particles are associated with hospital admissions for heart disease, there is little evidence about the role of pre-admission medication. Our aim was to investigate how pre-admission cardiovascular treatment modifies the effect of PM_{10} on hospitalization for cardiovascular diseases.
Methods: We examined cardiovascular hospital admissions (ICD-9-CM 410 – 429) occurred during 2005 in the residents of six cities of Lombardy (Northern Italy), accounting for roughly 500.000 inhabitants. For each inpatient we obtained his/her pre-hospitalization medical prescriptions of cardiovascular drugs. Daily average concentration of PM_{10} and temperature were provided by the Regional Agency for Environmental Protection of Lombardy. The modification of the effect of PM_{10} exposure on hospital admissions for cardiovascular diseases due to medical treatment was assessed through a case-only approach. We fitted separate models for statins, antiarrythimcs, and all other cardiovascular drugs, accounting for the simultaneous presence of more than one among the three aforementioned classes of drug, long and short term confounding, heterogeneity among cities and effect of temperature.
Results: During the study, 8,527 hospital admissions with cardiovascular diagnosis occurred to 6,467 subjects. Cardiovascular prescriptions related to patients hospitalized for cardiovascular causes were 52,205. 76.83% of the admitted patients had a pre-hospitalization cardiovascular therapy. The results of case-only analyses showed a significant modification of PM_{10} effect for all the examined active agents. The strongest effect modification was due to pre-admission treatment with lipid modifying agents (OR treated vs non treated, related to a 10 $\mu g/m^3$ increment in PM_{10} concentration: 0.967, 95% CI, 0.945 – 0.989). The trend observed for the whole year was confirmed both in warm and cold season, though the results were not statistically significant after stratification for season.
Conclusions: Our study gives some interesting indications of cardiovascular treatments, and in particular statins, having a protective effect against the negative consequences of exposure to PM_{10}.

CASE-ONLY ANALYSIS OF INTERACTION BETWEEN PRE-HOSPITALIZATION RESPIRATORY TREATMENTS AND PM_{10} EXPOSURE. RESULTS FROM ADMINISTRATIVE DATABASES

Background and Aims: While many studies have reported associations of air pollution with hospital admissions, little is known about whether pre-event medical treatments modify those associations. Our study analyzed how pre-admission respiratory pharmacological treatments affect the relationship between PM_{10} and hospitalizations for respiratory diseases.
Methods: Hospital admissions for respiratory causes (ICD-9-CM 460-466, 480-487, 491, 493, 5130 and 5188) during 2005 in the residents of six cities of Lombardy (Northern Italy), accounting for roughly 500.000 inhabitants, were selected. For each hospitalized subject we determined which respiratory treatment he/she was undergoing, using record linkage with pre-hospitalization medical prescriptions for respiratory drugs. Daily average concentration of PM_{10} and temperature were provided by the Regional Agency for Environmental Protection of Lombardy. We used a case-only approach to analyze the modification of the effect of PM_{10} on respiratory hospital admissions due to medical treatments. Separate models were fitted for systemic glucocorticoids, inhaled adrenergics, inhaled glucocorticoids, inhaled anticholinergics and theophylline. The models accounted for the simultaneous presence of different classes of respiratory treatments, long and short term confounding, heterogeneity among cities and effect of temperature.
Results: We selected 4,248 hospital admissions with a respiratory diagnosis and 7,717 respiratory prescriptions, related to 3,604 subjects. Pre-admission respiratory therapy was present in 39% of the admissions. The observed modification of the effect of PM_{10} on respiratory hospitalizations was modest for all of the examined treatments. We observed a significant effect modification (results shown for a 10 • g/m^3 increment in PM_{10} concentration) associated with the use of systemic glucocorticoids before the hospitalization (OR=0.929, 95% CI, 0.892 – 0.967), which persists during the cold season (OR=0.927, CI 95% 0.881 – 0.976).
Conclusions: This pilot study, conducted on a reduced sample of the Northern Italian population, shows interesting evidences of a potential protective effect of systemic glucocorticoids against adverse respiratory consequences of exposure to PM_{10}.

THE INFLUENCE OF INDOOR TEMPERATURE AND RELATIVE HUMIDITY ON BUILDING-RELATED SYMPTOMS AMONG NON-SMOKING OFFICE EMPLOYEES

Chung-Yen Lu, PhD; Fung-Chang Sung, PhD

Chung-Yen Lu, *School of Post-baccalaureate Chinese Medicine and Department of Public Health, China Medical University and Hospital, Taiwan.*

Fung-Chang Sung, *Department of Public Health, China Medical University and Hospital, Taiwan.*

Presenting author: Chung-Yen Lu; 91 Hsueh-Shih Road, Taichung 404, Taiwan; Tel: 886-4-2205-3366, ext 6119; E-mail: d89844003@ntu.edu.tw

Background and Aims: Building-related symptoms and complaints experienced in non-industrial buildings remain important issues. This study investigated whether indoor temperature and relative humidity (RH) was associated with risk of building-related symptoms among non-smoking office employees.

Methods: We performed on-site measurements of indoor air temperature and RH during working hours for 87 office units of 8 randomly selected government agencies and commercial organizations. All of these offices located in high-rise buildings with heating, ventilation and air condition (HVAC) in the Taipei city, Taiwan. With informed consents, 417 healthy subjects worked at these office units completed the self-reported questionnaires for measures of the presence of building-related symptoms experienced at work within a month.

Results: The prevalence rates of building-related syndromes are 22.5% for eye, 15.3% for upper respiratory, 6.5% for lower respiratory, 1.9% for skin dryness and 22.4% for non-specific syndromes. The Multivariable generalized estimating equations logistic regression analyses showed that the adjusted odds ratios per increase of 1 □ of indoor temperature was statistically significant for Sneezing (1.51), difficulty in breathing (2.09) and dizziness (1.69).The adjusted odds ratios per 1% increases in RH was statistically significant for runny nose (1.30), sneezing (1.19), Tiredness (1.07), difficulty concentrating (1.07) and skin dryness (0.81).

Conclusions: Elevated indoor temperature and RH correlate to increased risks of some symptoms among upper respiratory, lower respiratory, and non-specific syndromes, while increased indoor RH tends to protect non-smoking office employees from suffering eye dryness in this study.

TRANSPLACENTAL TRANFER OF PERSISTENT ORGANIC POLLUTANTS IN HUMANS

Joan O. Grimalt, *Institute of Environmental Assessment and Water Research, Catalonia (IDÆA), Spain*

Background and Aims: Transplacental transport of Organohalogen Compounds (OHs) from mother to fetus occurs during pregnancy. Fetuses are more sensitive to environmental pollutants than adults and early exposure may lead to severe repercussions for the newborn health. However, the mechanisms of OHs transference are still not well understood.
Methods: The present study included 477 mother-infant pairs from a population-based cohort in Valencia, Spain, as part of the INMA (Environment and Childhood) project. We measured levels of organochlorine pesticides (OCPs) polychlorinated biphenyls (PCBs) and polybromodiphenyl ethers (PBDEs) in maternal and cord serum samples collected during 2004-2006.
Results: OHs profiles showed very similar distributions in maternal and cord serum. Concentration ratios of OHs between paired samples varied between 0.40 and 0.94 on fresh weight and between 0.89 and 1.86 on lipid basis. In general, fresh weight cord concentrations of OHs were lower than in maternal serum, but when adjusted on lipid-basis cord concentrations were similar or even slightly higher than in mothers. Spearman correlations between mother-cord paired serum samples ranged from very weakly negative to strongly positive (Spearman rho= -0.01 to 0.71), we observed positive and significant correlations for concentrations of PCBs and OCPs while BDE congeners were not correlated.
Conclusions: Differences in lipid content between maternal and cord serum seem to be affecting the distribution of OHs; the lipid content of fetal cord blood is low, thus its potential to accumulate OHs is also limited. When concentrations are lipid adjusted, they are about the same in the maternal-fetal system and so the placenta barrier does not prevent OH exchange. The variations observed in concentration ratios of the different OHs analyzed are likely due to dissimilar metabolism rates in mother than fetus.

TRAFFIC POLLUTION AND BIOMARKERS OF PULMONARY OXIDATIVE STRESS IN HEALTHY HUMANS

Background. Traffic-related air pollution is associated with increased cardiopulmonary morbidity and mortality. Evidence suggests that oxidative stress may mediate these adverse effects. We hypothesized that passenger vehicle rides simulating a rush-hour commute would cause measurable acute changes in biomarkers of airway oxidative stress among healthy volunteers.
Methods. Twenty nonsmoking subjects aged 18-45 were passengers in a Ford Taurus sedan for two 2-hr car rides. The route was primarily on a major highway with heavy diesel truck traffic with the car's external air intake open. Subjects wore a powered air-purifying respirator (PAPR) ('Air-Mate,' 3M) during all car rides. In randomized order at least one week apart, each subject had one ride with, and one ride without, a HEPA filter in place in the PAPR. Subjects were blinded to the presence of the filter. In-vehicle measurements included total particle count, $PM_{2.5}$, nitrogen dioxide, and carbon monoxide. We collected exhaled breath condensate (EBC) with an Ecoscreen® device before and 0, 6 and 24 hr after each ride. We measured the concentration of EBC nitrite and nitrite + nitrate, markers of nitrosative stress, using chemiluminescence detection, and EBC malondialdehyde (MDA), a marker of oxidative stress, using HPLC with fluorescence detection. To date, 12 subjects have completed the protocol with samples analyzed.
Results The filter reduced particle counts by >99%. We found a significant 2-fold increase in mean nitrite+nitrate in EBC collected immediately following the car rides without HEPA filtration compared to the rides with HEPA filtration, as well as non-significant increases in nitrite and MDA. The increases did not persist at 6 hr and 24 hr after the car ride.
Conclusions These results suggest that the PM exposure during car rides in heavy diesel truck traffic causes acute increases in oxidative/nitrosative stress in the respiratory tract.

PHTHALATE EXPOSURE AND BREAST-CANCER RISK ACCORDING TO *PPARγ* AND *PPARGC1B* GENOTYPES

Gabriela A. Martínez-Nava, *National Institute of Public Health, Cuernavaca, Morelos, Mexico*

Raúl U. Hernández-Ramirez *National Institute of Public Health, Cuernavaca, Morelos, Mexico*
Ana I. Burguete-García, *National Institute of Public Health, Cuernavaca, Morelos, Mexico*

Background and Aims: Some phthalic acid diesters (phthalates) have recently been associated with breast cancer (BC). In this study we evaluated if that association is modified according to *PPARγ* and *PPARGC1B* genotypes.
Methods: 208 BC cases were age-matched with 220 population controls from the north of Mexico. Urine concentrations of nine phthalate metabolites were determined by isotope dilution/high-performance liquid chromatography and mass spectrometry. Genotyping of variant *Pro12Ala* (rs1801281) of the *PPARγ* gene and variants *Ala203Pro* (rs7732671) and *Val279Ile* (rs17572019) of the *PPARGC1B* gene were carried out by traditional PCR with TaqMan probes.
Results: The three polymorphisms under study were in Hardy-Weinberg equilibrium, with a minor allele frequency of 0.11*,* 0.14, and 0.14 for the *Pro12Ala*, *Ala203Pro*, and *Val279Ile* variants respectively. Only the association between the higher levels of urinary mono-(2-ethylhexyl) phthalate (MEHP) concentration with BC was modified after the stratification by the *PPARγ* gene *Pro12Ala* polymorphism alleles (for G carriers: OR=0.59 CI95%=0.25-1.39; for C carriers: OR=1.50 CI95%=1.08-2.08); and the association between the mono-iso-butyl phthalate (MiBP) with BC in women with higher urinary concentrations was modified after the stratification by the *PPARGC1B* gene *Ala203Pro* polymorphism alleles (for C carriers OR=1.12 CI95%=0.55-2.27; for G carriers OR=0.67 CI95%=0.44-1.01).
Conclusions: Our results suggest the presence of a gene-environment interaction influencing BC risk that could be determined by the magnitude of exposure.
Keywords: breast cancer, phthalates, urinary metabolites, PPARγ*, PPARGC1B*, gene-environment interaction.

AN ALTERNATIVE METHOD FOR ESTMATING A THRESHOLD POINT OF TEMPERATURE IN A PEICEWISE LIENAR REGRESSION MODEL USING KOREAN DATA

Youn-Hee Lim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, Republic of Korea*
Ho Kim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, Republic of Korea*

Background and Aims: Due to U-, V-, or J-shaped pattern of temperatre effects, a threshold effect on mortality has been researched using a piecewise linear regression model (PLRM) by fitting left and right slopes based on the smallest Akaike information criterion (AIC). However, in Korean data, the estimated threshold was higher than a point shown on a smoothing spline plot. We experimentally applied an alternative method to find better estimate of a threshold.
Methods: We evaluated meteorological and mortality data from 6 metropolitan areas in Korea from 1992 to 2009. Smoothing spline plots were drawn using a generalized additive model (GAM). We applied PLRM for quantifying the estimated threshold point of temperature on mortality. In GAM and PLRM, relative humidity, air pressure, day of the week, and seasonal and long-term trends were controlled for. Instead of using the AIC, we selected a threshold point based on the smallest left slope estimate (LSE) of the nonlinear associations.
Results: The threshold based on the LSE was lower than the one using the AIC. In Seoul, the threshold temperature was 26°C and 28.4°C, in Incheon; 25.2°C and 28°C, in Daegu; 27°C and 28.6°C, and in Gwangju; 23.4°C and 25°C based on the LSE and the AIC, respectively. Two other cities (Daejeon and Busan) showed diverged estimates of the threshold based on the AIC. Consequently, the threshold based on the LSE showed closer to the point on the smoothing spline plot.
Conclusions: The study demonstrated that the estimated threshold based on the LSE was closer to the smoothing spline plot and was lower than the one based on the AIC. However, the experimental study may need to be elaborated in mathematical logic.

Background and Aims: Infant leukemia (IL) is a rare hematological neoplasm associated with *MLL* gene rearrangements. Maternal exposures during pregnancy to pesticides, hormones, dipyrone, and topoisomerase-II DNA inhibitors and high birth weight were associated risk factors.
Methods: This is a hospital-based multicenter case-control study. Mothers of 252 IL cases and 423 controls were interviewed and data were obtained regarding environmental maternal exposure during periconceptional, pregnancy and breast-feeding periods, including exposure to pesticides. Unconditional logistic regression was performed and odds ratios (OR) on the association between maternal pesticides exposure and IL, including their 95% confidence intervals (CI), were ascertained after adjustment to hormonal intake during pregnancy, mother's age, mother's level of education, birth weight and infant's skin color.
Results: An adjusted OR, 2.39, 95% CI, 1.63-3.51 was observed for the association between IL and maternal exposure to pesticides during pregnancy, being higher for acute myeloid leukemia (adjusted OR 3.50, 95% CI, 2.01-6.11). The use of pyrethroids during pregnancy revealed an OR 2.18 (95% CI, 1.44-3.29), while the use of other pesticides showed an OR 3.61 (95% CI, 1.69-7.73). The reported household use of pesticides revealed an adjusted OR 2.25 (95% CI, 1.48-3.43), and agriculture exposure showed an adjusted OR 9.26, (95% CI, 2.82-30.4). According to frequency of exposure, an adjusted OR, 2.48 (95% CI, 1.50 - 4.00) was seem among those reporting up to 1 contact weekly, and an adjusted OR 2.34 (95% CI, 1.30–4.21) among those with > 1 contact (p-trend < 0.0001). Mixed exposure to different pesticides showed an adjusted OR, 3.83 (95% CI, 1.33-11.0) and the exposure to different chemical classes revealed an adjusted OR, 8.87 (95% CI, 1.55-50.6).
Conclusions: The observed results seem to support the hypothesis that mothers' household use of pesticides and other contaminants may be involved in the etiology of infant leukemia.

THE INTERACTION BETWEEN SOCIAL DISADVANTAGE AND ENVIRONMENTAL HEALTH: SES, LEAD, AND BLOOD PRESSURE

Howard Hu, *Department of Environmental Health Sciences, University of Michigan, USA*

Background and Aims: Some studies suggest that social disadvantage may potentiate the effects of environmental exposures. In this study, we test the hypothesis that socioeconomic status (SES) and race may moderate the relationship between blood lead and increased blood pressure (BP).
Methods: Data come from the National Health and Nutrition Examination Survey (2001-2008). OLS regression is used to test three-way interactions between race, SES (education and poverty), and lead, adjusting for age and hypertension risk factors.
Results: Blood lead was related to higher blood pressure, but only for Blacks. Among Blacks, the association was stronger for lower SES than higher SES groups. For example, Black men without a high school (HS) education show a 5.6mmHg increase in SBP (se=1.3, $p<0.001$) for each doubling of BL while Black men with a HS education show a 1.8mmHg increase (se=0.8, $p<0.05$). Similar effects are seen for Black women. No associations between blood lead and blood pressure were found for White men and women regardless of SES.
Conclusions:
The relationship between blood lead and high blood pressure appears to vary by race and SES. These findings are consistent with theories suggesting that social disadvantage may moderate the association between some environmental exposures and health.

ENVIRONMENTAL EXPOSURES AND CHILDHOOD LEUKEMIA: AN EXPLORATORY ANALYSIS IN BRAZIL

Jeniffer Dantas Ferreira, *Environment and Public Health Post-graduation Program, National School of Public Health, Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, Brazil*
Arnaldo Cézar Couto, *Environment and Public Health Post-graduation Program, National School of Public Health, Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, Brazil*

Sergio Koifman, *Environment and Public Health Post-graduation Program, National School of Public Health, Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, Brazil*

Background and Aims: Childhood leukemia is a rare hematological neoplasm and several factors related to environmental exposures and individual characteristics existing in our environment may have on the process of leukemogenesis.
Methods: This investigation is part of a national multicenter study that included 292 cases of leukemia in children aged 0-12 years and 541 controls of similar age, centers of origin of cases and hospitalized for non-neoplastic causes. The information of selected environmental exposures was obtained through interviews with mothers of cases and controls tied to a standardized questionnaire from a database of clinical and epidemiological case-control study of hospital based on risk factors for childhood leukemia.
Results: The principal component analysis and factor analysis identified factors associated with leukemogenesis. Further, an unconditional logistic regression was carried out aiming to ascertain the magnitude of association between the selected factors, and their composing variables, with childhood leukemia. The model displaying the highest power explained 52% of the total variance, including 3 factors, each one of the showing factors loadings higher than 0.6: “conditions related to chemical exposure during pregnancy”, which explained 20% of the variance; “ lifestyle exposures”, such as smoking and hair dyes and hair cosmetics use during pregnancy, explaining 17% of the total variance; and “consumption of health services during pregnancy”, such as X rays and delivery type (cesarean or vaginal delivery), explaining 15% of the total variance. Logistic modeling revealed statistically significant association between childhood leukemia and chemical exposure during pregnancy (OR=1.36; 95% IC=1.16-1.59), and also with consumption of health services during pregnancy (OR=1.27; 95%IC =1.08-1.49).
Conclusions: The observed results are suggestive of the contribution of environmental exposures to childhood leukemia development, not just individually, which has been supported by the literature according to carcinogenesis and leukemogenesis as resulting from several mutations triggered by joint environmental exposures.

EPIGENETIC IMPACT OF COMMUTING TO WORK BY CAR OR USING PUBLIC TRANSPORTATION: A CASE-CONTROL STUDY

Alfredo Morabia, *City University of New York, USA*
Fang Fang Zhang, *Tuft University, USA*
Maya Kappil, *Columbia University, USA*
Janine Flory, *City University of New York, USA*
Frank E Mirer, *City University of New York, USA*
Regina Santella, *Columbia University, USA*
Mary Wolff, *Mount Sinai School of Medicine, USA*
Steven B Markowitz, *Center for the Biology of Natural Systems, USA*

Background and Aims: Using public transportation (PT) entails more physical activity and energy expenditure during the commute than driving cars. We assessed here whether these two types of commuters have different levels of inflammatory response, and eventually different cardiovascular and cancer risks.
Methods: We compared adults commuting to Queens College, New York, whose normal commute was either by car (n=79) or using PT (n=101). To maximize differences, the two groups were randomly sampled without attempt to match on socio-demographical factors. Besides questionnaires about their diet, physical activity and perceived stress and measured weight and height, we measured white blood cell (WBC) counts, C reactive protein (CRP) and DNA global Line-1 methylation.
Results: Preliminary results show that, as expected, the two commuter types vary greatly by age, BMI, physical activity, ethnicity and diet. There are however no differences in median WBC, (car=6700 cells/mm3; PT=6400, p=0.30) in CRP, (car=1.18 mg/dl; PT=1.26, p=0.65) and in Line-1 DNA methylation, (car=78.2%; PT=78.3%, p=0.73).
Conclusions: Levels of inflammatory response and DNA methylation do not appear to differ according to commute modes even when conditions are set to maximize the observed differences if any.

HIGH CHEMICAL TOXICANT LEVELS AMONG URBAN POPULATION WITH HISTORY OF LIVING IN AGRICULTURAL AREAS OR USE OF PESTICIDES

Nelson Gouveia, *Department of Preventive Medicine, School of Medicine, University of Sao Paulo, Brazil*
Rubia Kuno, *CETESB, Environmental Agency of the state of Sao Paulo, Brazil*

Background and aims: there are many chemical toxicants in the environment capable of producing adverse health effects. Surveillance systems using bio-markers are a tool to identify potentially exposed populations and sources of exposure. A study was conducted to assess the feasibility of implementing such a system in Brazil using multiple biologic matrices.
Methods: blood and hair samples were obtained from blood donors attending 10 donation centers in the metropolitan region of Sao Paulo. Hair and blood levels of metals (Hg, As, Cd, Co, Cu, Mn, Pb, Se, Tl, U, Zn, Pt, and Sb) were determined by ICP-MS. Serum levels of organochlorines were determined by gas chromatography. A detailed questionnaire was also applied to each participant.
Results: 547 blood donors aged 18-65 year old (mean 34.8) were included in the study (64.7% male). Levels of most metals were similar to those reported in other surveys except for mercury in blood with 3 individuals with levels greater than 15 µg/L. Lead and cadmium in blood, but not in hair, were significantly higher among smokers and mercury among those with higher fish consumption. Arsenic levels in hair were significantly higher among those who lived in agricultural areas (0.025 x 0.018 µg/g) or with history of dealing with pesticides in the past (0.037 x 0.019 µg/g), while blood levels of this metal were higher for those that reported eating home grown vegetables. Levels of β-HCH, pp´DDE, cobalt, lead and thallium were also higher among those with possible pesticide exposure in the past. Correlations between hair and blood measurements were low with the highest correlation for mercury ($r=0.45$ $p<0.001$).
Conclusion: Methodologies tested in this study will help the implementation of a monitoring system in Brazil. Results evidenced possible sources of contamination such as pesticides or fertilizers used in the past that must be further investigated.

THE MODIFYING EFFECT OF SOCIOECONOMIC POSITION IN THE AIR POLLUTION - MORTALITY ASSOCIATION: THE ESCALA PROJECT

Nelson Gouveia, *Universidade de São Paulo, Brazil*
Luis Cifuentes, *Pontificia Universidad Catolica de Chile*
Antonio Ponce de Leon, *Universidade Estadual do Rio de Janeiro, Brazil*

Magali Hurtado-Díaz, *Instituto Nacional de Salud Publica, México*
Washington Junger, *Universidade Estadual do Rio de Janeiro, Brazil*
Isabelle Romieu, *Instituto Nacional de Salud Publica, México*

Background and aims: Socioeconomic position (SEP) has been identified as a factor that can modify the effects of air pollution on health, although few studies have examined this in detail. We examined this hypothesis in 4 Latin American Cities (São Paulo, Rio, Santiago and Mexico City) which were part of the ESCALA project.
Methods: We developed a common area-based SEP index using variables related to education, income and housing conditions. Each area was ranked according to the SEP index using principal component analysis. The final scores were grouped into tertiles. Deaths were assigned to their respective areas according to the residential address. For Mexico City we assigned the level of air pollution registered in the monitoring station of each area, while for the other cities we averaged air pollution levels across all monitoring stations. Generalized Linear Models in Poisson regression was used to fit the time-series data for PM_{10} and O_3.
Results: In Mexico, a gradient was observed for respiratory mortality with RR% = 1.46 (95%CI 0.76 to 2.16)) in the low, RR% = 0.81 (0.20 to 1.43) medium and RR% = -0.8 (-1.46 to -0.22) in the high SEP, while cardiovascular and cerebrovascular mortality were higher in the medium and high SEP. In Brazilian cities we observed an opposite trend for respiratory mortality with higher effects in the high SEP and no trends for cardiovascular and cerebrovascular mortality. In Santiago, COPD and cardiovascular mortality were significantly increased in the low SEP but no clear gradient could be observed. Results were more consistent for PM_{10} than for O_3 in all cities.
Conclusion: Our data suggest that SEP may play a role in the susceptibility to air pollution, especially for respiratory mortality. However results are inconsistent with regards to the more susceptible subgroups to respiratory mortality and other causes of mortality.

DELIVERY TYPE NOT ASSOCIATED WITH DIFFERENTIAL METHYLATION AT BIRTH

S. Virani, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, Michigan, USA*
S. Halubai, *Department of Pediatrics, University of Michigan, Ann Arbor, Michigan, USA*
M.S. Nahar, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, Michigan, USA*
D.C. Dolinoy, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, Michigan, USA*
S.E Domino, *Department of Obstetrics and Gynecology, University of Michigan, Ann Arbor, Michigan, USA*
L.S. Rozek, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, Michigan, USA*
V. Padmanabhan, *Department of Pediatrics -Department of Obstetrics and Gynecology, University of Michigan, Ann Arbor,Michigan, USA*

Background: Birth by Cesarean section is associated with adverse health outcomes later in life, including diabetes and allergies. Epigenetic mechanisms are one way early life exposures can affect later health outcomes. Differences in global methylation by type of birth have been described, but the sample sizes have been small. We measured global methylation in a large, ongoing birth cohort to identify epigenetic changes that may cause predisposition to disease in later life due to delivery type.
Methods: DNA was obtained from umbilical cord blood collected immediately after term deliveries from the University of Michigan Hospital (n=417). Global methylation levels were assessed via the Luminometric Methylation Assay (LUMA), and DNA methylation at four CpG sites in LINE-1 repetitive elements was assessed via bisulfite pyrosequencing. Samples were run in duplicate and averaged for analyses. Nonparametric analyses tested the association between type of birth, vaginal delivery (VD) or Cesarean section (CS), gender and measures of global methylation.
Results: LUMA data were available from 301 births (53% male; 61% CS) and LINE-1 methylation was available for 212 births (50% male; 67% CS). There were 154 samples with both LUMA and LINE-1, and the measurements were negatively correlated (Spearman's r = -0.22, p = 0.006). Global methylation values were not significantly different by gender. Type of birth was not associated with global methylation as measured by LUMA (mean CS = 73.66, mean VD = 74.98, p-value = 0.12) or by LINE-1 (mean CS = 81.19, mean VD = 81.05, p-value = 0.31). These results did not change when stratifying by gender.
Conclusion: Type of delivery was not associated with global methylation in our population regardless of infant gender. While type of birth may be associated with later health outcomes, our data suggest that it does not do so through changes in global genomic methylation.

TRAFFIC POLLUTION AND COGNITIVE FUNCTION IN COMMUNITY-DWELLING SENIORS: THE MOBILIZE BOSTON STUDY

Gregory Wellenius, *Center for Environmental Health and Technology, Brown University, Providence, RI, USA*
Luke Boyle, *Center for Environmental Health and Technology, Brown University, Providence, RI, USA*
Brent Coull, *Department of Biostatistics, Harvard School of Public Health, Boston, MA, USA*
William Milberg, *West Roxbury Department of Veterans Affairs Medical Center, Boston, MA, USA*
Alexandros Gryparis, *Department of Applied Mathematics, University of Crete, Crete, Greece*
Joel Schwartz, *Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA*
Lewis Lipsitz, *Institute for Aging Research, Hebrew SeniorLife, Boston, MA, USA*

Background and Aims: A small number of epidemiologic studies report an association between long-term exposure to traffic pollution and decreased cognitive function, but additional studies are needed. Accordingly, we evaluated the association between long-term exposure to black carbon (a marker of traffic pollution) and cognitive function in a population-based cohort of community-dwelling seniors.
Methods: Between 2005 and 2008, we evaluated cognitive function among 765 elderly participants from the MOBILIZE Boston Study (64% female, aged 64-97 years). Neurocognative assessments included the Mini Mental State Exam (MMSE) and a battery of five tests designed to evaluate verbal memory and executive function. Subjects with moderate or severe cognitive impairment, as determined by an MMSE< 18 were excluded. We geocoded participants' residential addresses and assessed average long-term exposure to traffic pollution in the 12 months prior to neurocognitive assessment using a validated spatiotemporal land-use regression model for black carbon. We used generalized linear models to evaluate the association with an interquartile range increase (IQR: 0.1 $\mu g/m^3$) in predicted black carbon levels.
Results: Adjusting for age, sex, race, history of stroke, and education, an interquartile range increase in predicted residential exposure to black carbon was associated with a 19% (95% Confidence Interval [CI]: 1%, 39%; p=0.032) increase in risk of having an MMSE score in the lowest quartile (MMSE≤25). Further adjustment for household income, smoking history, body mass index, season, and census level covariates attenuated the results slightly (excess relative risk: 17%; 95% CI: -1%, 40%; p=0.060). Among the other tests, only verbal memory functioning was associated with black carbon (p= 0.056).
Conclusions: In this population-based cohort of elderly subjects, long-term residential exposure to traffic pollution was associated with decreased cognitive function. The increasing prevalence of cognitive impairment expected with the aging population underscores the need for additional studies in this area.

COMPARING PARTICULATE MATTER AND OZONE EXPOSURE METRICS FOR PERINATAL EPIDEMIOLOGY IN MEXICO CITY, MEXICO

Luis O. Rivera-González, *University of Michigan, Ann Arbor, MI*

Alvaro Osornio-Vargas, *Instituto Nacional de Cancerología, Mexico City, Mexico*
Felipe Vadillo-Ortega, *Universidad Nacional Autónoma de México (UNAM), Mexico City, Mexico*
Marie S. O'Neill, *University of Michigan, Ann Arbor, MI*

Background and Aims: Emerging evidence suggests a relationship between air pollution and adverse birth outcomes, but many studies consider only temporal variation in exposure. We compare spatial methods for assessing exposure to outdoor air pollutants in Mexico City with citywide averages.

Methods: Three metrics of daily exposures to PM_{10}, $PM_{2.5}$, and ozone were calculated for a simulated population (n=1,000) in Mexico City during 2008: the citywide average (CWA) (same for all women), and metrics unique to each of the 1,000 hypothetical residential locations: nearest monitor (NM) and inverse distance weighting (IDW). Correlations, mean differences, and their variances were calculated for each pollutant across all three methods, using citywide averages as the reference.

Results: Ozone was moderately correlated with PM_{10} (r=0.54) and $PM_{2.5}$ (0.65) using CWA. Correlations were lower for IDW (r=0.49 for ozone vs. $PM_{2.5}$; and r=0.42 for ozone vs. PM_{10}) and NM (r= 0.32 for ozone vs. PM_{10}; and r=0.48 for ozone vs. $PM_{2.5}$). In southern zones of the city (low PM_{10}), CWA overestimated PM_{10} by 10.6 and 14.7 $\mu g/m^3$, when compared to NM and IDW, respectively. In the north, CWA underestimated the exposure by 8.3 and 2.4 $\mu g/m^3$ when compared to NM and IDW, respectively. For $PM_{2.5}$ estimated metrics were relatively similar across methods. In southern zones (high ozone), CWA underestimated the ozone exposure by 5.1 ppb compared to NM, and overestimated (2.4ppb) compared to IDW. In the north (low ozone), the CWA overestimates the exposure when compared to NM and IDW (5.2 and 5.1 ppb, respectively).

Conclusions: Depending on residence location, the citywide average could over/under estimate exposure to air pollutants. These differences could bias epidemiological associations if other risk factors for adverse birth outcomes are associated with residence in a particular zone. Future analyses in Mexico City will evaluate kriging, other air pollutants, and implications of seasonal variation for exposure assessment.

EXPOSURE TO AMBIENT FINE PARTICULATE MATTER ALTERS CEREBRAL BLOOD FLOW IN THE ELDERLY: THE MOBILIZE BOSTON STUDY

Gregory Wellenius, *Center for Environmental Health and Technology, Brown University, Providence, RI*
Luke Boyle, *Center for Environmental Health and Technology, Brown University, Providence, RI*
Elissa Wilker, *Beth Israel Deaconess Medical Center, Boston, MA*
Brent Coull, *Department of Biostatistics, Harvard School of Public Health, Boston, MA*
Petros Koutrakis, *Department of Environmental Health, Harvard School of Public Health, Boston, MA*
Lewis Lipsitz, *Institute for Aging Research, Hebrew SeniorLife, Boston MA*

Background and Aims: Previous studies suggest that short-term elevations in ambient fine particulate matter ($PM_{2.5}$) may increase arterial blood pressure. However, the consequences of these systemic effects on the tightly-regulated cerebral circulation have not been examined. Accordingly, we evaluated the association between $PM_{2.5}$ and cerebral hemodynamics in a cohort of community-dwelling seniors.
Methods: We repeatedly assessed cerebral hemodynamics at rest and in response to blood pressure changes associated with standing from a seated position according to a standardized protocol in 424 participants (757 measurements) from the MOBILIZE Boston Study. We measured blood flow velocity in the middle cerebral artery using transcranial Doppler ultrasound and mean arterial blood pressure (MAP) non-invasively with a Finapres device. We calculated cerebral vascular resistance as the ratio of MAP to blood flow velocity. $PM_{2.5}$ levels were measured at a nearby monitoring site. We used linear mixed effects models with random subject intercepts to evaluate the association between hemodynamic parameters and mean $PM_{2.5}$ levels 1 to 28 days earlier adjusting for age, race, medical history, meteorologic covariates, day of week, temporal trends, and season.
Results: An interquartile range increase (3.0 $\mu g/m^3$) in mean $PM_{2.5}$ levels over the previous 28 days was associated with a 6.9% (95% confidence interval [CI]: 2.3%, 11.8%; p=0.003) higher cerebral vascular resistance and a 6.7% (95% CI: 3.4%, 9.9%; p<0.001) lower cerebral vascular blood flow at rest. Results at shorter $PM_{2.5}$ averaging times were qualitatively similar but weaker. Upon standing from a seated position MAP, cerebral vascular blood flow and resistance decreased, as expected. These responses were not associated with $PM_{2.5}$ levels.
Conclusions: In this cohort of community-dwelling seniors, exposure to $PM_{2.5}$ was associated with alterations in cerebral blood flow. If replicated, these novel findings suggest a mechanism by which ambient air pollution might increase the risk of acute cerebrovascular events.

ASSOCIATION OF RESIDENTIAL UVR EXPOSURE WITH CHILDHOOD BLOOD PRESSURE AND CAROTID INTIMA- MEDIA THICKNESS

Talat S. Islam,PhD, *University of Southern California, Dept of Preventive Medicine, Los Angeles, California*
Carrie V. Breton, ScD, *University of Southern California, Dept of Preventive Medicine, Los Angeles, California*
Wendy J. Mack, PhD, *University of Southern California, Dept of Preventive Medicine and Atherosclerosis Research Unit, Los Angeles, California*
Howard N. Hodis, MD, *University of Southern California, Dept of Preventive Medicine and Atherosclerosis Research Unit, Los Angeles, California*
Lora Whitfield-Maxwell, RN, *University of Southern California, Atherosclerosis Research Unit, Los Angeles, California*
Myles Cockburn, Ph.D., *University of Southern California, Dept of Preventive Medicine, Los Angeles, California*
Nino Künzli MD, *Swiss Tropical and Public Health Institute, Basel, Switzerland and University of Basel, Basel, Switzerland*
Ed Avol, MS *University of Southern California, Dept of Preventive Medicine, Los Angeles, California*

Background and Aims: Emerging data suggest that serum vitamin D level is inversely associated with carotid intima-media thickness (CIMT) and blood pressure. Because sun exposure (Ultra violet radiation, UVR) is a major determinant of serum vitamin D level, we hypothesized that residential UVR level is also associated with CIMT and blood pressure.
Methods: We investigated our hypotheses in 738 children (mean age=11.3 years, standard deviation (SD) = 0.63) of the Children's Health study on whom we measured CIMT, systolic (SBP) and diastolic (DBP) blood pressure. UVR estimates were obtained from an ANUSPLIN model for the year of study participation based on the latitude and longitude of participant residences. We derived one-square-kilometer ground surface level UVR values using spatial smoothing techniques for data from UVR measurement stations throughout the United States, adjusted for local climate and terrain features. All association analysis utilized multivariate linear regression models with adjustment for age, sex, race, family income, and town of residence. Models for UVR and CIMT were additionally adjusted for blood pressure.
Results*:* The residential UVR level ranged from 4980 to 5361 Watt-hour (WH)/m^2 with a SD of 81 WH/m^2. The mean (SD) of CIMT, SBP and DBP in these children were 56.6 µm(4.4), 104 mm Hg(8.5) and 57 mm Hg (6.2), respectively. Residential UVR level was an independent determinant of CIMT and diastolic blood pressure. Each 162 WH/m^2 (2 SD) increase of UVR exposure was associated with 3.6 (95% confidence interval (CI) 0.04, 7.23) µm decrease in CIMT and 5 (95%CI 0.04, 9.7) mm Hg decrease in diastolic blood pressure. No significant association was observed between UVR level and SBP.
Conclusion*:* Residential UVR level is inversely associated with CIMT and DBP in children which might be important for their cardiovascular health.

THE PREVALENCE OF BREAST CANCER IN SLOVAKIA

Janka Poracova, *Presov University in Presov, Excellence Centre of Human and Animal Ecology, Slovakia*;
Tatiana Kimakova, *Pavol Jozef Safarik University in Kosice, Faculty of Medicine, Department of Public Health, Slovakia*
Lucia Frankova, *Presov University in Presov, Faculty of Humanities and Natural Sciences, Department of Biology, Slovakia*
Marta Blascakova, *Presov University in Presov, Excellence Centre of Human and Animal Ecology, Slovakia*

Background: Breast cancer is one of the most serious diseases in terms of epidemiological indicators on the whole world. In the last fifty years the incidence of disease has increased continuously. Currently such disease threatens every tenth woman and in this way it also endangers the lives of thousands. One of the reasons of high mortality is late diagnosis of the disease. Prevention is the most essential. Mammography screening for breast cancer presents the most effective method. By systematic mammography screening it is possible to reduce mortality up to 30%, mainly in the age group 50-69.
Material and methods: In the work we focused on the statistics of mammography screening in the Slovak republic. The analysis compares mammography, examinations provided and estimation of the required number of preventive mammography examinations.
Results: The largest number of mammography examinations is provided in Bratislava (23.95%), Košice (16.41%) and the region of Banska Bystrica (14.57%), the least in the region of Trnava (5.63%). Women from the age 40 are invited to a regular preventive mammogram every two years. This group becomes greater from year to year (by 1.78%). Evaluating the calculations according to individual regions it may be concluded that the number of conducted examinations are below the claimed number of preventive - the required examinations.
Conclusion: Improving the availability of mammography screening in SR depends not only on increasing the state of medical instrumentation techniques, but also on the organization of work, eddification, information about the claims for preventive examinations and limition of the performance by health insurance organizations.
Acknowledgement:This work was supported by the Agency of the Ministry of Education, Science, Research and Sport SR for EU Structural funds projects: ITMS 26220120023, ITMS 26220120041.

CALCIUM IN POSTMENOPAUSAL WOMEN PREŠOV (SLOVAKIA)

Tatiana Kimakova, *Pavol Jozef Safarik University in Kosice, Faculty of Medicine, Department of Public Health, Slovakia*
Lucia Frankova, *Presov University in Presov, Faculty of Humanities and Natural Sciences, Department of Biology, Slovakia*

Background: Nutrition is one of many factors that affect bone quality. Dietary intake of mineral elements plays an significantly role in maintaining homeostasis of soft tissue, in protection of the skeleton, etc. Calcium is an essential nutrient for healthy bones, is needed for the heart, muscles, nerves, blood clotting, participate in processes inside cells. It is lost every day in the organism by sweating, urine, faeces, therefore, is necessary to monitor the balance between his intake and spending for healthy bones.
Material and Methods: In this study, we focused on the monitoring of calcium (Ca^{2+}) and calcium loses in the urine in 150 postmenopausal women, regardless of the diagnosis of thyroid.
Results: In this group, we found that the average value of calcium in the urine was 3.033 mmol/l (minimum value 0.45 mmol/l, the maximum value 9.23 mmol/l). The average value lost calcium in the urine was 0.168 mmol/l higher than the average value of calcium (Ca^{2+}).
Conclusion: Biochemical indicators provide primary information on the rate of bone remodeling, the functional state of bone metabolism and they are necessary for differential diagnosis of osteoporosis. Through them, we can estimate the risk of fractures in the future.

SELECTED CHEMICAL AND PHYSICAL PROPERTIES OF MINERAL SPRING FROM LOCATIONS OF CENTRAL SPIŠ (HORNÁDSKA BASIN)

Marta Blascakova, *Presov University in Presov, Excellence Centre of Human and Animal Ecology, Slovakia*
Janka Poracova, *Presov University in Presov, Excellence Centre of Human and Animal Ecology, Slovakia*;
Jozef Mydlar, *Presov University in Presov, Department of Geography and Regional Development, Slovakia*

Lucia Frankova, *Presov University in Presov, Faculty of Humanities and Natural Sciences, Department of Biology, Slovakia*

Background: Water is an essential condition of life on earth. Mineral and medicinal properties of water has great medical, economic and social importance.
Material and methods: In our work we focused on the determination of selected physical properties (temperature) and chemical composition (pH, hardness, ammonia concentration) of mineral water springs St. Kríž, St. Ondrej on the Siva Brada and the source Deák in Baldovce, which are located in the eastern part of Hornádska basin.
To determine the characteristics we used a compact laboratory Aquamerck ® 11151 for analysis of water by MERCK. On the sampling site was determined temperature from physical characteristics and pH from chemical indicators.
Results: The water temperature was lowest in Baldovce - spring Deák 11.4 °C, spring St. Kríž - 13.8 °C and spring St. Ondrej - 13.1 °C. pH values was measured from 6.8 to 6.9, so we can classified as a mineral water – acidulous water. The content of ammonia ($NH4^+$) was the same in the source of St. Kríž and Ondrej (1.29 mg/ l) in the source of Deák in Baldovce - 0.32 mg/ l. Hardness value was in all the sources above 6.25 mmol/ l.
Conclusion: The Regional Public Health Authority in Poprad (Slovakia), the quality of mineral springs St. Kríž and Ondrej is unstable. This is reflected by higher occasional incidence of ammonium ions, and rarely by microbiological harm, it can be a result of poor care of clean environment of those springs, possibly due to human activity.

Background. Bakery and hairdressing rank high among occupations at risk of asthma. We explored the early incidence of occupational asthma (OA) along the first years of activity among young workers.
Methods. Subjects who graduated between 2001 and 2006 underwent telephone interviews on the occurrence of respiratory symptoms. Workers in occupations not exposed to known airways irritants or allergens were also included. Subjects who had asthma when starting apprenticeship were excluded. Those who declared work-related respiratory or ENT symptoms and a sample of asymptomatic subjects were proposed a medical visit (spirometry tests, exhaled NO measurements, daily surveillance of peak flow values, blood sample for assessment of common allergens and work-specific IgE). Diagnosis of OA was established by expert judgment and the sensitivity and specificity of symptoms declared during the telephone interviews were assessed.
Results. 866 subjects were interviewed (mean age: 25.3 years), among which 282 underwent a medical visit. The cumulative incidence of 'probable' OA among bakers was high in the first quartile of exposure duration (median value=3.0 years; risk = 15.8 % [95%CI=10.0–21.8]); several had to quit this activity because of this condition. It was reduced to 11.9 % [6.3–17.6] in the second exposure duration quartile (5.3 years) and increased regularly across the third (7.4) and fourth (9.5) quartiles, with 14.1 % [7.3–21.0]) and 16.5 % [8.1–24.8]), respectively. The corresponding figures among hairdressers are 5.3 % [0.0–11.5]), 4.6 % [0.2–9.3], 2.0 % [0.0–7.5] and 3.7 % [0.0–7.5]. Atopy is highly associated with incidence of probable OA among bakers (RR= 10.0 [2.8-35.4]), and, to a lesser extent, among hairdresser (RR= 3.9 [0.7-20.9]). OA is very rare in the reference group (risk = 1.2 % for the longer exposure quartile).
Conclusion. Incidence of OA starts soon after engaging in bakery and hairdressing, activities that entail exposure to low or high molecular weight agents.

SIMULTANEOUS DETERMINATION OF PERFLUORINATED COMPOUNDS, OXIDIZED PHTHALATE METABOLITES, BIS-PHENOL A AND COTININE IN SMALL VOLUMES FROM SERUM BANKS FOR USE IN EPIDEMIOLOGICAL STUDIES

1. Bo AG Jönsson, *Lund University Hospital, Sweden*
2. Åsa Amilon, *Lund University Hospital, Sweden*
3. Christian H Lindh, *Lund University Hospital, Sweden*

Background and Aims: Perfluorinated compounds (PFCs), phthalates and bis-phenol A are suspected endocrine disrupters and may therefore induce health effects such developmental and neurobehavioral disorders, obesity, diabetes, asthma etc. Moreover, smoking is often an important confounder in studies of these diseases. There is often a large lag between the exposure and the development of the disease. Furthermore, for many diseases it is believed that it is the exposure of the mother during pregnancy that is of importance. It is therefore desirable to measure exposure back in time. There are many samples stored in freezers in serum banks which may be used for this purpose. However, the stored volumes are often very limited. Methods for analysis of these samples should therefore preferably use only a small volume as well as being possible to be applied for many different compounds of interest. The aim of this study was to develop such a method for simultaneous analysis of a number of different suspected endocrine disrupters as well as the tobacco smoke indicator cotinine.
Methods: For the analysis of perfluorinated compounds, oxidized phthalate metabolites, bisphenol A and cotinine aliquots of 100 µl serum were added with glucoronidase, ammonium acetate buffer and a water:acetonitrile (50:50) solution containing ^{2}H-^{13}C- or ^{18}O-labeled internal standards for all evaluated compounds. The samples were then digested at 37°C for 90 min. The proteins were precipitated with 175 µl acetonitrile and vigorously shaking for 30 min. The samples were thereafter centrifuged and 3 µl of the supernatant was injected on a triple quadrupole linear ion trap mass spectrometry equipped with a TurbolonSpray source (Sciex QTRAP 5500).
Results: The method developed is easy and fast to perform. The precisions were better than 10% for most analyzed compounds and the detection limits were sufficiently low to be able to detect most of the analyzed compounds in a majority of the samples from the general populations, at least in Sweden, Ukraine, Poland and on Greenland. For the compound where it was possible the method was applied in inter-laboratory control programs with results within the tolerance limits.
Conclusions: The developed method may be valuable in epidemiological studies on associations between exposure to PFCs, phthalates and bis-phenol A and health effects.

Risk of acute kidney injury after exposure to gadolinium-based contrast in patients with renal impairment

Shih-Bin Su, *Chi-Mei Medical Center, Taiwan*
Chih-Chiang Chien, *Chi-Mei Medical Center, Taiwan*
Ching-Yih Lin, *Chi-Mei Medical Center, Taiwan*

Background and Aims: Gadolinium-based contrast media (Gd-CM) are reported to induce acute kidney injury (AKI) in a high-risk population group at the usual dose for magnetic resonance imaging (MRI) and magnetic resonance angiography (MRA) examinations. We assessed gadolinium-induced nephropathy in patients with renal impairment who underwent MRI or MRA examinations, and evaluate the risk factors.
Methods: In this retrospective study, 238 patients with baseline renal impairment, who received MRI or MRA examinations with Gd-CM, were recruited.
Results: After all other AKI causes—liver decompensation, severe heart failure, all kinds of shock, and severe sepsis—and patients on dialysis were excluded, 158 patients were enrolled. AKI was defined as a decrease in GFR > 10% of baseline data within 3 days after Gd-CM administration. Regression analysis was used to find independent risk factors for gadolinium-induced ARF (Gd-AKI). Twenty-six of the 158 patients (16.5%) developed Gd-ARF. There were no significant differences in gender, age, or baseline eGFR between those who did and who did not develop AKI. Co-morbid coronary artery disease, liver cirrhosis, diabetic mellitus, and hypertension were not significantly associated with the development of Gd-ARF. However, sepsis was an independent risk factor for Gd-AKI after multivariate regression analysis (adjusted odds ratio: 4.417; 95% confidence interval: 1.671, 11.676, P =.03).
Conclusions: Sepsis was an independent risk factor for Gd-CM nephropathy at the usual dose for MRI and MRA examinations. It is important to identify high-risk patients and closely monitor renal function after Gd-CM administration.

Background: Great efforts have been invested worldwide to better understand and mitigate the impact of air pollution on human health. However, the debate about safe standards is still open. This study aims to describe the health benefits that would be achieved by meeting the World Health Organization air quality guidelines (WHO-AQG) for PM_{10}, $PM_{2.5}$ and ozone in the Spanish cities of Barcelona, Bilbao, Granada, Malaga, Seville and Valencia.

Methodology: Traditional standard procedure for HIA of urban air pollution updated under the EU-sponsored APHEKOM project was applied in each city. Short-term impacts of ozone and PM_{10} on mortality and morbidity, as well as the long-term of $PM_{2.5}$ on mortality, life expectancy (LE) and monetary health benefits were quantified based in published concentration-response functions and economic values. Pollutants and health outcome data were recorded for the period 2004-2006. Results were referred to population 30 years of age and older.

Results: Although annual mean of PM_{10} for the study period did not exceed the legislative limit value in Europe (40 $\mu g/m^3$) in any of the cities, our findings show that compliance with WHO-AQG of 20 $\mu g/m^3$ would prevent each year more than 313 deaths, and between 284 and 658 hospital admissions for cardiovascular and respiratory diseases, respectively, in the six cities. Larger health benefits were recorded when considering a decrease in $PM_{2.5}$ concentrations at the long-term. The compliance with WHO-AQG of 10 $\mu g/m^3$ in annual mean would avoid more than 2732 deaths for the six cities each year, accounting for a monetary health benefit of more than 4,500 millions Euros. This decrease would result in a LE gain that would range between 13.8 and 2.3 months.

Conclusions: Ours findings support the need to revise current air quality legislative limit values, especially in the case of fine particles $PM_{2.5}$

THE EFFECT OF PRENATAL AND POST NATAL EXPOSURE TO SECOND HAND SMOKE ON THE DEVELOPMENT OF WHEEZING BEFORE THE AGE OF 2: A EUROPEAN STUDY

On behalf of the ENRIECO cohorts, www.enrieco.org

Background-Aim. It has been estimated that at least 700 million children worldwide breathe air polluted by second hand smoke (SHS) at home. We assessed the independent and combined role of prenatal and postnatal exposure to SHS on the development of wheeze in infants before age 2.

Methods. We examined pooled data for 49415 mother-child pairs from 19 birth cohorts in 9 countries participating in the EU funded ENRIECO project (ALSPAC, AMICS-Barcelona, AMICS-Menorca, BAMSE, CONER, DARC, EDEN, Generation R, GINI, INMA Guipuzkoa, INMA Sabadell, INMA Valencia, KOALA, Leicester, LISA, MAS, NINFEA, PIAMA-NHS, and RHEA). Information on prenatal exposure to maternal active smoking, prenatal exposure to SHS (paternal or others smoking in the mother's environment) and postnatal SHS exposure (parents or others smoking in the child's environment) was collected. We used multilevel mixed-effects logistic regression. Complete information on wheeze, active and passive smoking and covariates used in adjusted models was available for 25727 children.

Results. Among non-smoking mothers an increased risk towards the development of wheeze during the first 2 years of life was associated with any exposure to SHS as a fetus and/or during infancy in both the pooled (OR=1.18, 95%CI 1.10-1.27) and in the meta-analysis (OR = 1.16, 1.06-1.26). Increased risks were observed for fetal exposure to SHS only during pregnancy (OR= 1.14, 1.05-1.24) and to children exposed to SHS during both pregnancy and infancy (OR=1.29, 1.18-1.42). Combined active maternal smoking during pregnancy and SHS exposure during infancy led to the highest risks observed (OR=1.76, 1.60-1.93). Approximately 8% of wheeze during the first 2 years in children of non-smoking mothers could be attributed to SHS.

Conclusions. SHS exposure during pregnancy and infancy was associated both mutually and independently with the development of wheeze before the age of 2 indicating the importance of adopting smoke free homes and environments.

PREVENTING COLD-RELATED MORBIDITY AND MORTALITY IN A CHANGING CLIMATE

Kathryn C Conlon, *University of Michigan School of Public Health, USA*
Nicholas B Rajkovich, *University of Michigan Taubman College of Urban & Regional Planning, USA*
Jalonne White-Newsome, *University of Michigan School of Public Health, USA*
Larissa Larsen, *University of Michigan Taubman College of Urban & Regional Planning, USA*
Marie S O'Neill, *University of Michigan School of Public Health, USA*

Background and Aims: Overall, higher death rates are observed in winter months compared to summer months. General circulation models used in climate change research indicate a trend towards more intense winter storms occurring in the Northern Hemisphere, particularly between northwestern Europe and the Upper Midwest and Northeast of the United States. To understand current efforts to reduce risk during cold weather, epidemiological, and adaptive behaviour research is compiled and presented.
Methods: We critically reviewed evidence relating temperature variability, health outcomes, and adaptation strategies to cold weather. Health outcomes included cardiovascular-, respiratory-, cerebrovascular-, and all-cause morbidity and mortality. Population and geographic-specific studies were assessed to highlight associations between individual- and neighborhood-level characteristics that contribute to one's vulnerability to cold weather. Adaptation strategies were evaluated at personal-, building-, and neighborhood scales.
Results: Cardiovascular-cause mortality was the most commonly identified health outcome associated with cold weather. Vulnerable populations include the elderly, populations living in typically mild winter climates, and rural populations. Successful adaptation to cold weather was found mostly at the personal level, yet building modifications such as insulation greatly improve thermal comfort of building inhabitants, suggesting that dwelling modifications could protect human health from cold weather.
Conclusions:
Evidence suggests that variability in climate contributes to morbidity and mortality during winter. Results from this research justify the need for (i) immediate actions to promote an awareness among homeowners, property managers, and housing authorities of the importance of building integrity in protecting human health (ii) an allotment of resources for weatherization efforts and (iii) focused research to evaluate the impact of infrastructure-level adaptation to protect human health. We propose that future climate change adaptation research couple building energy and thermal comfort models with epidemiological data as a novel approach to evaluate and quantify the impacts of adaptation strategies.

PRELIMINARY CHARACTERIZATION OF REAL TIME PM MASS AND COMPOSITION PROFILE IN SMOKES FROM DIFFERENT SOURCES: CIGARETTE, INCENSE STICKS, POTATO FRYING AND URBAN POLLUTION

Grisa Mocnik, *Aerosol d.o.o., Ljubljana, Slovenia*
Ario A. Ruprecht, *Tobacco Control Unit, Istituto Nazionale dei Tumori /SIMG-ISDE Milan, Italy.*

Background and Aims: airborne nicotine is the only specific marker of ETS, but real time analysis is not possible. Aim of study is to explore the existence of a specific mass and composition profile of ETS originated Particulate Matter (PM) whose measure could identify the presence and amount of ETS in real time with quick and reliable ETS monitoring.
Methods: Analyzers: Aerocet 531, (MetOne) to record mass of PM_{1}, $PM_{2.5}$ PM_{10} and Aethalometers AE51 (Magee) for Elemental Carbon (BC) and Organic Carbon (OC).
Procedure: Instruments operated in 40 m^3 room with 0.3/0.6 ach and adequate mixing factor measuring urban pollution, cigarette smoke and incense stick burning. Background and cooking combustion pollution was measured in a kitchen of 35 m^3 frying two portions of potatoes.
Results: Ratios of the means of peak concentrations of different pollutant in different types of smokes

	BC/OC	BC/PM1	BC/PM2.5	BC/PM1	OC/PM1	OC/PM2.5	OC/PM10	PM1/PM2.5	PM1/PM10	PM2.5/PM10
Urb.bckg	0.35	0.24	0.21	0.15	0.69	0.61	0.43	0.88	0.63	0.71
Pot.frying	0.33	0.02	0.01	0.01	0.06	0.04	0.03	0.72	0.57	0.80
ETS	**0.11**	**0.06**	**0.05**	**0.04**	**0.55**	**0.44**	**0.42**	**0.80**	**0.76**	**0.96**
Inc. stick	0.04	0.01	0.01	0.01	0.15	0.14	0.14	0.91	0.91	1.00

BC/OC and BC/PM ratios were lower in ETS as compared to urban background, while OC/PM were similar. In contrast, OC/PM was remarkably higher in ETS vs potato frying and incense sticks. Ratios between PM of different size did not show relevant differences.
Conclusions: Differences in mass profile of different parameters are promising about possibility to identify a real time "fingerprint" of ETS presence in the environment. Further studies are necessary to confirm these preliminary results extending to other categories of indoor confounders, and to evaluate the suitability of this approach to ETS monitoring in public places.

Environmental lead exposure, Catechol-*O*-methyltransferase (COMT) Gene, and Systolic Blood Pressure in Children.

Aimin Zhang, Howard Hu, Brisa N. Sánchez, Adrienne S. Ettinger, Sung Kyun Park , David Cantonwine, Lourdes Schnaas, Robert O.Wright, Hector Lamadrid-Figueroa, Martha Maria Tellez-Rojo

Objective: Environmental lead exposure and a COMT polymorphic variant, Val108/158Met (rs4680), have both been shown to be associated with increased risks of hypertension in adults. We hypothesized that low-level lead exposure influences blood pressure in children and that the COMT mutation modifies this effect. We tested these hypotheses in 309 children at 7–15 years of age from a sub-study of the Early Life Exposures in Mexico to Environmental Toxicants (ELEMENT) project, an environmental birth cohort study.

Materials and Methods:

We used a mercury sphygmomanometer with appropriate-size cuffs to measure systolic and diastolic blood pressure (SBP and DBP), and Inductively coupled plasma mass spectrometry (ICPMS) to measure blood lead levels (BLLs); all measurements were taken concurrently. Multiple linear regression models were used to estimate the association between blood pressure and BLL, and effect modification by COMT genotype.

Results: Of the 309 children, 126 (42.4%), 136 (45.8%) and 35 (11.8%) were COMT Val/Val, Val/Met and Met/Met genotype, respectively. The median [interquartile-range (IQR)] concurrent BLL was 3.4 (1.83) μg/dl. After adjusting for child's age, height, body mass index, gestational age, weight at birth, and maternal education blood pressure, smoking during pregnancy, an interquartile range increase in BLL (1.83 μg/dl) was associated with 2.98 mm Hg (95% CI 0.42-5.54 mm Hg) increase in SBP among Val/Val wild-type children, while no significant effects were found for DBP. Compared with children having Val/Met or Met/Met genotype, BLL was significantly associated with steeper increases in SBP in children having Val/Val wild-type (p for interaction = 0.02).

Conclusion: These results indicate that concurrent low environmental lead exposure (less than 10 μg/dl) was associated with increased SBP in children, and that genetic polymorphisms in COMT may modify lead's toxicity, suggesting a gene-environment interaction.

GENOMIC METHYLATION OF PERIPHERAL BLOOD LEUKOCYTES AMONG ARSENIC-EXPOSED MATERNAL-NEWBORN PAIRS

Rick Pilsner, University of Massachusetts –Amherst, USA
Megan Hall, *Columbia University, USA*
Xinhua Liu, *Columbia University, USA*
Vesna Ilievski, *Columbia University, USA*
Vesna Slavkovich, *Columbia University, USA*
Pam Factor-Litvak, *Columbia University, USA*
Mahfuzar Rahman, *ICDDR, B: Centre for Health and Population Research, Bangladesh*
Joseph Graziano,*Columbia University, USA*
Mary Gamble, *Columbia University, USA*

Background and Aims: An emerging body of evidence indicates that early-life arsenic (As) exposure may influence the trajectory of health outcomes later in life; however, the mechanisms underlying these observations are unknown. Our previous work indicates that chronic As exposure causes epigenetic dysregulation, including increases in DNA methylation in adults. The objective of this study was to investigate the influence of prenatal As exposure on genomic methylation of cord blood DNA in a study of mother/newborn pairs in Bangladesh.
Methods: Maternal and cord blood DNA was available from a convenience sample of 101 mother/newborn pairs. Measures of As exposure included maternal urinary As (uAs), maternal blood As (mbAs) and cord blood As (cbAs). Several measures of genomic DNA methylation were assessed, including the [3H]-methyl-incorporation assay and three Pyrosequencing assays; Alu, LINE-1 and LUMA.
Results: After adjustment for covariates, increasing quartiles of maternal uAs were positively associated with cord blood genomic DNA methylation as measured by the [3H]-methyl-incorporation assay ($p_{trend} < 0.05$), and LINE-1 methylation (Q1 vs. Q3; p=0.03), indicating that newborn DNA methylation increased with maternal As exposure. The effects appear to be gender specific: among male newborns (N=58), mbAs was associated with increased DNA methylation as measured by Alu (r=0.28; p=0.03), LINE-1 (r=0.23; p<0.1) and [3H]-methyl-incorporation (r=-0.22; p<0.1). Among female newborns (N=42), the correlations between maternal uAs and cbAs and Alu and Line-1, while not significant, were negative (r=-0.24; p=0.12) and (r=-0.18; p=0.24), respectively.
Conclusions: Consistent with our previous studies in adults, these results suggests that prenatal As exposure is associated with increases in genomic DNA methylation in newborn cord blood DNA. Although the sample size is small, the data suggest that this may occur in a gender-specific manner. Arsenic-induced epigenetic modifications *in utero* may potentially influence disease outcomes later in life.

PRENATAL EXPOSURE TO PBDE'S AND CHILD BEHAVIOR AT 3-5 YEARS

Julie Herbstman, *Columbia University Mailman School of Public Health, USA*
Sally Ann Lederman, *Columbia University Mailman School of Public Health, USA*
Andreas Sjödin, *Centers for Disease Control and Prevention, USA*
Robin Whyatt, *Columbia University Mailman School of Public Health, USA*
Virginia Rauh, *Columbia University Mailman School of Public Health, USA*
Frederica Perera, *Columbia University Mailman School of Public Health, USA*

Background and Aims: Polybrominated diphenyl ethers (PBDEs) are widely used flame retardant compounds that are persistent and bioaccumulative. Exposures are relatively low in the EU but ubiquitous in the U.S. We have previously shown adverse associations between prenatal PBDE and child neurodevelopmental outcomes. Here we evaluate effects of prenatal exposure to PBDEs on child behavior at 3 and 5 years (Herbstman et al 2010).
Methods: This study was conducted within a longitudinal cohort study initiated to examine the impact of prenatal exposures to toxicants, including PBDEs, which may have been emitted from the World Trade Center (WTC) buildings in New York City following the 9/11/2001 attack. PBDE levels were measured in cord blood collected from 210 non-smoking women delivering at hospitals near the WTC site between 12/2001-6/2002. Child behavioral problems were measured by maternal report using the Child Behavior Check List (CBCL) for ages 1.5 to 5 years on 143 children who also had cord PBDE measurements. Multiple variable Poisson regression analyses assessed associations between concentrations of PBDE congeners 47, 99, 100, and 153 and various indices of child behavior.
Results: Among girls, one or more PBDE congeners were significantly ($p<0.05$) inversely associated with Emotionally Reactive, Withdrawn and Internalizing behaviors. Among boys, one or more congeners were significantly inversely associated with Sleep problems. We observed child sex-by-PBDE interactions for a number of Syndrome scales.
Conclusions: The PBDE congeners were inversely associated with several Syndrome scales but results differed significantly by child sex. Few prior studies have examined this association; confirmation is needed in additional larger studies.

AIR TRANSPORTATION AND FLIGHT ATTENDANT HEALTH

Eileen McNeely, *Harvard School of Public Health, USA*
Sara Gale, *University of California, Berkeley, USA*
Julie Bradley, *Harvard School of Public Health, USA*
Ira Tager, *University of California Berkeley, USA*
Judith Murawski, *Association of Flight Attendants-CWA, AFL-CIO, USA*
Laurel Kincl, *University of Oregon, USA*
Steve Hecker, *University of Washington, Seattle, USA*

Background and Aims: Few studies about the health consequences of flight attendant work exist, even though attending and safeguarding passengers is demanding work, usually involving circadian rhythm disruption and hazardous aircraft cabin exposures i.e. flame retardants, pesticides, jet fuel by-products, ozone, cosmic radiation, infectious diseases, and hypoxia. To understand the impact of these hazards, we conducted the largest survey of flight attendant general health to date. Importantly, flight attendant health provides a window into the healthiness of air travel for the flying public.
Methods: Flight attendants from two major US airlines were surveyed; by mail or in person (n=4011). We analyzed reported symptoms, health conditions, personal and job characteristics using Deletion/Substitution/Addition algorithm (DSA) in R statistical package.
Results: Respondents were 80% female with a mean age of 47; 87% were non-smokers; 41% had ≥ 20 years experience as a flight attendant. Health complaints reported as lasting >4 of the past 7 days included sleep problems (35%), all types of musculoskeletal pain (between 23-28%), sinus congestion (28%), fatigue (26%), anxiety/stress (20%) and bloating (20%). The most common conditions associated with seeking medical care in the past year included respiratory (55%), fatigue (37%), diffuse joint pain (33%) and neurological (17-19%). The most prevalent diagnoses included low back pain (52.6%), allergies (39%) depression/anxiety (36%), and sleep disturbances (34%); approximately 1/5 of respondents who reported these conditions were receiving treatment for these problems. Regression analysis of prevalent conditions showed that fatigue, musculoskeletal problems, neurological and psychological problems are significantly associated with greater flight hours.
Conclusions: Several health problems affected a significant portion of the flight attendants. These conditions may affect the safe performance of the work, representing further risk to both crew and passengers. More research on the association between workplace exposures and crew health must be undertaken.

INTERACTION EFFECTS BETWEEN MATERNAL PRENATAL VITAMIN INTAKE AND PYRETHROID PESTICIDE EXPOSURE IN RELATION TO AUTISM SPECTRUM DISORDERS IN THE CHARGE CASE-CONTROL STUDY

Rebecca J. Schmidt, *University of California Davis, USA*
Lora Delwiche, *University of California Davis, USA*
Robin L. Hansen, *University of California Davis, USA*
Irva Hertz-Picciotto, *University of California Davis, USA*

Background and Aims: Autism spectrum disorder (ASD) is an increasingly prevalent neurodevelopmental disorder affecting 1:110 children in the United States (CDC, 2009). Evidence supports large heritable contributions to the etiology of ASD, though environmental factors are likely to modify both the development and the course of ASD. Prenatal nutrient-environment interactions are unstudied in relation to autism etiology and risk. The objective of this study is to examine interaction effects between maternal supplemental nutrient intake and pyrethroid pesticides in relation to ASD.
Methods: Northern California families were enrolled from 2003-2009 in the population-based case-control CHARGE (Childhood Autism Risks from Genetics and the Environment) Study. Children aged 24-60 months were evaluated and confirmed to have autism (n=288), autism spectrum disorder (n=141), or typical development (n=278) at the M.I.N.D. Institute using standardized clinical assessments. Maternal prenatal vitamin intake before and during pregnancy and use of products containing pyrethroid pesticides were retrospectively collected through telephone interviews. Adjusted odds ratios (OR) were estimated for associations between ASD and combinations of prenatal vitamin and pyrethroid pesticide exposure.
Results: Estimated risk for having a child with autism when mothers did not take a prenatal vitamin and were exposed to pyrethroid pesticides during pregnancy (OR=5.4, 95% CI: 2.4-11.9) was over twice what was expected for that combination by either an additive (OR=2.2) or multiplicative model (OR=2.6). Though still significantly elevated, the observed risk for having a child with ASD associated with pyrethroid exposure during pregnancy was much lower if the mother reported taking a prenatal vitamin during the period around conception (OR=1.7, 95% CI: 1.0-2.8).
Conclusions: These findings suggest that vitamin supplements taken before or early in pregnancy could potentially reduce the risk of ASD associated with pyrethroid pesticides. Further studies are warranted.

Adriana Mercado-García, I*nstituto Nacional de Salud Pública, Mexico*

Martha Maria Téllez-Rojo, I*nstituto Nacional de Salud Pública, Mexico*

Background and Aims: Mercury and lead, two established neurodevelopmental toxicants, comprise two of the top three chemicals of concern on the EPA/ATSDR Priority List of Hazardous Substances. Yet, there is limited epidemiological data regarding the relationship, including potential interactions, between mercury and lead exposure upon neurodevelopmental outcomes in children. The objectives of this study were to determine the associations between biomarkers of postnatal mercury and lead exposure and visual-motor development in adolescents aged 13-15 years living in Mexico City.

Methods: The Wechsler Abbreviated Scale of Intelligence and the Wide Range Assessment of Visual Motor Activity (WRAVMA) were used to assess children's cognitive and visual-motor development. Biomarker levels for lead and mercury were collected via ICP-MS and DMA-80. Data were analyzed using generalized linear models adjusting for maternal age, maternal IQ, child's IQ, sex, and child's age.

Results: In the 135 eligible adolescents, aged 13-15 years, mean levels of total mercury in blood, hair, and urine were:1.43 µg/L, 0.39 µg/g, and 0.60 µg/L; and whole blood lead levels were 3.21 µg/dL, respectively. A one-log increase in concurrent blood lead and mercury levels resulted in a -4.08 (95%CI -7.58, -0.59) and -2.86 (95%CI -5.85, 0.13) decrease in the WRAVMA composite score, respectively. Inclusion of hair mercury levels, instead of blood mercury, resulted in a stronger, more significant adverse relationship with the WRAVMA composite score. While no significant interactions between blood lead and mercury were detected with the WRAVMA, there was a significant positive interaction term (p-value=0.04) between hair mercury and blood lead levels.

Conclusions: Our study demonstrates adverse relationship between concurrent biomarkers of methylmercury exposure, blood lead, and adolescence's visual motor development.

ETHICAL CONCERNS IN USING PUBLIC DATA SOURCES: ISSUES IN ACCESS AND LINKAGE

W. Douglas Thompson *University of Southern Maine, USA,*
Gerald Harris, *UMDNJ-Robert Wood Johnson Medical School, USA*

Background and Aims: Public health research and practice often have been facilitated through the evaluation and study of population-based data collected by local, state and federal governments. However, recent concerns about identify theft, confidentiality, and patient privacy have led to increasingly restrictive policies on data access, often preventing researchers from using these valuable data. We believe that these restrictions, and the research impeded or precluded by their implementation and enforcement, have had a significant negative impact on important public health research. Further, the details of the regulations vary greatly across the administrative jurisdictions that control access and manage the data. We present a case study.
Methods: We requested individual level birth certificate data from several states for use in a series of analyses investigating the possible association between environmental exposures and birth outcomes using public data. We also explored some strategies to overcome some of the access obstacles without violating the regulations.
Results: Some states provided exact maternal residential locations and residential histories, enabling us to conduct the planned analyses, while others would not release precise maternal residence location, limiting our ability to link birth outcomes to local neighborhood and environmental quality data. We developed data linkage approaches with some states that enabled us to obtain the desired results without complete individual level data records.
Conclusions: Limited access to routinely collected health related data limited our ability to conduct studies assessing the effects of environmental exposures. In some instances, but not all, we were able to achieve our goals with particularly cooperative health departments. We welcome input on the experiences of others and ideas for overcoming these barriers. This session will be a moderated open forum to discuss the ethical dilemmas around using public data sources with a focus on identifying emerging priorities from the papers presented in this session.

ACUTE EFFECTS OF OZONE AND PM_{10} ON PEAK EXPIRATORY FLOW: A PANEL STUDY OF SCHOOLCHILDREN IN THE WESTERN BRAZILIAN AMAZON

Ludmilla Viana Jacobson, Fluminense Federal University, Brazil
Sandra Hacon, Oswaldo Cruz Foundation , Brazil
Hermano Castro, Oswaldo Cruz Foundation, Brazil
Eliane Ignotti, Mato Grosso State University, Brazil
Paulo Artaxo, University of São Paulo, Brazil
Antônio Ponce de Leon, Rio de Janeiro State University, Brazil

Background and Aims: Epidemiological studies suggest significant effects on health caused by exposure to air pollutants. The purpose of this study was to evaluate the acute effects of exposure to O_3 and to PM_{10} in the peak expiratory flow (PEF) of schoolchildren, in the western Brazilian Amazon.

Methods: Panel study with a sample of 279 schoolchildren from 6 to 15 years old. Repeated measures of PEF were carried out during 97 days, in the dry season. Daily measurements of O_3, PM_{10}, temperature, humidity as well as respiratory symptoms were recorded. Other individual characteristics, such as weight, height, and spirometry were measured. Further, a questionnaire was answered by child's responsible. The analysis was based on mixed effects models. The effects of pollutants were evaluated considering levels on the current day, 1 to 3 days lag and cumulative effects of 2 and 3-days. The variance function of random error was estimated.

Results: The overall average of the PEF was 276.53 l/min. Averages of PM_{10} ranged from 6.1 to 108.6 $\mu g/m^3$ and averages of O_3 varied from 0.25 to 57.25 $\mu g/m^3$. The estimated models consisted of: i) temporal trends, temperature and humidity lagged by 2-days, fitted via quadratic parametric splines with random coefficients; ii) respiratory symptoms with random coefficients; iii) individual characteristics such as height, weight, gender, asthma diagnosis (ISAAC), and the ratio FEV1/FVC. Adjusted models revealed significant effects of the exposure to PM_{10} and O_3. For each increase of $10\mu g/m^3$, there was a reduction in the PEF average ranging from 0.72 to 0.83 l/min for PM_{10} on the 3 days lag. For an increase of $10\mu g/m^3$ of O3, the PEF average decrease varied between 2.28 to 4.26 l/min for all exposure evaluated, except for the current day levels.

Conclusions: We observed a significant association between PEF and levels of air pollutants.

Cancer mortality among Brazilian soybean agricultural workers

Juliana Chrisman, *ENSP/FIOCRUZ, Brazil*
Dyana Balestieri ,*IESC/UFRJ, Brazil*
Rosalina Koifman, *ENSP/FIOCRUZ, Brazil*
Sergio Koifman,*ENSP/FIOCRUZ, Brazil*
Armando Meyer, *IESC/UFRJ, Brazil*

Background and Aims: Currently, Brazil is the largest consumer of pesticides in the world, and soybean crops are the main destination of this very intensive consumption of pesticides. In addition, Brazil is the second largest producer of soybean in the world. Although soybean production has been increasing over decades and is a major target of pesticide use in Brazil, few studies were devoted to investigate the health of Brazilian soybean agricultural workers.
Methods: Therefore, this study was designed to compare cancer mortality among agricultural workers living in regions of intensive production of soybean with that experienced by three reference populations: residents of the same area, but not agricultural workers; agricultural workers of regions not producing soybeans; and non-agricultural workers of areas not producing soybeans. To do so, mortality odds ratios (MOR) were calculated, stratified by sex and age, for several types of cancer, according to the Chapter II of International Classification of Diseases, 10th edition.
Results: Female agricultural workers living in regions of intensive production of soybeans had a higher risk to die by melanoma (MOR: 2.99, 95% CI 1.72 to 4.58) and esophageal cancer (MOR: 2.11 , 95% CI 1.58 to 2.66), when compared to non-agricultural population of areas not producing soybeans. In addition, male agricultural workers were at higher risk to die by melanoma (MOR: 4.10 95% CI: 3.32 to 5.08) and bladder cancer (MOR: 2.23, 95% CI: 1.88 - 2.64), if compared with agricultural workers of areas not producing soybeans.
Conclusions: Results of the present study suggest that agricultural workers from regions of intensive production of soybean in Brazil maybe be at higher risk to die by specific cancers. It also indicates that this possible association should be further investigated.

PROXIMITY TO INDUSTRIAL PLANTS, NEIGHBOURHOOD SOCIO-ECONOMIC CHARACTERISTICS AND THE RISK OF INFANT MORTALITY – A BAYESIAN ANALYSIS IN LYON, FRANCE

Denis Zmirou-Navier , *EHESP School of Public Health–Rennes-France; IRSET – Research Institute of environmental and occupational health-France; INSERM U954–Vandoeuvre-les-Nancy-France ; ancy University Medical School–Vandoeuvre-les-Nancy-France*
Séverine Deguen , *EHESP School of Public Health–Rennes-France; IRSET – Research Institute of environmental and occupational health-France*

Background: Exposure to environmental nuisances is suspected to explain a part of social health inequalities. Recent literature data suggest that perinatal health might be affected by air pollution and industrial emissions.
Objective:To investigate the association between infant mortality and proximity to polluting industries and to explore the role of socio-economic characteristics in this relation.
Methods: An ecological study was conducted in Lyon (1,260,348 inhabitants, France). Location of industry plants was drawn from the French database of the European-Pollutants-Emission-Registry. A proximity index was constructed using the buffer method. We used census data to characterize neighborhood socioeconomic status. Mortality information is collected at the French-census block level (n=510). A Bayesian approach was applied to consider spatial dependence and the high mortality rates variability; a Poisson model was accommodated to test the association between infant mortality and proximity to industries.
Results:There were 714 infant death cases in Lyon between 2000 and 2009 (average rate of 4.1 per 1000 live births). A significant interaction was found between the proportion of single-parent families and the proximity to industries using a buffer of 500 meters. The risk of infant mortality is significantly greater among census blocks with at least one industry compared to where is no local industry, but only when the proportion of single families in the census block population is “high” (greater then 15,9%): RR=1.32 (p-interaction=0.036). No significant association was shown with the level of unemployment or of education.
Conclusion: This observation may result from a greater exposure to industrial pollution due to a higher number of industries in the deprived census blocks. It could also stem from a vulnerability phenomenon whereby residents might be more sensitive to the effect of exposure because of a poorer health status and/or lower access to appropriate care. More refined analyses are underway to identify the most plausible explanations.

AIR QUALITY IMPLICATIONS OF ALTERNATIVE FUELS: A SPATIALLY AND TEMPORALLY EXPLICIT LIFECYCLE MODELING APPROACH

Christopher Tessum, *University of Minnesota, Minneapolis, USA*
Kristina Wagstrom, *University of Minnesota, Minneapolis, USA*
Jason Hill, *University of Minnesota, St. Paul, USA*
Julian D. Marshall, *University of Minnesota, Minneapolis, USA*

Background and Aims: The current US Renewable Fuel Standard (RFS2) requires increasing amounts of biofuel production through 2022. We use lifecycle assessment, air dispersion modeling, and health risk assessment to estimate air pollution-related health impacts of an additional 7.5 billion gallons of corn grain ethanol and 5 billion gallons of cellulosic ethanol from corn stover.
Methods: *Emissions* – Process-specific emissions for the lifecycle of fuel production and use were extracted from the GREET lifecycle model and allocated to a 12km grid over the continental US, in one hour time steps, during a 1-year model simulation. The lifecycle analysis included feedstock production (mining, farming, or harvesting), conversion to fuel, distribution, and combustion in vehicles, plus the necessary inputs, such as fossil fuels, electricity, and fertilizer, for each step. *Air dispersion* – A state-of-the-science photochemical air dispersion model (CAMx) predicts the fate and transport of emissions, estimating marginal pollution changes attributable to RFS2. We focus here on $PM_{2.5}$ and ozone. *Health risk assessment* – Our mortality estimates employ concentration-response functions from Pope et al. (2002) for $PM_{2.5}$ and from Bell et al. (2004) for ozone, using EPA's BENMAP model.
Results: Preliminary results suggest that the RFS2 ethanol scenario will annually yield 23 more deaths due to ozone, and 112 more deaths due to $PM_{2.5}$, relative to an energy equivalent amount of gasoline. This is equivalent to a value of statistical life (VSL) based increase in public health burden of 0.09 USD per gasoline equivalent gallon (0.02 USD/liter).
Conclusions: Preliminary results suggest that the RFS2 will worsen air-quality and related mortality in the US. However, transportation fuel choice impacts society in many ways, and it is important to quantify and compare all impacts when considering changes in fuels.

CARDIOPULMONARY EMERGENCY HOSPITAL VISITS WERE ASSOCIATED WITH NO_2, PM_{10} AND H_2S LEVELS IN ICELAND'S CAPITAL AREA DURING 2006-2010

Hanne Krage Carlsen, *University of Iceland, Reykjavik, Iceland*
Thorarinn Gíslason, *Faculty of Medicine, University of Iceland, Department of Respiratory Medicine and Sleep (E7), Landspitali University Hospital, Reykjavík, Iceland*
Bertil Forsberg, *Occupational and Environmental Medicine, Public Health and Clinical Medicine, Umeå University, Umeå, Sweden*
Kadri Meister, *Occupational and Environmental Medicine, Public Health and Clinical Medicine, Umeå University, Umeå, Sweden*
Anna Oudin, *Occupational and Environmental Medicine, Public Health and Clinical Medicine, Umeå University, Umeå, Sweden*

Background and Aims: Air quality in Iceland's capital region is generally good, but following the spring 2010 volcanic eruption of Eyjafjallajökull natural particle matter (PM) storms reaching Reykjavik have increased in severity. Another pollution concern is hydrogen sulfide (H_2S) emitted from geothermal harnessing plants located east of Reykjavik. The aim of this time series study was to analyse the association between daily air pollution levels and emergency room (ER) visit rates and determine if volcanic dust modified that association.

Methods: The daily number of all ER visits to Landspítali University Hospital for the period 1st of January 2003 to 31st December 2010 for cardiovascular, pulmonary and cerebrovascular diseases in adults (≥18 years old) was extracted from the patients file register. Pollution and weather data were provided by local authorities. Regression analysis was performed with a multipollutant generalized additive model (GAM) using Poisson distribution. Individual lags were included for each pollutant for same day (lag0), lag1 and lag2. Results were adjusted for traffic pollutants nitrogen dioxide (NO_2) and ozone (O_3), influenza epidemics, weather variables and time trends.

Results: During the study period, there were 17700 ER visits (53% males), median number of ER visits per day was 5 (Quartile (Q)1-Q3: 3-8). The most common diagnosis category was Cardiac (53%), followed by Pulmonary (31%) and Stroke (17%). A positive association was found between ER visit rates and NO_2 levels on the same day, RR 1.04 (95% CI 1.01 1.07) per 10 $\mu g/m^3$ increase; and PM_{10} and H_2S levels two days before, RR 1.01 (95% CI 1.00 1.02) and RR 1.04 (95% CI 1.01 1.07) per 10 $\mu g/m^3$ respectively.

Conclusion: In this preliminary analysis, significant associations between ER visits for cardiovascular, pulmonary, cerebrovascular diagnoses and NO_2, PM_{10} and H_2S levels were found. Immediately, no effect modification was seen during the Eyjafjallajökull volcanic eruption.

PREDICTING AIR EXCHANGE RATES AND PARTICLE LOSSES INSIDE VEHICLES

Fruin Scott, *University of Southern California, USA*
Hudda Neelakshi, *University of Southern California, USA*
Kostenidou Evangelia, *University of Southern California, USA*
Delfino Ralph, *University of California - Irvine, USA*
Sioutas Constantinos, *University of Southern California, USA*

Background and Aims: Ultrafine particle (UFP) losses inside vehicles are strongly negatively correlated with air exchange rate (AER), but the literature only reports AER measurements for 16 vehicles total during real-world driving. UFP losses cannot be predicted without knowing AER, but AER is a complicated function of vehicle characteristics and speed. We used improved AER measurement methods to test a much larger, representative sample, from which we developed predictive models of AER and UFP losses.
Methods: A 60-vehicle sample was selected to be representative of the California fleet in terms of age, mileage, and model. We measured CO_2 build-up rates from vehicle occupants and then calculated AER from equilibrium CO_2 concentrations (where occupant CO_2 production balanced CO_2 removal rates due to AER). AER was then correlated with particle loss fractions for a subset of 90 AER measurements. Predictive models for both AER and particle loss fraction were developed.
Results: A predictive model for AER using only vehicle age, mileage, speed, and manufacturer (all easily ascertained information) could account for 70% of the variation in AER in the low AER recirculation (RC) conditions. Across all AER conditions (RC or outside air [OA]), nearly 90% of AER variation was explained. AERs ranged from ~0 to 145 hr^{-1}, and UFP losses correspondingly ranged from nearly 100% to 40%. Using only the ventilation setting (OA or RC), relative fan setting (for OA), speed (for RC), and vehicle age, 87% of the variability in particle loss was explained.
Conclusions: Our models successfully predict AER and expected UFP concentrations as functions of easily-obtained vehicle characteristics, thus are useful for epidemiological studies. Variables include occupant choice of ventilation setting (OA or RC), vehicle age and mileage, speed, and fan setting. These models will be used in an upcoming cohort of Los Angeles commuters to predict UFP exposure.

LUNG FUNCTION, RESPIRATORY AND MENTAL SYMPTOMS AMONG INHABITANTS EXPOSED TO VOLCANIC ASH FROM THE EYJAFJALLAJÖKULL ERUPTION, ICELAND

Hanne Krage Carlsen, *Centre of Public Health Sciences, University of Iceland, Reykjavik, Iceland*
Thorarinn Gíslason, *Faculty of Medicine, University of Iceland, Department of Respiratory Medicine and Sleep, Landspítali University Hospital, Reykjavík, Iceland*
Bryndís Benediktsdóttir, *Faculty of Medicine, University of Iceland, Department of Respiratory Medicine and Sleep, Landspítali University Hospital, Reykjavík, Iceland*

Throstur Thorsteinsson, *Institute of Earth Sciences, Reykjavík, Iceland*
Haraldur Briem, *Centre for Health Security and Communicable Disease Control, Directorate of Health, Seltjarnarnes, Iceland*

Background and aims: The explosive eruption of the Eyjafjallajökull volcano, 14 April to 20 May 2010, produced abundant fine-grained ash, some estimate 8 million tons of particles 2.8-28 µm in diameter. Residents of the rural region near the volcano were heavily exposed to volcanic ash, of which possible health risks are little known. This study aimed to estimate effects of exposure to ash from Eyjafjallajökull to near-by residents' health.
Methods: After ashfall ceased, all residents in the most affected areas were invited for a medical examination, spirometry and questionnaires about mental and physical health and use of protective equipment. Parents reported symptoms in their children. The study was conducted in the affected area from 31 May to 11 June 2010.
Results: Altogether 167 adults (83 men, 84 women), and 40 children (<18 years) participated. According to local health officials, most residents of the area participated. In questionnaires, 46% of adults reported irritation symptoms from nose and throat, 27% eye irritation, when exposed to ash. Less common were shortness of breath (23%) and nausea (7%). In children, throat irritation was most common (28%). Less than 10% reported symptoms of stress, anxiety or depression in the previous week. Almost all (98%) had used outdoor protective equipment during ash fall. Altogether 18% showed abnormal results when lung function was tested (both pre- and porstbronchodilator testing) according to a standardized protocol (www.boldstudy.org). Spirometry results are being compared to an age- and gender matched general population sample. According to physician's reports, those with preexistions conditions, respiratory or mental, were prone to experiencing adverse symptoms following the eruption.
Conclusions: No severe immediate health effects (hospitalizations or fatalities) could be attributed to ash exposure. Individuals with history of respiratory or mental disease were more likely to experience adverse symptoms.
References: Burden of Lung Disease (BOLD). www.boldstudy.org. 2011.

VALIDITY OF INSTRUMENTS TO MEASURE PHYSICAL ACTIVITY MAY BE QUESTIONABLE DUE TO A LACK OF CONCEPTUAL FRAMEWORKS: A SYSTEMATIC REVIEW

Background and Aims: Regulators' guidance documents for the development and validation of patient reported outcomes (PROs) advise the use of conceptual frameworks, which outline the structure of the concept that a PRO aims to measure. It is unknown if currently available PROs are based on conceptual frameworks. This study, limited to a specific case, aimed (i) to identify conceptual frameworks of physical activity in chronic respiratory patients or similar populations (chronic heart disease patients or the elderly), and (ii) to assess if the development and validation of PROs to measure physical activity in these populations were based on a conceptual framework of physical activity.
Methods: Two systematic reviews were conducted through search in Medline, Embase, Psychinfo, and Cinahl databases up to January 2010.
Results: In the first review only 2 references, identified from 581 references about physical activity in the defined populations, provided a conceptual framework of physical activity in COPD patients. In the second review, out of 103 studies developing PROs to measure physical activity or related constructs, none of them was based on a conceptual framework of physical activity.
Conclusions: These findings raise concerns about how the large body of evidence from studies that use physical activity PRO instruments should be evaluated by health care providers, guideline developers, and regulatory bodies.

This work was conducted within the PROactive project which is funded by the Innovative Medicines Initiative Joint Undertaking [IMI JU # 115011]. Judith Garcia-Aymerich has a researcher contract from the Instituto de Salud Carlos III (CP05/00118), Ministry of Health, Spain. CIBERESP is funded by the Instituto de Salud Carlos III, Ministry of Health, Spain.

ASSESSING REAL-TIME RELATIONSHIPS AMONG PHYSICAL ACTIVITY, GREEN SPACE, AND COMMUNITY DESIGN IN CHILDREN

Estela Almanza, *University of California, Berkeley, USA*
Michael Jerrett, *University of California, Berkeley, USA*
Genevieve Dunton, *University of Southern California, USA*
Edmund Seto, *University of California, Berkeley, USA*
Maryann Pentz, *University of Southern California, USA*

BACKGROUND AND AIMS: Community design to promote active living may increase physical activity and reduce obesity. The mechanisms, however, by which the built environment affects behavior are not well understood. Through the Healthy PLACES study near Chino, California, we collected objective mobility and activity data with global positioning system (GPS) and accelerometer units to study cross-sectional and longitudinal associations among community design, micro-environments, and physical activity. This 4-year, quasi-randomized, natural experiment monitors personal behavior in free-living settings for 800 participants who either recently moved to a newly developed smart-growth community or reside in nearby conventional communities. Continuous personal monitoring presents new challenges for data processing. We highlight key methods from the literature and our own experience for processing biomonitoring data. We also present results associating a remotely-sensed indicator of green space, the Normalized Difference Vegetation Index (NDVI), with physical activity
METHODS: We analyzed GPS and accelerometer measures of neighborhood activity for 208 children (30-second epochs, 7 days). Geovisualizations including kernel density surfaces of moderate-vigorous physical activity (MVPA) were generated to detect spatial patterns. We tested the effect of green space (measured by NDVI) on the within-person variation of physical activity based on 30-second epoch data in a multilevel model clustered on the individual. We included a moving average term on MVPA to address lack of independence among momentary measures.
RESULTS: Geovisualization showed MVPA patterns in proximity to neighborhood green spaces. In modeling, we found NDVI positively associated with MVPA on a momentary basis (p-value < 0.001). For greener locations the odds of MVPA increased by 35% over the 10-90th percentile increment of exposure. We found a significant interaction with the smart-growth design, with effects of green space being larger there.
CONCLUSION: Using objectively-measured physical activity and locational data we demonstrated a strong association between elevated physical activity and green space.

ASSESSING THE ASSOCIATION BETWEEN AIR POLLUTION FROM INDUSTRIAL CHEMICAL COMPLEX "RANAT HOVAV", ADULT MORBIDITY AND MORTALITY IN SOUTHERN ISRAEL USING AN INTEGRATED COMPUTERIZES INFORMATION SYSTEM

Natalya Bilenko, *Ben-Gurion University of the Negev, Ministry of Health, Israel*

***Rimon Wenkart**, Ben-Gurion University of the Negev, Israel*

Hillel Vardi, *Ben-Gurion University of the Negev, Israel*

***Ruslan Sergienko**, Ben-Gurion University of the Negev, Israel*

Drora Fraser, *Ben-Gurion University of the Negev, Israel*

Background: The existence of causal associations between levels of industrial air pollutants, morbidity and mortality is well established. This study evaluated the feasibility of establishing and maintaining an ongoing integrated computerized information system (ICIS) to estimate and monitor association between mortality rates among Jewish and Bedouin adult population of the Negev, and environmental air pollution by about 100 chemicals, from air monitoring stations of the industrial complex Ramat Hovav (RH).

Methods: We intend to develop the ICIS system for monitoring chronic diseases morbidity and all-causes and cause-specific mortality in the Negev region, for adult Jews and Bedouins in the Negev based on the linkage of several data sources in an ongoing manner. These are; a) Beer-Sheva regional office of Ministry of Health (MOH) computerized mortality database (mortality causes, socio-demographic details, place of residence since 2004 and occupation from personal interview); b) A sample of the Health maintenance Organization's Negev population; c) Soroka Hospital hospitalizations records; d) Data of air pollutants emissions from RH by date.

Results: The current analysis was based on data for sample of 100,000 health insured Jewish and Bedouin patients (the settlements served as a statistical unit), mortality data from MOH and air pollutant concentrations, as recorded by monitoring stations of RH for 2007-2010. The overall and cause-specific mortality rates were calculated, continuous air pollution values were cut off by national "Almog" and international Texas reference. Data was linked to measurements of air pollutants from the air dispersion AERMOD models using GIS.

Conclusions: Low rates of excess pollutant levels were shown. Since the long-term exposure to low doses environmental hazards have important impact on human health we intend to use the air pollutants concentration in their original continuous scale in future work and meteorological data will also be taken into account.

LUNG FUNCTION AND AIR POLLUTION IN AUSTRALIAN SCHOOL-CHILDREN

Gail Williams, *University of Queeenslans, Australia*
Guy Marks, *Woolcock Institute of Medical Reseach, Australia*
Bin Jalaludin, *NSW Health, Australia*
Lyn Denison, *Environmental Protection Agency, Victoria, Australia*

Background and Aims: Motivated by the review of Australian air quality standards, we aimed to quantify the effect of air pollution on lung function in a national sample of Australian school-children.
Methods: Nationally monitored data was assembled for a recent five-year period, and 30 sites chosen to maximise variation in exposure to 'criteria' pollutants. Two schools were chosen from each site, within 2.5 km of monitoring site. We recruited 50-60 children per school and obtained a sample of 3,200 children. Children had to live and go to school within a 2.5 km radius of the air monitoring stations. GEE models were used to examine associations after adjustment for design factors and covariates. Multi-pollutant models were examined.
Results: Lung function was significantly adversely affected by NO2 with declines in pre-bronchodilator FEV1, post-bronchodilator FEV1, and FVC of 26.2 ml/s (95% CI 10.1-42.2) , 25.9 ml/s (10.4, 41.4) and 25.3ml (10.0-40.6), respectively, per IQR of mean NO2 over the last 12 months. Results were similar for mean lifetime exposure, and when other pollutants were adjusted for. SO2 showed adverse effects in atopic children and in males. Mean lifetime NO2 levels were 9.3 ppb (range 2.8 – 18.3 ppb).
(Need to add something re particle results – weak associations for limited outcomes as this something that they will be interested in).
Conclusion: Long-term exposure to NO2 reduces lung function in Australian school-children at levels below current air quality standards.

PRENATAL MERCURY EXPOSURE AND ANTHROPOMETRIC MEASURES AT BIRTH

Background and Aims: Prenatal exposure to high levels of mercury has been associated with adverse reproductive outcomes. However, results are inconsistent regarding if moderate chronic exposure, mainly due to elevated fish consumption, has an effect on newborn anthropometry. To assess the association between prenatal mercury exposure and anthropometric measures at birth in a multicenter population based birth cohort.
Methods: Between 2004 and 2008, 2506 mothers gave a live birth in the context of a mother and child cohort study (INMA) in four Spanish areas (Valencia, Sabadell, Asturias, and Gipuzkoa). The study population included 1886 children with available T-Hg determination in cord blood samples. Maternal characteristics and estimated fish intake were obtained through questionnaires. Birth weight, length and head circumference were standardized for gestational age by sex. The association between T-Hg and anthropometry was ascertained using linear and logistic regression and meta-analysis.
Results: Overall, T-Hg (geometric mean 8.2 µg/L) was not significantly associated with birth outcomes; however, all models showed negative patterns and adjustment for fish intake groups decreased the coefficients in all of them. The effect of T-Hg on birth weight was heterogeneous between cohorts (I^2>50%): higher T-Hg levels were significantly associated with lower birth weight in the Mediterranean areas (Valencia and Sabadell), but not in the Atlantic ones (Asturias and Gipuzkoa). Higher T-Hg was also related with lower birth length in Sabadell. When T-Hg was categorized in quartiles, the main differences were found between the first (<5 µg/L) and the fourth quartile (≥15 µg/L).
Conclusions: Prenatal exposure to Hg may be related with restricted size at birth. Heterogeneity in the relation between mercury exposure and birth weight deserves further investigation.
Funding sources: Instituto de Salud Carlos III, Spanish Ministry of Science and Innovation, Generalitat Valenciana, Generalitat de Catalunya, Gobierno Vasco and Fundacio Roger Torné.

Background . Perchlorate is a w idely occurring contaminant. At sufficiently high doses, perchlorate competitively inhibits iodide uptake and thus thyroid hormone production. The health effects of chronic low dose perchlorate exposure on healthy individuals are largely unknown.

Objectives. We undertook a community-based epidemiologic study to compare thyroid function and disease in women w ith differing likelihoods of prior and current perchlorate exposure.

M ethods. Residential blocks were randomly selected from areas: 1) in the drinking water plume with potential perchlorate exposure; 2) with potential exposure to airborne environmental contaminants; and 3) neighboring but without such know n exposures. Eligible w omen had lived in the area for ≥6 months and were aged 20-50 years during 1988-1996 (during documented drinking w ater well contamination). We interview ed 814 w omen and collected blood samples (assayed for thyroid stimulating hormone [TSH] and free thyroxine [fT4]) from 431 interview ed w omen. Daily urine samples were collected, pooled, and assayed for perchlorate and iodide for 178 interview ed premenopausal w omen w ho provided blood samples. We performed multivariate regression analyses comparing thyroid function and disease by residential area and modeled urinary perchlorate dose in relation to TSH, fT4, and thyroid disease adjusted for urinary iodide levels.

Results. Residential location and computed current perchlorate dose were not associated with thyroid function or thyroid disease. Computed perchlorate dose did not exceed reference dose in any participants.

Conclusions. No persistent effect of perchlorate on thyroid function or disease w as found several years after contaminated w ells w ere capped.

AIR POLLUTION FROM INDUSTRIAL SWINE OPERATIONS AND BLOOD PRESSURE IN NEIGHBORING RESIDENTS

Steve Wing, *University of North Carolina, United States*
Rachel Avery Horton, *University of North Carolina, United States*
Kathryn Rose, *University of North Carolina, United States*

Background and Aims: Industrial swine operations emit odorant chemicals including ammonia, hydrogen sulfide, and volatile organic compounds. Malodor and pollutant concentrations have been related to self-reported stress and altered mood in prior studies. Because blood pressure responds to environmental stressors, we conducted a longitudinal study of hog odor, pollutant levels, and blood pressure of swine operation neighbors.
Methods: For approximately two weeks, 101 non-smoking adult volunteers living near industrial swine operations in 16 neighborhoods in eastern North Carolina, USA, sat outdoors for 10 minutes twice daily at pre-selected times. Afterwards, they reported levels of hog odor on a 9-point scale and measured their blood pressure twice using an oscillometric, automated device. Simultaneously, we measured ambient levels of hydrogen sulfide (H_2S), particulate matter (PM_{10}), and semi-volatile PM_{10} ($SVPM_{10}$) at a central location in each neighborhood. Relationships between systolic and diastolic blood pressure (SBP, DBP) and pollutant measures were assessed using fixed effects (conditional) linear regression with adjustment for time-of-day.
Results: Hog odor during the 10 minutes outside was reported present on 59.4% of study days; hourly H_2S varied from 0 to 90 ppb. On average, DBP (±standard error) increased 0.23±0.08 mmHg/unit of reported hog odor during the 10 minutes outdoors and 1.16±0.77 mmHg for every 10 ppb increase of H_2S concentration in the same hour; it was not associated with hourly PM_{10} or $SVPM_{10}$. SBP increased 2.88±1.18 mmHg per 10 ppb increase of H_2S in the same hour, while it was not associated with odor reported during the 10 minutes outdoors nor with hourly PM_{10} or $SVPM_{10}$.
Conclusions: Like noise and other environmental stressors, malodor may be associated with repeated acute blood pressure increases that could contribute to development of chronic hypertension. We will discuss the modifying influences of antihypertensive medication use and coping style.

A COMPREHENSIVE ANALYSIS OF DNA METHYLATION IN HEAD AND NECK SQUAMOUS CELL CARCINOMA INDICATES DIFFERENCES BETWEEN VIRAL AND CHEMICAL INDUCED CARCINOGENESIS

Background: Head and neck squamous cell carcinomas (HNSCC) are the eighth most commonly diagnosed cancers in the U.S population. The risk of developing HNSCC is increased with exposure to tobacco, alcohol and infection with human papilloma virus (HPV). HPV-induced cancers have a distinct risk profile as well as improved prognosis compared to chemically induced cancers associated with tobacco exposure and alcohol use. Epigenetic changes are an important mechanism in carcinogenic progression, but how these changes differ between viral- and chemical-induced head and neck cancers remains unknown.

Methods: We quantified CpG methylation at 1505 CpG sites across 807 genes in 70 well-annotated HNSCC tumor samples from the University of Michigan Head and Neck SPORE patient population using the Illumina Goldengate Methylation Cancer Panel. CpG methylation levels at each locus were normalized based on probe length and guanine-cytosine content.

Results: Unsupervised hierarchical clustering based on methylation values identified 3 distinct tumor clusters, which were found to significantly differ by age and smoking status. HPV status did not differ between clusters, indicating some common shared epigenetically-regulated pathways between chemically- and HPV-induced tumors. Weighted linear modeling was used to identify differentially methylated genes based on epidemiological characteristics. Consistent with previous *in vitro* findings by our group, methylation of sites in the *CCNA1* promoter region was found to be significantly higher in HPV+ tumors. After adjusting for cancer site, stage, age, gender, alcohol consumption, and smoking status, HPV status was found to be a statistically significant predictor for DNA methylation at an additional 11 genes, including *CASP8* and *SYBL1*.

Conclusions: Findings from this study provide insight into the epigenetic regulation of viral vs. chemical carcinogenesis and could provide novel targets for development of individualized therapeutic regimens based on environmental exposures.

This study was funded by NIH/NCI CA097248 and NIH/NIEHS T32 ES07062.

TRANSPORTATION, AIR POLLUTION AND PHYSICAL ACTIVITIES (TAPAS): GENERAL DESCRIPTION OF THE 6-CITY ACTIVE TRAVEL POLICY INTEGRATED HEALTH RISK ASSESSMENT PROGAM

Audrey de Nazelle, *Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain. anazelle@creal.cat*
Zorana Jovanovic Andersen, *Institute of Cancer Epidemiology, Danish Cancer Society, Strandboulevarden 49, 2100 Copenhagen, Denmark.*

Mark Nieuwenhuijsen, *Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain.*
on behalf of the TAPAS consortium.*

Background: Active travel policies can address some of the greatest global public health challenges - physical inactivity and urban air pollution - while generating multiple co-benefits. Risks may also arise for some who shift to active travel and increase air pollution inhalation and traffic hazard exposure. TAPAS aims at assessing health impacts of such policies in an integrated framework in 6 case-study cities: Barcelona, Basel, Copenhagen, Paris, Prague, and Warsaw.
Methods: TAPAS operates at the interface of policy and scientific research. Program steps include: 1) development of a conceptual framework linking active travel policies to health, 2) expert international workshop assessing conceptual framework and state-of-the art knowledge on relevant exposure-response functions; 3) criteria development for identifying policies of interest in case-study cities; 4) local stakeholder involvement to confront potential choice of policies with local needs and interest; 5) identification of commonalities across case study policies for comparable assessments; 6) identification of local data sources for model inputs; 7) quantitative model development. Also, TAPAS case-study city partners develop specific research projects to provide new knowledge filling research gaps in the current framework.
Results: Steps 1-2 have been reported (de Nazelle et al. 2011). Candidate policies were classified in terms of a) known or quantifiable effectiveness, b) local and international interest, and transferability to other cities; c) time and scale of implementation. TAPAS partners identified policies of greatest interest (see accompanying posters), from which the most common themes were selected for preliminary assessments: Bike -lane network; Bike parking; inter-modality; traffic-calming; pricing (parking/congestion); bike sharing systems. A preliminary quantitative model was built and will be populated with local data.
Conclusion: TAPAS is viewed as a useful framework by stakeholders. It will provide an evidence-base for designing policies that encourage a shift to active transportation providing physical activity and other health benefits and mitigate risks.

Stress and Menstrual Cycle Characteristics

Rajeshwari Sundaram, *NICHD, USA*

Germaine Buck Louis, *NICHD, USA*

Courtney Lynch, *Ohio State University, USA*

Alexander McLain, *NICHD, USA*

Cecilia Pyper, *Oxford University, UK*

Background:

Menstrual cycle patterns are often used as indicators of endocrine function. There is increasing interest in the relationship between the impact of stress on fecundity within the context of environmental stressors. This analysis addressed the effect of stress on the menstrual cycle characteristics.

Objectives: To prospectively assess the relationship between salivary stress biomarkers (cortisol and alpha-amylase) and menstrual cycle characteristics in a cohort of women attempting conception.

Methods: Three hundred and seventy women contributed 1088 cycles for analysis; all provided basal saliva samples for the measurement of cortisol (mg/dL) and alpha-amylase (U/ml) on day 6 of each cycle and completed daily diaries on menstruation until either a human chorionic gonadotropin confirmed pregnancy or the women completed 6 menstrual cycles without conception. A linear regression model with a mixture distribution was used to identify the association between stress levels and variations in menstrual cycle: follicular and luteal phase lengths after adjusting for age (years) at menarche and at enrollment and body mass index.

Results: A 2-day increase in menstrual cycle length for 1 mg/dL increase in cortisol level was estimated for women [$\beta = 1.93$; 95% CI (0.21, 3.66)]. Also, a 3-day increase in luteal phase length was estimated for 1 mg/dL increase in salivary cortisol level in women [$\beta = 2.94$; (95% CI 0.63, 5.24)]; no significant association was observed for follicular phase length, nor any significant associations were observed for alpha-amylase.

Conclusion(s): Stress as measured by cortisol significantly increased cycle length, especially during the luteal phase. Understanding the nature of association between stress and menstrual variability will enable improved understanding of the causes of reproductive problems, such as infertility.

PRENATAL MOLYBDENUM EXPOSURE AND INFANT NEURODEVELOPMENT IN MEXICO

Ruth Argelia Vazquez-Salas, *National Institute of Public Health, Mexico*
Luisa E. Torres-Sánchez, *National Institute of Public Health, Mexico*

Mariano E Cebrián, *Departamento de Toxicología. Centro de Investigación y Estudios Avanzados (Cinvestav), México D.F. México.*

Background and Aims: Molybdenum (Mo) is a naturally occurring element, considered an essential dietary nutrient in humans and animals. Information about its possible adverse health effects is scarce. Our aim was evaluate the association between prenatal Mo exposure and neurodevelopment of Mexican children, during the first 30 months of age.
Methods: In 2000-2009 we carried out a cohort study in the state of Morelos, Mexico with the objective to evaluate prenatal organochlorine exposure and child neurodevelopment. During pregnancy, each mother was monitored and interviewed about diet and health aspects related with her pregnancy evolution; from each we obtained a spot urine sample at least in one trimester. We evaluated Mental and Psychomotor indexes of the Bayley Scales for Infant Development from 1 to 30 months of age of children without perinatal complications. For this report, maternal Mo urine concentrations were determined by electrothermal atomic absorption spectrometry in a random subset (n=106). As potential confounders, we considered quality of the home environment, maternal IQ, birth weight, sex of child, and maternal lead levels. Separate generalized mixed effects models were used to estimate the effect of Mo exposure on mental and psychomotor neurodevelopment.
Results: Mo Geometrics mean ranged from 32.0 to 52.9 μg/L; significant higher levels were observed during the second trimester in comparison to first and third trimester ($p<0.05$). Doubling the Mo concentration during the 3rd trimester was associated with a significant reduction ($\beta=-0.73$) in mental development. A similar change of Mo levels at 1st trimester was associated with significant decrease in psychomotor development ($\beta=-0.85$).
Conclusions: This is the first report suggesting a negative association between prenatal Mo exposure and infant neurodevelopment. Mo levels observed are similar to those reported by CDC and a recent study with Mexican children. Further and larger studies are needed to confirm these findings.

Background: Absence of a suitable biomarker of prenatal Mn exposure remains a major obstacle for epidemiologic studies.

Methods: Data are presented from two long-term cohorts. The Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS) study based in California, USA, recruited pregnant women before 20 weeks gestation and collected environmental and biological matrices, including shed deciduous teeth, prospectively over a period of ~8 years to evaluate environmental Mn exposures from agricultural use of Maneb and Mancozeb fungicides. In Italy, a group of children aged 11-14 years were recruited from Valcamonica, where Mn exposure from ferroalloy plants occurred until 2001, and from a reference area. Using laser ablation-ICPMS, tooth Mn (as $^{55}Mn:^{43}Ca$) was measured in pre- and postnatally formed regions of 31 deciduous teeth from the CHAMACOS study and compared with concentrations and loading in house dust collected at the 26th gestational week as well as cord blood, and maternal and child blood and urine. Analyses of >300 teeth are underway. In the Italian study, 11 of >50 teeth have been analyzed and tooth Mn levels compared with concentrations in soil.

Results: In the CHAMACOS cohort, Mn levels in prenatally formed dentine were significantly associated with Mn loading in house dust ($\mu g\ Mn/m^2$ floor area) (Spearman's $\rho_{prenatal}$=0.53, p=0.002, n=31). This association was stronger when we restricted analyses to Mn levels in dentine formed in second trimester, when housedust was collected ($\rho_{prenatal}$=0.60, p=0.0006, n=29). Concentrations in cord blood were significantly associated with Mn levels in dentine adjacent to the neonatal line corresponding to the perinatal period ($p<0.05$), but not with Mn levels in other parts of teeth. In the Italian study, Mn levels in dentine showed a positive correlation with soil Mn (Spearman's $\rho_{prenatal}$=0.46, n=11, p=0.16).

Conclusions: Deciduous tooth dentine is a potentially useful biomarker of prenatal Mn exposure.

CLIMATE CHANGE AND DENGUE: ANALYSIS OF HISTORICAL HEALTH AND ENVIRONMENT DATA FOR PERU

Charlotte Picard, *McGill University, Canada*
Lea Berrang-Ford, *McGill University, Canada*
Antonio Ciampi, *McGill University, Canada*
Eduardo Gotuzzo, *Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia; Peru*
Timothy Brewer, *McGill University, Canada*

Background and Aims:
Dengue, a mosquito-borne virual infection that is the most common cause of hemorrhagic fever globally, is rapidly spreading worldwide. An estimated 40% of the world's population is at risk for this disease that is transmitted by *Aedes sp*. mosquitos (WHO 2009). The *Aedes* mosquito-Dengue virus lifecycle varies with temperature, and climate change may increase the risk of Dengue epidemics in the future (Watts et al. 1987). We examined whether changes in sea surface temperature (SST) along the Peruvian coast were associated with dengue incidence from 2002-2010. In Peru the effects of the El Niño cycle on weather conditions are pronounced, providing an ideal place to study fluctuations in climate and dengue incidence.
Methods:
We used negative binomial models (Hilbe 2007) to examine the relationship between Dengue cases and changes in SST across regions of Peru. Spearman's rank test was used to determine the lagged SST term that was most correlated with Dengue incidence in each region. The negative binomial models included terms for tthe optimum lagged SST and a term for the trend of increasing Dengue incidence over the study period.
Results:
The magnitude and sign of the correlation coefficient of dengue and SST varied between the 15 regions of Peru with Dengue cases. 9 provinces had positive correlations between the two while 6 had negative correlations. The optimum lag ranged from 0 months to 6 months. In all of the regions but 1 lagged SST was a significant predictor of Dengue cases in the negative binomial model.
Conclusions:
The relationship between dengue and sea surface temperature in Peru appears to be significant across the country. Given the varied nature of the relationship between regions it is not possible to make accurate generalisations about this relationship in Peru. Accounting for additional climatic variables such as precipitation may help in improving the predictive model.

BRONCHIOLITIS DIAGNOSED BEFORE 2 YEARS OF AGE AND LOWER INCOME FAMILIES CAN BE AN IMPORTANT RISK FACTOR OF BRONCHIAL HYPERSENSITIVITY

Jong Han Leem, *Inha University Medical College, South Korea*
Ji Young WooLee, *Inha University Medical College, South Korea*
Han Cheol Kim, *Inha University Medical College, South Korea*
Jong-Ryeul Sohn, *Korea University College of Health Sciences, South Korea*

Background & Aims: The prevalence of asthma has increased in recent decades globally. The objective of our study is to identify important risk factors of bronchial hyperreactivity (BHR) in school children.
Method: We studied 522 children age 13~14 years attending schools in rural and urban areas to investigate the risk factors for BHR, defined as a provocation concentration of methacholine that causes a decrease of 20% (PC20)in forced expiratory volume within 1 second. Clinical examination, skin prick test, spirometry, and methacholine challenge were performed on all patients. We used logistic regression to investigate the risk factors for BHR.
Results: Forty-six (10.3%) positive BHR cases were identified. From the multivariable logistic analysis, as independent predictors of BHR, the odds ratio of bronchiolitis diagnosed before 2 years is 4.12 (95% CI: 1.21 □14.04), the odds ratio of female children is 2.30 (95% CI: 1.01 □5.28), the odds ratio of low family income is 2.21 (95% CI: 1.03 □4.76), the odds ratio of positive skin prick test is 2.19 (95% CI: 1.05 □4.57), and the odds ratio of residential environment is 4.14 (95% CI: 1.62 □10.60).
Conclusions: This study shows that sensitization to allergens and bronchiolitis diagnosed before 2 years in lower income families may respectively be considered as risk factors of bronchial hypersensitivity. Avoidance of allergens and prevention of acute respiratory infection in early childhood are important to prevent BHR as a precursor of asthma.
Key Words: Children, BHR, bronchiolitis, asthma, skin prick test.

EXPOSURE TO POLYCYCLIC AROMATIC HYDROCARBONS AFFECTS SPERM QUALITY

Hueiwang Anna Jeng, *Old Dominion University, US*
Chih-Hong Pan, Institute of Occupational Safety and Health, Taiwan
Ming-Tsang Wu, Kaohsiung Medical University, Taiwan
Radim Sram, Institute of Experimental Medicine, Czech Republic

Background and Aims: The objective of this study was to explore whether exposure to polycyclic aromatic hydrocarbons (PAHs) contribute to the alteration of male sperm quality. Our specific aims were to 1) assess sperm quality of coke-oven workers; 2) determine the correlation between PAH biomarkers and sperm DNA integrity; 3) determine sperm oxidative damage by identifying specific DNA lesions; and 4) determine specific gene polymorphisms modifying PAH biotransformation related to sperm DNA integrity.
Methods: A longitudinal study included repeated measurements to account for PAH exposure as it relates to toxic effects on sperms during spermatogenesis. Personal breathing-zone air samples and urine samples were collected to determine PAH external and internal exposure levels, respectively. Semen was collected to assess sperm quality, DNA adducts, and oxidative damage. Blood samples were collected for genotyping. Features of this design include efficient control for confounding factors, accurate exposure ascertainment, and sufficient power to detect exposure related changes in sperm quality.
Results: The high exposed group had a significantly lower percentage of mobile, viable and normal morphological sperms as compared to the control. The concentration of 1-OHP levels negatively correlated with normal sperm morphology, motility and viability. The PAH exposed group experienced higher DNA fragmentation percentages, 8-oxodG concentrations, bulky DNA adducts, and BaP like DNA adducts. GSTM1 null and CYP1A1 MsP1 men had higher sperm DNA fragmentation and 8-oxodG concentration.
Conclusions: Exposure to PAHs decreased sperm quality and increased oxidative DNA damage. Genetic polymorphisms influence the susceptibility of men to sperm DNA damage related to exposure to PAHs. Research results laid a foundation for future study related to the effects of PAHs on reproductive health. Also, the results are useful for reforming best management practices and policies, thus protecting the reproductive health of individuals and/or workers exposed to PAHs.

EXPLORING A NEW GENERATION OF ENIVIRONMENTAL HEALTH OUTCOME INDICATORS FOR ASTHMA

Ying-Ying Meng, *UCLA Center for Health Policy Research,* University of California, Los Angeles, CA *USA*
Christina Lombardi, *UCLA Center for Health Policy Research, University of California, Los Angeles, CA, USA*
Michelle Wilhelm, *Department of Epidemiology, University of California, Los Angeles, CA, USA.*

Background and Aims: In response to the call for a new generation of outcome-based environmental health indicators for asthma, we investigated the feasibility of combining existing environmental monitoring and state-wide health survey data (California Health Interview Survey (CHIS)) to develop a comprehensive set of health outcome indicators, such as asthma-related emergency department (ED) visits, absences from school/work, medication use, and frequency of asthma symptoms for those with asthma. The current U.S. EPA outcome-based indicators for asthma are limited to prevalence of asthma and asthma attack.
Methods: Linking 2003 CHIS respondents' residential address with ambient air pollution monitoring data within 5-miles, we assessed whether health outcome indicators (e.g., ED visits) are associated with annual average air pollution exposures for criteria air pollutants for CHIS 2003 adults using logistic regression. The analyses were adjusted for age, sex, race/ethnicity, and poverty level.
Results: Higher exposures to O3, PM10, and PM2.5 were associated with taking daily asthma medication (O3: OR, 1.27, 95% CI, 1.04-1.43; PM10: OR, 1.12, 95% CI, 1.01-1.24; PM2.5: OR, 1.263, 95% CI, 1.045-1.52) and ED visits for asthma (O3: OR, 1.19, 95% CI, 0.96-1.47; PM10: OR, 1.20, 95% CI, 1.00-1.43; PM2.5: OR, 1.22, 95% CI, 0.96-1.56). An association was also observed for missed work days due to asthma and PM10, as well as frequent asthma symptoms (daily or weekly symptoms) and PM2.5.
Conclusions: Taking daily asthma medication and ED visits due to asthma may be new health outcome indicators for ozone and particulate matter exposures. Further investigation is needed to see whether missed work days due to asthma or frequency of asthma symptoms could serve as useful indicators.

IS NON-HODGKIN'S LYMPHOMA MORTALITY ASSOCIATED TO PESTICIDE USE IN BRAZIL?

Patricia Boccolini, *IESC/Universidade Federal do Rio de Janeiro, Brasil*
Juliana Chrisman, *ENSP/Fundação Oswaldo Cruz, Brasil*
Rosalina Koifman, *ENSP/Fundação Oswaldo Cruz, Brasil*
Sergio Koifman, *ENSP/Fundação Oswaldo Cruz, Brasil*
Armando Meyer, *IESC/Universidade Federal do Rio de Janeiro, Brasil*

Background and aims: Brazil has been among the main world pesticides consumers. The continued use of pesticides may be associated with the etiology of cancer, such as the non-Hodgkin's lymphoma (NHL). Estimate the correlation between per capita pesticides sales in 1985 and NHL mortality rates between 1996-2005, by Brazilian micro-regions.
Methodology: This is an ecological study where pesticides per capita consumption in 1985 was taken as a population exposure proxy to these chemicals in Brazil. There was studied all the NHL deaths among subjects between 20 and 69 years old, of both sexes, that occurred in the 446 Brazilian regions, out of the urban area, accordingly to the Geography and Statistical Brazilian Institute. These micro-regions were categorized into low, medium, high and very high pesticides consumption, according with per capita consumption quartiles. NHL mortality rates and the rate ratios for each quartile were obtained using the lowest quartile as reference. Spearman correlation were estimated between pesticide exposure and NHL mortality.
Results: A moderate correlation between per capita pesticides consumption and standardized mortality rate for NHL were found (r = 0,597). Employing the micro-regions with low per capita consumption of pesticides as a reference, were observed a gradual increase in NHL risk death according to the consumption quartile of these substance: men - (second quartile – MRR= 1.69, CI 95% 1.68-1.84; third quartile - MRR=2.41, CI 95% 2.27-2.57; fourth quartile - MRR = 2.92, CI 95% 2.74-3.11) and females (second quartile – MRR= 1.87, CI 95% 1.69-2.06; third quartile - MRR=2.28, IC 95% 2.10-2.47; fourth quartile - MRR = 3.20; CI 95% 2.98-3.43).
Conclusion: These results suggest that Brazilian population exposure to pesticides in regions outside the urban areas in eighties may be associated with NHL mortality observed between 1996 and 2005.

BRAZILIAN AGRICULTURAL WORKERS AND NON-HODGKIN'S LYMPHOMA: A DEATH CERTIFICATE CASE-CONTROL STUDY

Patricia Boccolini, *IESC/Universidade Federal do Rio de Janeiro, Brasil*
Juliana Chrisman, *ENSP/Fundação Oswaldo Cruz, Brasil*
Rosalina Koifman, *ENSP/Fundação Oswaldo Cruz, Brasil*
Armando Meyer, *IESC/Universidade Federal do Rio de Janeiro, Brasil*

Background and aims: The use of pesticides in Brazil has been high compared to others countries of the world, and it is important assess the risk of diseases related to the use of this substance, particularly non-Hodgkin lymphoma (NHL) cancer, that has been closely associated with farm work. The aim of this study was to estimate the NHL mortality risk among agricultural workers between 1996 to 2005, in Brazilian southern states.
Methodology: Cases (n=1317) were the NHL deaths occurred between 1996 to 2005, for both men and women, which cause of death were obtained from the Brazilian Mortality Information System (SIM/SUS), classified according to ICD-10 aged between 20 to 69 years old, living in the states of Parana, Santa Catarina and Rio Grande do Sul, in non-urban municipalities (classified according to the IBGE - Brazilian Institute of Geography and Statistics). Controls (n = 2634) were paired by sex, age, year of death and residence state, which the underlying cause of death had not included cancer (ICD10 - C00 - D48) or hematologic disease (ICD10 D 50 -- D89). Occupational data were obtained from the SIM/SUS.
Results: An increased NHL death risk was observed among the agricultural workers aged 20 to 39 years (OR = 1.55 CI95%: 1.10-1.87) compared to non-agricultural workers. In adjusted analysis, there was observed an increased NHL death risk among agricultural workers aged 20 to 39 years (OR =2.06 CI95%: 1.20 – 3.14) compared to non-agricultural workers. Stratification by sex showed that magnitude of non-Hodgkin lymphoma mortality risk was higher for male agricultural workers (OR: 1.31 CI95%: 1.10-1.92) than for female ones (OR: 1.17 CI95%: 1.12-1.80).
Conclusion: Our results suggest that the agricultural workers residents in the South are more likely to die by NHL compared to non-agricultural workers.

IS LOW BIRTH WEIGHT RELATED TO PESTICIDES EXPOSURE IN BRAZIL?

Cristiano Boccolini, *ENSP/Fiocruz, Brazil*
Patrlcia Boccolini, *IESC/UFRJ, Brazil*
Juliana Chrisman,
Armando Meyer, *IESC/UFRJ, Brazil*
Geisiele Veríssimo, *IESC/UFRJ, Brazil*
Márcia Lazaro de Carvalho, *IESC/UFRJ, Brazil*
Raphael Guimarães, *IESC/UFRJ, Brazil*

Background and Aims: Brazil has been one of the biggest global pesticides consumer, and exposure to these substances can affect fetal growth and pregnancy outcomes. The objective is to estimate the correlation of pesticides per capita sales in 1996 with prevalence of low birth weight from 1996 to 1998, among Brazilian micro-regions.
Methodology: This was an ecological study that employed secondary data, aggregated at the micro-regions level (defined by the Brazilian Institute of Geography and Statistics – IBGE). The prevalence of low birth weight in 1996, 1997 and 1998 was obtained from the National Databank System (DATASUS). The per capita pesticides sale in 1996 was analyzed as an indirect measure of population exposure to these chemicals. We estimated the degree of Spearman correlation for the total population, and Prevalence Ratio by quartile of consumption, correlating pesticides exposure and the prevalence of low birth weight.
Results: A total of 452 non urban and 106 urban micro regions clusters was analyzed. Pesticides per-capita consumption in non-urban microregions was directly associated with greater prevalence of children born with low birth weight ($r = 0.403$; $p < 0.001$), with birth weight between 1500 and 2500 grams ($r = 0.366$; $p < 0.001$) and with very low birth weight at birth ($r = 0.476$; $p < 0.001$). In urban areas there was no significant correlation . There was a gradual, and statistically significant, increase in the prevalence ratio of low birth weight as the quartiles of pesticides consumption increases.
Conclusions: The pesticides per capita consumption may affect the prevalence of low birth weight among the non-urban microregions of Brazil, indicating the need to strengthen policies and actions for protecting the health of populations exposed to pesticides, as well as review its use of these substances.

EFFECTS OF PRENATAL AND POSTNATAL EXPOSURE TO CHLORDECONE ON INFANT NEURODEVELOPMENT

Background and Aims: The estrogenic insecticide chlordecone was extensively used from 1973 to 1993 in the French West Indies, to control banana root borer. Its persistence in soils has led to the widespread pollution of the environment including tap water sources and crops. Chlordecone was shown to have neurological effects in humans such as tremor, ataxia, oculomotor dysfunctions and memory loss. Thus, the aim of the study was to evaluate the impact of prenatal and postnatal exposure to chlordecone on the neurodevelopment of 7-month-old infants from Guadeloupe.

Methods: Umbilical cord blood samples (n=169) were collected from newborns and analyzed for chlordecone concentrations (mean = 0.58 ng/L). Infants were tested at 7 months. Visual recognition memory and speed of processing visual information into memory were assessed with the Fagan Tests of Infant Intelligence (FTII), visual acuity with the Teller Acuity Card test and fine motor development with the Brunet Lezine. A maternal interview was conducted to document infant health, diet and family situation. Chlordecone concentrations were quantified in breast milk. Postnatal exposure was determined through frequency of contaminated food consumption by the infants.

Results: In adjusted models, cord chlordecone concentrations in tertile were associated with reduced novelty preference on the FTII in the highly exposed group (β=-0.22, p=0.005), as was consumption of contaminated food (β=-0.15, p=0.038). Postnatal exposure through contaminated food consumption was also related to longer time to process visual information (β=0.18, p=0.045). Detectable levels of chlordecone in cord blood were associated with higher risk of having a score below the third percentile on the fine motor development scale (OR=1.27, p=0.002). Chlordecone in breast milk was not associated with neurodevelopment scores.

Conclusion: These results suggest that pre- and postnatal low chronic exposure to chlordecone is associated with deleterious effects on several domains of neurodevelopment during infancy.

STOMACH CANCER MORTALITY AMONG AGRICULTURAL WORKERS*:* RESULTS FROM A BRAZILIAN DEATH CERTIFICATE-BASED CASE-CONTROL STUDY

Patricia Boccolini, *IESC/Universidade Federal do Rio de Janeiro, Brasil*
Juliana Chrisman, *ENSP/Fundação Oswaldo Cruz, Brasil*
Ubirani Otero, CONPREV/ Instituto Nacional do Câncer, Brasil
Armando Meyer, *IESC/Universidade Federal do Rio de Janeiro, Brasil*

Backgrounds and aims: The use of pesticides in Brazil is very intense. Thus, it is important to assess the risk of diseases related to the use of these substances, particularly stomach cancer, which has been closely associated with pesticide exposure in several studies, especially among agricultural workers. This study aimed to estimate the risk to die by stomach cancer among agricultural workers from an intensive pesticide-use area in Brazil, between 1996 and 2005.
Methodology: Therefore, a death certificate-based case-control study was designed to achieve this objective. Cases were individuals from both genders, 20 or more years old, for whom basic cause of death was stomach cancer. For each case two controls were randomly selected, from the universe of deaths, excluding those from neoplasms and hematologic digestive system diseases. In addition, controls were matched with cases by sex and age. Crude and adjusted odds ratios were then calculated to estimate the magnitude of the risk.
Results: Results showed that agricultural workers were at statistically significant higher risk to die by stomach cancer (OR: 1.41; CI95%: 1.10-1.82) compared to non-agricultural workers. Stratified analysis revealed that the magnitude of such risk was higher among younger (OR: 3.34; CI95%: 1.58-7.08) agricultural workers. Stratification by sex showed that magnitude of stomach mortality risk was higher for male agricultural workers (OR: 1.51 CI%: 1.13-2.02) than for female ones (OR: 1.47 CI%: 1.12-1.93). **Conclusions**: These results suggest that agricultural workers living in the Serrana Region of Rio de Janeiro State were at significantly higher risk to die by stomach cancer compared to non-agricultural workers.

Hepatitis B virus infection among immigrant women in Taiwan

Yu-Jen Lin, *National Health Research Institutes, Taiwan*

Wei-Te Wu, *National Yang Ming University, Taiwan*

Wen-Ru Yu, *Taipei City Hospital-Zhongxiao Branch, Taiwan*

Wei-Han Wu, *China Medical University Hospital, Taiwan*

Trong-Neng Wu, *China Medical University, Taichung, National Health Research Institutes, Taiwan*

Background and Aims Around 15-20% of adults born before 1984 in Taiwan are chronically infected with hepatitis B virus (HBV). A nationwide vaccination program was initated to control HBV infection in Taiwan since 1984. Most countries in Asia have not introduced HBV vaccination into their national immunization agenda. Cross-national marriages have gained increasing popularity in recent years in Taiwan. This study investigated the prevalence of hepatitis B surface antigen (HBsAg) and antibody to hepatitis B surface antigen (anti-HBs) among immigrants from other Asian countries.

Methods This study recruited 595 immigrant women who provided blood samples for HBsAg and anti-HBs tests.

Results The prevalence of HBsAg(+) was 8.4% (50/595), HBsAg(-) and anti-HBs(-) was 50.5% (301/595), and anti-HBs(+) was 40.7% (242/595).

Conclusions Immigrant women were susceptible to HBV infection. Public health agencies should provide vaccination programs to decrease HBV carrier and infection rates for this population.

SKINJEM: A JOB EXPOSURE MATRIX FOR OCCUPATIONAL SKIN CANCER RISK

Cheryl E. Peters, *University of British Columbia, Canada*

Paul A. Demers, *Occupational Cancer Research Centre, Cancer Care Ontario, Canada*

Background and Aims: Estimating occupational exposure to skin carcinogens at a population level is challenging due to a lack of specific tools to do so. The objective of this project is to create a job exposure matrix for skin carcinogens (SkinJEM), flagging industries and jobs with high potential for exposure in Canada.

Methods: SkinJEM is a 2-dimensional matrix created with a standard coding system (n=520) on one axis and exposure categories on the other. Exposures were selected from the CAREX Canada database and IARC monographs. Jobs were flagged as exposed if ≥25% of workers were likely to be exposed. SkinJEM also includes a flag for 'expert re-evaluation', where exposures in a job differ by industry, or where there is textual information available. For situations where exposure is more industry-based than occupationally (i.e. arsenic exposure in wood preservation plants), data lines have been added to reflect this. There is also an indicator of confidence for each job line.

Results: Eight compounds (solar, artificial, and ionizing radiation; PAHs, creosotes, mineral oil, coal-tars; arsenic) in 3 categories (radiation, petroleum-related, metals) were identified. All 520 unique 4-digit job codes were included in the matrix, in addition to all roll-ups to less specific codes (to accommodate varying data quality in epidemiologic studies). Of note, many jobs had expected exposure to several skin carcinogens, including welders in construction, roofers, medical staff in hospitals, and workers in utilities.

Conclusions: Many Canadian workers are potentially exposed to agents that are known to or suspected of causing skin cancer. Through SkinJEM, we have found that these carcinogens may be encountered together in some workplaces. Further research is required to assess the skin toxicity of chemical/radiation mixtures. Next steps will include linkages of SkinJEM to cancer registries to examine risk for melanoma from occupational exposure to skin carcinogens.

MORTALITY AMONG MINERS FROM TWO IMPORTANT MINING REGIONS IN BRAZIL, 1979-2005

Gesiele Veríssimo, *Institute for Studies in Collective Health, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.*
Patricia Boccolini, *Institute for Studies in Collective Health, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.*
Juliana Chrisman, *Postgraduate program in Environment and Public Health, National School of Public Health, Oswaldo Cruz Foundation, Brazil.*
Armando Meyer, *Institute for Studies in Collective Health, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background and Aims – Miners are exposed to risk factors related to their working environment such as coal dust, noxious gases, lack of oxygen, high temperature, metals, and radioactivity. Mining contributes for around 5% of the Brazilian Gross Domestic Product (GDP) and more than 70% of all mines are located in the South and Southeast regions of the country. The aim of this study was to evaluate the mortality by Respiratory Disease (RD) of Brazilian miners from 1979 to 2005, comparing it with that experienced by the general population.
Methods – The data of respiratory disease deaths occurred among Brazilian miners, 20 years or older, resident in the south or southeast regions, were obtained from the Brazilian Mortality Information System (SIM) according to ICD-9 (1979-1995) and ICD-10 (1996-2005). Then, the Mortality Odds Ratio (MOR), stratified by age (20-39; 40-59; <60; 60+ yrs old) and periods of death (1979-1987; 1988-1996; 1997-2005) was calculated.
Results – In both regions, it was observed an increased risk of death by RD among miners for the entire studied period and for all ages, and it was higher among miners of the southeast region (MOR_{SOUTH}1,45 95%CI=1,33-1,59; $MOR_{SOUTHEAST}$1,25 95%CI=1,08-1,45). The youngest strata (40-59 years) had the highest risk of dying by RD (MOR_{SOUTH}1,90 95%CI=1,19-1,45; $MOR_{SOUTHEAST}$1,47 95%CI=1,13-1,91), compared to the oldest strata (60 years or more) in both regions and in all studied periods (MOR_{SOUTH}1,31 95%CI=1,55-2,32; $MOR_{SOUTHEAST}$1,41 95%CI=1,18-1,69). When stratified by selected causes of death, miners showed a statistical significant elevated risk of dying by lung disease due to external agents in both regions (MOR_{SOUTH}14,74 95%CI=12,06-17,99; $MOR_{SOUTHEAST}$26,92 95%CI=19,62-36,07), and this elevated risk was maintained when the population was stratified by period and age.
Conclusions – When compared to general population, Brazilian miners were at higher risk to die by RD, specifically by lung disease due to external agents.

CAREX CANADA: OCCUPATIONAL AND ENVIRONMENTAL CARCINOGEN SURVEILLANCE

Paul A Demers, *Occupational Cancer Research Centre, Canada*
Eleanor S Setton, *University of Victoria, Canada*
Cheryl E Peters, *University of British Columbia, Vancouver, Canada*
Perry Hystad, *University of British Columbia, Vancouver, Canada*
Amy L Hall, *University of British Columbia, Vancouver, Canada*
Hugh W Davies, *University of British Columbia, Vancouver, Canada*
Anne-Marie Nicol, *University of British Columbia, Vancouver, Canada*

Background and Aims: CAREX was created by the Finnish Institute for Occupational Health in the 1990s. It raised awareness regarding occupational cancer, is widely quoted, and used to assess the impact of workplace carcinogens. In 2008 we launched CAREX Canada as a population level occupational and environmental surveillance project. The objectives of the project are to identify how many people are exposed, how and where they are exposed, and their level of exposure.
Methods: CAREX Canada adopted the general approach of the original CAREX project for occupational carcinogens, although estimates are produced at a finer level of resolution and groups (based on industry/occupation) are flagged for potential exposures greater than half the occupational limit. Several different approaches were taken for environmental exposures, including spatial modeling and general risk assessment using published measured concentrations. Environmental estimates were converted into benzene equivalent doses or population-level cancer risks in order to compare the relative contribution from various sources or different exposures.
Results: To date we have assessed exposure to 50 occupational and 30 environmental known and suspected carcinogens. The 10 most common occupational are shift work, solar radiation, diesel exhaust, other PAH-related exposures, silica, benzene, wood dust, lead, asbestos and chromium. In the environment, highest estimated lifetime excess cancer risks (>100/million) were due to formaldehyde (indoor air) and diesel particulates (outdoor air). Elevated risks (>10/million-<100/million) were also predicted for diesel particulates, acetaldehyde, benzene, 1,3-butadiene and total chromium (indoor air); arsenic, chloroform, hexavalent chromium and bromodichloromethane (drinking water); and arsenic (food). Traffic, residential wood burning, and industrial emitters dominate emissions in watersheds and ecoregions.
Conclusions: CAREX Canada is the first program of its kind in Canada. It is raising awareness of the importance of occupational and environmental cancer, providing essential data for prevention, and is already being used for surveillance, risk assessment, and epidemiology.

AMBIENT AIR POLLUTION AND ITS INFLUENCE TO THE CARDIOVASCULAR SYSTEM DISEASE IN ULAANBAATAR CAPITAL CITY OF MONGOLIA

Enkhjargal Altangerel, *Doctorate student of Health Science University of Mongolia, Ulaanbaatar, Mongolia*
Suvd Batbaatar, *Public Health Institute, Ulaanbaatar, Mongolia*
Burmaajav Badrakh, *Ministry of Health, Ulaanbaatar, Mongolia*

Background and Aims: Air pollution is an increasingly serious problem in Mongolia, especially in the capital city of Ulaanbaatar, Darhan and several other urban areas. The purpose of this study is to determine the relationships between air pollutants (PM10, PM2.5, NO2 and SO2) and meteorological parameters (average temperature, humidity, and wind speed) cardiovascular morbidity of all secondary level and tertiary level hospitals of Ulaanbaatar and 8 primary level hospitals.
Methods: This is a cross sectional study using secondary air quality and hospital morbidity and mortality data.
Results: The daily concentrations of PM10, PM2.5, SO_2 and NO_2 had exceeded the MNAAQS mainly in the winter months from November to February. The correlation mainly between cardiovascular disease case admissions with meteorological parameters is because the cold winter conditions and excessive ambient air pollution due to burning raw coal in Ulaanbaatar result in the accumulation of pollutants in the atmosphere. Thus, population exposure to air pollution is increase significantly during winter months. Based on resent study result, during winter 1/3 of cardiovascular system disease admission cases were caused due to average temperature, relative humidity, NO_2, and PM10 and cardiovascular disease also caused due to relative humidity, NO_2, and PM10 level.
Conclusions: So thus, not only fuel based pollutants but also vehicle related pollutants and meteorological conditions also causing onset of cardiovascular system disease. Cardiovascular disease admission more registered among older age group of people. In addition, residents of ger area are more visited to the FGPs than the residents of apartment area. For the chronic cardiovascular disease admission, the highest effects of exposure to the air pollution (PM2.5 and PM10 level) were observed at the second and fourth days of exposure. PM2.5 exposure for cardiovascular system chronic disease admission was significantly higher than the PM10 level.
Keywords : air pollution, Mongolia, hospital admission, cardiovascular system disease

META-ANALYSIS OF HEALTH EFFECTS ASSOCIATED WITH RESIDENTIAL PROXIMITY TO TRAFFIC

Tegan Boehmer, *Centers for Disease Control and Prevention, Atlanta, GA, USA*
Vickie Boothe, *Centers for Disease Control and Prevention, Atlanta, GA, USA*
Arthur Wendel, *Centers for Disease Control and Prevention, Atlanta, GA, USA*
Fuyuen Yip, *Centers for Disease Control and Prevention, Atlanta, GA, USA*

Background and Aims: A growing body of research suggests an association between residential exposure to traffic emissions and a variety of health outcomes, including respiratory and cardiovascular disease and premature mortality. In the U.S., an estimated 30.3 million people live within 500 feet (150 m) of an interstate or highway, and this population is disproportionately low-income and minority. Currently, no national and few state policies exist that address this important environmental health issue. Thus, the U.S. Centers for Disease Control and Prevention conducted a systematic review and meta-analysis of observational studies to better understand the health burden associated with residential proximity to traffic.

Methods: We searched 15 electronic databases for original peer-reviewed articles, abstracts, and dissertations published during 1980–2008. Each reference was independently screened, abstracted, and reviewed for quality by two people. Separate meta-analyses were conducted for each health outcome with enough unique studies. We calculated weighted pooled effect estimates using a random effects model to address variability in study design, assessed study heterogeneity, conducted subgroup analyses, and assessed publication bias.

Results: Over 14,500 references were screened, of which 149 met the inclusion criteria (84 respiratory and allergic diseases, 22 cancer, 10 cardiovascular diseases, 9 reproductive outcomes, 8 mortality, and 16 other). Preliminary analysis of 10 case-control studies suggests that residential proximity to traffic is associated with childhood leukemia (odds ratio=1.5, 95% confidence interval=1.1–2.1); however, the effect estimate varied by study quality and evidence of publication bias was observed. Analysis of other outcomes will be completed by summer 2011.

Conclusions: Roughly 10% of the U.S. population lives near heavy traffic, which may contribute to substantial disease burden, including childhood leukemia. Findings from this review will inform the development of national, state, and local policies to reduce traffic emission exposures and improve population health through zoning and infrastructure changes.

International Society for Environmental Epidemiology — Barcelona, Spain, Sep 13 – 16, 2011

DO RESIDENTS OF SPRAWLING U.S. METROPOLITAN AREAS EXPERIENCE GREATER HEAT- AND AIR POLLUTION-RELATED MORTALITY?

Tegan Boehmer[1], Brian Stone[2], Dana Habeeb[2], Jason Vargo[2], and Fuyuen Yip[1]
[1]*National Center for Environmental Health, Centers for Disease Control and Prevention, Atlanta, GA, USA*
[2]*School of City and Regional Planning, Georgia Institute of Technology, Atlanta, GA, USA*

Word count = 300

Background and Aims: Recent research has found that sprawling U.S. metropolitan regions have experienced double the rate of increase in extreme heat events (EHE) and 50% more high ozone days compared with compact metropolitan regions. During the 2003 European heat wave, heat exposure and elevated pollutant levels were identified as the leading causes of excess mortality. Climate change is projected to increase the frequency and intensity of EHE and air pollution episodes; thus, we sought to examine the link between urban sprawl and climate-induced mortality among large U.S. cities. Specifically, we hypothesize that more sprawling cities have experienced greater mortality from extreme heat and air pollution.

Methods: We compiled a database for 60 metropolitan statistical areas (MSAs) that contains a sprawl index (composite measure of population density, land-use mix, street connectivity, and centeredness) and daily ozone concentrations, meteorological variables, and age-standardized warm-season (May–September) mortality rates from all-cause, cardiovascular disease, and respiratory disease during 1987–2006. We calculated the trend in mortality rates over 20 years using linear regression for each MSA and the correlation between urban sprawl and mortality trends for all 60 MSAs. Second, we determined excess mortality during episodes of concurrent EHE and ozone exceedances and examined the association between urban sprawl and excess mortality using multivariate analysis.

Results: We found a positive correlation between urban sprawl and mortality trends for respiratory disease ($r=0.47$, $P<0.01$) and all causes ($r=0.36$, $P<0.01$), but not for cardiovascular disease. Analysis of excess mortality during episodes of concurrent EHE and ozone exceedances will be completed by June 2011.

Conclusions: The preliminary results from this ecologic study, combined with previous research, suggest that metropolitan structure may be associated with climate-induced mortality from extreme heat and air pollution. These findings will inform practitioners in urban planning and public health on potential climate adaptation strategies.

BISPHENOL A-ASSOCIATED EPIGENOMIC CHANGES IN PREPUBESCENT GIRLS FROM GHARBIAH, EGYPT

Laura S. Rozek , *University of Michigan, Ann Arbor, Michigan, USA*
Amr S. Soliman, *University of Michigan, Ann Arbor, Michigan, USA*
Jung H. Kim, *University of Michigan, Ann Arbor, Michigan, USA*
Maureen A. Sartor, *University of Michigan, Ann Arbor, Michigan, USA*
Ahmed Hablas, *Tanta Cancer Center and the Gharbiah Cancer Society, Gharbiah, Egypt*
Ibrahim A. Seifeldin, *Tanta Cancer Center and the Gharbiah Cancer Society, Gharbiah, Egypt*
Justin A. Colacino, *University of Michigan, Ann Arbor, Michigan, USA*
Muna S. Nahar, *University of Michigan, Ann Arbor, Michigan, USA*
Dana C. Dolinoy, *University of Michigan, Ann Arbor, Michigan, USA*

Background and Aims: There is now compelling evidence that epigenetic modifications link adult disease susceptibility to environmental exposures during specific life stages, including pre-pubertal development. Animal studies indicate that bisphenol A (BPA) may impact health through epigenetic mechanisms. Epidemiological data associate BPA levels with metabolic disorders and reproductive effects. Here, we conducted an environmental epidemiology study of BPA exposure and epigenetics in pre-adolescent girls in Gharbiah, Egypt, hypothesizing that CpG methylation profiles will exhibit exposure-dependent trends.
Methods: Total urinary BPA was measured by the CDC for 46 girls aged 9 to 12. We concurrently evaluated genome-wide CpG methylation using the Infinium HumanMethylation27 array in saliva DNA samples. The Linear Models for Microarray Data (Limma) library in R program was used to model age, BMI, specific gravity, creatinine, and log BPA to predict % change in methylation. Top hits below a p-value of 0.05 were subjected to enrichment analysis including pathway and gene ontology via Molecular Concepts Map (MCM).
Results: Overall, urinary BPA levels were lower in Egyptian girls compared to similarly aged U.S. females as reported in NHANES. CpG methylation varied widely between girls, and BPA levels were associated with less genomic methylation. Pathway analyses indicated that genes with decrease in methylation % associated with BPA were involved in immune function, transport activity, metabolism, and caspase activity. In particular, hypomethylation of CpG targets on chromosome X was associated with BPA. Using the Comparative Toxicogenomics Database, we identified candidate genes with upregulated expression associated with BPA and found that many of the targets had BPA-associated hypomethylation in our sample, and visa versa.
Conclusions: Our data indicate that BPA may affect human health through specific epigenomic modification of genes in relevant pathways. Epigenetic epidemiology holds promise for the identification biomarkers of previous exposure and the development of epigenetic-based diagnostic and therapeutic strategies.

ENVIRONMENTAL TOBACCO SMOKE AND HOSPITALIZATION FOR RESPIRATORY DISEASES AMONG CHILDREN UNDER ONE YEAR OF LIFE IN BRAZILIAN STATE CAPITALS AND FEDERAL DISTRICT

Patricia Boccolini, *IESC/Universidade Federal do Rio de Janeiro, Brasil*
Cristiano Boccolini, *ENSP/Fundação Oswaldo Cruz, Brasil*
Márcia Lázaro de Carvalho, *ENSP/Fundação Oswaldo Cruz, Brasil*

Background and Aim: Passive exposure to tobacco smoke is responsible for diseases related to respiratory system. The objective of this study is to evaluate the relationship between environmental tobacco smoke and hospitalization due to pneumonia, asthma, bronchitis and bronchiolitis among children.
Methodology: This is an ecological study, which had employed Brazilian secondary data (from the Public Health System – DATASUS) of hospitalization among children under one year of life due to pneumonia, asthma, bronchitis and bronchiolitis (as three different outcomes), and the prevalence of tobacco smoking in Brazilian Capitals and the Federal District population as a proxy for enviromental tobacco smoke (obtained from VIGITEL, 2008). The Rate Ratio (RR) of hospitalization was estimated by negative binomial statistical model (CI=95%) for each outcome, adjusted by the Gini Index of the city, and the prevalence of breastfeeding and low birthweight.
Results: We considered for the study 642,792 children under one year of age living in the 26 Brazilian Capitals and Federal District in 2008. The prevalence of smokers in the city population was associated with a higher rate of hospitalization for pneumonia (RR=1.108, 95%CI=1.009-1.216), asthma (RR=1.187, 95%CI=1.047-1.344), and acute bronchitis or bronchiolitis (RR=1.170, 95%CI=1.008-1.357) among children under one year old. The more unequal the conditions of people's income (Gini index) and the higher the prevalence of low birth weight, highest are the rates of hospitalization; and the more prevalent the breastfeeding, lowest are the hospitalization rates.
Conclusion: The prevalence of smoking appears to be associated to hospitalizations for respiratory problems in children under one year of life, and the ecological study was evidenced as an useful tool to evaluate these associations, providing data for policy and public health management.

EVALUATION OF HEARING IN A BRAZILIAN FARMING COMMUNITY EXPOSED TO PESTICIDES

Maria Isabel Kós, *Universidade Federal do Rio de Janeiro, Brazil*
Armando Meyer, *Universidade Federal do Rio de Janeiro, Brazil*
Martha Marcela Bazílio , *Universidade Federal do Rio de Janeiro, Brazil*
Maria de Fátima Miranda, *Universidade Federal do Rio de Janeiro, Brazil*

Introduction: Several studies have shown that chemicals can cause damage to humans and the environment. Although the main focus of studies on hearing health is exposure to noise, studies on the impacts of chemical exposures on hearing ability are becoming more frequent, especially for workers.
Objectives: This study aimed to evaluate the peripheral auditory system, through pure tone audiometry in farmers living in areas of intensive use of pesticides in the State of Rio de Janeiro/Brazil.
Methods: 70 persons of both sexes, residents in a small city, aged between 25 and 59 years, 35 farmers and 35 non-farmers were evaluated. All individuals had their peripheral hearing evaluated by means of audiometry in frequencies of 0.25, 0.5, 1, 2, 3, 4, 6 and 8 kHz. Individuals with external and/or middle ear problem were excluded from the search. All individuals were interviened regarding their health issues, socioeconomic status, education and exposure to pesticides. Hearing loss was considered for thresholds higher or equal to 25dB at any frequency tested.
Results: The frequency of hearing loss was 3.67 times (95% CI: 2.08 to 6.48) among farmers (94.3%) compared to non-farmers (25.7%). Moreover, most of the hearing losses were more observed on high frequencies.
Conclusion: This study suggests that agricultural activity and possible exposure to pesticides increases the risk of hearing loss.

EXPOSURE OF AIR POLLUTION AND CONGENITAL MALFORMATIONS IN STATE OF MATO GROSSO, BRAZILIAN AMAZON

Jane Ignotti, *Federal University of Mato Grosso, Brazil*

Eliane Ignotti, *University of State of Mato Grosso and National School of Public Health, Brazil*

Background and Aim: Exposure to air pollutants has been associated with congenital malformations MC). In the last decade many municipalities of the state of Mato Grosso has shown concentrations of fine particulate matter ($PM_{2.5}$) higher than recommended by the WHO.

Objective: To analyze the association between air pollution from biomass burning and MC during 2000 to 2007 in the municipalities of Mato Grosso, Brazilian Amazon. Methods: Ecological study of the association between MC at birth or at death and air pollution from biomass burning. The dependent variables were the outcomes of birth and/or death with records of any MC and the independent variables were the number of hotspots during the period in study, as a proxy of the concentration of air pollution from the fires, as well as, the percentage of annual hours of $PM_{2.5}$ above 25• g/m^3. Poisson regression models for rates were carried out adjusted by pesticides marketed and HDI for municipalities. Results: Association between the rates of births with MC and the number of hotspots recorded in 2001 (RR: 1.003, 95%:1.0004-1. 00006), with the percentage of $PM_{2.5}$ above 25• g/m^3 in 2004 (RR: 1.007, 95% :1.0003-1.014), and with the HDI for 2005 (RR: 6.48, 95% :4.06-1.03) were verified. There were association between rates of death with MC with the HDI in 2001 (RR: 1.25, 95%:3.50-4.46) and 2004 (RR: 2.01, 95%: 6.41-6.29).

Conclusion: Congenital malformations registered at birth showed a weak association with air pollutants from biomass burning in Mato Grosso.

Association between coarse particles air pollution and hospital admissions for respiratory and cardiovascular diseases in Busan, Korea

Okhee Yi, *Department of Preventive Medicine, Dankook University College of Medicine, Cheonan, Republic of Korea*
Ho Kim, *Graduate School of Public Health, Seoul National University, Seoul, Republic of Korea*
Seung-Hoon Lee, *Inkwang Climate Change Institue, Seoul, Republic of Korea.*

Background and Aims: Research on the health effects of coarse particles, greater than 2.5 μm and 10 μm or less in diameter ($PM_{10-2.5}$) is limited and findings have been mixed. The chemical composition of particulate matter differs by size with more crustal materials in $PM_{10-2.5}$ and more combustion related constituents in $PM_{2.5}$. This study aims to estimate risk of hospital admissions for respiratory and cardiovascular diseases associated with $PM_{10-2.5}$ and $PM_{2.5}$ exposure.

Methods: A dataset was collected from for Busan in Korea, which had daily hospital admission rate for respiratory and cardiovascular disease, meteorological variables (temperature, humidity and air pressure), and $PM_{10-2.5}$ and $PM_{2.5}$ concentrations for the periods 2005–2006. We employed a time-stratified case-crossover design.

Result: There were a total of 126,083 and 137,839 inpatient admissions for respiratory and cardiovascular diseases, respectively. During the study period a 10 $\mu m/m^3$ increase in $PM_{10-2.5}$ and $PM_{2.5}$ were also associated with increase in respiratory disease admissions by 2.91% (95% CI: 2 to3.82) and 0.96% (0.35 to 1.58), respectively. However, when mutually adjusted, the association of $PM_{10-2.5}$ and $PM_{2.5}$ with respiratory disease admission were 0.08% (-0.24 to 0.39) and 0.77% (0.3 to 1.25) for exposure on the previous day of hospital admission, respectively.

Conclusions: After adjusted by $PM_{2.5}$, there was no statistically significant association between coarse particulates and hospital admissions for respiratory and cardiovascular diseases.

IMPACTS OF PARTICULATE MATTER ($PM_{2.5}$) EMITTED FROM BIOMASS BURNING IN THE BRAZILIAN AMAZON REGARDING HOSPITAL ADMISSIONS AND MORTALITY BY CARDIOVASCULAR DISEASES

Eliane Ignotti, *University of State of Mato Grosso and National School of Public Health, Brazil*
Sandra Hacon, *National School of Public Health, Brazil*
Karla Longo, *National Institute of Spatial Research, Brazil*
Saulo Freitas, *National Institute of Spatial Research, Brazil*

Background and aim: Air pollution from biomass burning is an important environmental problem in the Amazon. The aim of this study is to analyze the impacts of exposure of particulate matter emissions from biomass burning in the Brazilian Amazon on hospitalization and mortality by cardiovascular diseases.
Methods: Ecological study using an environmental exposure indicator presented as annual hours percentage (AH%) of $PM_{2.5}$ above 25 • g/m^3. The following outcome variables were considered: rates of hospitalization and mortality due to cardiovascular diseases in elderly. Multiple regressions of outcomes and the predictive variable AH% for $PM_{2.5}$ above 25 µg/m^3 threshold were used. The Human Development Indices (HDI) and average number of blood tests per 100 inhabitants in the Brazilian Amazon region were the control variables.
Results: The association of the exposure indicator (AH%) is significant for the elderly in terms of hospitalization and mortality by cardiovascular diseases (• = 0.01; • = 0,22). For each 1% increase in the exposure indicator there was an increase of 1% in the rate of hospitalization and 22% in the rate of mortality, even controlled by HDI and average number of blood count tests.
Conclusion: The indicator of atmospheric pollution in the Brazilian Amazon region as the annual hour percentage of $PM_{2.5}$ above 25• g/m^3 showed association with the occurrence of cardiovascular diseases in elderly.

BREASTFEEDING PATTERNS EVOLUTION BETWEEN 1999 AND 2008 AND ITS RELATIONSHIP WITH DIARRHEA HOSPITALIZATION

Cristiano Boccolini, *ENSP/Fiocruz, Brazil*
Patrlcia Boccolini, *IESC/UFRJ, Brazil*

Backgrounds and Aims: Breastfeeding prevalence has been increased in the last two decades in Brazil, as pro breastfeeding policy result**.** The objective of this study is to correlate the increase in the prevalence of breastfeeding with hospitalization taxes due to diarrhea.
Metodology: It is an ecological study, with secondary database of Brazilian Capital City and Federal District. The breastfeeding prevalence of 1999 and 2008 was obtained from the "II Pesquisa de Prevalência de Aleittamento Materno" and the under one year of life children population was obtained from National Health Databank (DATASUS) for the same years. The outcome (hospitalization due to diarrhea) was obtained from the Hospitalary Information System (SIH). It was employed a Spearman Correlation and Wilcoxon Correlation as statistical analysis to evaluate correlations and tendencies. A Rate Ratio of diarrhea hospitalization (per 1000 children under one year of life) in 1999 and 2008 was estimated.
Results: 1.329.618 children under one year of life was studied in 1999 and 2008. The hospitalization taxes due to diarrhea had a decrease of 6,96/1000 children between 1999 and 2008 (from 13.18 to 6.22, respectivelly). The increase of exclusive breastfeeding among under 4 months prevalence was correlated with a decrease of hospitalization due to diarrhea (Rho=-0.483, p<0,01), this correlation was stronger for girls (Rho=-0.521, p<0,01) than for boys (Rho=-0.476, p<0,01).
Discussion: The increase of breastfeeding prevalence between 1999 and 2008 seems to reduce hospitalization due to diarrhea at the same period, what brings the importance of public policies that protect, support and promote breastfeeding.

VITAMIN D RECEPTOR POLYMORPHISM INTERACTS WITH SUNLIGHT EXPOSURE IN PARKINSON'S DISEASE IN THE CENTRAL VALLEY OF CALIFORNIA

Nicole M. Gatto, *Department of Epidemiology, School of Public Health, UCLA, USA* ngatto@ucla.edu
Myles Cockburn, *Department of Preventive Medicine, USC, USA*
Janet Sinsheimer, *Departments of Human Genetics, Biomathematics, and Biostatistics, UCLA, USA*
Jeff Bronstein, *Department of Neurology, UCLA, USA*
Beate Ritz, *Departments of Epidemiology, Environmental Health Sciences and Neurology, UCLA, USA*

Background: Vitamin D is a critically important vitamin/hormone that influences numerous biological processes. Evidence from studies including our own suggests that sunlight exposure leading to vitamin D production may be inversely associated with Parkinson's disease (PD) possibly by protecting against oxidative damage.
Methods: We are examining whether variations in genes in the vitamin D biologic pathway coupled with long-term sunlight exposure decreases PD risk among 288 incident Caucasian PD cases and 472 Caucasian population controls enrolled in the Parkinson's Environment and Genes study. Patients were diagnosed between 1998 - 2007 and clinically confirmed as probable or possible idiopathic PD. Controls >65 years were recruited from Medicare or randomly selected residential parcels. We developed a model using geographic information systems (GIS) tools linking geocoded participant addresses with solar radiation data to estimate historical ultraviolet radiation (UV) exposure. We genotyped single nucleotide polymorphisms (SNPs) rs1544410 (BsmI), rs2228570 *(*Fok1) and rs4334089 in the vitamin D receptor (*VDR*) based on previous studies, potential functional relevance or amino acid change.
Results: High lifetime UV (≥90th percentile) weakly protected against PD (OR = 0.78, 95% CI = 0.46, 1.31), compared to levels <90th percentile. Compared to *Fok1* GG genotype, GA (OR = 0.84, 95% CI = 0.56, 1.24) or AA genotypes (OR = 0.95, 95% CI = 0.56, 1.63) were not individually associated with PD. Among subjects with high lifetime UV, carriers of AA genotype had a lower odds of PD (OR = 0.04, 95% CI = 0.01, 0.84) compared to GG genotype; GA heterozygotes experienced some protection (OR = 0.28, 95% CI = 0.05, 1.65). Subjects with both high lifetime UV exposure and AA genotype were less likely to have PD (OR = 0.14, 95% CI = 0.02, 1.29) compared to subjects with combined lower UV exposure and GG genotype.
Conclusions: Results suggest that *VDR* variations may interact with UV exposure, a surrogate for vitamin D, in PD.

AN OCCUPATIONAL EXPOSURE ASSESSMENT OF POLYCHLORINATED DIBENZO-*p*-DIOXIN AND DIBENZOFURANS IN FIREFIGHTERS

Jing-Fang Hsu, *National Cheng Kung University, Taiwan*
How-Ran Guo, *National Cheng Kung University, Taiwan*
Pao-Chi Liao, *National Cheng Kung University, Taiwan*

Background and Aims: Polychlorinated dibenzo-*p*-dioxins and dibenzofurans (PCDD/Fs) are unintentional byproducts of combustion and industrial processes. Firefighters face the risk of occupational exposure to PCDD/Fs. A survey of the PCDD/F levels in firefighters was conducted. Furthermore, we intended to identify potential risk factors associated with the exposure to high PCDD/F levels in firefighters and confirm the presence of high PCDD/F levels in fire accidents.
Methods: Congener-specific analyses of 17 PCDD/Fs were performed on 20 serum samples collected from firefighters and fire scene investigators, and four soot samples that had deposited on the surfaces of the fire helmets and were collected after the firefighters had fought fires.
Results: The PCDD/F concentrations on the helmets that were contaminated by being worn at the fire scenes were 63 - 285 times higher than those on a clean helmet. The median serum PCDD/F concentration of the 16 firefighters (12 pg WHO_{2005}-TEQ g^{-1} lipid) was not different from those of the males from the general Taiwanese population (9.4 pg WHO_{2005}-TEQ g^{-1} lipid). However, the median PCDD/F level in the four fire scene investigators (15 pg WHO_{2005}-TEQ g^{-1} lipid) was higher than those in the male from the general Taiwanese population (Mann-Whitney U test, $p < 0.01$). Furthermore, the serum samples from the firefighters and fire scene investigators, and the soot samples from the fire scenes presented similarly distinctive PCDD/F profiles that had elevated proportions for 10 PCDF congeners.
Conclusions: Firefighters face an elevated risk of occupational exposure to PCDD/Fs due to the large amounts of PCDD/Fs deposited on the surfaces of the fire helmets at the fire scene. The firefighters' thermal protective uniforms provided a protective barrier for exposure to PCDD/Fs. However, the fire scene investigators may have had more occupational exposures to PCDD/Fs due to poor personal protection; however, this requires further investigation.

STRUCTURAL EQUATION MODELING OF INFLAMMATION RESPONSE TO SHORT-TERM LOCAL TRAFFIC POLLUTION EXPOSURE

Emmanuel S. Baja, *Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA*
Joel D. Schwartz, *Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA*
Brent A. Coull, *Department of Biostatistics, Harvard School of Public Health, Boston, MA, USA*
Gregory A. Wellenius, *Center for Environmental Health and Technology, Brown University, Providence, RI, USA*
Pantel S. Vokonas, *VA Normative Aging Study, Veterans Affairs Boston Healthcare System, Boston, MA, USA*
Helen H. Suh, *Environmental Health Program, NORC at the University of Chicago, Boston, MA*

Background and Aims: Some epidemiological studies have reported conflicting results on the effect of traffic-related pollutants on markers of inflammation. An alternative approach is proposed to comprehensively interpret study results and to help advance our understanding of air pollution-mediated biological impacts on inflammation. In a Bayesian framework, we examined the effect of local traffic pollution on inflammation using structural equation models (SEMs).
Methods: We studied measurements of C-reactive protein (CRP), soluble vascular cell adhesion molecule-1(sVCAM-1), and soluble intracellular adhesion molecule-1(sICAM-1) on 816 elderly men from the Normative Aging Study. Using SEMs, a latent variable for local traffic pollution that is reflected by levels of black carbon, CO, NO, and NO_2 was fit to estimate its effect on a latent variable for inflammation that included sICAM-1, sVCAM-1 and CRP. Exposure periods were assessed using 1-, 2-, 3-, 7-, 14-, and 30-day moving averages pre-visit. We compared our findings using SEMs with those obtained using Bayesian linear mixed models.
Results: Local traffic pollution was related to increased inflammation. Results from structural equation modeling showed that a 1 $\mu g/m^3$ increase in local traffic pollution (reference pollutant: BC) exposure was associated with an 8.2% (95% posterior interval (PI), 1.6–15.5%) and 16.3% (95% PI, -2.0–37.8%) increase in mean of inflammation (reference marker: sVCAM-1) 1 and 7 days later, respectively. Additionally, in linear mixed modeling, the percentage change in mean of sVCAM-1 per 1 $\mu g/m^3$ increase in black carbon pollution was also associated 1 [6.4% (95% PI, 3.1–9.9%)] and 7 [9.2% (95% PI, 2.5–16.0%)] days later. Furthermore, results from the SEMs gave consistent larger effect estimates and wider PI than results from the linear mixed models.
Conclusions: Local traffic pollution adversely impacts inflammation in the elderly. Structural equation modeling may be an alternative approach in air pollution-cardiovascular epidemiological studies.

ADVERSE PERINATAL OUTCOMES AND ENVIRONMENTAL HAZARDS USING A WATERSHED APPROACH

Anders C. Erickson MSc, University of Victoria, Canada
Laura Arbour MD FRCPC FCCMG, University of Victoria, Canada
Hing Man Chan PhD, University of Northern British Columbia, Canada

Background and Aims: Environmental contaminants linked to increased risks of adverse perinatal outcomes are varied and numerous. The watershed approach framework is able to accommodate a multi-stressor environment as it focuses on hydrologically-defined geographic regions rather than on a single discharger or specific media (e.g. air, water). This paper examines the feasibility of using a watershed approach in the analysis of environmental contaminants and reproductive health in British Columbia, Canada.
Methods: Point-source pollution data and adverse birth outcomes were mapped using two similar sized but vastly different spatial tessellations of local watershed areas and administrative census subdivision areas. Pollution data was modelled using the cumulative annual release of a substance within both spatial tessellations and visually compared. Similarly, risk ratios of small-for-gestational age, preterm births and congenital anomalies were calculated for both spatial tessellations and a sensitivity analysis performed to assess rate stability.
Results: Unlike administrative census boundaries, watershed areas are independent of population size and therefore were more appropriate to model the environmental hazard data particularly for rural and remote areas with low population densities. With respect to birth outcomes, both tessellations were able to pick up many of the same community-level risk estimates thus confirming and often spatially refining the found result. Due to their slightly larger size, the watershed areas produced more stable risk ratios with less variability when sensitivity analyses were performed (70% vs. 50% of areas remaining significant after sensitivity analysis).
Conclusions: The watershed defines an appropriate small-area unit in which to investigate the cumulative impact of multiple physical, chemical, and biological stressors on human populations.

EXPOSURE TO FINE AND ULTRAFINE PARTICLES OF REGULAR BIKE USERS COMMUTING THROUGH DIFFERENT ROUTES IN SANTIAGO, CHILE

Paulina Pino, *School of Public Health, Faculty of Medicine, University of Chile*
Pablo Ruiz, *School of Public Health, Faculty of Medicine, University of Chile*
Faustino Alonso, *School of Public Health, Faculty of Medicine, University of Chile*
Verónica Iglesias, *School of Public Health, Faculty of Medicine, University of Chile*

Background and aims: In Santiago (Chile), high levels of fine (PM2.5) and ultrafine particles (UFP) might pose a hazard to cyclists who inhale more air volume than those who commute passively. This could be particularly true in less affluent areas with older vehicular fleet. Our objective was to evaluate the exposure of regular cyclists to fine and ultrafine particles during 30' bike rides in four routes differentiated by affluence of the area and degree of vehicular traffic.
Methods: Experimental study with cross-over assignment to 4 routes with different degrees of exposure (high and low vehicular traffic) in two geographic areas socially differentiated in Santiago. 55 healthy bike users of 18-35 y, nonsmokers, were recruited. Informed consent, questionnaire and assignment order to the routes was performed. Measurements were done (n=200) at morning traffic peak hours and participants were brought up directly from their domiciles. On each measurement participants made a ride of 30 minutes along the assigned route. Exposure to PM2.5 (by DUSTTRAK, TSI INC) and ultrafine particles (by P-TRAK, TSI INC) was measured continuously every 1 second.
Results: In affluent areas the means (±SD) for PM2,5 (ug/m^3) was 29.0 (14.7) vs 47.4 (20.7) in the less affluent ($p<0.05$); for UFP (pt/cc) this figures were 45200 (25200) vs 51900 (19600), $p>0.05$. High traffic routes had a mean PM2.5 of 38.6 (17.5) vs 38.1 (22.3) in the low traffic roads ($p>0.05$) whereas for UFP the means were 56700 (22100) for the high traffic routes vs 39100 (19600) for those roads with low vehicular traffic ($p<0.05$).
Conclusion: Differences in PM2.5 for bike users in Santiago seems likely to be determined by contextual characteristics of wider zones in the city. By the other hand UFP have higher variability related to differences in vehicular traffic emissions forming microenvironments within those wider contextual areas.

Pilot study results for a novel system of networked, low cost personal air quality monitors

Ricardo Piedrahita, University of Colorado Boulder, USA
Yifei Jiang, University of Colorado Boulder, USA
Kun Li, University of Colorado Boulder, USA
Lei Tian, University of Colorado Boulder, USA
Xiang Yun, University of Michigan, USA
Lan Bai, University of Michigan, USA
Robert Dick, University of Michigan, USA
Shang Li, University of Colorado Boulder, USA
Qin Lv, University of Colorado Boulder, USA
Michael Hannigan, University of Colorado Boulder, USA

Background and aims: This project uses the latest in personal air quality monitoring to understand the links between location, activity choices and exposure to air pollutants. The aim of the initial user study is to demonstrate the utility of this novel real-time exposure characterization system at developing and comparing distributions of exposure for a small population of students over the course of multiple months.

Methods: The individual personal monitors, referred to as E-pods (exposure-pods), communicate with Android mobile phones via Bluetooth, providing geo-tagged real-time personal pollutant levels and activity logs. We have incorporated low cost sensors, including carbon dioxide, and metal oxide sensors to monitor volatile organic compounds, carbon monoxide, ozone, and nitrogen dioxide. A critical component of the exposure characterization system is calibration; as such details will be presented.

Users and observers may view the exposure, location, and activity data on a web-based GIS interface with built-in analysis tools. In order to track indoor location, a novel WiFi-based room localization system has been built into the mobile phone application.

Results: Calibrations have shown high sensitivity and fast responses for all the sensors. Uncertainty estimates are near +-5% for the metal oxide sensors and near +-2% for the carbon dioxide sensors. Pilot study results are presented from an initial user-deployment of five people. Grouping pollutants by locations and activities showed statistically significant differences in concentrations. Room localization has proven beneficial in this regard.

Conclusions: The personal exposure characterization results are promising and should be of interest to health researchers. Additionally, users and community members have greater awareness and interest in air quality after using the device. There are many opportunities in this area, though the sensors used require significant time and effort for calibration.

TIME TRENDS IN RESIDENTIAL DUST CONCENTRATIONS OF POLYCYCLIC AROMATIC HYDROCARBONS

Stephen Rappaport, UC Berkeley, Berkeley, CA, USA

Background and Aims:
Exposure information gathered after diagnosis in case-control studies is often used to estimate exposures that occurred before diagnosis. For diseases with long latency periods, the delay between exposure and diagnosis presents a challenge for retrospective exposure assessment. The goal of the study is to examine time trends in dust concentrations of polycyclic aromatic hydrocarbons (PAHs) from households participating in the Northern California Childhood Leukemia Study, and assess whether current dust concentrations of PAHs are predictive of past contamination levels.

Methods:
Household vacuum cleaner contents were sampled twice from 203 homes during years 2001-2007 (initial sampling) and 2010 (repeat sampling). Samples (0.2 g) of fine (<150μm) dust were spiked with an internal standard [d^{12}-benzo(*a*)pyrene], extracted by accelerated solvent extraction, chromatographically purified, solvent-exchanged into tetradecane, and spiked with a recovery standard (d^{10}-pyrene). Eight PAHs were analyzed using gas chromatography-mass spectrometry. Using mixed-effects models we will test for trends in PAH levels while estimating the within- and between-household variance components of PAH concentrations in residential dust.

Results:
To date, we have analyzed 116 initial dust samples and will complete analyses for all initial and repeat samples (n=203x2). Because the analyst must be blinded to residential identities while conducting laboratory work, analysis of time trends cannot be conducted until all samples have been analyzed. Time trend results will be presented at the conference. From preliminary analyses, median concentrations for benzo(*a*)anthracene, chrysene, benzo(*b*)fluoranthene, benzo(*k*)fluoranthene, benzo(*a*)pyrene, indeno(*1,2,3-c,d*)pyrene, dibenzo(*a,h*)anthracene, and benzo(*g,h,i*)perylene in these 116 households were 29, 90, 61, 34, 38, 42, 9, and 98 ng/g, respectively.

Conclusions:
By sampling home dust during two distinct periods, we will evaluate household changes in PAH contamination over up to 10 years and assess the suitability of using post-diagnosis concentrations of PAHs in residential dust to estimate pre-diagnosis exposure levels in a case-control study of childhood leukemia.

RESIDENTIAL WOOD SMOKE $PM_{2.5}$ AND A BIOMARKER OF OXIDATIVE STRESS IN ASTHMATIC CHILDREN

Marcy McNamara, *University of Montana, USA*
Erin Semmens, *University of Montana, USA*
TonyWard, *University of Montana, USA*
Curtis W. Noonan, *University of Montana, USA*

Background and Aims: Exhaled breath condensate (EBC) is a biofluid that can be analyzed for biomarkers of respiratory stress. Our randomized trial targets in-home interventions to improve air and quality of life among asthmatic children. Results presented here compare baseline measures of indoor fine particulate matter ($PM_{2.5}$) and EBC biomarkers in these children, as well as results from a clinically recognized Pediatric Asthma Quality of Life Questionnaire (PAQLQ).
Methods: Indoor $PM_{2.5}$ was recorded in 28 woodstove homes over a 48-hour period (DustTrak; TSI). EBC samples were collected using Rtubes (Respiratory Research) and were analyzed for 8-isoprostane, a marker of oxidative stress. Regression analyses were performed to establish the relationships between $PM_{2.5}$ exposure, levels of 8-isoprostane in EBC, and PAQLQ score.
Results: The mean (sd) indoor $PM_{2.5}$ concentration was 48.6 (41.1) $\mu g/m^3$. Mean 8-isoprostane concentrations in EBC were 2.42 (± 4.0) pg/mL. Subjects with 8-isoprostane concentrations above the median had a 0.75 (-1.63, 0.14) point lower mean overall PAQLQ score, relative to those with below-median concentrations, though this relationship was not statistically significant. Subjects with above-median 8-isoprostane tended to have lower PAQLQ sub-scale scores with the strongest effects observed for the activity domain (-0.93, 95% CI: -1.9, 0.07). Observed indoor $PM_{2.5}$ effects on PAQLQ were most pronounced, though still modest, in those with above-median 8-isoprostane in EBC (10 $\mu g/m^3$ increase in $PM_{2.5}$ associated with 0.1 decrease in mean score, 95% CI -0.2, 0.02).
Conclusions: Presented here are baseline observations for approximately 30% of the ultimate cohort. We observed an inverse relationship between 8-isoprostane and PAQLQ scores. Our data suggest that subjects with higher EBC concentrations of oxidative stress markers may be more susceptible to $PM_{2.5}$ exposure effects on PAQLQ. Continued tracking of these and other biomarkers will enable us to evaluate the causal and temporal natures of these relationships.

Profile of lead exposure to children from two socioenvironmental distinct regions of Rio de Janeiro's city

Maíra Lopes Mazoto, *Federal University of Rio de Janeiro, Brazil*
Carmen Ildes Rodrigues Fróes Asmus, *Federal University of Rio de Janeiro, Brazil*
Volney de Magalhães Câmara, *Federal University of Rio de Janeiro, Brazil*
Maria Izabel de Freitas Filhote, *Federal University of Rio de Janeiro, Brazil*
Raphael Mendonça Guimarães, *Federal University of Rio de Janeiro, Brazil*
Mônica Magnanini, *Federal University of Rio de Janeiro, Brazil*

Background and Aims: Lead is a ubiquitous metal in the environment for its natural occurrence and its wide industrial use to which children are particularly sensitive (Ahamed et al., 2005). This work is part of a population survey of chemical exposure, constituting a sub-project that has as target children 8 to 10 years. It is structured as a pilot project conducted in two public schools in the municipality of Rio de Janeiro, whose criterion of choice was to be located in regions with different socioenvironmental characteristics (level of urbanization, pollution sources). The aim of this study was to evaluate lead exposure in schoolchildren of both sexes.
Methods: Cross-sectional study with the study population comprised 270 students. Two questionnaires were applied: in one child and another on the parent / guardian. Anthropometric measurements were taken of the child and performed collection of biological samples (blood and hair nail). The analysis of biological material was performed by ICP-MS. Statistical analysis was performed using SPSS 17.0.
Results: The mean age of the population is 19.9 ± 0797 years. The average concentration of lead in capillary blood of the population studied was 0.0035 mg / dL ± 0.0022, below the limit set by the Centers for Disease Control (CDC) of 10 mg / dL l. There is a statistically significant difference between the schools studied by comparing the concentration of lead in children's blood, in quartiles of distribution. This difference can be explained by environmental pollution that are distinct among the schools studied.
Conclusion: These results suggest that children living in areas with high environmental pollution are more exposed to lead.

Comparing changes in air pollutant concentration before and after cook-stove replacement in rural Ghana

Ricardo Piedrahita, University of Colorado Boulder, USA
Michael Hannigan, University of Colorado Boulder, USA
Rajul Pandaya, National Center for Atmospheric Research, USA
Thomas Hopson, National Center for Atmospheric Research, USA
Mary Hayden, National Center for Atmospheric Research, USA
Christine Wiedinmyer, National Center for Atmospheric Research, USA

Background and Aims: Using novel, low cost, real-time air quality monitors,we performed a pilot study to analyze the impact of transitioning from open flame cooking to efficient, low emission cookstoves (Envirofit) in a region of Northern Ghana where studies of meningitis epidemics and climate are currently underway. These emissions are important since exposure to air pollution may be a contributing factor towards meningitis transmission and susceptibility.
Methods: Monitors were equipped with sensors to measure concentration of total volatile organic compounds (VOCs), ozone, carbon monoxide (CO), and carbon dioxide (CO2). Typical cooking takes place in a enclosed room with an open doorway and burns dried millet stalks between three rocks on which a pot sits. The monitors were placed inside the enclosed cooking areas at 6 sites.
Results: Cooking resulted in elevated concentrations of CO, CO2, and total VOCs. These three pollutants were positively correlated during cooking with correlation coefficients ranging from 0.34 to 0.88. The cookstoves emit between 1/5 and 1/18 of the combusted carbon as CO. During cooking events, concentrations of those three pollutants, which are products of combustion, were negatively correlated with ozone concentrations, as expected since emissions of nitrogen oxides from the cookstoves consume ambient ozone. After installing the cookstoves, CO2 concentrations decreased, but VOCs and CO increased slightly.
Conclusions: Low cost portable monitors are robust and effective at analyzing variations of concentrations over time. We applied these monitors to evaluate the emissions and air quality in kitchens of rural Ghana before and after new cookstoves were put into use. It is yet unclear whether the long-term use of Envirofit stoves will lead to reduced exposure to various air pollutants within kitchens.

A CASE-CONTROL STUDY OF GLIOMAS AND RESIDENCY WITHIN COUNTIES OF POTENTIAL ELEVATED RADON

Background and Aims: The only established environmental risk factor for brain tumors is ionizing radiation. Radon gas is the chief source of natural background ionizing radiation humans encounter. We aimed to assess the association between potential radon levels within residential counties and the risk for gliomas.
Methods: A case-control study, conducted between 2005 and 2009, included 505 cases and 811 hospital controls recruited from the NorthShore University Health System (Illinois) and the Duke University Medical Center (North Carolina) (National Cancer Institute Grant P50 CA108786-01). This study population represented twenty-eight states in the mid-west and southern United States. Residential counties were linked to potential radon levels from the U.S. Environmental Protection Agency's (EPA) Map of Radon Zones using geographic information systems. The EPA determined these levels with five factors: indoor radon measurements, geology, aerial radioactivity, soil permeability and foundation type of structures. Logistic regression analyses, adjusted for age and gender, were completed to estimate odds ratios (OR) and 95% confidence intervals (CI).
Results: Living within a county where potential radon was high or moderate (>=2 pCi/L) (pico Curies per Liter)) versus low (<2pCi/L) resulted in an OR of 2.3 (95% CI:1.9 –2.9). Living within a county where potential radon was high (>4pCi/L) versus low (<2pCi/L) resulted in an OR of 5.6 (95% CI:3.9–8.2).
Conclusions: To conclude, there is evidence in these data of an association between potential elevated radon and gliomas although usage of the EPA Map is limited as a substitute for personal exposure.

SOURCES OF HETEROGENEITY IN THE CORRELATION BETWEEN AMBIENT, OUTDOOR AND PERSONAL CONCENTRATIONS OF PM_{10}: IMPLICATIONS FOR BIAS IN EPIDEMIOLOGIC STUDIES

Katelyn Holliday, *University of North Carolina, Chapel Hill, North Carolina, United States of America*

Background and Aims: Although ambient and outdoor concentrations of particulate matter ≤ 10μm (PM_{10}) are often used as surrogates for personal exposure in epidemiologic studies, the observed correlation between ambient, outdoor, and personal measurements vary. Factors underlying this variation among studies remain poorly understood despite their potential impact on exposure measurement error in PM_{10}-health associations.
Methods: We therefore conducted a systematic review of seven electronic reference databases for literature examining the longitudinal, within-person correlation between ambient, outdoor and personal PM_{10} concentrations.
Results: This review identified 699 studies, of which 15(2%) met inclusion criteria. The studies were published between 1990 and 2009, conducted in five countries, and included 336 participants (age range: 7, 86 years; 14% with chronic obstructive pulmonary disease (COPD)). Of 19 populations represented by the studies, 9(47%) examined ambient-personal correlations and 10(53%) outdoor-personal correlations. The median correlation coefficient (r), based on a median of 9 ambient, outdoor-personal PM_{10} pairs per participant, was 0.48 (range: 0.13, 0.72). There was little evidence of funnel plot asymmetry (P_{Begg}=0.9; P_{Egger}=0.4), but substantial among-study heterogeneity of r (P<0.001). In random-effects meta-regressions, r was higher among studies with ambient, outdoor PM_{10} concentrations at or above the median of 28.9 $\mu g/m^3$ (difference in r: 0.27, 95% confidence interval 0.03, 0.48), with personal: ambient, outdoor concentration ratios below the median of 1.5 (difference in r: 0.34, 95% confidence interval 0.12, 0.53), and in participants without versus with COPD: (difference in r: 0.38, 95% confidence interval 0.10, 0.60).
Conclusions: The observed magnitude and heterogeneity of correlations between ambient, outdoor and personal PM_{10} concentrations are similar to those described by recently published meta-analyses of $PM_{2.5}$. Together, the findings help quantify a common form of measurement error associated with reliance on ambient, outdoor PM mass concentrations as proxies for personal exposure to coarse and fine particulates in epidemiologic studies.

CARDIOVASCULAR MORTALITY AND OCCUPATIONAL EXPOSURE IN AN ALUMINUM COHORT

Sadie Costello, *University of California, Berkeley, USA*
Daniel M Brown, *University of California, Berkeley, USA*
S. Katharine Hammond, *University of California, Berkeley, USA*
Elizabeth M Noth, *University of California, Berkeley, USA*
Ellen A Eisen, *University of California, Berkeley, USA*
Mark R Cullen, *Stanford University, Stanford, USA*

Background and aims: Increased risk of cardiovascular mortality related to combustion-generated particulate matter (PM) in air pollution has become a major public health concern. Although occupational exposures to PM can be orders of magnitude higher than ambient levels, evidence regarding cardiovascular disease risk associated with workplace exposure to PM is scant.
Methods: We examined cardiovascular mortality from 1996 to 2008 in a cohort of over 11,700 aluminum workers which has been under observation for over a decade. Individual level exposure metrics for total PM and $PM_{2.5}$ are being developed for the cohort based on job histories and personal sampling results in smelters, refining and fabrication facilities.
Results: Initial analyses using broad classifications of plant type (smelter vs other) show no increased risk of all-cause mortality among those who worked in a smelter. Thirty percent of the deaths were due to cardiovascular disease (CVD). Stratifying by active versus inactive person-time, we found a 14% increased risk for death from CVD (N = 78) and a 28% increased risk for death from ischemic heart disease (N = 55) for active workers who worked at smelters, although all confidence intervals include the null.
Conclusions: Higher peak and mean PM exposures occurred at smelting facilities compared to refining and fabrication facilities, lending support to the hypothesis that there is an exposure-response association between quantitative exposures to PM and CVD mortality.

Abstract title: PREDICTORS OF INDOOR ENDOTOXIN CONCENTRATIONS IN DUST AND AIR

Noth, Elizabeth, University of California, Berkeley, USA
Hammond, S. Katharine, University of California, Berkeley, USA
Lurmann, Fred, Sonoma Technology Inc., USA
Tager, Ira B., University of California, Berkeley, USA

Background and Aims: Endotoxin, a component of the outer membrane of gram-negative bacteria, has been found to cause airway inflammation. It has been hypothesized that exposure to endotoxin may have a profound effect on asthma sufferers, but little is known about either the exposure levels or the scale of the impact. One goal of the Fresno Asthmatic Children's Environment Study (FACES), a 10-year epidemiology study to evaluate the role of ambient air pollution and bioaerosols on the natural history of childhood asthma, was to understand and evaluate the exposure to airborne and dust endotoxin. Using data collected in the FACES study, we explore these relationships for use in predicting daily indoor endotoxin exposure for FACES participants.

Methods: Daily ambient endotoxin samples were collected at the US EPA Supersite in Fresno, CA from 5/2001-3/2009. From 2/2002-2/2003, intensive air sampling took place at 84 homes with 4-10 matched pairs of indoor and outdoor 24-hr airborne endotoxin (airEU) measurements per home. During these visits, children completed daily lung function tests and health questionnaires. All FACES subjects completed home visits during which bed and floor dust samples (dustEU) were collected for endotoxin analysis. Information on home characteristics, home activities, pets, mildew, and meteorology was collected. These data, as well as the outdoor airEU concentrations, were candidate covariates in a regression analysis.

Results: Endotoxin concentrations at the Supersite show a seasonal pattern of higher concentrations from May to October, the dry season (mean=2.8 vs 0.8 EU/m3), as did outdoor airEU at residences (dry season, mean=5.6EU/m3, wet season: mean=1.1EU/m3); however, the indoor seasonal dependency was weaker. The dustEU did not show seasonality.

Conclusions: Indoor endotoxin concentrations can be predicted using individual home characteristics. This provides a method for calculating the daily individual indoor endotoxin exposure for FACES participants.

USE OF SELF-ORGANIZING MAPS TO CATEGORIZE EXPOSURE PATTERNS IN AIR POLLUTION MONITORING DATA

AUTHOR: John L. Pearce[a*]

AFFILIATION: [a] School of Geography and Environmental Science, Monash University, Melbourne, Australia

Background and Aims: Spatial variation in air pollution processes has presented a problem for exposure classification in time-series studies of air pollution health effects. The aim of this study is to examine the usefulness of self-organizing maps as a means to assess spatial patterns in the air pollution data and relate them to mortality data in a traditional time-series study design.

Methods: A self-organizing map (SOM) has been applied to daily 1-hr maximum nitrogen dioxide (NO2) observations collected by the Port Phillip Bay air monitoring network in Melbourne, Australia over the period of 1999 to 2006 in order to identify spatial patterns of exposure. Smooth maps for each archetype were created using ordinary kriging. Once the archetypes are defined by the SOM, the daily exposure data was then categorized under the archetype in which it is most similar. This produced a time-series of exposure charts that were then compared to daily mortality using the framework of a generalized additive Poisson regression model.

Preliminary Results: The SOM approach produced 20 archetypes in order to display the range of spatial patterns that occur across the monitoring network. Frequency analysis found the average occurrence of any particular type to be 5% with a range of 1 to 9%.

Conclusions: SOMs are a promising method for assessing spatial variation in air pollution data sets. They provide a visualization of spatial patterns in the data and frequency information – powerful tools in understanding space-time data. Moreover, the output provided is suitable for examination of spatial effects on human health in standard time-series approaches.

ASSOCIATION OF SOCIAL AND ENVIRONMENTAL FACTORS WITH PEDIATRIC ASTHMA

Sheryl Magzamen, *University of Oklahoma Health Science Center, USA*
Sara Gale, *University of California, Berkeley, USA*
John Radke, *University of California, Berkeley, USA*
Ira Tager, *University of California, Berkeley, USA*

Background and Aims: Asthma is the most common chronic disease of childhood, affecting approximately seven percent of children in the United States. Evidence has indicated that the social environment and physical environment contribute to asthma prevalence as well as asthma-related morbidity.
Methods: We implemented a geographic information system to determine the relation between ecological level factors and asthma diagnosis and emergency department use in a school-based cohort of adolescent students in Oakland, CA. Social factors were derived from Census 2000 variables from students' census tract; environmental exposures were calculated from distance to non-residential land use designations, toxic release inventory (TRI) sites, and major roadways in the area.
Results: Over a two-year period, 4,017 students completed a brief, in-class asthma survey and provided residential addresses that were able to be geocoded. Controlling for individual level variables, students diagnosed with asthma who resided in the 1st and 2nd quartiles of distance to industrial areas had increased odds of emergency department visits (OR: 1.84, 95% CI: 1.01, 3.36; OR: 1.76, 95% CI: 1.05, 2.94, respectively) ; elevated and non-significant effects were found for asthma diagnosis. Distance to closed-access freeways was not significantly associated with either outcome. With regard to social factors, increases in percent of census tract residents who were currently married was associated significantly to decreased odds of diagnosed asthma (OR: 0.98, 95% CI: 0.96, 0.99). Increases in percent of census tract residents with household income less than $25,000 was significantly associated with odds of asthma diagnosis (OR: 1.03, 95% CI: 1.01, 1.05). When social factors were included in the model, environmental factors were no longer significantly related to outcomes.
Conclusion: Both the physical and social environments are associated with asthma outcomes among adolescents in an urban community. Ecological factors measured have distinct relations with prevalence and morbidity outcomes.

EXPOSURE TO ENVIRONMENTAL TABACCO SMOKE AMONG SOUTH KOREAN ADULTS: A CROSS-SECTIONAL STUDY OF THE 2005 KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY.

Bo-Eun Lee, *Department of Preventive Medicine and Medical Research Institute, School of Medicine, Ewha Womans University, South Korea*
Eun-Hee Ha, *Department of Preventive Medicine and Medical Research Institute, School of Medicine, Ewha Womans University, South Korea*

Background
Studies have identified that environmental tobacco smoke exposure is associated with sociodemographic factors such as age, sex, and socioeconomic status, but few studies have been conducted in South Korea. In this study, the authors investigated the extent of environmental tobacco smoke exposure and factors related in a nationally representative sample of Korean adults.
Methods
The data of 7,801 adults aged 19 years and over collected during the 2005 Korea National Health and Nutrition Examination Survey were analyzed. Information on smoking habits and exposure to environmental tobacco smoke was obtained by self-reports using a standardized questionnaire. Risks of environmental tobacco smoke exposure conferred by sociodemographic variables and behavioral risk factors were evaluated using logistic regression methods.
Results
Overall, 36.1% of nonsmokers (defined as those not currently smoking) and 50.1% of current smokers were found to be exposed to environmental tobacco smoke either at work or at home. Among the nonsmokers, women were more likely to be exposed to environmental tobacco smoke at home (OR=5.29, 95%CI, 4.08-6.67). Furthermore, an inverse relationship was found between education level and the risk of environmental tobacco smoke exposure at home (OR=1.73, 95%CI, 1.38-2.17 for those with a high school education; OR=2.30, 95%CI, 1.68-3.16 for those with a middle school education; and OR=2.58, 95%CI, 1.85-3.59 for those with less than an elementary school education vs. those with a college education or more). In addition, those with office, sales service, or manual labor jobs were found to be at significantly higher risk of environmental tobacco smoke exposure at work than those with professional, administrative, or managerial jobs. Also, the risk of environmental tobacco smoke exposure in the workplace was significantly higher for alcohol drinkers than non-drinkers (OR=1.23, 95%CI, 1.07-1.47). After adjusting for age, sex and education, it was found that those exposed to environmental tobacco smoke at home were more likely to have been admitted to hospital during the previous year (OR 1.26, 95%CI, 1.002-1.66).
Conclusions
In this study of Korean adults, exposure to environmental tobacco smoke at home or work was found to be affected by sex, age, marital status, educational level, and type of occupation. Accordingly, these factors should be given appropriate consideration by those developing policies or interventions designed to control exposure to environmental tobacco smoke.

Title: THE RATE OF CEREBRAL PALSY AND INTELLECTUAL DISABILITY IN CHILDREN OF MOTHERS WITH AN ALCOHOL-RELATED DIAGNOSIS

Presentation type: Oral
Theme: Child Health

Dr. Colleen M O'Leary, National Drug Research Institute, Curtin University, Perth Western Australia
Ms Jenny Bourke Telethon Institute for Child Health Research, Perth, Western Australia
Dr. Helen Leonard Telethon Institute for Child Health Research, Perth, Western Australia
Ms. Heather D'Antoine Menzies School of Health Research, Darwin, Northern Territory
Professor Anne Bartu School of Nursing, Curtin University, Perth, Western Australia
Ms Linda Watson Telethon Institute for Child Health Research, Perth, Western Australia
Professor Fiona Stanley Telethon Institute for Child Health Research, Perth, Western Australia
Professor Carol Bower Telethon Institute for Child Health Research, Perth, Western Australia

Background and Aims: Heavy prenatal alcohol exposure is reported to increase the risk of cerebral palsy (CP) and intellectual disability. However they are difficult to attribute to prenatal alcohol exposure when the characteristic facial features of Fetal Alcohol Syndrome are absent. This paper presents the rate of CP and intellectual disability in a large, population-based cohort of children born in Western Australia (WA) to mothers with an alcohol-related diagnosis.

Methods: The exposed cohort includes all children of mothers with an alcohol-related diagnosis recorded on the WA linked administrative health datasets 1983-2007 and a randomly selected comparison cohort of children of mothers without an alcohol-related diagnosis. The comparison cohort was frequency matched on maternal age within maternal race and year of birth of her child with women at a ratio of approximately 4:1 for non-Aboriginal and 2:1 for Aboriginal women. There were 23,997 children in the exposed cohort (59.2% non-Aboriginal) and 61,325 comparison children. These data were linked with data from the WA Cerebral Palsy Register (n=293 cases) and the WA Intellectual Disability (IDEA) Database (n= 1,502 cases). Children with a documented genetic cause of intellectual disability were excluded from the analyses.

Results: The overall rate of CP was 4.1/1,000 births in exposed and 3.2/1,000 in the comparison children and for intellectual disability the rates were 34.1/1,000 and 18.4/1,000 respectively. Rates varied by Aboriginal status for CP and intellectual disability and by geographical region for intellectual disability. The results of regression analyses investigating the association between the presence of any maternal alcohol-related diagnosis and the timing of the diagnosis in relation to pregnancy and (1) Pre/perinatally and post-neonatally acquired CP and (2) intellectual disability will be presented.

Conclusions: Prenatal exposure to maternal alcohol-related problems increases the risk of CP and intellectual disability, while post-natal exposure also increases the risk of CP.

CHILDHOOD ACUTE LYMPHOCYTIC LEUKEMIA AND ESTIMATED EXPOSURE TO HAZARDOUS AIR POLLUTANTS

Robert Gunier, *University of California, School of Public Health, Berkeley, CA, USA*
Catherine Metayer, *University of California, School of Public Health, Berkeley, CA, USA*
Stephen Francis, *University of California, School of Public Health, Berkeley, CA, USA*
Peggy Reynolds, *Cancer Prevention Institute of California, Fremont, CA, USA*
Patricia Buffler, *University of California, School of Public Health, Berkeley, CA, USA*

Background and Aims: Leukemia is the most common cancer in children and yet there are few established risk factors for the disease. Previous studies evaluating the risk of childhood leukemia associated with exposure to outdoor air pollutants have included all types of leukemia and reported mixed results. Our objective was to evaluate the relationship between childhood acute lymphocytic leukemia (ALL) and estimated exposure to hazardous air pollutants.
Methods: We collected residential history information from 630 cases and 984 controls matched on birth date, sex and race/ethnicity enrolled in the Northern California Childhood Leukemia Study (1995-2008). We used a geographic information system to assign residential addresses to census tracts. Corresponding outdoor concentrations for 20 potentially carcinogenic hazardous air pollutants modeled by the USEPA were used to estimate average ambient concentration during the first year of life and from birth to diagnosis/reference date for the matched cases and controls. We used conditional logistic regression to calculate odds ratios based on the interquartile range of the concentrations of individual air pollutants adjusted for household income.
Results: In multi-pollutant models, we observed an increased risk of ALL with an increase in estimated average ambient concentrations of methylene chloride, a solvent used in residential and industrial settings, equivalent to the inter-quartile range (0.38 $\mu g/m^3$) during the time period from birth to diagnosis date (OR=1.3, 95% CI 1.0 – 1.6). The results were similar for the first year of life. We did not observe significantly elevated odds ratios for estimated exposure to any of the other hazardous air pollutants.
Conclusions: Our results suggest that exposure during the first year of life and over lifetime near a child's residence to higher ambient concentrations of methylene chloride are associated with an increased risk of acute lymphocytic leukemia.

MOBILE PHONES AS PERSONAL ENVIRONMENTAL SENSING PLATFORMS: DEVELOPMENT OF THE CALFIT SYSTEM

Edmund Seto, *University of California, Berkeley, School of Public Health, Berkeley, CA, 94720, USA*
Posu Yan, *University of California, Berkeley, Electrical Engineering and Computer Science, Berkeley, CA, USA*
Philip Kuryloski, *University of California, Berkeley, Electrical Engineering and Computer Science, Berkeley, CA, USA*
Ruzena Bajcsy, *University of California, Berkeley, Electrical Engineering and Computer Science, Berkeley, CA, USA*
Ted Abresch, *University of California, Davis Medical Center, Sacramento, CA, USA*
Erik Henricson, *University of California, Davis Medical Center, Sacramento, CA, USA*
Jay Han, *University of California, Davis Medical Center, Sacramento, CA, USA*

Background and Aims: Mobile phones are pervasive computing technologies that offer opportunities for sensing personal behaviors and exposures to environmental hazards. The CalFit system uses the combination of global positioning system (GPS) and accelerometry on mobile phones for continuous measurements of an individual's time-activity patterns, which can greatly inform spatial and temporal variations in exposures for environmental health studies. As a research platform, CalFit was designed for flexibility, allowing its use in air pollution epidemiology, built environment, and active living research. Here, we describe the development of CalFit's algorithm for estimating energy expenditure for physical activity and minute ventilation for air pollution studies.

Methods: We describe the capabilities of the CalFit software that runs on Android mobile phones, which includes time-location tracking using GPS and the estimation of energy expenditure from triaxial accelerometry. To develop the energy expenditure algorithm, the CalFit phone was compared against the COSMED cardiopulmonary exercise monitor for 24 adult subjects (10 men and 14 women aged 19-59 years) who wore both systems simultaneously during a series of prescribed activities (four levels on treadmill spanning 1-6 mph, stair climbing, sit to stand, lie to stand, jump, and 6-minute walk test). Generalized linear equations were used to estimate COSMED measured energy expenditure and ventilation rate from the CalFit phone's vertical and horizontal accelerometry counts.

Results: In the linear model, CalFit vertical and horizontal accelerometry counts/min were significant predictors (β=0.623 P<0.001 and β=1.65 P<0.001, respectively) of COSMED energy expenditure (R^2=0.80). Inclusion of 2-minute counts improved the linear model (R^2=0.86), as did generalizing the model to account for differences between subjects (R^2=0.81). Moreover, energy expenditure and minute ventilation were linearly related (R^2=0.80).

Conclusions: Environmental epidemiology studies that require the combined assessment of energy expenditure from physical activity, minute ventilation, and time-location patterns may benefit from the CalFit phone system.

Blood Lead Levels and Risk Factors in a Low-Income Latino Population in Seattle, WA USA

Cornelius Van Niel, *Seattle Children's Hospital*

Christine Loftus, *University of Washington*

Nicole Thomsen, *Seattle King County Public Health*

Catherine Karr, *University of Washington*

Background and Aims

This study determined blood lead levels (BLLs) and predictors in a low-income urban Latino pediatric population in the northwestern United States (Seattle, WA). Surveillance for lead exposure is historically rare in this region.

Methods

Study subjects comprised a cross-sectional sample of 278 children ages 1 to 6 years attending a clinic serving largely Mexican American and Central American immigrant families. An interviewer administered questionnaire was conducted with the child's caregiver. Measurement of BLL was done using an ESA Lead Care II analyzer. Comparison to national data and multivariate analysis of known and suspected risk factors was performed.

Results

The geometric mean BLL was 1.43 ug/dL (95% CI: 1.13, 1.79). For comparison, nationally representative data from 2007-2008 estimated the geometric mean BLL for children under age 6 years was 1.51 mcg/dL (95% CI: 1.37, 1.66). Most (252, 91%) had a BLL lower than the Lead Care II limit of detection, 3.3 µg/dL. Two children's (0.7%) BLL was higher than 5 µg/dL. None were above 10 µg/dL.

The most informative predictor of detectable BLL included nationality other than the US or Mexico (OR=16.1; 95% CI: 1.6, 220.7), living in homes built before 1950 (OR=5.1; 95% CI: 1.4, 16.9) and observed to put paint chips in the mouth (OR=3.6; 95% CI: 1.1, 11.2). Culturally specific risk factors such as ingesting Mexican candies, use of home remedies, and use of ceramic or clay food receptacles were not associated with elevated risk of a detectable BLL.

Conclusions

Lead exposure in this urban Latino population appeared comparable to observations in other U.S. children. Sample size and power to fully investigate exposure risk factors was a limitation. These preliminary data support targeted screening based on lead based paint and immigration status as conducted in other pediatric U.S. populations.

Air pollution has been implicated to be associated with a wide range of early responses in the lung, the circulation and even at more distant organs. Oxidative stress, immune activation, changes in autonomic function and direct impact on various organs has been implicated. The paper will describe the identified modes of actions of ambient air pollution. It will highlight the role of the different physico-chemical characteristics of aerosols in inducing systemic responses in humans.
In order to further establish the role of the various hypothesised mechanisms, the genomic variability was assessed as potential modifier of the air pollution responses. The paper will review advances made by candidate gene approaches focussing on the cardiovascular system. This evidence will be contrasted with recent advances of genomic control in relevant response-pathways based on genome-wide association studies.

Environmental tobacco smoke increases the risk of breast cancer among pre- and post-menopausal Mexican women

Olivia Chilian-Herrera, *National Institute of Public Health, Cuernavaca, Morelos, México.*
Kenneth P. Cantor, *formerly of the National Cancer Institute, Rockville, Md, USA; currently of KP Cantor Environmental LLC, Silver Spring, Md, USA.*
Raúl Ulises Hernández-Ramírez, *National Institute of Public Health, Cuernavaca, Morelos, México.*
Lizbeth López-Carrillo, *National Institute of Public Health, Cuernavaca, Morelos, México.*

Background and Aims: Tobacco smoke exposure is considered modifiable risk factor for female breast cancer (BC). According to a recent expert panel report, active smoking (AS) increases the risk of BC by 20%, while the association between environmental tobacco smoke exposure (ETS) or passive smoking, and BC in young non-smoking women, especially premenopausal women, is consistent with causality; however, evidence in relation to postmenopausal status is inconclusive (1).
BC has become the leading cause of female cancer in Mexico with highest incidence in northern states (2). By other hand, 6.5 million Mexican women between 12 and 65 years, who have never smoked, are currently exposed to ETS (3). For that reason the aim was to determine the association between cumulative ETS exposure and AS, and BC in pre- and postmenopausal women residing in northern Mexican states, as well as to explore potential windows of susceptibility.
Methods: We study 504 histologically confirmed incident BC cases and 504 age-matched controls from an ongoing population-based case-control study. AS and ETS lifetime exposure, at home and the workplace, targeting periods of suspected susceptibility, were estimated from direct interviews. Active and passive smokers were compared with never active smokers without a history of ETS exposure. Odds Ratios (OR) were estimated using multivariate logistic regression models, including known reproductive BC risk factors as covariables.
Results: ETS exposure significantly increased BC risk (OR T_3vsT_1=3.31, 95%CI 2.36-4.64, p-trend<0.001) even after stratifying by menopausal status. BC risk was also associated with AS (OR T_3vsT_1=1.49, 95%CI 1.06-2.09, p-trend<0.001). No window of susceptibility was found for ETSS; risk associated with AS increased when women began smoking between menarche and first childbirth.
Conclusions: Our results provide evidence that ETS exposure is a risk factor for both pre- and postmenopausal Mexican women, and confirm that AS is a risk factor for BC.

DEVELOPMENT AND IMPLEMENTATION OF A COMMUNICATION PLAN FOR THE FRESNO ASTHMATIC CHILDREN'S ENVIORNMENT STUDY (FACES)

S Katharine Hammond *University of California, Berkeley USA*
Michelle Wong *California Department of Public Health, USA*
Ilinisa Hendrickson *University of California, Berkeley USA*
Ira B. Tager *University of California, Berkeley USA*
Jennifer Mann *University of California, Berkeley USA*

Background and Aims: Communities are often disappointed in their participation in research studies, sometimes because researchers do not report the results to the community or provide assistance with application of the results to improve the well being of the community. A sense that researchers are indifferent to the community may lead to an unwillingness to participate in future research studies. This communication plan had aimed to assess the communication needs; to establish regular communication; and to communicate results to participants and to stakeholders.
Methods: Communication needs of FACES participants were assessed by a telephone survey of 50 participants. An invitation to participate in an online survey was emailed to 28 relevant organizations and 23 stakeholders from various community, non-governmental, and governmental organizations completed the survey.
Results: The results of interviews and surveys with key stakeholders were used to refine and revise the methods of providing feedback to participants and stakeholders. Regular communication was established with newsletters and fact sheets mailed to participants and a website; these included asthma related news and, later, aggregate study results. Individual results initially provided to participants ceased based on participant feedback. Key project results were communicated via three stakeholder meetings with planners, the Asthma Coalition, and the Fresno Medical Association; information packets were sent to school stakeholders.
Conclusions: This communications plan connected our research team with the participant and stakeholder community, fostered relationships and the collaborations have facilitated participant and community trust and satisfaction with the study, in addition to increasing dissemination of study results.

AIR POLLUTION AND AIRWAY INFLAMMATION: A TIME LAG BETWEEN NO_2 AND O_3

Su Ryeon Noh, *School of Public Health, Seoul National University, Seoul, Republic of Korea*
Sujin Park, *Korea Forest Research Institute, Seoul, Republic of Korea*
Domyung Paek, *School of Public Health, Seoul National University, Seoul, Republic of Korea*

Background and Aims: Although studies have demonstrated that air pollution is associated with adverse health effects, little is thought about a time lag, particularly between NO_2 and O_3. Ozone is a secondary pollutant produced by the reaction of NO_2 in the presence of sunlight. So we observed a time difference between NO_2 and O_3 in detail when we evaluated acute effects of air pollution on biomarkers of airway inflammation.
Methods: The fraction of exhaled nitric oxide (FE_{NO}), a non-invasive measure of airway inflammation, was measured in 939 subjects. Air pollution levels were collected at a stationary monitoring site, and meteorological factors were monitored at a meteorological tower.
Results: NO_2 and O_3 showed a strong negative correlation. Air pollutant concentration was matched with a FE_{NO} level on various lags adjusting age, gender, and meteorological factors. Both NO_2 and O_3 were associated with changes in the FE_{NO}. However, NO_2 and O_3 worked in the opposite direction. When we look the lag structure, NO_2 effects persisted from lag 0 until lag 9, whereas O_3 effects remained from lag 9 up to more than lag 24, prior to FE_{NO} testing. NO_2 and O_3 were significantly associated with 8.3% (lag 0, $p<.0001$) and 11.9% (lag 12, $p=0.0008$) higher FE_{NO} levels over the inter-quartile range of 19 ppb and 14 ppb, respectively.
Conclusions: Short-term increases in NO_2, a pollutant associated with traffic emissions and industry, and O_3, a secondary pollutant formed by the action of sunlight on NO_2, were associated with airway inflammation with an 8~12 hour difference in lag time.

METEOROLOGICAL EFFECTS ON AIRWAY INFLAMMATION AS MEASURED BY EXHALED NITRIC OXIDE

Su Ryeon Noh and Domyung Paek, *School of Public Health, Seoul National University, Seoul, Republic of Korea*

Background and Aims: To study the effect of outdoor weather conditions on airway inflammation as measured by exhaled nitric oxide during summer month in Korea.
Methods: A total of 991 residents were tested the fraction of exhaled nitric oxide (FE_{NO}), a non-invasive measure of airway inflammation during the summer month, August 8-30, 2005. Air pollution and meteorological parameters were obtained from a near ambient air monitoring station.
Results: The average outdoor temperature, relative humidity, and air pressure were approximately 27.3℃, 81.5%, and 1005.7 hPa, respectively during the study. The hourly average of meteorological concentration was matched with a FE_{NO} level on various exposure windows after adjusting for confounders including age, gender, smoking, cough, asthma, allergic rhinitis, bronchial hyper-responsiveness, skin prick, and air pollutants. Ambient temperature, relative humidity, and air pressure were associated with 7.8% (lag 39, p<.0001), 7.8% (lag 8, p<.0001), and 4.9% (lag 37, p=0.0169) higher FE_{NO} levels over the inter-quartile range of 4.3℃, 20.2%, and 4.0 hPa, respectively. The relations of both air temperature and relative humidity with FE_{NO} appear graphically as a very wide U-like shape, and optimum air temperature and relative humidity with lowest FE_{NO} level are about 25-26℃ and 60-70%, ranging from 18.0℃ to 36.9℃ and 32.1% to 99.5% in study month, respectively.
Conclusions: Adverse inflammatory reactions are expected for both below and above the optimum temperature and relative humidity. However, ambient weather conditions of the summer month in Korea should not have too much effect on airway inflammation as measured by FE_{NO} level.

FETAL VOCS EXPOSURE AND INFANTILE NEUROBEHAVIORAL DEVELOPMENT IN MOTHERS AND CHILDREN'S ENVIRONMENTAL HEALTH (MOCEH) STUDY

Bo-Eun Lee, *Department of Preventive Medicine and Medical Research Institute, School of Medicine, Ewha Womans University, South Korea*
Ju-Hee Seo, *Department of Preventive Medicine and Medical Research Institute, School of Medicine, Ewha Womans University, South Korea*
Byung-Mi Kim, *Department of Preventive Medicine and Medical Research Institute, School of Medicine, Ewha Womans University, South Korea*

Background and Aims :Prenatal exposures to VOCs are treated as environmental toxicant which has health effect on fetus and their last of life. However, regarding to postnatal neurobehavioral development, limited studies were done and even failed to find a significant relationship between them. Therefore, we aimed to investigate the relationship between prenatal exposure to VOCs and postnatal neurobehavioral development of 6 and 12month.
Methods: 1,751 pregnant women were enrolled in birth cohort of MOthers and Children's Environmental Health(MOCEH) study from 2006 to 2010. We investigated maternal general characteristics including socio-economic and obstetric characteristics by questionnaires. Environmental hygienist assessed total volatile organic compound(TVOC) and formaldehyde(HCHO) exposure by using passive samplers for 382 pregnant women during pregnancy. After delivery, birth outcomes such as gestational age, birth weight and gender of newborns were obtained from delivery records. Certificated investigators performed baley test for measuring mental developmental index(MDI) and psychomotor developmental index(PDI) of infants on 6 and 12month. After excluding twins, undelivered cases and missing values for important covariates, we used 338 newborn's data and multiple general linear models in statistical analyses(SAS version 9.2).
Results: The median values of TVOC and HCHO were 183.8 and 69.5ug/m3. The mean of newborn's birth weight is 3289.3g and 7cases were low birth weight(2%). The mean of infantile MDI scores were 96.4 and 103.8 at 6 and 12month, and PDI were 96.2 and 96.6 at each point, respectively.
In adjusted model controlled covariates including breast-feeding and maternal education, a quartile increase of TVOC showed statistically significant decrease in MDI(ß=-1.7, SE:0.8. p=0.05) at 6 month, however, not statistically significant decrease in PDI score(ß:-1.2,SE=0.9).
Conclusions:These results indicated that elevated exposure to TVOC of fetal period may decrease postnatal neurobehavioral development during early life.

TITTLE (THE RELATIONSHIP BETWEEN ENVIRONMENTAL FACTORS AND DEVELOPMENT OF ALLERGIC DISEASE OF INFANT OVER THE TWO YEARS IN MOCEH (MOTHER AND CHILDREN'S ENVIRONMENTAL HEALTH STUDY))

Byung-Mi Kim, *Department of Preventive Medicine, School of Medicine, Ewha Medical Research Center, Ewha Womans University*

Eun-Hee Ha, *Department of Preventive Medicine, School of Medicine, Ewha Medical Research Center, Ewha Womans University*

Hyesook Park, *Department of Preventive Medicine, School of Medicine, Ewha Medical Research Center, Ewha Womans University*

Mina Ha, *Department of Preventive Medicine, Dankook University College of Medicine, Cheonan, Korea*

Yangho Kim, *Department of Occupational and Environmental Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Korea*

Yun -Chul Hong, *Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea*

Background and Aims: The prevalence of allergic diseases has increased in Korean children since 1995. Previous studies suggested that environmental factors may influence on the development of allergic diseases, but the relationship between environmental factors and allergic diseases remain unclear. Moreover, research for infant has been limited. The aim of study was to investigate the relationship between environmental factors and development of allergic disease over the two years

Methods: The prospective cohort study of Mothers and Children's Environmental Health (MOCEH) have been built up in 2006 and we enrolled 1,751 women before second trimester of their pregnancy and their partners in 2006-2010. Information on socio-demographic characteristics, psychosocial status, health behavior and environmental exposure were collected from an interview with trained nurses. After delivery, infants were followed up at 6, 12 and 24 months and the mothers are asked for information on hospital visits due to symptoms of atopic dermatitis, asthma and allergic disease such as allergic rhinitis, food allergy, and allergic conjunctivitis using the questionnaire. The relationships between environmental factors and development of allergic disease were measured by the generalized estimating equations (GEE) model. Statistical analyses were performed using SAS statistical software Version 9.1.

Results; Prevalence (%) of hospital visits due to symptoms of allergic disease was increasing with increase of age, even though atopic dermatitis and asthma were decreasing by age. The use of sofa was significantly associated with an increased development of atopic dermatitis of infants during the two years (Adjusted OR 2.87; 95% CI 1.87 to 1.108) after adjusting for gestational age, maternal age, maternal education, infant's sex, parity, breast feeding, postnatal ETS exposure and maternal weight by the GEE. In addition, use of air freshener was also related to increase the risk of allergic disease (Adjusted OR 3.72; 95% CI 1.001 to 1.143).

Conclusions; This study demonstrates that usage of sofa and air freshener may be risk factors that influence on the development of allergic disease. We also plan to examine the relationship among environmental factors, biomarker, and allergic disease using path analysis.

ANALYSIS OF AEROSOL SIZE DISTRIBUTION DURING SAHARAN DUST EVENTS AT MT. CIMONE (ITALY)

Angela Marinoni, *Institute of Atmospheric Sciences and Climate (ISAC), Italy*
Paolo Cristofanelli, *Institute of Atmospheric Sciences and Climate (ISAC), Italy*
Rocco Duchi, *Institute of Atmospheric Sciences and Climate (ISAC), Italy*
Stefano Zauli Sajani, *Regional Agency for Environmental Protection of Emilia-Romagna, Italy*
Paolo Lauriola, *Regional Agency for Environmental Protection of Emilia-Romagna, Italy*
Paolo Bonasoni, *Institute of Atmospheric Sciences and Climate (ISAC), Italy*

Background and Aims: There is a growing concern about the health effects of Saharan dust outbreaks but exposure characterization needs to be largely improved both from a physical and chemical point of view. In this work, we investigated the typical aerosol size distribution observed during Saharan dust outbreaks over Northern Italy.
Methods: Saharan dust outbreaks over North Italy were identified by analysing the hourly number concentration of coarse aerosol particles (geometric particle diameter, Dp >1 μm) observed at the Italian Climate Observatory "O. Vittori" at Mt. Cimone (2165 m a.s.l., Italian Northern Apennines), a global GAW station representative for a wide area extending over South Europe/Mediterranean basin. Here, the coarse aerosol particle are considered a marker of mineral dust transported. These measurements were carried out using a optical particle counter (model 1.109; Grimm, Ainring, Germany) following the experimental protocol described by Marinoni et al.(2008). In order to clearly deduce the Saharan origin of coarse particle peak events, 3D air mass back-trajectories from Mt. Cimone were calculated using the FLEXTRA model. Following Bonasoni et al. (2004), in order to corroborate the Saharan dust event identification, the classification procedure involves satellite data and transport modelling analyses.
Results: We found that Saharan dust outbreaks brought pronounced changes in the aerosol size distribution observed at Mt. Cimone.
Conclusions: Our results suggest that Saharan dust outbreaks can influence aerosol concentration from the accumulation to the coarse mode. Further work should be carried out to clarify the relationship between observed mineral dust size distribution, typical atmospheric transport patterns as well as evolution in time and space of the mineral dust plumes along the transport from North Africa to North Italy.

THE EFFECT OF PM_{10} EXPOSURE ON MORTALITY BY THE TIME OF DEATH

Haeyong Pak, *Department of Epidemiology and Biostatistics, School of Public Health and the Institute of Environment and Health, Seoul National University, Seoul, Republic of Korea*
Okhee Yi, *Department of Preventive Medicine, DANKOOK UNIVERSITY College of Medicine Cheonan, Republic of Korea*
Ho Kim, *Department of Epidemiology and Biostatistics, School of Public Health and the Institute of Environment and Health, Seoul National University, Seoul, Republic of Korea*

Background: Many studies have established PM_{10} effects on mortality. However, it is not clear that the relationship between the time of death and PM_{10} exposure. We focused on the relationship between the time of death and PM_{10} exposure in Seoul, Korea.
Data and Methods: We employed a temperature matched case-crossover design. Mortality data (except accidental death) from the Korean National Statistics Office consisted of records for Seoul, Korea for 2008, and included individual characteristics such as age, address, cause of death and time of death etc. A total of 33,728 deaths were identified, including 8,693 and 1,816 for cardiovascular and respiratory mortality, respectively. Stationary monitoring data of PM_{10} at the 25 sites in Seoul was analyzed together with weather data and hourly data of PM_{10} was acquired.
We divided a day into 3 time groups by subject's time of death followed as: Morning time (1 a.m. to 8 a.m.), Day time (9 a.m. to 4 p.m.), Night time (5 p.m. to midnight).
Result: We found that the associations between PM_{10} and mortality were significant during the morning and day time after 24 hours of lag, but not significant during the night time. During the study period, $10ug/m^3$ increase in PM_{10} with the lag of 24 hour was associated with the increases in morning and day time mortality by 1%(95% CI : 1.002, 1.017), 0.8%(1.001, 1.014), respectively for total mortality, 1%(1.001, 1.031), 1%(1.000,1.028), respectively, for cardiovascular mortality.
Conclusion: The effect of PM_{10} exposure with lag of 24 hour on mortality was different by the time of death. Especially, the effect of PM_{10} on mortality was positively associated for the subjects who died in the morning and during the day. However, the subjects who died at night time showed less association with PM10 than other subjects who died between 1 a.m. and 4 p.m.

THE DEVELOPMENT OF NATIONAL SURVEILLANCE SYSTEM FOR THE CLIMATE CHANGE-RELATED HEALTH IMPACTS IN KOREA

Won-Woong Na, *Ajou University, South Korea*
Su-Nam Jo, *Communicable Disease Surveillance and Reponse Center & Public Health, South Korea*
Hyung-Nam Myung, *Ajou University, South Korea*
Bo-Yuel Choi, *Hanyang University, South Korea*
Hae-Kwan Jung, *Sungkyunkwan University, South Korea*
Eun-il Lee, *Ajou University, South Korea*
Gyeong-Jun Song, *Seoul National University, South Korea*
Jae-Chul Song, *Hanyang University, South Korea*
Jae-Yeon Jang, *Ajou University, South Korea*

Background and Aims: Climate changes have definite influence on health. The assessment and identifying of climate change-related health impacts is required to establish proper policy for government. Korea has developed the national surveillance system to make reliable data for evidence of policy and investigation about epidemiologic characteristic.
Methods: Delphi technique was performed to identify the climate change-related area among the expert. The study made suggestions about the system building by examining the current state of the nation and additionally required elements in order to help to set up a monitoring system in each subarea.
Results: The following field is selected to be monitored: 1) Influences of severe heat, 2) Influences of meteorological disasters, 3) Infectious diseases via insects and rodents, 4) Infectious diseases via water and food, 5) Influences of pollens, allergens, and air pollution, 6) Cardiocerebrovascular and chronic diseases, and 7) Influences of UV light. Heat related-health impact can be monitored by heat stroke patients based on ER, usage status of emergency department or ambulance service, mortality and predictive model for daily mortality. Morbidity due to meteorological disaster, such as injuries, acute diseases, exacerbations of chronic disease or psychological problems like post-trauma stress disorder is monitored as well as mortality. Surveillance system for arthropod and rodent-borne disease is relatively well implemented under statutory infectious diseases monitoring system. Because water-borne or cadiocerebrovascular diseases does not have enough evidence related to climate change, further researches about relation between them are needed. National cancer registry system can be used for UV light-related health surveillance system. Advanced studies for validity of national surveillance systems are conducted and will be performed in 2011.
Conclusions: National surveillance system can be established by use of existing systems and data and improved by compensation for the defects. It will be helpful for making policy and various studies.

THE RELATIONSHIP BETWEEN INDOOR PM_{10} EXPOSURE DURING PREGNANCY AND INFANT NEURODEVELOPMENT : THE BIRTH COHORT OF MOTHERS AND CHILDREN`S ENVIRONMENTAL HEALTH (MOCEH)

Background and Aims : A few studies have reported that the effect of ETS in indoor on infant neurodevelopment. However, most of researches did not deal with infant neurodevelopment for PM exposure. Therefore, the aim of this study was to investigate the association between prenatal PM10 exposure and infant neurodevelopment.
Methods: We collected the eligible data of 1,751 pregnant women from three collaborating centers metropolitan area(Seoul), industrial area(Ulsan), and medium-sized urban area(Cheonan). Questionnaire was composed of residential factors, environmental exposure and general characteristics. We measured indoor PM_{10} for 271 houses. And we estimated for emission rate of indoor PM_{10} by using air exchanges per hour for residential characteristics of questionnaire (i.e., smoker in indoor, number of family, house type). We tested correlation coefficient between estimated and measured indoor PM_{10}. PM_{10} spatial estimations were adjusted to correspond to relevant pregnancy periods (i.e., whole pregnancy and trimesters) for each woman. We measured mental developmental index (MDI) and psychomotor developmental index (PDI) score using bayley test [The Korean Bayley Scales of Infant Development (K-BSID-II)] on 6 month. We examined the relationship between indoor PM_{10} during pregnancy and infant neurodevelopment for among 494 babies on 6 month.
Results: In multiple linear regression model after adjusting for maternal age, education, income, breast milk on 6 month, ETS, and gestational age, MDI was decreased by indoor PM_{10} exposure during first trimester (β=-4.67, SE=0.09) and during total period (β=-3.81, SE=0.18). PDI was decreased by indoor PM_{10} exposure during first trimester (β=-5.86, SE=0.11), during second trimester (β=-2.77, SE=0.14), and during total period (β=-6.03, SE=0.22).
Conclusions: Prenatal exposure to indoor PM_{10} may affect infant neurodevelopment. These results suggest that developing strategies to reduce PM_{10} exposure during pregnancy are required in order to prevent risks for fetal health.

MULTIPOLLUTANT ASSESSMENT OF SHORT-TERM MORTALITY EFFECTS OF FINE PARTICULATE MATTER, ITS CHEMICAL CONSTITUENTS AND GASEOUS POLLUTANTS IN U.S. CITIES.

Kazuhiko Ito, Ramona Lall, Arthur Nádas, Morton Lippmann, George D. Thurston. NYU School of Medicine, Tuxedo, NY, USA.

Zev Ross , ZevRoss Spatial Analysis, Ithaca, NY, USA

Background and Aims: U.S., European, and Canadian multi-city studies have shown relatively consistent short-term mortality effects of particulate matter (PM) and ozone. However, there is less information available for the effects of other gaseous pollutants and the role of PM chemical components. The objective of this study was to identify specific characteristics (e.g., source type) of the air pollution mixture in major U.S. cities.

Methods: We assembled and analyzed mortality and air pollution data for 64 major U.S. cities where fine particulate matter ($PM_{2.5}$), key $PM_{2.5}$ chemical constituents, ozone (O_3), nitrogen dioxide (NO_2), carbon monoxide, and sulfur dioxide were all available for the years 2001-2006. In addition to analyzing individual pollutants, we conducted factor analysis with $PM_{2.5}$ chemical constituents and gaseous pollutants. All-cause mortality risk estimates for the pollutants at lag 0 through 3 days were estimated using Poisson regression models in individual cities, adjusting for temporal trends, immediate and delayed temperature, and day of week. Risk estimates from individual cities were combined in a second-stage random effects model.

Results: Of the criteria pollutants, PM_{25}, NO_2, and O_3 were each associated with all-cause daily deaths, with NO_2 showing the strongest association (e.g., percent excess death of 0.33% [95%CI: 0.17, 0.49] per 10 ppb increase in 24-hr average at lag 1 day). Factor analysis yielded several components that could be interpreted as traffic (EC, OC, NO_2), soil (Al, Si), metals (Pb, Zn), coal (As, Se), sea salt (Na, Cl), and residual oil (Ni, V). Soil and traffic factors showed significant or nearly significant associations with mortality, with magnitudes similar to those for the criteria pollutants per comparable distributional increment, despite the smaller sample size.

Conclusion: Both regional and local pollutants contribute to short-term mortality effects.

Acknowledgement: This research supported by the Health Effects Institute's National Particle Component Toxicity Initiative.

IS THERE SYNERGY IN THE TEMPERATURE AND AIR POLLUTION EFFECTS ON HEALTH? RESULTS FROM THE CIRCE PROJECT IN 10 MEDITERRANEAN CITIES

Antonis Analitis, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Greece*
Klea Katsouyanni, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School, University of Athens, Greece*
Paola Michelozzi, *Lazio Region Department of Epidemiology, Rome, Italy*
Daniela D'Ippoliti, *Lazio Region Department of Epidemiology, Rome, Italy*
Francesca de'Donato, *Lazio Region Department of Epidemiology, Rome, Italy*
Michela Leone, *Lazio Region Department of Epidemiology, Rome, Italy*
Tanja Wolf, *WHO Regional Office for Europe, Climate change, green health services and sustainable development, Rome, Italy*
Bettina Menne, *WHO Regional Office for Europe, Climate change, green health services and sustainable development, Rome, Italy*

Background and Aims: Climate, meteorology as well as air pollution are known to affect health. There is accumulating evidence for synergy between temperature and air pollution. Within the framework of the CIRCE project (Climate Change and Impact Research: the Mediterranean Environment) we studied the joint effects of apparent temperature and air pollution on mortality.
Methods: Mortality, meteorological and air-pollution data from 10 cities around the Mediterranean were available (Athens, Bari, Barcelona, Istanbul, Lisbon, Palermo, Rome, Tel Aviv, Tunis and Valencia). We used GEE models to estimate the confounding and synergistic effects between temperature and air-pollution on total natural and cause-specific mortality. The effect of apparent temperature on mortality was estimated before and after adjustment for air-pollution. To investigate possible synergy we included interaction terms between each pollutant, alternatively and apparent temperature.
Results: The effect of temperature on mortality was consistently smaller when we adjusted for air-pollution. The largest difference was observed when we controlled for PM_{10} which resulted in a reduction of about 15% in the temperature effect estimate. We observed a higher temperature effect in days with higher PM_{10} and ozone concentrations. The synergistic effect was significant in the elderly. Specifically, in a day with low PM_{10} levels (25^{th} percentile of the PM_{10} distribution) the increase in mortality associated with an increase of 1ºC in temperature was 2.37% (95%CI: 1.15-3.60) whilst the increase in days with high PM_{10} levels (75^{th} percentile) was 3.02% (95%CI: 1.71-4.35). The increase in mortality associated with an increase of 1ºC in low and high ozone days was 3.56% (95%CI: 2.36-4.78) and 4.03% (95%CI: 2.65-5.43), respectively.
Conclusions: There is evidence for a synergistic effect between PM10, ozone and high temperature on mortality. Adjustment for particles should be applied in the estimation of the effect of temperature on mortality.

Background and Aims

Increasingly, scientists and consumers alike are concerned about the environmental costs of food, such as greenhouse gas emissions generated by transportation. Food miles, the distance food travels from farm to plate, are used to gauge the environmental impact of food transport. Previous studies have merely assessed transportation distance, fuel consumption, or CO_2 emissions at the aggregate level. We developed a comprehensive method for assessing CO_2 emissions per weight of the edible portion of different types of foods, transported from farm to consumer in California.

Methods

We identified the food distribution networks from production farms to processing plants, to central regional markets/distribution centers of three different food commodity types: produce (grapes), meat (beef), and dry groceries (almonds). Using GIS we mapped the transportation pathways of the trucks for each food and computed CO_2 emissions according to specific fuel efficiencies, payload standards, and distribution practices of a supermarket chain in southern California. Fuel efficiencies were customized as payload changes throughout the distribution network, including empty-truck distance. Additionally, we accounted for commodity-specific changes in weight from source to customer.

Results

Grapes, beef, and almonds travel by road from production farms to southern California consumers 899, 1348, and 1291 miles, respectively. This results in 161, 92, and 400 g of CO_2 emissions per kg of grapes, beef, and almonds, respectively. When adjusting for distance differences from farms to distribution center, the emissions are 130, 110, and 380 g of CO_2 per kg of grapes, beef, and almonds, respectively. These transportation emissions represent 38% for grapes, <1% for beef, and 29% for almonds of the respective production-related greenhouse gas emissions calculated in our previous work.

Conclusions

The presented methodology is a comprehensive approach for assessing the impact of food transportation on climate change. Independent of food mileage, there are commodity-specific transportation emissions.

We tested our model by using three foods: almonds, grapes, and beef.

Although, these studies examined different levels of food transportation systems (e.g., local *vs.* conventional sourcing) and parameters (e.g., fuel efficiency), other important elements were not investigated. Food miles were calculated by modeling distances from sources to central or institutional markets, instead of to the point of purchase; ~~fuel efficiencies were assumed not vary with payload; and weight losses due to spoilage and food processing were not taken into account~~. In this study we developed a methodological framework for comprehensively assessing the CO_2 emissions of food transportation from farm to consumer. We tested our model by using three foods: almonds, grapes, and beef.

First, we identified the geographic source areas in California for the food items of interest using county-level production statistics. A food distribution expert provided information on the locations of the main processing facilities (PF) as well as on the distribution patterns from farm to consumers, locations of distribution centers (DC) and logistics specifics pertaining to one the largest food retailers in southern California. Food-specific distribution pathways were constructed by connecting PFs with consumer point of purchase (POP). Each pathway is delineated through a series of nodes (PF, DC, and POP) and links (the intervening distance vectors). Emissions were quantified for transportation of commodities from agricultural source areas to PFs using midsize trucks, and of processed foods to DCs and to POP by large trailer trucks. Truck and fuel economy data for the U.S. and CO_2 emission factors for transportation fuels were obtained from the EPA, DOT, and DOE. A GIS was used to geocode the food distribution nodes and then to estimate the mileage between them. After the mileage for all truck categories was computed, emissions were calculated according to pre-specified truck- and food-specific maximum freight weights.

Fuel efficiencies were adjusted according to payload variation across the distribution pathways. Empty miles as well as weight losses due to spoilage and food processing were also modeled. Results are summed by means of a common functional unit of grams of CO_2 per Kg of food product at the POP.

THE LEAD-ACID BATTERY FACTORY HARM TO THE SURROUNDING ENVIRONMENT AND POPULATION HEALTH

Libo Pan, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Jinliang Zhang, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Xiuge Zhao, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Ling Liu, *Department of Environmental Pollution and Health,Chinese Research Academy of Environmental Sciences (CRAES), Ministry of Environment Protection, Beijing 100012, China*

Background and Aims: To explore the effects of lead-acid battery factory on surrounding air, water and soil, as well as the impacts to population health neighboring, in order to provide scientific evidences to the strategy of protection and governance.

Methods Literatures in the almost two decades concerning occupational lead contact, lead harm and lead poisoning level in battery manufacturers are analyzed and summarized to investigate the harm status.

Results Lead concentration in air, water and soil exceeds the allowed limit more slightly than before since 1998, and lead accumulation in the body of occupational population and children were higher than the resident around. According to the references, Children's BBL exceeded the allowed level above 70%, and the lead burden of occupational population arranged from 4.8% to 66.7%.

Conclusion The harm of occupational lead contact in our country is relatively serious, so the supervision should be strengthened to ensure the health of workers, staffs and all people involved.

PRENATAL EXPOSURE TO MERCURY AND COGNITIVE AND PSYCHOMOTOR DEVELOPMENT AT FIRST YEAR OF LIFE

Background and Aims: Mercury is a ubiquitous pollutant that is known to be neurotoxic to humans. Vulnerability of the central nervous system to these substances is increased during early development, especially during the prenatal period. Early mother-child cohort studies have reported evidence about deleterious effect of prenatal exposure to mercury, but others did not find it. The purpose of the current study is to assess whether prenatal Hg exposure may affect negatively both mental and psychomotor development among infants in a large population-based cohort study with moderate-high fish consumption.
Methods: Study subjects (n=1683) were participants in the INMA (Environment and childhood) Project, a multicenter cohort study from four areas of Spain (Valencia, Sabadell, Asturias and Gipuzkoa). Cord blood total mercury (T-Hg) was analyzed by atomic absorption spectrometry. Neurodevelopment of the children was assessed around age 14 months using the Bayley Scales of Infant Development. Covariates were obtained through questionnaire.
Results: Geometric mean of cord blood T-Hg was 8.4 µg/L (95%IC: 8.1, 8.7). At the multivariate analysis, including maternal fish consumption, T-Hg did not show an association with mental or psychomotor development delay. An interaction between sex and T-Hg was observed, with a negative association with psychomotor scores in girls (p=0.06) but not in boys.
Conclusions: Overall, prenatal exposure to mercury was not associated with mental or psychomotor development delay at the first year of life. Observed gender differences need to be confirmed by further studies.

HORMONAL CHANGES ASSOCIATED WITH DDT UPTAKE IN YOUNG MALES

Riana Bornman, *University of Pretoria, Pretoria, South Africa*
Rhena Delport, *University of Pretoria, Pretoria, South Africa*
Paulina Farias, *Instituto Nacional de Salud Publica, Cuernavaca, Mexico*
Natalie Aneck-Hahn, *University of Pretoria, Pretoria, South Africa*
Christiaan de Jager, *University of Pretoria, Pretoria, South Africa*

Introduction: The data of a cross-sectional study evaluating male fertility parameters in apparently healthy young men from Limpopo exposed to DDT, mainly from Indoor Residual Spraying (IRS) was analyzed to test for an association between DDT isomers and male hormone levels.
Method: Complete data on plasma DDT isomers, serum total testosterone (t-T) and sub-fractions, estradiol, LH, FSH, albumin and SHBG were available for 198 men - mean (SD) age 23(4) years. Information on life style, anthropometry and exposure to other pesticides was sourced from the questionnaire. Data was normalize using appropriate transformations where indicated. Only hormones significantly correlated with any DDE or DDT isomer ($p<0.2$) were further analyzed through linear regression models. Following bivariate linear regression analyses all independent variables having a statistical association ($p<0.15$) were included in an initial multiple linear regression model for each hormone as dependent variable. A manual stepwise elimination process was followed and variables with a 95% confidence interval not including zero or that changed other coefficients >10%, were kept in the final models. DDT or DDE isomers were introduced separately in each final model keeping the other predictors constant.
Results: Maximum levels for p,p'-DDE, o,p'-DDT and p,p'-DDT were: 997, 42 and 519 µg/g lipid, respectively. Fifty-five percent of subjects reportedly used pesticides and 43% smoked cigarettes (mean two/day for three years). Median (range) t-T and % free-T (%f-T) were 24.1(7.0, 53) nmol/L and 2% (0.6, 3.4%) respectively. Concentrations above reference values were observed for estradiol (27%), SHBG (25%) and bio-available testosterone (bio-T) (36%). Total-T, f-T and bio-T were explained by one or more of the DDT/DDE isomers, as well as other variables (adjusted R2 0.07. 0.06 and 0.05).
Conclusions: The results suggest that exposure to DDT from IRS may be associated with altered sex hormone homeostasis in young men.

Flexible heat-mortality models for projecting climate change impact on health

Keith Dear, *Australian National University, Australia*

Background and Aims: Projecting the future impact of climatic heat on human health requires three inputs:(1) climate changes scenarios, preferably downscaled at least to city-sized geographical areas (statistical divisions); (2) dose-response functions specific to local age-specific sub-populations; (3) consideration of the potential for acclimatisation to a changed environment, whether through physiology, technology or behaviour.This talk addresses the second input: how to arrive at heat-mortality response functions that are robust enough to support reliance on both extremes of the temperature distribution.

Methods: Regression analysis of daily mortality data in Australia in relation to local weather, 1998-2007.

Results: The choice of functional form bears greatly on the balance between reduced impact of cold and increased impact of heat in projected climates to 2050 and 2100 in Australian capital cities.

Conclusions: Care is needed in accurately modelling both ends of the temperature-mortality response function.

CHRONIC EXPOSURE TO ARSENIC VIA DRINKING WATER AND EVALUATION OF HEALTH EFFECTS IN 91 MUNICIPALITIES OF THE LAZIO REGION, ITALY

Daniela D'Ippoliti, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Paola Michelozzi, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Manuela De Sario, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Claudia Marino, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Adele Lallo, *Department of Epidemiology – Lazio Regional Health Service, Italy*
Marina Davoli, *Department of Epidemiology – Lazio Regional Health Service, Italy*

Background and aims: Chronic exposure to arsenic (As) via drinking water is associated to several health problems, i.e. cancers, diabetes, respiratory and cardiovascular diseases. In response, the EC Directive set a limit of As≤10 µg/L in drinking water. In Italy several areas exceed this limit, including 91 municipalities in the Lazio Region.
This study investigates the association between As exposure via drinking water and health effects (mortality, disease incidence) in the 91 municipalities during 1990-2009.
Methods: The 91 municipalities are located in three provinces: Viterbo (60), Rome (22), Latina (9). Mortality and disease incidence for internal malignancies (lung, bladder, kidney, liver, prostate), diabetes, cardiovascular and respiratory disease were investigated. Relative Risks (RR) were calculated for each municipality using cause mortality/incidence rate compared to the rate in the region.
Chronic As exposure was estimated using As level in drinking water from measurements campaigns and developing an indicator based on the subject's residence. Geographical analysis using GIS techniques was performed to identify disease incidence and mortality clusters. To validate the exposure indicator a bio-monitoring study will be conducted in a sub-sample of the population (500 subjects), using urine, blood and hair samples.
Results: Retrospective mortality analysis for the selected causes showed some clusters in exposed municipalities, most evident in Viterbo and Latina provinces. In Rome province, clusters were found only for lung and bladder cancer. The estimated mortality excess for bladder by province varied from +20% in Rome to +39% in Latina. These preliminary results will be better investigated taking into account population levels of exposure and duration.
Conclusions: Chronic exposure to As in drinking water is a major public health concern. Considering the significant impact of high As concentrations on health reported in the literature, future research should focus on the long-term effects of exposure to low-medium concentrations, as in Italy.

INTERACTIONS BETWEEN ENVIRONMENT AND THE IMMUNE SYSTEM IN DEVELOPMENT OF ALLERGIES

Background and Aims
Environmental factors may affect the development of atopic dermatitis, and this has been described to be already effective during pregnancy. The aim of the study was to determine prospectively whether the timing of exposures, prenatal and postnatal, especially the introduction of complimentary food during the first year of life, is associated with the development of atopic dermatitis according to different ages of onset. We further analysed the association between the expression of innate immune genes at birth and atopic dermatitis.
Methods: 1056 children who participated in a birth cohort study (PASTURE/EFRAIM) were included in this study. Atopic dermatitis (AD) was defined by doctor's diagnosis reported by the parents up to 4 years of age in combination with a SCORAD score indicative for atopic dermatitis at 1 year of age. Feeding practices were reported by parents in monthly diaries between the 3rd and 12th month of life. Gene expression of Toll-like receptors (TLRs) and CD14 were assessed in cord blood leucocytes by quantitative PCR.
Results: Prenatal exposure to farm animals and cats was associated with a decreased risk of developing early onset (during the first year of life) AD, but not with AD with first manifestations after the first year of life. The diversity of complementary food introduced in the first year of life was associated with a reduction of the risk of having late onset AD. Elevated expression of TLR5 and TLR9 in cord blood was associated with a decreased risk for doctor's diagnosis of AD. A significant interaction between polymorphisms in *TLR2* and prenatal cat exposure was observed on atopic dermatitis.
Conclusions: The timing of exposure has an influence on the development of atopic dermatitis in children according to the age of onset. Our results suggest a role of the innate immune system in mediating the protective effect of prenatal exposures and a slight effect of gene-environment interaction on the development of atopic dermatitis.

EXPOSURE TO SECONDHAND SMOKE AND ASTHMA AMONG KOREAN ADULTS: RESULTS FROM THE KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY(KNHANES), 2007-2009

Bo-Eun Lee *Department of Preventive Medicine and Medical Research Institute, School of Medicine, Ewha Womans University, South Korea*
Eun-Hee Ha *Department of Preventive Medicine and Medical Research Institute, School of Medicine, Ewha Womans University, South Korea*

Background: Although previous studies have suggested the exposure to secondhand smoke as an asthma risk factor, there is inconsistency between researches. The objective of this study was to evaluate whether an association of exposure to secondhand smoke with asthma exists and its relation is modified by gender.
Methods: The data of 17,240 adults aged 19 years and over retrieved from the Korea National Health and Nutrition Examination Survey (KNHANES IV). Information on outcome measures (ever asthma, current asthma and physician-diagnosed asthma) was obtained by self-reports using a standardized questionnaire. Participants were classified as being exposed to ETS at home if any household member smoked at home. Multiple logistic regression was used, adjusting for age, marital status, education, income, body mass index, smoking and physical activity.
Results: 4.2% of the participants reported having ever-asthma, while the prevalence of current asthma was 2.5%. Exposure to secondhand smoke at home was associated with increased risks of current asthma (OR 1.38, 95% CI 1.05 to 1.81). Men exposed with secondhand smoke relative to unexposed had odds ratios of ever asthma of 1.79 (95% CI 1.05 to 1.81) and current asthma of 2.60 (95% CI 1.64 to 4.11). In addition, a diagnosis of asthma in men was associated with secondhand smoke exposure (OR 2.23, 95% CI, 1.42 to 3.52).
Conclusions: Among Korean adults, exposure to secondhand smoke was associated with asthma and this tendency was observed apparently in men.

Conclusions: Among Korean adults, exposure to secondhand smoke was associated with asthma and this tendency was observed apparently in men.

Health impact assessments driven by classical epidemiological-based models: how reliable are our predictions in systems with feedback? A qualitative dynamical systems assessment

Simon Lloyd, *London School of Hygiene and Tropical Medicine, UK*
Zaid Chalabi, *London School of Hygiene and Tropical Medicine, UK*
Sari Kovats, *London School of Hygiene and Tropical Medicine, UK*

Background and aims: Scenario-based health impact assessment s– such those used to estimate future climate change impacts – are commonly driven by static equations fitted to observed conditions. When using these equations, variable values are changed to reflect scenario conditions, with equation coefficients remaining constant. However, when modelling systems with feedbacks or subject to perturbations, a change of variable value or context may percolate through the system leading to a change in the equation coefficients. In these cases, a static equation may not correctly predict outcomes under scenarios of interest. We use a qualitative dynamical systems approach to demonstrate this.
Methods: We analyse a previously developed regression equation that quantifies the relationship between weight gain, energy intake, and disease. The equation was fitted in a stable setting and then used to estimate population weight gain under various scenarios. Using this framework, we developed a dynamical system incorporating feedbacks. When possible, we quantified relations; when not, we represented them qualitatively (e.g. directionally). We then perturbed the system in various ways and assessed the impact on the coefficients of the original regression equation.
Results: The dynamical model showed that under certain perturbations, the system shifts and settles at a new equilibrium. When this occurs the correlations between the system variables - which represent the coefficients of the original regression equation – also change. This suggests that beyond the situation in which the regression equation was fitted, it does not correctly predict the outcome
Conclusions: This paper has shown that in systems subject to feedback or perturbations, it may not be appropriate to model health impacts under given scenarios using static equations. Additionally, in some situations, qualitative knowledge of relations is sufficient to gain insight into system behaviour and can guide the development of quantitative models.

Korean Research Project on the integrated Exposure Assessment to Hazardous Materials for Food Safety (2010)

Ji-ae Lim, *Dankook University, Korea.,* **Ho Jang Kwon**, *Dankook University, Korea.,* **Ho Kim**, *Seoul National University, Korea.,* **Mi Na Ha**, *Dankook University Korea.*, **Se Young Oh**, *Kyung Hee University, Korea.,* **Jeong Seon Kim**, *National Cancer Center, Korea.,* **Sang a Lee**, *KangWon national University, Korea.,* **Jung Duck Park**, *Chung-Ang University, Korea.,* **Seup Yeong Hong**, *Dong-A University, Korea.,* **Seok Jun Son**, *ChonNam national University, Korea.,* **Hee Soo Pyo**, *Korea Institute of Science And Technology, Korea.,* **Kyung Su Park**, *Korea Institute of Science And Technology, Korea.,* **Gwang Geun Lee**, *DongGuk University, Korea.,***Ki Kyung Jung,** *National institute of Food and Drug Safety Evaluation, Korea*

Background and Aims: "Korean Research Project on the Integrated Exposure assessment to hazardous Materials for Food Safety (KRIEFS)" is established by National institute of Food and Drug Safety Evaluation(NiFDS) in March 2010, this project has been operating for three years(2010-2012) .This is a representative and nationwide bio-monitoring project for environmental exposure and human health in Korea, particularly focused on the exposure from foods and health supplements and herbal medicines .This project is gathering integrated data of exposure to hazardous materials (1st year: Cadmium, Lead, Mercury, Methyl Mercury, 2nd year : Phthalate, Aflatoxine, Bisphenol A, 3rd year :integrated analsys, survey High-risk groups) through simultaneous inspection of food and bio samples(blood, 12hours and spot urine) against representative population - adults, infants, children and teenager, total 4000 people-and identifying hazardous materials exposure history in more comprehensive method, in order to protect public from exposure to hazardous materials through food, hebal medice and health supplements food.

Methods: Sample design-This project is a nationwide population survey.Selected sample groups are representative with regard to age, gender, region (urbal/rural). Samples were selected from the whole nation in 6 provinces (do), except Jeju-do. (Include Seoul, Gyeonggi, Gangwon, Chungcheong, Jeonra, Gyeongsang). Sample group's ages are from infant(include mother), schoolchild (elementary, junior, high) to adult, The total number of samples are more than 4000 over 2 years.

Survey-This project has 4 categories of survey; first, Investigating concentration of hazardous metrials in foods, health supplements and herbal medicines; second, dietary intake survey, third,human biomonitoring of exposure and health effect(questionnaires,clinical test, blood, 12hours and spot urine); fourth, analyzing of hazardous chemicals in food, hebal medicine and health supplements food. And residual components among the chemicals in body.

Results: In 2010 survey, we investigaed concentration of hevey metals (Cadmium, Lead, Mercury, Methyl Mercury) in foods (total 3,820 samples from 7 metropolis in the nationwide), health supplements and herbal medicines (total 679 samples from survey targeted groups), and surveied dietary intake survey and human biomonitoring of exposure and health effect. (total 2032 samples, infant 267, infant's mother 271, schoolchild 498, and adult 996) and analyzing of lead in food and residual components in body.

The average blood lead levels of adult is 1.29 μg /dL, accoding to sex, age, region can see that men (women 1.15 μg /dL, men 1.55 μg /dL), older age groups (18-29; 0.79 μg /dL 60<; 1.7 μg /dL), smaller towns (1.45 μg /dL, metropolis 1.12 μg /dL) trend to have greater level in lead.

Conclusions: This project is a representative and nationwide bio-monitoring project for environmental exposure and human health in Korea, particularly focused on the exposure from foods and health supplements and herbal medicines. In 2010 survey, we investigaed concentration of hevey metals (Cadmium, Lead, Mercury, Methyl Mercury) in foods, health supplements and herbal medicines and surveied dietary intake survey, human biomonitoring of exposure and health effect. and analyzied lead in food and residual components in body.

The average blood lead levels of adult can see that man, older age groups, and smaller town's trend to have greater level in lead.

Background and Aims. Work package 5 of the European multicenter ESCAPE project aims to delineate the role of long-term exposures to ambient particles in cardiovascular disease development and coronary artery and cerebrovascular disease incidence. Specifically the impact of ambient air pollution on markers of inflammation, and gene-environment interactions (aim1), on blood pressure and prevalence of hypertension (aim2), on the risk for build-up of preclinical atherosclerosis measured by intima-media thickness (IMT) of the carotid artery (aim3), and on incident coronary events (aim4) will be evaluated.

Methods. The 14 contributing adult cohort studies originate from Austria, Denmark, Finland, Germany, Italy, Norway, Spain, Sweden, and Switzerland and cover different geographical regions within Europe. All participating cohorts assessed the spatial variability of PM_{10}, $PM_{2.5}$ and NO_x within their communities based on the ESCAPE exposure protocol.
City-specific analyses with subsequent pooling of the regression coefficients applying methods for meta-analyses are underway and first results will be shown. Endpoint-specific confounders and effect-modifiers are considered and include e.g. gender, age, BMI, smoking, alcohol intake, social class indicators, dietary variables, and noise.

Results. A different set of cohorts will participate in each specific aim. There are 8 cohorts contributing to aim1 with 32,000 participants, 14 cohorts to aim2 with 228,800 participants, and 4 cohorts to aim3 with 9,500 participants. 9 cohorts participate to aim4 with a study population of 120,000. The follow-up time varied between studies ranging from 15 months to 15 years.

Conclusions. The project will provide important information for the assessments of the role of ambient air pollution on the development of cardiovascular disease integrating effects of pollution on systemic inflammation, hypertension, atherosclerosis, and incident events. Thereby, ESCAPE will provide important information for estimating the overall public health impact of air pollution and for developing prevention strategies for at risk populations based on air quality measures.

IMPACT OF MOTORISED TRAFFIC OF THE NEIGHBORHOOD ON THE INDIVIDUAL WALKING BEHAVIOUR: A MULTILEVEL ANALYSIS

Marta Olabarria, *Agència de Salut Pública de Barcelona, Spain Email: molabarr@aspb.cat*
Katherine Pérez, *Agència de Salut Pública de Barcelona, Spain*
Elena Santamariña-Rubio, *Agència de Salut Pública de Barcelona, Spain*
Francesca Racioppi, *WHO European Region*

Background and aims: Motorised traffic may discourage people walking. The main objective is to examine whether motorised transport volume influences the level of walking for transportation measured at individual level, and whether this association persist after controlling for the individual characteristics of the person who travel, and for the environmental and road safety characteristics of the neighbourhoods in Barcelona (area level).
Methods: A cross-sectional multilevel study will be developed. Individual socio-demographic and mobility information was obtained from the 2006 Daily Mobility Survey. 32.343 individuals older than 3 years reported travelling in a workday in Barcelona. Data were aggregated to calculate the total number of motorised trips made in each neighbourhood. Data about the environmental characteristics of the neighbourhoods, in terms of connectivity, aesthetics, land use mix and density, were obtained from the Barcelona Council's Register. Data of road traffic injuries were obtained from the Crash Register of the local police of Barcelona where each collision is geocoded. Road safety indicators include rate of people injured in each neighbourhood in 2004-2008 per 10.000 person who travelled and per 10.000 trips made. Multilevel models will be used to estimate associations between individual levels of walking and motorised traffic volume of the neighbourhood, controlling for individual and neighbourhood variables (environmental, road safety and traffic volume related).
Results: Ecological analysis, using neighbourhood as the unit of analyses, are presented as preliminary results. In each neighbourhood 27.0%[95%CI 23.9-30.0] of the trips made are motorised, ranging from 17.3% in the less motorised to 51.6% in the most one. The total number of motorised trips of the neighbourhood predicted 63% of the variance of the percentage of people who walked in each neighbourhood, $p < 0.001$.
Conclusion: Motorised traffic volume varies across the neighbourhoods and may influence walking behaviour. Results of the multilevel analyses will be presented.

PESTICIDE CONSUMPTION AND PERINATAL OUTCOMES IN BRAZIL

Raphael Guimarães , Federal University of Rio de Janeiro/ Institute of Studies in Public health

Isabel Braga, Federal University of Rio de Janeiro/ Institute of Studies in Public health

Cristiano Boccolini, Oswaldo Cruz Foundation/ National School of Public Health

Patrícia Boccolini, Federal University of Rio de Janeiro/ Institute of Studies in Public health

Gesiele Veríssimo, Federal University of Rio de Janeiro/ Institute of Studies in Public health

Maíra Mazoto, Federal University of Rio de Janeiro/ Institute of Studies in Public health

Juliana Chrisman, Oswaldo Cruz Foundation/ National School of Public Health

Background and Aims: to evaluate the degree of correlation between pesticide consumption in all brazilian´states in 2000 and perinatal outcomes the period between 2001 and 2005.
Material and Methods: Informations about perinatal outcomes occurred in children born from 2001 to 2005 were collected from National Birth System. Spearman´s correlation coefficients were obtained for pesticide consumption (per capita), total and types (herbicide, acaricide, fungicide, insecticide) and the following types of perinatal outcomes: low birth weight, preterm delivery, sex ratio and congenital abnormalities and twin births. In addition, ststes were divided into three groups according to their level of pesticide use (tertiles) and prevalence ratios were then calculated using first tertile as reference.
Results: Pesticide consumption showed moderate positive correlation with congenital abnormalities (r=0,469, p=0,016), low birth weight (r=0,498, p=0,010), preterm delivery (r=0,419, p=0,033), criptorchidism (r=0,452, p=0,020), spontaneous abortion (r=0,499, p=0,009) and twin birth (r=0,672, p<0,001). We also observed weak and non-significative negative correlation between pesticide consumption and sex ratio (r=-0,383, p=0,053). For most of perinatal outcomes, perinatal outcomes´ prevalence rates were higher in the states of moderate (2^{nd} ertile) and high (3^{rd} tertile) pesticide consumption.
Conclusions: Moderate-to-high correlation coefficients between pesticide consumption and some perinatal consumption were observed. The results suggest that population exposure to pesticides in 1999 in Brazilian states may have been associated with selected types of perinatal outcomes in the 2000s.

RESIDENTIAL TRAFFIC EXPOSURE AND HYPERTENSION IN AUGSBURG, GERMANY

Wolf, Kathrin, Institute of Epidemiology II, Helmholtz Zentrum München - German Research Center for Environmental Health, Germany
von Klot, Stephanie, Institute of Epidemiology II, Helmholtz Zentrum München - German Research Center for Environmental Health, Germany
Heber, Anne, Institute of Epidemiology II, Helmholtz Zentrum München - German Research Center for Environmental Health, Germany

Thorand, Barbara, Institute of Epidemiology II, Helmholtz Zentrum München - German Research Center for Environmental Health, Germany
Heinrich, Joachim, Institute of Epidemiology, Helmholtz Zentrum München - German Research Center for Environmental Health, Germany
Cyrys, Josef, Institute of Epidemiology II, Helmholtz Zentrum München - German Research Center for Environmental Health, Germany and ESC-Environmental Science Center, University of Augsburg, Augsburg, Germany
Peters, Annette, Institute of Epidemiology II, Helmholtz Zentrum München - German Research Center for Environmental Health, Germany

Background and Aims. It has been suggested that long-term exposure to air pollution may lead to chronic increase in arterial blood pressure possibly resulting in hypertension. In this study, we investigated the influence of long-term residential traffic exposure on the prevalence of hypertension.
Methods. We used data on 9116 individuals aged 25 to 74 years who participated in the cross-sectional MONICA S3 (1994/95) and the KORA S4 (1999-2001) surveys conducted in the region of Augsburg, Germany. The residential traffic exposure was assessed by specifying daily traffic intensity of and distance to nearest street, and of daily traffic load (sum of product of traffic intensity and length of all segments divided by area) and total road length within buffers of 50, 100 and 300 meters around the residences. Hypertension was defined according to the AHA definition as systolic blood pressure $\geq$140 mmHg or diastolic blood pressure $\geq$90 mmHg. We used logistic regression adjusting for age, BMI, education, alcohol consumption, LDL-cholesterol and smoking status. Additionally, sex was examined as effect modifier.
Results. Traffic load within a radius of 100 meters of a person's residence was associated with an elevated risk for the prevalence of hypertension with an odds ratio of 1.05 (95% CI, 1.01 to 1.10) per increase in 36.2 vehicles/(day*m). The odds ratio for participants living near major roads within 100 meters compared to other persons was 1.14 (95% CI, 1.01 to 1.28). Results for 50 meter buffers were similar. Traffic intensity of the nearest road and inverse distance to nearest road showed positive but not significant effects. Almost 60% of participants with hypertension were male. However, in stratified analyses significant associations were found in women only.
Conclusions. Long-term residential exposure to high traffic may induce hypertension. An influence only in women has to be verified by other studies.

CATALUNYA ESCAPE LUR MODEL PERFORMANCE IN COMPARISON TO LOCALLY DEVELOPED MODELS.

Background: The crux of ESCAPE (European Study of Cohorts for Air Pollution Effects) is uniform air pollution exposure assessment methodologies applied to 37 study areas across Europe. Land Use Regression (LUR) models are developed for within-city to large regional scales to capture air pollution spatial variability. Catalunya, Spain, presents interesting opportunities to compare the large area ESCAPE model with two LUR models estimated specifically for local cohorts. Our aim is to compare ESCAPE NO_2 models with more measurement-intensive locally-derived LURs, keeping in mind different modelling philosophies in the three projects.
Methods: The Catalan ESCAPE LUR model domain is 513 km^2, including the Sabadell-INMA study area (38km^2), and the REGICOR region of Girona (375km^2, including 12 towns). We discuss differences in methodologies (monitoring campaign spatial-temporal coverage, NO_2 samplers, input variables) to contextualize contrasting model results. We regress the three model outputs against values measured from the project monitoring campaigns, and against predictions made at cohort subjects' addresses. Further we will: estimate Pearson's correlations and Bland&Altman plots testing agreement between different measures, visualize spatial patterns of discrepancies between models, and perform stratified analyses comparing conditions affecting model performance (urban, rural, semi-urban, high-to-low traffic).
Results: The Catalan ESCAPE LUR model, based on 80 measurement-sites, has a leave-one-out crossvalidation R^2 of 0.69. Initial results show that it explains in Sabadell 55% of the variability in the 57 INMA measurement-sites, and 31% of the 547 REGICOR measurements. The Sabadell model explained 74% and the REGICOR model 47% of the variability measured at the ESCAPE sites.
Conclusion: The region-wide ESCAPE model explains less variability in measured NO2 in Sabadell and Girona region than suggested by the cross-validation R2. It explains more variance in our within-city than our larger regional scale context. Further analyses are being conducted. We discuss result interpretations given contrasting model development contexts, and lessons learned for ESCAPE model applications.

IMPROVING ESTIMATES OF TRAVEL ACTIVITY AND AIR POLLUTION EXPOSURE THROUGH UBIQUITOUS SENSING TECHNOLOGIES

Background: Travel activity may have important influences on health, potentially contributing meaningfully to both physical activity (PA; walking and cycling) and inhaled air pollution. Ubiquitous sensing technology is a promising innovation to track locations of travel activity and associated levels of energy expenditure. We present results of a pilot study testing the use and performance of Calfit, a novel smart-phone based software that continuously records geo-positioning and PA estimated from an accelerometer integrated into Android cell-phone technology.
Methods: We equipped 36 volunteers with an Android phone that had Calfit software installed. Subjects were monitored during 5 days of regular activities in Barcelona, Spain. Volunteers kept a travel diary and wore two additional commercially-available accelerometers (Actigraph and Bodymedia Sensewear). We identified travel periods and compared energy expenditure levels as measured by the three devices for their activities. We estimated the contribution of transport to PA and to overall daily air pollution exposure of nitrogen dioxide estimated by a land use regression model.
Results: Preliminary results show the cell phone measurements of energy expended (kilocalories) correlated highly with the Actigraph (Spearman coefficient > 0.90 for each of 4 travel modes) and correlated well against the Bodymedia Sensewear, for which the lowest correlation was for cycling trips (Spearman coefficient 0.63). We estimated inhaled dose for a subject who spent 2% of their time daily in active travel (walking or biking). Active travel contributed disproportionately to inhalation dose, accounting for about 12% of the daily total.
Discussion: Ubiquitous sensing technology provides unparalleled data collection opportunities to measure travel-related PA and route choices, which can be highly relevant for built environment research and air pollution exposure assessment. In addition to monitoring large populations, cell phone technology may in the future improve activity measures compared to accelerometry by accounting for speed and topography collected using GPS.

WHY A CHILDREN ENVIRONMENTAL HEALTH? DIFFERENCES IN CHILDREN'S VULNERABILITY TO POLLUTION AND SANITATION.

Raphael Mendonça Guimarães, *Federal University of Rio de Janeiro, Brazil*
Isabel de Fátima Alvim Braga, *Federal University of Rio de Janeiro, Brazil*
Carmen Ildes Rodrigues Fróes Asmus, *Federal University of Rio de Janeiro, Brazil*
Maíra Mazoto, *Federal University of Rio de Janeiro, Brazil*
Juliana Chrisman, *Institute of Studies in Public Health, Brazil*

Background and Aims: To discuss the differential susceptibility of children to environmental exposures, as illustrated in the environmental impact on mortality rates for children and adults for infectious respiratory and gastrointestinal problems.
Materials and Methods: We conducted an ecological study of time series from the trend of the mortality rate and proportional mortality rate from acute respiratory infections and acute diarrheal diseases and, respectively, the consumption of chlorofluorocarbons - CFCs (air pollutant) and coverage of sewage services in Brazil. We used the polynomial regression model for assessment of trends, which were compared according to age categories with air pollution or water pollution proxy (coverage of exhaustion).
Results: The consumption of CFCs was proportional mortality due to respiratory acute infection and, similarly, it is observed that the higher the percentage of coverage, the lower the mortality rate. This relationship becomes more acute in children than in adults.
Conclusion: Therefore, the increase in knowledge and information about children and their windows of susceptibility to environmental agents will help to identify subgroups and age sensitive to planning specific preventive actions.

INCREASE INCOME AND MORTALITY OF COLORRECTAL CANCER IN BRAZIL.

Raphael Mendonça Guimarães, *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Charlene Faissal Queiróz, *Federal University of Rio de Janeiro/ Anna Nery Nursing School*
Raquel Ramos, *Brazilian National Cancer Institute*
Camila Drumond Muzi, *Brazilian National Cancer Institute*

Background and Aims: The objective of this study is to determine the correlation between average per capita income and the rate of colorrectal cancer mortality in Brazil between 2000 and 2007.
Materials and methods: We obtained data on median household income and mortality rate for colon, rectum and anus between 2001 2007 by DATASUS. A trend analysis was performed using linear regression, and correlation between variables by Pearson's correlation coefficient**.**
Results: There was a tendency towards an increase average family income and standardizedmortality rate of colon, rectum and anus in Brazil. There was also strong positive correlation ($r = 0.81$, $p < 0.001$) between incomeand mortality for this cancer located throughout the study period.
Conclusion: Theincrease in income may partially explain the increased occurrence of cancer of thecolon, rectum and anus, and this is possibly due to differential access to food recognized as a risk factor, such as red meat and fat food.É therefore important Assess the priority of public health programs addressing nutrition in countries with intermediate economy, as is the case in Brazil.

SERUM CONCENTRATION OF HCH, DDT AND METABOLITES IN ADOLESCENTS EXPOSED TO ORGANOCHLORINE PESTICIDE RESIDUES IN BRAZIL

Isabel de Fátima Alvim Braga , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Carmen Ildes Rodrigues Fróes Asmus, *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Angélica dos Santos Vianna , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Raphael Mendonça Guimarães , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*

Background and Methods: To evaluate the concentration of biomarkers of exposure to residues of organochlorine pesticides in adolescents in Rio de Janeiro, Brazil.
Methods: We obtained laboratory results of serum concentrations of the isomers of HCH and DDT metabolites from the data collection from medical records at a local health unit from a previous screening.
Results: We observed concentrations were considered well above the tolerance limits allowed. The distribution shows typical asymmetrical pattern, because of the presence of individuals with concentrations outliers distribution. Deserve special attention from the HCH congeners, the p,p'DDT and p,p'DDE; whose serum concentration mean and median are much higher than the level of tolerance permitted. Concentration obtained were from α HCH (115.81 Mean ± SD 1438.529) , β HCH (1616,266 Mean ± SD 135.15), γ HCH (Mean ± 5373.357SD 447.66), p, p'DDE (Mean 94.92 ± 884,979 SD), p, p 'DDD (5:23 Mean ± 43,350 SD), o, p 'DDT (3596 Mean 1.82 ± SD) and p, p' DDT (45.61 Mean ± SD 464,389). In measuring the correlation between different types of organochlorine compounds evaluated, it is observed that the majority has mayor correlation ($r = 1.000$), or nearly so, with great statistical significance ($p < 0.0001$).
Conclusion: There is needing for monitoring and periodic evaluation of health of this population, considering that the blood is altered especially at this critical period of development.

CORDBLOOD ACRYLAMIDE AND GLYCIDAMIDE HAEMOGLOBIN ADDUCTS, METABOLIC POLYMORPHISMS AND MICRONUCLEUS FREQUENCY

Domenico Franco Merlo, *National Institute for Cancer Research, Epidemiology, Biostatistics and Clinical Trials, Genoa, Italy*

Background and Aims: Exposure to acrylamide (AA) in the non-smoking general population occurs almost exclusively via foods cooked at higher temperatures (i.e., potato chips and fries). AA is metabolized to glycidamide (GA by cytochrome P450 enzyme 2E1, CYP2E1). AA and GA bind to glutathione and are excreted with the urine. Concerns about acrylamide exposure in utero and the risk of adverse health effects are justified by AA/GA potential carcinogenicity. Hemoglobin adducts (HbAA and HbGA) are well-established biomarkers of exposure to these chemicals. The cytokinesis-block micronucleus assay (CBMN) quantifies early genetic effects associated with cancer risk. Furthermore, individuals may be at increased risk due to particular genetic predisposition. The relationship between cord blood HbAA and HbGA and the frequency of micronuclei in cord blood lymphocytes, and the effect of CYP2E1 (Rs2480258 and Rs915906 single nucleotide polymorphisms) were studied in EU funded Integrated Project NewGeneris (Newborns and Genotoxic exposure risks).

Methods: The study included newborns from Greece, Norway, Spain, Denmark, and the United Kingdom (n.=1040) whose mother gave informed consent at recruitment. Hb adducts were measured by the “adduct FIRE procedure” using LC-tandem mass spectrometry. CBMN assay was used to measure micronuclei in binucleated and mononucleated cells (n.= 470).

Results: HbAA and HbGA were highly correlated (r=0.85, p<0.0001). Multiple regression analysis failed to show a linear relationship between HbAA and the frequency of micronucleated-binucleated cells (p-trend=0.161) but revealed an increased frequency of micronucleated-binucleated cells in the highest quintile of HbAA compared to the lowest quintile (RR= 1.36, 95%CI: 1.00-1.86, p=0.05). The CYP2E1 variant was associated with a 50% higher frequency of micronuclei in binucleated cells (RR=1.53, 95%CI:1.02-2.23, p=0.04).

Conclusions: The association between cord blood hemoglobin adducts from AA and micronuclei frequency is suggestive of the role of a maternal intake of foods with a high content of acrylamide during pregnancy and genotoxic effects on the fetus, with CYP2E1 enzyme possibly playing a role as an effect modifier.

TREND OF MORTALITY OF BREAST AND CERVIX CANCER IN THE BRAZILIAN CAPITALS FROM 1996 TO 2007

Raphael Mendonça Guimarães, *Federal University of Rio de Janeiro - Institute of Studies in Public Health*
Marcelle da Silva Ribeiro, *Federal University of Rio de Janeiro - Anna Nery Nursing School*
Carolina Chagas, *Federal University of Rio de Janeiro/ Anna Nery Nursing School*
Juliana Capilupi, *Federal University of Rio de Janeiro/ Anna Nery Nursing School*
Camila Drumond Muzi, *Brazilian National Cancer Institute*
Andréia Rodrigues Gonçalves Ayres, *Rio de Janeiro Health State Department*

Background and Aims: To analyze the trend in mortality from breast cancer and cervical cancer in Brazilian capitals from 1996 to 2007.
Materials and Methods: We calculated mortality rates for breast cancer and cervical cancer in Brazilian capital cities from 1996 to 2007, standardized for the Brazilian population and for the world's population. Trend analysis was performed using the polynomial regression model, considering the simple linear regression models, parabolic, exponential and third degree. It was considered as the best model, the one with the highest coefficient of determination (R^2).
Results: The cancer of the cervix showed a considerable reduction in the mortality rate in most capitals, although this trend is present in the opposite way in some cities. In opposition to this, breast cancer, most of the capital showed up with a high rate of mortality. Most of the trends for both was linear.
Conclusion: You could say that, according to the epidemiological transition, mortality from cancer of the cervix may be suffering a reduction on account of improvement in relation to adherence and completion of Pap smear, whereas the same ratios for breast cancer may show increased in recent years, the fact that cancer is related directly to the habits, lifestyles and culture.

RELIABILITY OF CLINICAL AND PUBERTAL SELF-ASSESSMENT IN ADOLESCENTS EXPOSED TO ENDOCRINE DISRUPTERS

Isabel de Fátima Alvim Braga , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Carmen Ildes Rodrigues Fróes Asmus, *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Angélica dos Santos Vianna , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Raphael Mendonça Guimarães , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*

Background and Aim: To assess the reliability of the information self-refeered assessment of pubertal development in adolescents exposed to endocrine disrupters.
Methods: This cross-sectional study included 72 adolescents (18 boys and 54 girls) between 12 and 20 years incomplete residents of Cidade dos Meninos, Rio de Janeiro, local contaminated by organochlorine pesticide residues. Each participant had their pubertal assessment performed by professional and self-evaluation. To assess the correlation of data for assessing the Tanner scale was used weighted kappa test and Mc Nemar´s chi-square test.
Results: The Kappa showed moderate to self-evaluation of both the developing penis (Kw = 0.51, Ep = 0.20) and the pubic hair (Kw = 0.54, Ep = 0.22). This means that the level of agreement between adolescent and evaluator is regular. In the same way, when analyzing the correlation between self-assessment of the stage of development of the Tanner girls, kappa showed moderate to self-assessment, both thelarche (Kw = 0.55, Ep = 0.11) and the pubarche (Kw = 0.48, Ep = 0.12). This means that the level of agreement between adolescent and evaluator is regular.
Conclusion: Among adolescents exposed to organochlorines, by being more aware of changes in pubertal development, this study suggests that self-assessment of Tanner stages is not valid as a proxy measure for clinical evaluation.

PUBERTAL DEVELOPMENT IN ADOLESCENTS EXPOSED TO ORGANOCHLORINE COMPOUNDS: A CROSS- SECTIONAL SURVEY IN BRAZIL

Isabel de Fátima Alvim Braga , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Carmen Ildes Rodrigues Fróes Asmus, *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Angélica dos Santos Vianna , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*
Raphael Mendonça Guimarães , *Federal University of Rio de Janeiro/ Institute of Studies in Public Health*

Background and Aims: To evaluate pubertal development in adolescents exposed to residues of organochlorine pesticides, known to act as endocrine disrupters.
Methods: We conducted a survey with a population of 100 adolescents between 12 and incomplete 20 years residents of Cidade dos Meninos, Brazil. Each participant had their pubertal assessment according to Tanner Stages, and performed by trained nurses.
Results: The mean age of adolescents was 15.5 years (SD ± 2.5) in a total of 76 girls and 24 boys. The ages found for the male pubertal development were: pubarche, 12.4 years (SD ± 1.4), semenarche 11 years (SD ± 6.10), and penis enlarge 12.5 years (SD ± 1.5). As well, the girls had the following ages for development: menarche 11.8 years (SD ± 1.4), thelarche 11.1 years (SD ± 1.5) pubarche and 11.1 years (SD ± 1.4). The data show a typical pattern of distribution by age, being more frequent change of the structure of the genitalia observed between 12 and 13 years old. However, observed values were outliers, 10 and 15 years. It's shown up outliers higher values for the distribution of hair, with 14 and 15 years. At group of girls, the infants has two outlier values (15 and 16 years) than the appropriate default development. A similar analysis it is up to the age of thelarche, where there is a higher outlier (16 years).
Conclusion: The pattern of the sample, therefore, is adolescents reaching menarche, thelarche and pubarche at ages considered normal.

DISSIMILAR ACCUMULATION OF ORGANOCHLORINE COMPOUNDS, PBDES AND HBCD IN COLOSTRUM FROM MOTHERS LIVING IN URBAN/INDUSTRIAL AREAS ACCORDING TO GEOGRAPHIC ORIGIN

Marta Fort, *Institute for environment assessment and water research (IDAEA-CSIC), Barcelona, Catalonia, Spain*
Joan O. Grimalt, *Institute for environment assessment and water research (IDAEA-CSIC), Barcelona, Catalonia, Spain*
Jordi Sunyer, *Centre for Research in Environmental Epidemiology, Barcelona, Catalonia, Spain*
Mònica Guxens, *Centre for Research in Environmental Epidemiology, Barcelona, Catalonia, Spain*
Jesus Ibarluzea, *Department of Health Gipuzkoa, San Sebastian, Basque Country, Spain*
Loreto Santa Marina, *Department of Health Gipuzkoa, San Sebastian, Basque Country, Spain*

Background and Aims: Human milk is lipid-rich and a good store of lipophilic pollutants such as organohalogen compounds. This study is aimed to determine the accumulation patterns of organochlorine compounds (OCs), PBDEs and HBCD in colostrum samples of general population from two urban/industrial areas, to compare them and to identify the main determinants of their accumulation in these populations.
Methods: 368 colostrum samples from Gipuzkoa and Sabadell INMA cohorts (1) were analysed for OCs (HCB, • -HCH, DDTs and PCBs), PBDEs (including BDE209) and HBCD. Maternal factors such as cohort area and geographic origin of mother were evaluated.
Results: In both cohorts 4,4'-DDE was the most abundant pesticide and PCB153 the main PCB congener, whereas PBDE levels were one-fold lower than OCs, BDE153 being the most abundant congener. Median levels were similar to previous observations in other European studies (2, 3). HBCD was detected in more than 50% of samples, with similar levels to those found for main PBDEs. Gipuzkoa cohort had significantly higher levels of main OCs (especially PCBs) and PBDEs, compared to Sabadell. Regarding geographic origin of mothers in both cohorts, those from Latin America had significantly higher concentrations of 4,4'-DDT and 4,4-DDE than European mothers, whereas HCB, • -HCH, PCBs and BDE153 were significantly higher in European women than in those from Latin America.
Conclusions: OCs and PBDEs were higher in Gipuzkoa than in Sabadell colostrum samples, reflecting the influence of heavy industry in Gipuzkoa area. In both cohorts, geographic origin of mothers was the main determinant of OC and PBDE concentrations. Those from Latin America have higher concentrations of 4,4'-DDT and 4,4'-DDE whereas European mothers exhibit higher concentrations of compounds of industrial origin. The higher accumulation of industrial pollutants is observed independently of the European banning regulations that control the present use of these compounds.

THE RELATIONSHIP BETWEEN DDT UPTAKE, HORMONAL CHANGES AND CIRCULATING HOMOCYSTEINE CONCENTRATIONS

Rhena Delport, *University of Pretoria, Pretoria, South Africa*
Riana Bornman, *University of Pretoria, Pretoria, South Africa*
Piet Becker, *Medial Research Council, Pretoria, South Africa*
Natalie Aneck-Hahn, *University of Pretoria, Pretoria, South Africa*
Christiaan de Jager, *University of Pretoria, Pretoria, South Africa*
Konrad Schmidt, *University of Innsbruck, Innsbruck, Austria*

Background and aims: As sex hormones reportedly alter homocysteine metabolism, we hypothesised that pesticides that exert anti-androgenic and estrogenic may affect total homocysteine (t-Hcy) concentrations. Plasma samples for total homocysteine (t-Hcy) were collected during some of the visits of an on-going cross-sectional study evaluating male fertility parameters with Indoor Residual Spraying (IRS).
Methods: The t-Hcy concentration and its determinants, estradiol (E2) and testosterone sub-fractions, and SHBG and Albumin were compared between young males from sprayed (n=219) and unsprayed villages (n=215), taking the variance of the data and co-variates into account. Regression analyses were performed in the exposure group.
Results: The mean (SD) t-Hcy concentrations in sprayed villages were significantly lower (7.7(2.4) vs 8.3(2.5) µmol/L; $p<0.05$), while t-Hcy determinant concentrations did not differ significantly. Lowertotal testosterone (t-T) concentrations (21.3(6.0) vs 25.2(9.1) nmol/L; $p<0.001$), % bio-available testosterone (%bio-T) (40.9(8.3) vs 50.3(14.5); $p<0.005$), albumin (44.8(4.5) vs 46.0(6.0) mg/dL; $p<0.05$) and E2 concentrations (115.6(32.5) vs 136.2(36.8) pmol/L; $p<0.001$) were observed in non-sprayed villages. After correcting for vitamin B12 and either *p,p'*DDE or *p,p'*DDT, t-Hcy concentration no longer differed significantly between groups. In sprayed villages significant Spearman rank correlation coefficients were observed for t-Hcy with *p,p'*DDE, *p,p'*DDT,and bio-T (respective r-values: -0.260, -0.289, 0.197; $p<0.005$). When comparing regression lines for Log_Hcy = %bio_T, the slopes did not differ significantly between groups, while elevation differed significantly ($F=7.28$, $DF=1, 423$, $p= 0.007$). Concentration-dependent linear trends were observed, using Polynomial contrast, across *p,p'*DDE and *p,p'*DDT quartiles for Log-Hcy (decreasing) and for serum creatinine (increasing) ($p<0.001$).
Conclusions: Lower t-Hcy concentrations appear to be related to DDT uptake. This stucy does not explain these findings. Association between t-Hcy and sex hormones is not clearly evident, except for the association with %bio-T. What is apparent is that uptake of DDT may be associated with altered sex hormone and homocysteine homeostasis.

DERMAL EXPOSURES TO SARIN IN MILITARY VETERANS AT PORTON DOWN

Keegan TJ, *School of Health and Medicine, Lancaster University, Lancaster,UK*
Brooks C, *Department of Public Health, University of Oxford, Oxford UK, UK*
Walker S, *Department of Public Health, University of Oxford, Oxford UK, UK*
Langdon T, *Department of Public Health, University of Oxford, Oxford UK, UK*
Carpenter LM, *Department of Public Health, University of Oxford, Oxford UK, UK*
Venables KM, *Department of Public Health, University of Oxford, Oxford UK, UK*

Background The modification of dermal exposures by clothing, which may either protect from exposure or increase its effect, is of considerable interest. Here, we describe early analyses of the effects of dermal exposures to the nerve agent sarin, using data drawn from our previous cohort study of military veterans of chemical tests at Porton Down between, 1939-1989.
Methods Data on exposures were abstracted from the Porton Down historical archive. For each nerve agent test we abstracted data on date and type of test, the principal chemical(s) used and exposure intensity, duration and route. We also noted the presence of exposure modifiers. Maximum percentage change in the following cholinesterase (ChE) measures were abstracted or calculated: unspecified, whole blood, plasma and/or red blood cell (RBC) ChE.
Results 3597 veterans were recorded as involved in 4299 tests with nerve agents, 1945-1987. The most tested nerve agent was sarin: 2980 veterans were involved in 3511 tests. 288 sarin exposures were dermal (9.6%) and most of those were modified physically, eg by clothing (188; 65%). Dermal sarin tests took place 1951 - 1953.
Quantity of exposure to dermal sarin was measured for 273 tests and ranged from 0.13 to 300 mg. Applied exposures were higher in tests with modification (IQR 200-300 mg with modification and 0.28-8 mg without).
Change in ChE activity was available for 279 dermal sarin tests (97%). The median change was -22% (IQR -10 to -37%, range +12.5 to -99%). The median without modification was -4.5% (IQR 0 to -13%) and -31% (IQR -19 to -46%) with modification.
Conclusions The quantity of dermal exposure to sarin influenced effect. However, modifier use may be confounded by exposure so further investigation of the relationships between exposure, effect, and modification will be carried out.

ENVIRONMENTAL EXPOSURE OF CHILDREN TO POLYCHLORINATED BIPHENYLS AND DEFICITS IN COCHLEAR STATUS

Tomáš Trnovec, *Department of Environmental Medicine, Slovak Medical University, Bratislava, Slovakia*
Ľubica Palkovičová, *Department of Environmental Medicine, Slovak Medical University, Bratislava, Slovakia*
Soňa Wimmerová, *Department of Environmental Medicine, Slovak Medical University, Bratislava, Slovakia*

Irva Hertz-Picciotto, *Department of Public Health Sciences, School of Medicine, University of California, Davis, USA*

Background and aims: The mammalian auditory system forming a part of CNS, with its complex development, is a typical target of neurodevelopmental toxicity. Polychlorinated biphenyls (PCBs), a member of neurodevelopmental toxicants, can induce hearing impairment in rats (Crofton 2000) and humans (Trnovec 2008, 2010). The underlying process is a damage of the outer hair cells in cochlea. A mode of action based on deficit of thyroid hormones proposed for rodents does not hold for humans (Crofton and Zoeller 2005). In our cross-sectional studies the level of otoacoustic emissions (OAE), a marker of cochlear status, was associated with actual PCB exposure and not related to thyroid hormones. However, no data on prenatal exposure, a marker of which is PCB cord blood concentration, were available (Trnovec 2008, 2010).
Methods: Longitudinal cohort study, complex audiological examination.
Results: n a random cohort of 485 infants exposed to PCBs from Michalovce district, eastern Slovakia (Hertz-Picciotto 2003), children were audiologically examined at the age of 45 months. The transient evoked (TE) OAE and distortion product (DP) OAE were related to PCB serum concentration at birth, 6, 16 and 45 months of age. The gender specific deficits were manifested in decreased amplitudes of both TEOAE and DPOAE in a similar way as with noise trauma or effect of cochleotoxic substances. For DPOAE two primary tone f2 frequencies, 3364 and 2828 Hz for left and right ears, resp., showed highest sensitivity from 11 tested frequencies. The BMDL (p_0=0.1; BMR=0.05) for this effect in left ears of males is 419.3 ng PCB/g lipids and an alarming MOE = 1.11 at median PCB serum concentration of 377.4 ng PCB/g lipids.
Conclusions: Multivariate regression has shown that the OAE amplitudes were significantly related to PCB exposure at 16 and 45 months. There was no relationship with neurodevelopmentally relevant prenatal time period.

ADDITION OF MEASUREMENTS OF BISPHENOL A IN URINE TO THE STUDY PROTOCOL FOR A EUROPEAN HUMAN BIOMONITORING (HBM) PILOT STUDY

Background and Aims:
In December 2009 the COnsortium to Perform Human Biomonitoring on a European Scale (COPHES) financed by FP7 EU, began work towards an EU HBM framework. This will be accompanied by a feasibility study called DEMOCOPHES, co-financed by Life+, which started in autumn 2010 and requires shared contribution from EU and the participating countries.
In all countries participating in the pilot study of Human Biomonitoring in Europe[1] a basic scenario will be followed measuring cadmium, cotinine and phthalates in urine and mercury in hair. In addition, some countries will analyse other substances, including measurements of Bisphenol A in urine. Bisphenol-A is considered a high-volume chemical (>1000 tons produced or imported in the EU) used in a wide range of applications. BPA is mainly used as a monomer in the production of polycarbonate and epoxy resins. Polycarbonate is a hard and transparent plastic used in reusable drinking bottles and baby bottles, electrical and electronic household and office equipment. Epoxy resins are mainly found in coil coatings and as coating in food and drink cans. The concern about human exposure to BPA has risen since recent findings that BPA has estrogenic effects in *in vivo* animal experiments at low doses which are within the expected human exposure range. Following oral administration, BPA appears to be rapidly absorbed from the gastro-intestinal tract and undergoes a practically complete first pass metabolism in the liver by conjugation with glucuronic acid. Subsequently, the formed glucuronide is rapidly cleared from the blood and eliminated through urine.

Methods: Urine samples will be collected in autumn 2011 from children in the age range of 6-11 years and their mothers with a 60 pairs rural and 60 pairs urban distribution in each of the participating countries (Belgium, Denmark, Luxembourg, Poland, Sweden, Slovenia, Cyprus and Spain). The samples will be analysed following a harmonised protocol with interlaboratory harmonisation presently ongoing.

Selection of Indicators for Green Growth by applying OECD's Framework

Estella SatByul Kim, Department of Epidemiology and Biostatistics, School of Public Health and the Institute of Environment and Health, Seoul National University, Republic of Korea
Ho Kim, Department of Epidemiology and Biostatistics, School of Public Health and the Institute of Environment and Health, Seoul National University, Republic of Korea

Background and Aims: Climate change is emerging as one of the world's biggest environmental problems. Global warming causes weather disasters and ecological chaos, and even threatens the survival of mankind. Thus, it is imperative that economic growth and environmental substantiality be harmonized through what is termed "green growth." In order to achieve such growth, green indicators and statistics are essential, since these not only measure environmental progress and sustainable development but also monitor and evaluate policy integration.
Methods: Existing indicators relevant to green growth were first collected and compared, in order to select a potential pool of indicators. This pool was sorted according to OECD's framework. Each indicator was scored on a scale of 1 to 3 for each criterion, that is, policy relevance, analytical soundness, and measurability. For each indicator, the scores of the three criteria were summed, and the indicators were ranked according to the scores. Twelve international indicators were chosen from the indicator pool. The current data for each international indicator was compared to the OECD countries' 25th percentile data and evaluated on a scale of 1–5 within the framework.
Results: The average scores for five categories were 2.00, 1.67, 3.50, 3.00, and 2.50, respectively; (i) environmental efficiency of production and changes in production patterns, (ii) environmental efficiency of consumption and changes in consumption patterns, (iii) stocks of natural capital and environmental quality, (iv) objective and subjective environmental quality of life, and (v) responses by economic actors.
Conclusions: These findings can be interpreted as they are not at the same levels within the framework. It seems the qualities of Korea's natural capital, environment, and life are high. In comparison, its economic activity scores (production, consumption, trade) are relatively low when compared to the OECD's 25th percentile level. However, Korea's current green growth strategy emphasizes economic value, such as development of new technologies; it is moving, therefore, in the right direction.

HEALTH STATUS OF THE POPULATION LIVING IN THE GEOTHERMAL AREA OF TUSCANY REGION, ITALY

Fabrizio Minichilli, *CNR Institute of Clinical Physiology, Unit of Environmental Epidemiology, Pisa, Italy*
Simone Bartolacci, *Regional Health Agency of Tuscany, Dept. of Epidemiology, Florence, Italy*

Daniela Nuvolone, *Regional Health Agency of Tuscany, Dept. of Epidemiology, Florence, Italy*
Anna Pierini,*CNR Institute of Clinical Physiology, Unit of Environmental Epidemiology, Pisa, Italy*; *CNR-Tuscany Region "Gabriele Monasterio" Foundation, Unit of Epidemiology, Pisa, Italy*
Maria Angela Protti, *CNR Institute of Clinical Physiology, Unit of Environmental Epidemiology, Pisa, Italy*
Anna Maria Romanelli,*CNR Institute of Clinical Physiology, Unit of Environmental Epidemiology, Pisa, Italy*
Maria Angela Vigotti, *CNR Institute of Clinical Physiology, Unit of Environmental Epidemiology, Pisa, Italy*
Fabrizio Bianchi, *CNR Institute of Clinical Physiology, Unit of Environmental Epidemiology, Pisa, Italy; CNR-Tuscany Region "Gabriele Monasterio" Foundation, Unit of Epidemiology, Pisa, Italy*

Background and Aims: in two areas of Tuscany 31 geothermal power plants have been operating since the eighties. Hydrogen sulphide (H_2S) and mercury vapours in the air, inorganic arsenic in groundwater and in drinking water are the main pollutants. Communities' concern for health effects increased in the last decade. A descriptive epidemiological study commissioned by the Tuscany Region was carried out in 2010.
Methods: sixteen municipalities, 43,400 inhabitants were considered; 60 causes of mortality 1980-2006 and of hospitalization 1998-2006 were compared with regional and local figures (80 municipalities around the study areas). For the total area, 2 subareas and 16 municipalities, standardized and Bayesian age-adjusted rates and clustering analysis were performed.
Results: in the whole area total mortality was in excess for men (SMR=106) but not for women; significant excesses emerged for respiratory causes (SMR=125) and infective diseases (SMR=236) in men, for hepatic cirrhosis among women (SMR=142). No excesses of hospitalization for all causes, all cancers, all cardiovascular diseases resulted; SHR was in excess for stomach cancers in males and females (SHR=146;185), for leukaemia among women (SHR=167). In the northern subarea excesses of hospitalization for leukaemia in women (SHR=250), digestive diseases in both genders (SHR=113) were found. In the southern subarea mortality excesses of total causes, all cancers, respiratory diseases emerged for men (SMR=113;119;128), for acute respiratory and digestive diseases among women (SMR=141;132). Excesses of hospitalization for stomach cancers in males and females (SHR=160;208), kidney failure in both genders (SHR=136), respiratory diseases among women (SHR=113) emerged. Excesses of mortality and hospitalization prevailed in municipalities of southern subarea. Bayesian and clustering analysis confirmed the main results.
Conclusions: although the mortality and hospitalization profiles did not show a critical situation and some excesses were likely to be associated with past occupational exposure or life-style determinants, a GIS assisted case-control study is in progress for some emerged signals, mainly regarding leukaemia, renal and respiratory diseases particularly to assess possible effects of H_2S low doses exposure.

SENTIERI – OCCUPATIONAL EXPOSURE CONTRIBUTION TO MORTALITY: THE CASE OF MASSA CARRARA POLLUTED SITE

Amerigo Zona, *Istituto Superiore di Sanità, Italy*
Roberta Pirastu, *Sapienza Università di Roma, Italy*
Pietro Comba, *Istituto Superiore di Sanità, Italy*

Background and Aims: SENTIERI project is aimed to describing health status of resident populations in Italian polluted sites defined as "of national concern" (Ministerial Decree n. 486, 2001, and successive Decrees) using mortality data. Identified sources of contamination were categorized as chemical industry, petrochemical plants & refineries, harbour area, asbestos or other mineral fibers, steel plants, thermoelectric power plants, mines or quarries, landfills, incinerators. Sixty-three groups of causes of death (ICD IX) were selected.
Methods: A descriptive analysis (1995-2002) of mortality for both gender was performed calculating Standardised Mortality Ratio (SMR), crude and adjusted for deprivation (90% Confidence Intervals). Regional population was used for comparison. SENTIERI adopted an *a priori* definition of contaminated site and an *a priori* evaluation of the epidemiological evidence of the association between *environmental exposure/s* and cause specific mortality. Epidemiologists in working group examined bibliographic information, assessing the presence of a causal association between environmental exposure/s and cause specific mortality following standardised criteria. Evidence was classified as: Sufficient or Limited to infer the presence of a causal association, Inadequate to infer the presence or absence of a causal association. To take account of occupational exposures, authoritative publications were considered.
Results: As an example, the case of Massa Carrara will be presented, as it is among the most complex polluted sites in terms of environmental contamination (asbestos, production of chemical substances, harbour area, incinerator, petrochemical plant and/or refinery, steel industry). Increased risk of death from several causes were found: diseases of cardiovascular, respiratory and digestive systems, malignant neoplasms of liver, lung, pleura.
Conclusions: The potential contribution of previous occupational exposures to overall mortality in the polluted sites should not be overlooked, and the a priori SENTIERI approach seems to be fruitful.

Anne Elie Carsin, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain
Nicole Probst-Hensch, Epidemiology and Public Health Unit, Swiss Tropical and Public Health Institute, Basel and University of Basel, Switzerland
Nino Künzli on behalf of the ESCAPE WP 4 Respiratory group, Epidemiology and Public Health Unit, Swiss Tropical and Public Health Institute, Basel and University of Basel, Switzerland

Background and Aims : Longitudinal studies on the long-term influence of air pollution on chronic respiratory disease in adults are rare. Workpackage 4 (WP4) of ESCAPE investigates this in six adult cohort studies in 12 European countries namely ECRHS, EGEA, E3N, SAPALDIA, SALIA and NSHD. This analysis compares prevalence of COPD by smoking status, as a first step to understand similarities and differences across the cohorts involved.

Methods: Four population-based studies of this workpackage have lung function data (ECRHS, NSHD, SALIA, SAPALDIA). Data were harmonised to ensure consistency of statistical analysis (by study and meta-analyses). COPD variability by sex, smoking status, SES (education level) and age were explored and logistic regression was used to determine cross-sectional associations with spirometrically defined COPD using the GOLD criteria where COPD is defined as an FEV1/FVC ratio <0.7.

Results : There were 13'282 participants with at least two spirometric measures and 18'088 participants with questionnaire data about chronic bronchitis symptoms. The follow-up time varied between studies from 10 to 20 years and mean age from 42.6 to 73.5 years among studies. The unadjusted prevalence of moderate COPD at the most recent follow-up varied across studies ranging from 1.6% to 4.6%. Smoking was significantly associated with COPD in all studies with OR's ranging 1.87 to 2.86 for 'current smoking', while women were found to have 40-70% of the risk of men. No significant association could be found for SES in all studies.

Conclusions: An important part of the ESCAPE project is harmonisation of datasets for use in future analyses of associations of respiratory outcomes with air pollution. Findings for cross-sectional associations of COPD with major risk factors were comparable despite differences in protocols, areas and timing of cohort studies. These analyses are being extended to all respiratory outcomes being investigated in WP4 and will inform analytic strategies.

INTERACTIONS BETWEEN DISINFECTION BY PRODUCTS IN DRINKING WATER AND GENETIC SUSCEPTIBILITY VARIANTS IN RELATION TO ADVERSE REPRODUCTIVE OUTCOMES (THE HIWATE STUDY)

Mariona Bustamante, *Center for Research in Environmental Epidemiology, Spain*
Ana Espinosa, *Center for Research in Environmental Epidemiology, Spain*
Juan R Gonzalez, *Center for Research in Environmental Epidemiology, Spain*
Asta Danilevičiūtė, *Vytautas Magnus University, Lithuania*
Cecile Chevrier, *Université Rennes, France*
Regina Grazuleviciene, *Vytautas Magnus University, Lithuania*

Cristina M Villanueva, *Center for Research in Environmental Epidemiology, Spain*
Mark Nieuwenhuijsen, *Center for Research in Environmental Epidemiology, Spain*
Manolis Kogevinas, *Center for Research in Environmental Epidemiology, Spain*

Background and Aims: The Hiwate project (Heath Impacts of Long-Term Exposure to Disinfection By-Products in Drinking Water) studied the relation between prenatal exposure to DBPs (Disinfection by-products) in drinking water and adverse reproductive outcomes, without finding evidence of any effect. This lack of association could be partially caused by differences in genetic background. Thus, a gene*environment (G*E) interaction study was undertaken within Hiwate project.
Methods: A nested case control study was designed using samples (maternal and child DNA) from four European birth cohorts (INMA, KAUNAS, PELAGIE and RHEA). Forty-nine Single Nucleotide Polymorphims (SNPs) and 4 Copy Number Variants (CNVs) in DBP detoxification genes (CYP1A cluster, CYP2A6, CYP2E1, CYP3A cluster, GSTP1, GSTT1 cluster, GSTZ1, GSTM1 and GSTM4) were successfully genotyped using Illumina and MLPA, respectively, blindly to the case-control status. Prenatal exposure to total trihalomethanes (tTHMs), the most abundant DBP group, was considered continuous in models. Main genetic effects were initially explored under an additive genetic model, and those with a p-val<0.2 (in mothers or children) were included in the G*E analysis.
Results: In total, 270/228 (mother/child DNAs) preterm cases, 368/377 small for gestational age (SGA) cases, and 416/429 controls were analyzed. A SNP in CYP1A cluster (in child DNA), and two SNPs in GSTZ1 (in maternal and/or child DNA) showed an interaction with tTHMs in relation to preterm (p int ≤0.052). Regarding SGA, mothers with 0 copies of the GSTT1 CNV tended to have children more susceptible to be SGA after prenatal exposure to tTHMs (p int=0.050). None of the interactions were statistically significant after correction for multiple testing.
Conclusions: Genetic variants in the CYP1A cluster, GSTZ1 and GSTT1 may modulate the effect of prenatal exposure to DPBs on reproductive outcomes. Although biologically plausible, the findings should be interpreted with caution because effects were small and only marginally significant.

ANALYTICAL UNITS BASED ON NATURAL SYSTEMS IN UNDERSTANDING ENVIRONMENTAL FACTORS ASSOCIATED WITH DISEASE: A CASE-STUDY OF PEDIATRIC DIARRHEA IN BRAZIL

John Nuckols, *Div of International Epidemiology and Population Studies, Fogarty International Center, National Institutes of Health, Bethesda, MD, USA - Department of Environmental & Radiological Health Sciences, Colorado State University, Fort Collins, CO, USA*
Stefan Leyk, *Department of Geography, University of Colorado, Boulder, CO, USA*
Thomas Philips, *Colorado Center for Astrodynamics Research, Dept. of Aerospace Engineering, University of Colorado, Boulder, CO, USA*
Jeremy Smith, *Department of Geography, University of Colorado, Boulder, CO, USA*

Background and Aims: Over two million children die annually due to disease attributed to enteric disease. The importance of an improved understanding of environmental factors associated with this disease has been widely recognized. An important factor is the geographic extent and framework of the unit of analysis. In this study we evaluate a geospatial method for identifying spatio-temporal patterns in mortality attributed to pediatric diarrhea in Brazil based on the natural system, hydrologic regime, rather than political census units.
Methods: We analyze trends in peak timing of pediatric mortality (MPT) attributed to diarrheal disease in Brazil. We evaluate multi-scale analytical units including: (1) Country-wide municipal level mortality data aggregated to Census Micro Regions (CMR) and to a grid of 20 Km^2 raster cells generated by geostatistical modeling; (2) Within eight officially designated Hydrographic Regions of Brazil based on results from the geostatistical models; and (3) Along longitudinal "vectors" of 1 km raster cells defining the stream network (hydrologic regime) within each Hydrographic Region.
Results: We found evidence of a country-level trend west to east of increasing MPT over an annual cycle. However, when we examined the model results across the Hydrographic Regions, we discovered greater geographic heterogeneity in MPT. At the spatial scale of the stream network within the Hydrographic Regions, trends were generally consistent and no longer predominantly east to west, but oriented in the direction of flow of the major river draining the basin.
Conclusions: We found the geographic orientation of trend in MPT to be highly dependent on the geographic extent and derivation of the analytical unit. We demonstrate that a unit based on natural boundaries, e.g., stream segments or watershed boundaries, resulted in more consistent and robust prediction of trends in MPT attributed to diarrhea.

RADON MONITORING IN GROUNDWATER FROM THE MT. ETNA AREA

Maria Fiore, *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Caterina Ledda, *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Gea Oliveri Conti, *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Roberto Fallico, *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Salvatore Sciacca, *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Margherita Ferrante *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*

Background and aims The natural radionuclides generally occurring in ground waters and those pose health risks are 222Rn, 226Ra, 228Ra and 232Th. Since no limits for radon in drinking water supplies have been set yet, radon monitoring by regulatory authorities has not been established. This had led to a lack of knowledge about the geographic distribution of radon, which is needed in water supply planning and development. Due to the high permeability of Mount Etna volcanic rocks, it hosts one of the biggest hydrogeologic reservoirs of Sicily. The Etnean groundwaters are very important being the only water resource for drinking, agricultural and industrial purposes not only for the people living in this area but also for those who live in the surrounding areas. This study reports the results of a groundwater radon survey in the Etnean area.

Methods: Evaluation radon progeny (214Pb and 214Bi) in water was developed by using gamma ray spectrometry. Groundwater samples were collected throughout the Etnean area from drainage galleries, springs and from wells with submerged pumps. These water are used for drinking purposes.

Results: The measured activity values range from 1.3 to 5.8 Bq/L.

Conclusions: The USEPA has proposed in 1991 a maximum contaminant level (MCL) of radon in public drinking water supplies serving more than 25 residences to be 11 Bq/L, that our samples are compliant. Is still necessary to integrate our results with temperature, salinity and CO_2 partial pressure and continue to make the monitoring seasonally.

RISK PERCEPTION OF TURKISH HIGH SCHOOL STUDENTS RELATED TO CELL PHONE USE AND BASE STATIONS IN BORNOVA, TURKEY

Hur Hassoy, *Department of Public Health Faculty of Medicine Ege University, Turkey*
Raika Durusoy, *Department of Public Health Faculty of Medicine Ege University, Turkey*
Ali Osman Karababa, *Department of Public Health Faculty of Medicine Ege University, Turkey*

Background and Aims: Cell phone (CP) use has increased rapidly; specifically adolescents' use is intensive (Söderqvist etal 2007). The question of potential risk for young age groups remains unresolved (Röösli etal 2010). This study aims to define the perceived risk for CP use and base stations and to determine the factors associated for Turkish high school students.
Methods: This cross-sectional study was conducted on December 2009-April 2010. The target population were 20,493 students, sample size was 2530 (p=50%, d=3%, design-effect=2 and 20% non-response). Stratified clustered sampling was used. Independent variables were; type of school, grade, age, gender, income, income perception, mother's and father's education, father's occupation, CP utilization and ownership, the presence of base stations. Risk perception (RP) was questioned with a five-item likert scale for 25 statements. RP scores of the students were classified into 5 dimensions as base station, CP, public, individual, general.
Results: Response rate was 88.5% (51.6% female, 48.4% male). The mean scores for RP for 5 dimensions were ranged 3.16-3.96. Type of school, gender, income, father's occupation, mother's and father's education, CP utilization, CP ownership was significantly associated with CP risk perception scores. Gender and presence of base stations were significantly associated with the base station RP scores. All the independent variables were significantly associated with the general RP scores except gender, income perception, CP ownership and presence of base station ($p<0.05$).
Conclusions:
The lowest RP scores for the CP and public and highest scores for individual dimensions were found. The girls' perception of risk was higher both for CP and base station. General RP significantly increased with increasing school grade and age. Low socioeconomic status was associated with high RP. Adolescents' participation in risky behaviour is consistent with their RP (Gullone 2000;Cecile M etal 2007). The student knowledge should be improved about the health effects of CP use and base stations.

Hye Jung Yoon, *National Institute of Food and Drug Safety Evaluation, Republic of Korea*

The objective of this study was to evaluate the internal exposure of acrylamide (AA) in Korean. We collected urine samples in the general population aged from 18 to 69 years(n=1,866) and measured concentration of AA, glycidamide (GA) and N-acethyl-S-(2-carbamoylethyl)cystein (AAMA) in urine samples.
Determination was developed by ESI-tandem mass spectrometry (ESI-MS/MS) in positive ionization mode.
The total geometric mean (GM) level was 5.39±0.35 ng/g creatinine for AA, 7.17±0.14 ng/g creatinine for GA and 20.13±1.03 ng/g for AAMA in sample. No significant difference was observed between male (n=803, 5.45±0.50 ng/g creatinine, 7.00±0.13 ng/g creatinine) and female (n=1,063, 5.33±0.36 ng/g creatinine, 7.34±0.22ng/g creatinine) both in AA and GA. But significant difference ($p<0.001$) was observed between male group (23.06±1.79 ng/g creatinine) and female group (17.56±0.91 ng/g creatinine) in AAMA level.

TOWARDS THE DEVELOPMENT OF PRACTICAL TOOLS FOR INTEGRATED ASSESSMENTS OF HEALTH EFFECTS OF TRANSPORT POLICIES: A CONCEPTUAL FRAMEWORK

Thomas Götschi, *Physical Activity and Health Unit, Institute of Social and Preventive Medicine, University of Zurich, Switzerland*
Sonja Kahlmeier *Physical Activity and Health Unit, Institute of Social and Preventive Medicine, University of Zurich, Switzerland*
Carlos Dora, *World Health Organization, Department of Public Health and Environment, Switzerland*

Background and Aims: Transport policies widely affect the environment and public health. Some even specifically address issues outside the transport domain, i.e. promotion of active travel to increase physical activity.
Transport and urban planners would benefit from practical tools to navigate and evaluate complex interrelations of health-related factors affected by transport, which would improve project assessments over current state of the art.
Methods: Intending to complement evidence-based modeling and feasibility-focused tool development, we created a conceptual map of health-relevant factors affected by transport policies and their relationships, based primarily on plausibility considerations and reviews of relevant publications. To ensure breadth, data availability or quantitative evidence were not requirements for inclusion in the map. Additionally, transport and health indicators from existing indicator systems were identified.
Results: The resulting conceptual map consists of a classification scheme for transport policies, and of pathways from policy targets to health endpoints. The map distinguishes two main target domains of policies: travel behavior and physical aspects of transport. Five main pathways link these to health: exposure to air pollution and noise, injury risk, impacts on physical activity and access to health-relevant goods, services and opportunities. Health endpoints include morbidities, injuries and mortality.
The map identified and linked over 350 factors. In addition, 40 existing indicators were identified, mainly on physical aspects of traffic.
Conclusions: The map showed that **e**xisting indicators address only limited aspects of the transport-health field. Although not comprehensive, the map assists the development of integrated evaluation tools for transport policies, as it visually digests the complexity of the matter, facilitating the identification of causal pathways of adverse and beneficial health effects of transport. Similar future efforts to dissect complex transport-health relationships would benefit from the use of interactive electronic applications, which may improve user-friendliness, which is often limiting the practical application of such tools.

EVALUATION OF METAL BIOACCUMULATION (Cd, As, Pb, Zn, Cu, Cr, Ni, Hg) AND RISK TO HUMAN HEALTH IN MUSCLE OF EUROPEAN ANCHOVY (SICILY-ITALY)

Chiara Copat *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Giovanni Arena *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Caterina Ledda *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*

Salvatore Sciacca *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*
Margherita Ferrante *Department of Hygiene and Public Health, University of Catania, Catania, Italy.*

Introduction: Marine pollution leads to environmental changes affecting biological components, and fish are certainly good bio-accumulators that provide information on the environmental quality. Hence, a monitoring to evaluate risks for human health associated with consumption of contaminated fish, is needed.
Methods: In this study 60 fish of European anchovy were sampled in the Gulf of Catania. In particular 30 fish were catched in winter and 30 in the summer period. For the lab tests 1 g of sample per fish was mineralized in a microwave system using a heated mixture of strong acids. The reading of Cd, As, Pb, Zn, Cu, Cr, Ni and Hg was performed with an ICP-MS.
Results: The average bioaccumulation level ($\mu g/g^{-1}$, w.w.) in winter follow the order Zn (8.96) > As (6.63) > Cr (0.89) > Cu (0.69) > Hg (0.10) > Cd = Pb (0.01) > Ni (< 0.007), in summer follow the order Zn (27.19) > As (5.61) > Cu (1.95) > Cr (1.15) > Ni (0.13) > Hg (0.05) > Cd = Pb (0.01). Zn, Cr, Cu and Ni concentrations are significantly higher in summer respect to winter ($p < 0.001$), and vice versa for As ($p < 0.05$).
We have also calculated the dietary exposure suggested by US-EPA (1994), and our estimate weekly intake are below the provisional weekly intake PTWI set by EFSA (2004, 2009_a, 2009_b, 2010) for Hg, As, Cd and Pb, and below the PTWI suggested by De et al. (2010) for Cu, Ni and Zn. Furthermore Cd, Pb and Hg concentration are below the limits set by E.C. 1881/2006 in muscle fish.
Conclusions: Results show that in the area of the Gulf of Catania, even if a bioaccumulation of metals is present, especially in the summer period, concentrations measured in European anchovy don't represent a risk for human health.

ASSOCIATIONS OF LUNG CANCER MORTALITY WITH LONG-TERM EXPOSURE TO $PM_{2.5}$ COMPONENTS

G. Thurston, *New York University School of Medicine, USA*
R.T. Burnett, *Health Canada, Canada*
D. Krewski, *University of Ottawa, Canada*
M. Turner, *University of Ottawa, Canada*
Y. Shi, *University of Ottawa, Canada*
K. Ito, *New York University School of Medicine, USA*
R Lall, *New York University School of Medicine, USA*
M. Jerrett, *University of California, Berkeley, USA*
M.J. Thun, *American Cancer Society, USA*
CA Pope III, *Brigham Young University, USA*

Background and Aims: Numerous epidemiological studies have now documented that long-term exposure to fine particulate matter air pollution mass ($PM_{2.5}$) is associated with an increased risk of mortality. The ACS study has found associations of $PM_{2.5}$ with increased risk of lung cancer mortality, but the types of particles that are most related to these associations have not been investigated. The focus of this new research was to determine which components of $PM_{2.5}$ mass were most explanatory of the previously reported $PM_{2.5}$ association with lung cancer mortality.
Methods: Using the ACS cohort (extended through 2004), and the U.S. EPA $PM_{2.5}$ Speciation data, we evaluated mortality associations between various composition and source components of $PM_{2.5}$ in 100 U.S. metropolitan areas. Source apportionments were conducted using methods by Thurston and Spengler (1982). Individual elements were also considered as exposure indices. Mortality analyses employed Cox Proportional Hazards modeling.
Results: The major U.S. $PM_{2.5}$ sources identified, their key tracer elements, and their mean nationwide $PM_{2.5}$ impacts were: Metals (Pb, Zn) 0.2 ug/m^3 ; Soil (Ca, Si) 0.8 ug/m^3 ; Traffic (OC, EC, NO_2) 4.6 ug/m^3 ; Steel (Fe, Mn) <0.1 ug/m^3 ; Coal Combustion (As, Se, S) 1.1 ug/m^3 ; Oil Combustion (V, Ni) 0.9 ug/m^3 ; Salt (Na, Cl) 0.1 ug/m^3 ; Biomass burning 1.3 ug/m^3; Other Sulfates (S) 4.3 ug/m^3; Other Nitrates (NO_3^-) 0.6 ug/m^3; and, Other Organic Carbon (OC) 0.6 ug/m^3. Coal combustion-related $PM_{2.5}$ and its key trace elements were most strongly associated with lung cancer $PM_{2.5}$-mortality associations.
Conclusions: Particles resulting from the combustion of fossil fuels, especially coal, are most associated with increased risk of lung cancer mortality from long-term $PM_{2.5}$ exposure.
Acknowledgement: This research supported by the Health Effects Institute's National Particle Component Toxicity Initiative.

Background and Aims:

A growing body of research has found associations between prenatal exposure to air pollution and adverse birth outcomes. The aim is to assess the association between exposure to traffic-related air pollution during pregnancy and anthropometric measures at birth in the Spanish INMA cohorts in Asturias, Gipuzkoa, Sabadell, and Valencia.

Methods:

Exposure to ambient nitrogen dioxide (NO_2) and benzene was estimated combining spatial modeling (land use regression) and temporal correction for a total of 2337 pregnant women's residence for each trimester and the whole pregnancy. Outcomes included birth weight, length, and head circumference adjusted by gestational age and sex. The association between air pollution exposure and birth outcomes was assessed with linear regression models controlled for potential confounders. We also examined the shape of the relationship using generalized additive models. We performed sensitivity analyses for the subset of women who spent ≥15 hr/day at home during pregnancy. Finally, we performed a combined analysis with meta-analysis techniques.

Results:

No significant improvement in the model was obtained with non-linear models. In the combined analysis, an increase of 10 $\mu g/m^3$ in NO_2 exposure during pregnancy was associated with a significant (at 95% confidence level) reduction in birth length near 1 mm. For the subset of women who spent ≥15 hr/day at home, the change in birth length was twice that. A nearly significant reduction in birth weight of 22 grams was found for the same NO_2 increase in the second trimester. We observed no significant relationship between benzene levels and birth outcomes.

Conclusions:

Residential NO_2 exposure during pregnancy was associated with reductions in size at birth. This association was clearer for the subset of women who spent more time at home.

CHALLENGES AND OPPORTUNITIES OF USING SYSTEMATIC SOCIAL OBSERVATION IN STUDIES OF NEIGHBOURHOOD AND HEALTH IN INFORMAL URBAN AREAS IN ALEPPO, SYRIA

Balsam Ahmad, *Institute of Health and Society, Newcastle University, UK*
Fouad M. Fouad, *Syrian Centre for Tobacco Studies, Syria*
Martin White, *Institute of Health and Society, Newcastle University, UK*
Tanja Pless-Mulloli, *Institute of Health and Society, Newcastle University, UK*

Background and Aims

Systematic social observation (SSO) is a method primarily used in studies of neighbourhood and health in western countries. The method is useful in measuring integral neighbourhood characteristics relevant to residents' health and well-being. Despite growing number of publications on the method, there has been none on its application to study informal urban neighbourhoods. The aim of this paper is to provide a critical discussion of the limitations and opportunities of using the SSO method to study characteristics of an informal area in Aleppo, Syria.

Methods

Twenty one observation points were randomly selected. Two teams of observers were trained to collect data on neighbourhood characteristics using an observational instrument with 32 items on land use; environmental quality and the social environment. The unit of observation (the spatial scale at which neighbourhood characteristics may differ) was identified as 100 meters of the right hand side of a street. Inter-rater reliability was calculated using percent agreement and Krippendorff's α.

Results

The inter-rater reliability ranged from poor to fair for most items. The main limitations included defining a meaningful unit of observation; the difficulties of validating whether the same points were observed and lack of routine health data at a small area level. The opportunities related to the novel application of a *Garmin* Global Positioning System and Google Earth maps to characterise an informal area and in finding out about variability in neighbourhood characteristics within the same area.

Conclusions

Systematic social observation is a valuable method to collect data on informal neighbourhoods especially, where routine environmental data are seldom available. However, special care should be taken to adapt the method and procedure of the observation to the context of informal areas. We offer several recommendations of how this method can be adapted to study informal areas.

PREVALENCE OF ASYMTOMATIC TOXIC AND NONTOXIC CLOSTRIDIUM DIFFICILE IN A BAVARIAN POPULATION

Christian Tuschak, Bavarian Health and Food Safety Authority, Oberschleissheim, Germany
Heribert Bischoff, Bavarian Health and Food Safety Authority Oberschleissheim, Germany
Roswitha Ullmann, Bavarian Health and Food Safety Authority, Oberschleissheim, Germany
Christiane Strauß, Bavarian Health and Food Safety Authority, Oberschleissheim, Germany
Bernhard Liebl, Bavarian Health and Food Safety Authority, Munich and Oberschleissheim, Germany
Christiane Höller, Bavarian Health and Food Safety Authority, Oberschleissheim, Germany
Caroline Herr, Bavarian Health and Food Safety Authority, Munich, Germany

Background and Aims:
Health care associated outbreaks especially with toxigenic C. difficile (CD) are difficult to control and increasingly reported from America and Europe with new, highly virulent strains, e.g. PCR-ribotype 027. Financial impact of CD associated disease (CDAD) on the healthcare system is substantial (5-15,000 euro/case in England and $1.1 billion/year in the USA). CD can be transmitted via personal contact or environmentally. In the majority of cases, it is associated with previous antibiotic exposure. The role of patients and healthcare workers who are symptom-free but colonised with CD in the intestinal tract is unclear, especially as CD is recognised increasingly in individuals previously not considered to be predisposed.
Most of these studies on prevalence of CD have looked at clinical or hospital admission specimens though, thus subjects with some recent previous medical treatment. Therefore they are inappropriate to assess the relevance of asymptomatic CD colonisation in the general population for health care associated CDAD.
We assessed gastrointestinal CD in asymptomatic subjects from a pool of routine stool samples of the Bavarian Health and Food Safety Authority.
Methods:
Stool of 767 individuals (gender, age and place of residence obtained during surveillance) was screened for CD and toxin production with an antibody-based test (C. diff Quick Chek Complete, Fa. Oxoid), supplemented by a culture-based approach and PCR -ribotyping.
Results:
Of 767 individuals 25 (3.3 %) were screened CD positive. From 12 (1,6 %) individuals toxigenic CD isolates were obtained, none were PCR-ribotype 027. In follow-up questioning 7 of these 12 individuals reported recent hospitalisation. When these are excluded prevalence to CD colonisation with toxigenic strains was 0.7% (5/767).
Conclusions:
CD prevalence was low in this asymptomatic population, indicating transmission in heath care and predisposition, i.e. antibiotic treatment being most relevant for health care associated CD.

ACTIVE TRAVEL, GENERAL PHYSICAL ACTIVITY, AND BODY MASS INDEX IN SWISS ADULTS: RESULTS FROM THE SWISS HEALTH SURVEYS 2002 AND 2007

Thomas Götschi, *Physical Activity and Health Unit, Institute of Social and Preventive Medicine, University of Zurich, Switzerland*
Miriam Wanner, *Physical Activity and Health Unit, Institute of Social and Preventive Medicine, University of Zurich, Switzerland*
Eva Martin-Diener, *Physical Activity and Health Unit, Institute of Social and Preventive Medicine, University of Zurich, Switzerland*
Sonja Kahlmeier, *Physical Activity and Health Unit, Institute of Social and Preventive Medicine, University of Zurich, Switzerland*

Background and Aims: Physical activity (PA) is associated with numerous health benefits. Active travel (AT), such as walking and bicycling, is of interest for health promotion as an opportunity to achieve activity recommendations of at least 150 minutes per week through routine activities, such as commuting or running errands. Therefore, AT may suit people which are not inclined to engage in sports or other forms of leisure time exercise.
Methods: Literature relating AT, total PA levels, and Body Mass Index (BMI) was systematically reviewed. The cross-sectional Swiss Health Surveys in 2002 and 2007 included over 18'000 participants each, assessing daily duration of walking and cycling, travel modes for daily routes, frequency of moderate- and vigorous-intensity PA, as well as BMI.
Means and proportions were age-standardized. Ordinal logistic regression models were calculated for BMI and PA as outcome variables and AT as predictor, adjusting for sports and other exercise, demographics, and other potential confounding variables.
Results: Most reviewed studies confirmed associations in the expected directions, such as more AT being associated with more PA and lower BMI, but varied in quality and quantitative comparability. Swiss adults (age 15-75) spent on average 33 minutes walking or bicycling with a marginal increase between 2002 and 2007; however, almost half did not report any time spent walking or cycling.
AT showed significant associations with total PA. Those reporting any AT (Ave. 62 min/day) were 16% (CI95%:11-22%) more likely to be in a higher activity category than drivers. Only travel mode was significantly associated with BMI. Associations with both outcomes were stronger for travel mode bicycling than for walking.
Conclusions: Swiss data confirm patterns between AT, PA, and BMI observed in the literature and thus the importance of AT for general PA. Cross-sectional analyses are limited in their capability to disentangle (reverse)-causality of the observed associations.

SEASONAL INFLUENZA: LINKS WITH METEOROLOGY AND SOCIAL NETWORK

Meena Doshi, *Tufts University, USA*
Sanjib Bhattacharyya, *City of Milwaukee Health Department Laboratory, USA*
David Bina, *City of Milwaukee Health Department Laboratory, USA*
Steve Gradus, *City of Milwaukee Health Department Laboratory, USA*
Yuri N. Naumov, *University of Massachusetts Medical School, USA*
Jack Gorski, *Blood Research Institute, BloodCenter of Wisconsin, USA*
Elena N. Naumova, *Tufts University, USA*

Background and Aims: Prevention of influenza is a long-standing public health objective. Recent observational studies demonstrate that complex seasonal influenza patterns are sensitive to changes in social networks. The experimental studies suggest potential links with meteorology, when influenza virus infectivity depends on the effect of ambient temperature and humidity. We examined the relationship between influenza, meteorological conditions, and social contacts' intensity using influenza virus surveillance in Milwaukee, Wisconsin, USA.

Methods: Laboratory-confirmed influenza cases were provided by the Milwaukee Health Department Laboratory during 5/22/2004-02/22/2011. Records contain weekly positive test results for the influenza A/H1N1, A/H3N2, 2009-A/H1N1 and Influenza-B strains detected in human subjects from six CDC-WHO-specified age groups (<1,1-4,5-24,25-44,45-64, and ≥65 yrs). Daily meteorological parameters (maximum/mean/minimum for temperature and relative humidity) were aggregated into weekly time series. Public school calendars were used to create the time series to reflect the probability of person-to-person contacts. Poisson harmonic regression models were used to assess seasonal characteristics: peak timing and absolute intensity for each strain and age group. Relative risks of influenza associated with temperature and humidity and their interactions with viral genome were estimated using non-linear regression models. The preliminary results are limited by the first 128 weeks of the study period (prior to the massive testing for 2009-A/H1N1 influenza).

Results: Three major influenza strains (A/H1N1, A/H3N2, Influenza-B) have distinct peaks at weeks: 8.6 [95%CI:8.0-9.1], 9.6 [95%CI:8.3-10.3], and 12.9 [95%CI:11.6-15.3] respectively. Influenza-A peaked at colder and less humid weather conditions compared to Influenza-B. The intensity of Influenza-B exhibited the 6-fold increase ($p<0.001$) over the study period. Intensity of community social network has minimal, impact on the influenza seasonality.

Conclusions: The seasonal influenza incidences are likely to be linked with meteorological conditions and school-related activities, however their effects on the circulating viruses and severity at a community level is inconclusive.

LEUKEMIA MORTALITY RISK FROM IONIZING RADIATION IN THE COHORT OF WISMUT URANIUM MINERS 1946–2003

Florian Dufey, Marion Sogl, Linda Walsh, Annemarie Tschense & Michaela Kreuzer.

Federal Office for Radiation Protection, Germany

Background and Aims: The dependence of the risk for leukemia mortality on ionizing radiation in the low dose range is of much interest in radiation protection. Data from the German Wismut uranium miner cohort study are analyzed here to further evaluate this topic.

Methods: The cohort includes about 59 000 men contributing 128 leukemia deaths and approximately 2 million person years during the time-span from 1946–2003 (uranium mining was done until 1989). The excess relative risk (ERR) and 95% confidence limits (CI) for leukemia in relation to absorbed red bone marrow (RBM) dose has been assessed using Poisson regression stratified by age and calendar year. Both linear and categorical models have been used. The average absorbed RBM dose was 48.8 mGy (range 0 to 989 mGy) to which external gamma radiation contributed on the mean 40.9 mGy (range 0 to 909 mGy).

Results: The linear trend in leukemia excess relative risk per unit absorbed RBM dose was ERR/Gy = 1.39 (95%CI −1.18 to 3.97, p = 0.29) assuming a lag-time of 2 years. The chronic lymphatic leukemia (CLL) and non-CLL sub-type linear risk estimates are 0.33 (95%CI: −3.44 to 4.11) and 2.08 (95%CI: −1.39 to 5.55), respectively.

Conclusions: The results do not show a statistically significant increase in risk of death from leukemia, but risk coefficients are consistent with published estimates. The present study is limited by low numbers of leukemia cases, a low dose range and lack of data on leukemia incidence. Presently information on medical radiation exposure is gathered in an ongoing nested case control study on leukemia based on an extended follow-up period.

DESIGNING RELEVANT STUDY ZONES FOR ECOLOGICAL STUDIES: THE PAISARC+ PROJECT

Wahida Kihal, *Ecole des Hautes Etudes en Santé Publique (EHESP), Rennes, France ; LIVE (CNRS/UdS) Department of Geography, Strasbourg University, France*
Clive E Sabel, *Geography, College of Life & Environmental Sciences, University of Exeter, Amory Building, Rennes Drive, Exeter, EX4 4RJ, UK.*
Denis Bard, *Ecole des Hautes Etudes en Santé Publique (EHESP), Rennes, France.*
Christiane Weber, *LIVE (CNRS/UdS) Department of Geography, Strasbourg University, France*

Background and Aims: Spatial boundaries constructed from population census data or for other administrative purposes do not necessarily match to the neighborhood contours that define a community. This in turn may hamper the relevant testing of epidemiologic hypotheses in ecological studies.
Our aim was to design the appropriate areal unit for testing the neighborhood influences on the relationship between ambient air pollution and 2 short-term health outcomes, that is, asthma exacerbation and onset of myocardial infarction, on a very small scale ecological basis.
Methods: Using GIS (Geographic InformationSystem) tools and concepts, we designed and applied five approaches for census-block population disaggregation, in cells of 250 x250 m (a common spatial unit to explored contextual variables available at different scales). Homogeneous neighbourhoods were constructed according to our Deprivation Neighbourhood Measure (The NDM is calculated from 27 relevant variables grouped into 3 domains -socio-economic feature; social cohesion and public resources). AZTool software (David Martin, University of Southampton, UK) was used to then re-aggregate cells into a new, both hypothesis-driven and data-driven, areal unit. Three criteria were considered: *(i)* output zone homogeneity as regards neighborhood context characterization, *(ii)* population target size, *(iii)* shape compactness. We tested several relative weighing combinations of these parameters.
Results: The original 1608 (at 250mx250m) cells were aggregated into 220 non-linear neighbourhoods including 2000 persons, and similar as regards neighborhood context (intra-area correlation = 0.58).
Conclusion: Our approach allows to design on a relevant basis, a very small scale spatial unit, to be used in further case-crossover studies, as indicated in the objectives.

A RETROSPECTIVE COHORT STUDY OF RESIDENTS NEAR MULTIPLE POINT SOURCES OF AIR POLLUTION

Chiara Badaloni *Department of Epidemiology Lazio Regional Health Service,Rome, Italy*
Giulia Cesaroni *Department of Epidemiology Lazio Regional Health Service, Rome, Italy*
Francesca Mataloni *Department of Epidemiology Lazio Regional Health Service, Rome, Italy*
Carla Ancona *Department of Epidemiology Lazio Regional Health Service, Rome, Italy*
Simone Bucci *Department of Epidemiology Lazio Regional Health Service, Rome, Italy*
Andrea Bolignano *Regional Environmental Protection Agency, Lazio Region, Rome, Italy*
Roberto Sozzi *Regional Environmental Protection Agency, Lazio Region, Rome, Rome, Italy*
Francesco Forestiere *Department of Epidemiology Lazio Regional Health Service, Rome, Italy*

Background and Aims: In the area of Malagrotta, a suburb of Rome (Italy), a large waste landfill, an incinerator and an oil refinery plant have been operating since the early 1960s. To evaluate the health effects due to airborne contamination, a retrospective cohort study is on-going using GIS and dispersion modelling to characterize the exposures.
Methods: The study area was defined as the 7 km zone around the landfill. The cohort was based on the Rome Longitudinal Study based on the 2001 census with a mortality follow-up until 2008. For each cohort member, individual (education, occupation, place of birth, civil status, area-based SES) and GIS variables (distance from motorways and from high traffic roads) were available. Exposures to NO_2 from traffic and from diesel trucks collecting waste were available from a land use regression model (R^2=0.72) and an ADMS dispersion model, respectively. Exposure assessment to the incinerator (NOx), the refinery plant (SOx) and the landfill (H_2S, indicator of diffuse emissions) was done with the SPRAY Lagrangian dispersion model. Cox regression analysis was used considering individual and GIS variables as confounders.
Results: The cohort included 85,559 individuals (8.5% distant less than 3km from the plants). During the study period, 4,848 deaths for all causes, and 1,741 for cancer were observed. There was some degree of correlation among the three exposure indicators of interest (NOx, SOx, and H_2S). No association with distance from the plants was observed. Exposures from the refinery plant (hazard ratio, HR=1.43, 95%CI:1.17-1.79, high vs low SOx) and from the landfill (HR=1.26, 95%CI:1.01-1.57, high vs low H_2S) were associated with overall mortality.
Conclusions: Evaluation of the health effects near multiple sources of air pollution is difficult. We used a large retrospective cohort with detailed exposure assessment. Health effects, not detectable using distance as a proxy of exposure, were observed.

LIVING CLOSE TO A MAIN ROAD DURING INFANCY IS ASSOCIATED WITH ATOPIC ECZEMA IN KOREAN SCHOOLCHILDREN

Ho-Jang Kwon, *Department of Preventive Medicine, Dankook University College of Medicine, Cheonan, Republic of Korea*
Yun-Chul Hong, *Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea*
Soo-Jong Hong , *Department of Pediatrics, University of Ulsan College of Medicine, Seoul, Republic of Korea*
Jong-Han Leem, *Department of Occupational and Environmental Medicine, Inha University School of Medicine, Incheon, Republic of Korea*

Background and Aims: The prevalence of allergic diseases has increased during the past decades in Korea, with the increasing tendency that more children are exposed to traffic-related air pollutants as potential risk factor of allergic diseases. The objective in our study is to assess the relationship between living close to a main road during infancy and atopic eczema in Korean children.
Methods: From 2005 to 2006, we studied the first or second grade elementary school children at the age 6~8years in ten South Korea cities as part of the first Children's Health and Environmental Research (CHEER) survey. During the first two years of the CHEER study, 2927 children were included in these analyses. To collect information on the medical history of the children, we used standardized questionnaires that include the International Study of Asthma and Allergies in Childhood (ISAAC) questions. In order to assign an exposure estimate to each subject, the residential address of each participant was geocoded and subsequently mapped using geographic information system (GIS) computer software ArcGIS 9.3. Distance of residence from the nearest main road was classified into four categories (<75, 75 to 110, 110 to 200, and >200 m) and length of main roads within a 200m buffer was also classified into four categories (0, 1 to 150, 151 to 300, and >300 m). Logistic regression analysis was performed to estimate odds ratios (ORs) and 95% confidence intervals (CIs) of atopic eczema relative to the distance of homes from the nearest main road and length of main roads.
Results: The lifetime and 12-month prevalence of atopic eczema, the lifetime atopic eczema diagnosis, and 12-month treatment were 37.7%, 21.9%, 33.4%, and 9.4%, respectively. Inverse associations were found between the distance to the nearest main road and atopic eczema. The highest adjusted odds ratios(ORs) for children living less than 75m from main roads were found for lifetime atopic eczema (OR, 1.36; 95% confidence interval(CI), 1.04-1.77), past year atopic eczema (OR, 1.50; 95% CI, 1.06-2.24), atopic eczema treatment (OR, 1.54; 95% CI, 1.06-2.24), respectively.
Discussion: The current cross-sectional study found that a shorter distance from the residence to the nearest main road during infancy, especially within 75m, was significantly related to an increased prevalence of doctor-diagnosed atopic eczema and symptoms of atopic eczema at the age 6~8years. Furthermore, a positive exposure-response relationship between length of road within 200m of the residential location was significant for doctor-diagnosed atopic eczema and symptoms of wheeze or atopic eczema. However, our findings were based on a proxy marker for traffic-related air pollution and on crude exposure period. Further investigation with longitudinal models are needed which incorporate life-time exposure to pollution.

INTEGRATED ENVIRONMENTAL HEALTH IMPACT ASSESSMENT OF DISINFECTION BY-PRODUCTS

James Grellier, *Department of Epidemiology and Biostatistics, Imperial College London, United Kingdom*
Lesley Rushton, *Department of Epidemiology and Biostatistics, Imperial College London, United Kingdom*
Mark J Nieuwenhuijsen, *Centre for Research in Environmental Epidemiology (CREAL), IMIM, CIBERESP, Barcelona, Spain; Department of Epidemiology and Biostatistics, Imperial College London, United Kingdom*
David J Briggs, *Department of Epidemiology and Biostatistics, Imperial College London, United Kingdom*

Background and Aims: Disinfection by-products (DBPs) in drinking water are associated with several health outcomes. Impact assessment of DBPs is dominated by unitary approaches relying on monitoring data and toxicological estimates of dose-response. This study aimed to carry out an integrated environmental health impact assessment (IEHIA) of DBPs that took into account the full chain between environmental drivers of DBP formation (organic carbon in surface water) and health impacts, under contrasting climate change scenarios.
Methods: The assessment was carried out for two UK regions for which land use scenarios had been previously developed for 2051. A regression model was constructed and validated using dissolved organic carbon (DOC) monitoring data. A published water balance model was modified and combined with the regression model, and DOC concentrations were estimated under each scenario. Estimates of total trihalomethane (TTHM) concentration were generated using laboratory-based models. Exposure-response functions (ERF) were derived from meta-analysis (SGA) and pooled analysis (bladder cancer). Health impacts were computed probabilistically, by applying the ERFs to projections of population and rates of disease.
Results: Estimated health impacts in the two study areas for SGA and bladder cancer increased under both climate scenarios relative to a 2001 baseline. Increases were greatest in the region where surface water is primarily used as a source: attributable cases of bladder cancer increased by 60-70%; cases of SGA increased by around 35%. The low emissions scenario yielded smaller impacts, but any health benefit from adopting low emission policies was small: in the order of a 20% reduction of cases of bladder cancer and 9% of SGA in the high surface water use region.
Conclusions: IEHIA was applied for the first time to DBPs, a systemic risk factor in drinking water. Modelling of the full chain produced estimates of health impacts under future climate scenarios.

USE AND PERCEPTION OF URBAN (INDUSTRIAL) FORESTS

Background and Aims

Urban nature and green areas are of a high value for public health (physical activity, climate adaptation strategies, reducing hazardous substances, etc.). The industrial forest Rheinelbe in Gelsenkirchen (Germany) also constitutes a health-promoting resource, especially for the local population. The extent to which this resource can unfold its various potentials, depends on how it is or is not used. Decisive factors here can be how the public perceives it as well as eventual obstacles to its use. In order to determine non-use, perception and possible obstacles to use in various population groups, in 2008/2009 a study was carried out on the use (or non-use) of the industrial forest by the (local) population.

Methods

In 2008 a conceptual study was done on procedures for developing the industrial forest (on-site observation, surveying, interviewing experts). As part of a follow-up study in 2009, a mail survey was taken of the population in the adjoining city district. The bilingual questionnaire developed specifically for this purpose included quantitative and (semi-)qualitative items which were then evaluated as descriptive statistics and compared with the results of the concept study.

Results

The industrial forest is used for rest and leisure, its road also for non-motor transport. People visiting the forest report positive health effects (e.g. relaxation, good air quality) and active/passive nature experience. While those surveyed in the forest reported coming there to visit it often, residents from the adjoining area came over less often. Furthermore, individuals with an immigrant background visited the forest less often than did natives. Potential obstacles to visiting the forest were feelings of low personal safety (dependent on gender and/or nationality), no knowledge of the forest, and little or no feelings of identity with the former colliery's area.

Conclusions

Visitors surveyed on site and people surveyed by mail in adjoining areas perceived the industrial forest as an important and long-term health factor. From a health sciences viewpoint, the salutogenic potential of natural urban green areas need to be communicated more broadly and clearly so these areas will be used by as many population groups as possible. Further research is needed to determine how the effect of targeted, long-term, target group-specific measures can be embedded already at the planning stage.

ASSOCIATIONS BETWEEN SHORT-TERM CHANGES IN AMBIENT PARTICULATES AND GASEOUS POLLUTANTS AND TRANSIENT ISCHAEMIC ATTACK

Getahun Bero Bedada, *Karolinska Institutet, Sweden*
Steve Hopkins, *University of Manchester, UK*
Adrian Hirst, *University of Manchester, UK*
Craig Smith, *University of Manchester, UK*
Pippa Tyrrell, *University of Manchester, UK*
Raymond Agius, *University of Manchester, UK*

Background and Aims: While several studies have investigated the effects of short-term air pollution on cardiac outcomes, less is known about its effects on cerebrovascular disease, including stroke and transient ischaemic attacks (TIA). The aim of this study was to assess the effects of short-term variation in air pollutants on the onset of TIA and minor stroke.
Methods: We performed secondary analyses of NORTHSTAR, a prospective multicentre study designed to investigate the prognostic role of peripheral and genetic inflammatory markers in patients with recent TIA or minor stroke. A case crossover study was conducted to determine the association between occurrence of TIA or minor stroke and changes in ambient PM_{10} or gaseous pollutants.
Results: A total of 709 cases of TIA and minor stroke were recruited from the Manchester (n=335) and Liverpool (n=374) areas. The participants were mostly elderly patients with an age range of 27-93 years and a mean of 66.8 ± 11. Data for the Manchester cohort showed an association between ambient nitric oxide (NO) and risk of occurrence of TIA or minor stroke with a lag of 3 days (odds ratio 1.06, 95% CI 1.01 – 1.11), whereas no association was found for the patients from Liverpool. Effects of similar magnitude, although not statistically significant, were generally observed with other pollutants. In a two pollutant model the effect of NO remained stronger and statistically significant when analysed in combination with CO and SO_2, but was marginal in combination with NO_2 or ozone and non-significant with PM_{10}. There was evidence of effect modification by age, gender and season.
Conclusions: Our data suggest an association between changes in ambient NO concentration (which may have been a surrogate for another pollutant), and the occurrence of TIA in Greater Manchester.

ANALYSIS OF TUBERCULOSIS IN CHILDREN UNDER 15 YEARS IN ONE OF THE MOST AFFECTED REGION IN ROMANIA

Venera Dinescu, *University of Medicine and Pharmacy of Craiova, Hygiene-Environmental Health Department,*
Elena Catalina Bica, *University of Medicine and Pharmacy of Craiova, Pediatrics Department*
Sorin N. Dinescu, *University of Medicine and Pharmacy of Craiova, Epidemiology Department*
Corneliu Miu, *Victor Babes Infectious Diseases Clinical Hospital, Craiova*

Background and Aims. Dolj County is one of the counties with highest incidence of tuberculosis in Romania. The purpose of this study was evaluation of tuberculosis in children under the age of 15 years in this region.
Method. Were included a 347 cases during 2001 and 2010. Inclusion criteria were diagnosis of tuberculosis, and age under 15 years. For statistically analyze it was used incidence, relative risk, and 95% confidence interval for risk.
Results. The average incidence was 32.79/100000 and was noticed a certain downward trend of incidence over the past 5 years (p <0.005). Decreased average incidence over the past five years was 43%. The risk of tuberculosis in the period 2001-2005 was 1.45 times higher compared with the period 2005-2010 (CI95% 1,09-2,11; p=0,018).
Pulmonary forms predominated (76.23%) compared with extrapulmonary (23.77%). The risk for pulmonary localization tuberculosis was 3.2 times higher (CI95% 2.5-4.04, p <0.005). He was also noted a higher frequency of extrapulomonary forms in children in urban areas (25.83%) compared with those in rural areas (19.81%). Analysis of smear positive rate showed a low rate of only 25.84%, the risk of BK negative sputum being 2.88 (IC95% 2,29-3,61; p<0,005). Risk of a positive sputum in children from urban was almost two times higher than rural children (RR=1,85 IC95% 1,20-2,86; p=0,004).
A total of 31 cases (7.75%) were from known outbreaks of tuberculosis. All cases of outbreaks of tuberculosis, however, were only identified in children from rural areas (21.09%).
Conclusions. Decreased incidence of tuberculosis in children under 15 is the result of joint efforts at regional and national level and WHO support. Lower rate of positive sputum in children continues to hamper the identification of new cases of tuberculosis in children. Outbreaks in rural areas require further combat and control of tuberculosis in rural communities.

OUTDOOR AIR POLLUTION AND SOCIAL STRESSORS ACROSS NYC COMMUNITIES: A GIS-BASED SPATIAL CORRELATION STUDY OF MULTIPLE EXPOSURES IN THE URBAN ENVIRONMENT

Jane E. Clougherty, *University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA - Summit Research Associates, New York, NY and Asheville, NC, USA*

Background and Aims: Chronic psychological stress has been linked to respiratory health, both independently and in combination with air pollution. Geographically patterned community-level social stressors (e.g., noise, violence) may impact upon individual psychological stress. Here, we address methodological challenges in characterizing spatial correlations among community stressors, and in interpreting publicly available data collected at different administrative areas. We then validate the utility of community-level stressor indices to explain differences in individual-level stress, enabling a meaningful exploration of synergistic effects of social and environmental exposures on urban health.
Methods:Building on the New York City Community Air Survey (NYCCAS), a year-round study of intra-urban variation in air pollutants, we use GIS-based methods to explore spatial correlation among community-level stressors (e.g. violent crime, noise annoyance, mental health, poverty, quality of life, childhood stressors), and with air pollution. We employ simultaneous autoregressive (SAR) modelling, leveraging spatial autocorrelation within indicators, to assess correlations among exposures, and developed a novel GIS-based method for comparison among incongruent administrative areas. Tests for sensitivity to unit of aggregation were conducted using high-resolution air pollution and census data.
Results: Using GIS-based spatial analysis, we identified spatial autocorrelation and inter-neighborhood variability in all covariates. Preliminary analyses showed that stressor and air pollution exposures were not uniformly correlated across the city. Leveraging autocorrelation revealed inconsistent influence on observed associations among these community-level exposures.
Conclusions:Our analyses suggest that community stressors are not consistently spatially correlated with neighbourhood poverty or air pollution. These spatial discrepancies enable examination of independent and synergistic effects on health, and characterization of potential differential air pollution impacts on susceptible communities. Unmeasured spatial confounding and autocorrelation may bias epidemiologic findings on multiple exposures. Next steps include participatory GIS to validate neighborhood boundaries, focus groups to identify important community-level stressors, and surveys to assess the relevance of community stressors in explaining individual-level stress.

Climate change adaptation and mitigation strategies: considerations with respect to electromagnetic fields

Rik Bogers, Centre for Environmental Health, National Institute for Public Health and the Environment, the Netherlands
Ronald van der Graaf, Knowledge Platform Electromagnetic Fields, the Netherlands
Leo Lagendijk, Knowledge Platform Electromagnetic Fields, the Netherlands
Erik Lebret, Centre for Environmental Health, National Institute for Public Health and the Environment, the Netherlands; Knowledge Platform Electromagnetic Fields, the Netherlands; Institute of Risk Assessment Sciences (Utrecht University), the Netherlands

Background and aims: Technological developments to mitigate or adapt to climate change may alter the population's exposure to electromagnetic fields (EMF), in particular extremely low frequency (ELF)-EMF. Our main objectives were to perform a "horizon scan" about potential effects of climate change adaptation/mitigation strategies on the design, use, location or quantity of sources of EMF, and concomitant changes in exposure to EMF of (groups of) the population. Existing knowledge about potential health effects is briefly summarised in the poster.
Methods: Information about EMF-related aspects of climate adaptation and mitigation strategies was obtained by consulting experts in electricity production and transport. The (scientific) literature was consulted about health effects of EMF exposure.
Results: A major developments will be that a central production process that is dependent on fossil fuels (coals, oil and gas) will be replaced with a combined central and decentral production process that uses solar panels, wind turbines and hydro-electric power stations. Further, (inter)national electricity systems will be more interconnected. Both developments require a strong expansion of the network of overhead or underground high-voltage power lines. If the electric car will be used on a large scale, this has to be accompanied by a dense charging infrastructure in public and private spaces.
How these developments will translate to the public's EMF exposure is dependent on a.o. how the electricity infrastructure will be designed in relation to residential areas.
Conclusions: The climate change induced adaptations in electricity production and transport may change average proximity to (overhead) power lines and exposure to ELF-EMF in the population, which may change the associated risk of childhood leukaemia. Moreover, we anticipate proliferation of idiopathic environmental intolerances attributed to EMF, and increased concerns about health risks.

METHYLMERCURY IN SPORT FISH AND ADVERSE REPRODUCTIVE OUTCOMES IN SOUTH CAROLINA

James Burch, *University of South Carolina, USA*
Sara Wagner, *University of Georgia, USA*
Robin Puett, *University of South Carolina, USA*
Bo Cai, *University of South Carolina, USA*
Wilfried Karmaus, *University of South Carolina, USA*
John Vena, *University of Georgia, USA*
John Besley, *University of South Carolina, USA*
Erik Svendsen, *University of South Carolina, USA*

Background and Aims: Sport and subsistence fishing are common in South Carolina (SC, USA), although there is limited information on the potential health effects of these activities. Mercury is a neurodevelopmental toxin with widespread distribution in aquatic ecosystems. Fish consumption advisories for methylmercury (MeHg) have been issued for many SC rivers.
Methods: Residential locations of live births from 1995 to 2005 (birth certificates, SC Vital Statistics Registry) were geocoded and statewide sportfish MeHg biomonitoring data were spatially interpolated via kriging to estimate MeHg concentrations at each location. Generalized estimating equations were used to test the hypothesis that risk of low birth weight (LBW, <2,500 grams) was greater among women living in areas with elevated MeHg in fish, after adjustment for maternal age, race, education, smoking, prenatal care, and parity. Separate analyses evaluated the proximity of each residence to rivers with MeHg fish consumption advisories (within or beyond 8 kilometers).
Results: There were 362,580 live births available for analysis (statewide LBW rate=7%). LBW cases were more likely to reside in residences in the upper quartile of predicted MeHg (odds ratio [OR]=1.04; 95% confidence interval [CI]: 1.00-1.09) or within 8 kilometers of a river with a 'do not eat' fish advisory (1.05; 1.00-1.11) compared to the lowest quartile, or to rivers without fish consumption restrictions, respectively. In general, stronger associations between low birth weight and elevated MeHg were observed among African compared to European American mothers. The monthly average number of sport fish meals among African American women in one region with elevated fish MeHg was five times greater than European American women (5 ± 8 vs. 1 ± 2, respectively).
Conclusions: This analysis suggests a need for more detailed, individual-level studies to assess reproductive health risks related to MeHg exposure from sport fish consumption in SC.

Adverse pregnancy outcomes and maternal urban or rural residence at birth

Juliana Chrisman, *ENSP/FIOCRUZ, Brazil*
Paula Sarcinelli, *ENSP/FIOCRUZ, Brazil*
Rosalina Koifman, *ENSP/FIOCRUZ, Brazil*
Sergio Koifman,*ENSP/FIOCRUZ, Brazil*
Armando Meyer, *IESC/UFRJ, Brazil*

Background and Aims: Adverse birth outcomes such as low birth weight, preterm birth, and congenital birth defects are important risk factors for infant mortality and are a major public health issue in rural areas. This study aimed to explore the distribution of selected adverse birth outcomes in newborns according to rural/urban status of maternal residence at birth in a Brazilian municipality.

Methods: Information about all live births occurred between 2004 and 2006 in the Municipality of Nova Friburgo, Brazil, was retrieved from the Live Birth Information System. Liveborns were classified as rural or urban, according to their mother's residence address. Prevalence ratios were then calculated, along with their respective confidence interval (CI95%). Analyses were stratified by education level, age, number of examinations, type of gestation (single or multiple), and type of delivery (natural or c-section) and by using Poisson regression we did adjust prevalence ratios.

Results: Among C-section births, we observed in pregnant women from rural zone an increased risk of malformation (PR: 2.14; CI95%: 1.06-4.33). Pregnant women from rural areas were also more likely to give birth to very low weighted babies (PR: 5.19; CI95%: 1.72-15.17) in twin pregnancies, when compared to pregnant women from urban areas.Adjustment prevalence ratio showed agreater risk of very low birth weight (PR:1.25; CI95%:0.80-1.95), and low APGAR score in the 5th minute (PR:1.61; CI95%:0.78-3.33) and an increased risk ofmalformation detectable at birth (PR:1.73; CI95%:0.89- 3.38).

Conclusions: Our results indicate that women residing in rural areas were at higher risk to give birth to an infant with very low birth weight, low Apgar index at the 5th minute and malformations detectable at birth, regardless of socioeconomic and gestational conditions.

EFFECTS OF PRENATAL EXPOSURE TO ORGANOCHLORINES AND MERCURY ON GROWTH PARAMETERS IN INUIT NEWBORNS FROM THE CANADIAN ARCTIC

Gina Muckle, *CHUQ Medical Research Center and Laval University, Canada*
Renée Dallaire, *CHUQ Medical Research Center and Laval University, 2875 boul. Laurier, 6th Floor, Édifice Delta 2, room 600, Québec City (Québec), Canada, renee.dallaire@crchul.ulaval.ca*

Éric Dewailly, *CHUQ Medical Research Center and Laval University, Canada*
Nadine Forget-Dubois, *CHUQ Medical Research Center and Laval University, Canada*
Sandra W. Jacobson, *Wayne State University, USA.*
Joseph L. Jacobson, *Wayne State University, USA*

Background: Maternal consumption of seafood during pregnancy has been shown to be a source of exposure for the foetus to several environmental contaminants (ECs), including polychlorinated biphenyls (PCBs), chlorinated pesticides (CPs) and methylmercury (MeHg). These ECs have been found to be related to impaired foetal growth and shorter pregnancy duration in previous studies. On the other hand, seafood products are also an excellent source of docosahexaenoic acid (DHA), which has been shown to have beneficial effects on pregnancy outcomes and foetal growth. So far, it remains unclear if DHA intake during pregnancy can attenuate the potential adverse effect of ECs on foetal growth.
Objectives: To investigate the association of *in utero* exposure to ECs with pregnancy duration and foetal growth while taking into account the possible beneficial effects of DHA.
Methods: Pregnant Inuit women (n = 251) from Nunavik (Canada) were interviewed at mid-pregnancy and 1 month postpartum. Umbilical cord blood samples were collected from their newborns and analyzed for contaminants and DHA. Birth weight, length and head circumference were measured, and gestational age was assessed from date of last menstrual period. Multiple linear regressions and path models were used to evaluate direct effects of exposure to ECs on growth parameters and indirect effect on foetal growth through their impact on pregnancy duration.
Results: PCB 153, two CPs and MeHg were negatively associated with pregnancy duration in multivariate models. Indirect models revealed that all ECs were negatively associated with growth measurements through their negative relationships with pregnancy duration. Conversely, umbilical cord DHA concentration was positively related to growth parameters through its positive association with gestation duration.
Conclusion: *In utero* exposure to ECs of Inuit newborns was associated with reduced pregnancy duration, which adversely affects foetal growth. However, cord DHA appears to mitigate these effects on growth by prolonging gestational length.

Beatriz Pérez-Gómez Environmental Epidemiology. ISCIII. C/ Monforte de Lemos 5. E28029, Madrid (Spain)

Background and Aims: BIOAMBIENT.ES Is the first Human Biomonitoring study made in Spain at national level including Canary Islands and the autonomous African province of Ceuta. The study is carried out under the responsibility of the National Spanish Institute of Health, Carlos III, and funded by the Ministry of Environment.
Methods: The study involved 1936 voluntaries, from 18 to 67 years old, using a complex design intended to reflect the Spanish active population structure by sex, economic activity sector and region. Recruitment campaign, started in March 2009 finished in July 2010, included four sampling periods in order to cover for season variability. Urine, blood, serum and scalp hair were analyzed for persistent organic pollutants, cotinine and heavy metals and followed up by epidemiological questionnaires of living style and diet.
Results: Analysis are not finished. The first results show: Geometric mean (GM) and 95% confidence intervals (CI) for urinary cadmium concentrations were 0.24 (0.23-0.25) µg Cd/g creatinine. Mercury concentration (GM) in scalp hair was 1.86 (1.76-1.97) µg Hg/g hair (only given by 31% of the participants volunteers) The GM (CI95%) for the sum of PCB 138, 153 and 180 was 135.6 (130.5-140.8) ng/g lipid. For PCB 28, PCB 52, 99% of the studied population was bellow 59 ng/g lipid and 94% bellow 11,8 ng/g lipid for PCB 101. Polybrominated diphenyl ethers (PBDEs) levels were below the quantification limit (0,01ng/mL)
Conclusions: Results from BIOAMBIENT.ES show that the concentrations of environmental pollutants in the Spanish population are similar to that reported in HBM studies from other countries (USA; CDC 2009, Germany; Schulz et al 2003). The exception is mercury in hair which is much higher in the Spanish population, probably because of a high consumption of fish and other marine products.
References: CDC. 2009. Fourth National Report on Human Exposure to Environmental Chemicals. Department of Health and Human Services, USA.

UNDERSTANDING WALKABILITY: HOW POLICYMAKERS ASSESS FACTORS THAT INFLUENCE ACTIVE TRANSPORT

Kevin M. Leyden,*Centre for Innovation and Structural Change, J.E. Cairnes School of Business & Economics, College of Business, Public Policy and Law, National University of Ireland, Galway, Ireland*
Lorraine Fitzsimons, *School of Health and Human Performance Dublin City University, Dublin, Ireland*
Catherine Woods, *Head of the School of Health and Human Performance, Senior Lecturer at Dublin City University, Dublin, Ireland*
James Wickham, *Trinity College Dublin, Dublin, Ireland*

Background & Aims: In recent years there has been considerable growth in the public health research area investigating the influence of the built environment on physical activity. Simultaneously, environmental, transport and planning professionals have been promoting a modal change to active transport modes to reduce traffic congestion and air pollution. A core factor in both areas of research is the concept of 'walkability'. International literature suggests that walkable areas are favourable to active transport (i.e., walking and cycling) but the factors used to identify what a walkable area or neighbourhood actually is can be varied and contradictory. In addition, many professionals and policy-makers have different ideas or expectations as to what makes an area walkable or not. The purpose of this paper is to examine how various professionals and policy-makers in Dublin understand and operationalize the concept of walkability. A key component of this study is to understand to what extent these decision-makers consider public health concerns as well as others concerns such as safety issues, traffic management, air quality, the nature of the local economy, and aesthetics, among others.
Methods:This study is part of a larger study called the The 'Cleaner, Greener, Leaner Study', which is funded in part by the Irish Environmental Protection Agency's STRIVE programme. The study aims to examine to what extent urban form impacts individual level health; transport behaviour; and hence the production of air pollution and greenhouse emissions in the Greater Dublin Area. The first stage of the study is to develop a local definition of 'walkability' that is suitable for use in an Irish context.
In order to understand the views of various relevant professions on the concept of 'walkability', we conducted a comprehensive survey targeting professionals and policymakers who work in the area of planning, urban design, engineering, and construction of the built environment and transport systems. Our final sample size was 218 professionals and policy-makers. In addition we conducted five in-depth focus groups with a sub-sample of these decision-makers. We use information from these focus groups to further interpret our quantitative based survey findings

Results: The data collection phase for this stage of the project was recently completed. We are in the process of analyzing our findings. Initial results, clearly indicate that whilst quality footpaths or sidewalks and nearby destinations are important to all professional groups and policy-makers there are some significant differences on how professionals view walkability and its value to the public. Many professionals and policy-makes do not adequately consider health concerns when making decisions about the nature of the built environment.
Conclusions: We feel our study is important because we work to "get inside the heads" of professionals and policy-makers who make decisions about the way our built environments function and the way we travel. In doing so, we provide key insights into the conceptualization of walkability and the thinking that affects decisions to build or not build places that enable active transport and improve health.

PLASMA HOMOCYSTEINE LEVELS ACCORDING TO TWO *METHYLENETETRAHYDROFOLATE* GENETIC POLYMORPHISMS AND SERUM FOLATE LEVELS IN A POPULATION-BASED STUDY IN SÃO PAULO, BRAZIL

Valéria Troncoso Baltar, *University of São Paulo, São Paulo, Brazil*
Josiane Steluti, *University of São Paulo, São Paulo, Brazil*
Roberta Schein Bigio, *University of São Paulo, São Paulo, Brazil*
Gilka Jorge Figaro Gattás, *University of São Paulo, São Paulo, Brazil*
Regina Mara Fisberg, *University of São Paulo, São Paulo, Brazil*
Dirce Maria Lobo Marchioni, *University of São Paulo, São Paulo, Brazil*

Background and Aims: Hyperhomocysteinemia is a risk factor of cardiovascular disease. Homocysteine remethylation requires vitamin B12, folate and methylenetetrahydrofolate reductase (MTHFR) enzyme. The TT homozygosis of the C677T and CC of A1298C in the MTHFR gene are associated with reduced MTHFR activity. This study aims to assess the impact of serum levels of B12 and folate on plasma homocysteine considering C677T and A1298C polymorphism in a Brazilian sample.

Methods: Serum vitamin B12, folate, and plasma homocysteine of 259 participants from a population-based survey in São Paulo were used. The genotypes were done with an *allele-specific* polymerase chain reaction. Two generalized linear models with gamma distribution and link identity were applied to model homocysteine according to sex, age, vitamin B12 as well as folate (cut-off at tercile 7.1 ng/mL) and each polymorphism (C677T: non-TT and TT; A1298C: non-CC and CC) interactions.

Results: Significant effects of males ($p<0.01$) and age ($p<0.01$) were found for both models. An increase of 50 pg/mL in vitamin B12 was associated with a reduction of 0.11 ng/mL ($p=0.01$) and 0.13 ng/mL ($p=0.01$) in homocysteine levels for C677T and for A1298C model, respectively. Finally, an interaction between C677T and folate was found ($p<0.01$) whereas between A1298C and folate was not significant. In the C677T model a mean difference of 5.7 ng/mL of homocysteine levels was observed between lower and higher folate among TT genotype ($p<0.01$) whereas a difference of only 1.1 ng/mL among non-TT ($p<0.01$). Homocysteine levels among participants with higher folate were similar between non-TT and TT ($p=0.57$). In the A1298C model a 1.86 ng/mL homocysteine levels difference was observed between higher and lower folate for non-CC and CC genotypes similarly.

Conclusion: Lower levels of folate are associated with higher levels of homocysteine, but in the presence of TT homozygote for C677T genotype homocysteine is even higher.

POLYBROMINATED DIPHENYL ETHERS AND SOCIAL AND EMOTIONAL DEVELOPMENT IN TODDLERS

KateHoff@email.unc.edu

Background and Aims: Polybrominated diphenyl ethers (PBDEs) are widely used flame retardants that have become ubiquitous environmental contaminants. PBDEs accumulate in breast milk and have been linked to adverse neurodevelopment in animals and humans, raising concerns about adverse health impacts of exposure during infancy. We investigated the association between breast milk exposure to PBDEs and social and emotional development in toddlers.

Methods: A longitudinal cohort study followed pregnant women and their children through 36 months of age in central North Carolina. Breast milk samples obtained at 3 months postpartum were analyzed for PBDEs. The Infant-Toddler Social and Emotional Assessment (ITSEA) was completed by mothers to assess children's social and emotional development at age 24 months (n=222). We assessed the relationship between the most commonly detected congeners in our study population, BDE-28, 47, 99, 100 and 153, and child social and emotional development using multivariate regression analysis, adjusting for maternal age, parity, income and education, as well as child's age, gender, and breastfeeding duration.

Results: Median breast milk concentrations of BDE-28, 47, 99, 100, and 153 were 2.2, 28.7, 5.5, 5.3, and 5.6 ng/g lipid, respectively. A small but consistent positive dose-response relationship between BDE-47, 99, and 100 and increased externalizing behaviors, specifically impulsivity, was apparent. Externalizing behavior scores ranged from 30 to 87 with a mean of 48. Compared to those with BDE-47 exposures below the median, adjusted externalizing behavior scores were 1.5 and 2.4 points higher for children with exposures in the 3rd and 4th quartiles (99% Confidence Intervals: -2.3, 5.2 and -1.4, 6.2, respectively). PBDEs were not associated with other social and emotional developmental domains.

Conclusions: Our results, although imprecise, are consistent with an association between early life PBDE exposure through breast milk and increased impulsivity in childhood. Confirmation of these results is needed in other longitudinal studies.

AIRBORNE TRICHLORAMINE (NCl_3) EXPOSURE IN INDOOR SWIMMING POOLS AND PREVALENCE OF SELF-REPORTED RESPIRATORY AND OCULAR SYMPTOMS IN OCCUPATIONALLY EXPOSED SUBJECTS

Gabriella Aggazzotti, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Guglielmina Fantuzzi, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Elena Righi, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Guerrino Predieri, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Pierluigi Giacobazzi, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Petra Bechtold, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Katia Mastroianni, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*

Background and Aims: The aim of this cross-sectional study was to investigate the association between airborne NCl_3 exposure in indoor swimming pools and the prevalence of self-reported respiratory and ocular symptoms in occupationally exposed subjects.
Methods: Twenty indoor swimming pools in the Emilia-Romagna region of Italy were included in the study. Information about the health status of 128 employees was collected using a self-administered questionnaire. Exposure to airborne NCl_3 was evaluated in indoor swimming pools by a modified DPD/KI method.
Results: The airborne NCl_3 levels ranged from 204 to 1020 µg/m^3 with a mean value of 648.7 ± 201.4 µg/m^3. More than 50% of the swimming pools showed airborne NCl_3 levels higher than 500 µg/m^3 (recommended WHO guidelines). Both ocular and upper respiratory symptoms were very frequent in the 128 employees: red eyes, runny nose, voice loss and cold symptoms were declared more frequently by pool attendants (lifeguards and trainers) when compared with employees working in other areas of the facility (office, cafe, *etc.*). Pool attendants exposed to airborne NCl_3 levels higher than 500 µg/m^3 experienced higher risks for runny nose (OR: 2.9; 95% CI: 1.22-6.94), red eyes (OR: 3.2; 95% CI: 1.5-6.8), voice loss (OR: 3.6; 95% CI: 1.6-8.0), itchy eyes (OR: 2.2; 95% CI: 1.0-4.8) than other employees. When high levels of airborne NCl_3 were taken into account (airborne NCl_3 levels ≥ 800 µg/m^3 *vs.* < 800 µg/m^3) ocular and respiratory symptoms became much more evident, with higher risks (as ORs) in exposed subjects (lifeguards and trainers) compared with other employees.
Conclusions: This study confirms that lifeguards and trainers are at risk for respiratory and ocular irritative symptoms more than other employees in indoor swimming pools, in particular in presence of high airborne NCl_3 levels.

RELATIVE IMPORTANCE OF CONCURRENT EXPOSURES TO MULTIPLE INDOOR BIOLOGICAL AGENTS ON CHILDHOOD ALLERGY AND REPORTING SYMPTOMS

Nai-Yun Hsu, *National Cheng Kung University, Taiwan*
Yi-Cheng Li, *National Cheng Kung University, Taiwan*
Hsin-Wen Chang, *National Cheng Kung University, Taiwan*
Jiu-Yao Wang, *National Cheng Kung University, Taiwan*
Pei-Chih Wu, *Chang Jung Christian University, Taiwan*
Huey-Jen Su*, *National Cheng Kung University, Taiwan*

Background and Aims: Literatures have consistently demonstrated associations between exposures to different kinds of bioaerosols in indoors and increasing risk of respiratory and allergic diseases, however, mostly based on measurements of single or selected agents while environmental microbes and allergens are often co-existing in nearly all environments at all times in reality. This study conducted concurrent assessment of related bioaerosol indicators to elucidate their individual or synergistic roles deriving at corresponding childhood health outcomes of concerns.
Methods: A total of 101 children (3-9 years old), recruited from a prior cross-sectional questionnaire survey, were investigated for exposure levels of fungal spores, total culturable bacteria and fungi in the air of their bedrooms, and the concentrations of endotoxin, 1,3-β-D-glucan and *der* p1 allergen in dusts on their bed. The health status of each child was verified during a clinic visit, and parents kept symptom diaries for the week during which environmental sampling took place on the 1st day of the week. Multivariate logistic regression models were applied to characterize the relative importance for individual bioaerosol indicator after adjusting mutually for each other, and other confounding factors, reported as aOR.
Results: Increasing concentrations of culturable fungal I/O ratio, endotoxin and glucan were associated with higher risk to be characterized as being the case subjects (aOR= 2.78), to report physician-diagnosed allergic rhinitis (aOR=1.60) and eczema (aOR=2.28) during clinical examination, respectively. Moreover, the level of culturable fungal I/O ratio (aOR=3.61) was found for influencing the presence of childhood reported respiratory symptoms while getting up as well as the concentrations of fungal spore (aOR=16.25) and *der* p1 (aOR=1.54) allergen were associated, respectively, with reported respiratory symptoms during sleeping and during daytime of children.
Conclusions: It was the first study to reveal the synergistic effect of various bioaerosol indicators on children health in tropical Asia where higher bioaerosol levels were reported frequently.

DEMOGRAPHIC AND LIFESTYLE FACTORS AFFECTING GENOMIC BLOOD DNA METHYLATION BIOMARKER LEVELS

Lissette Delgado-Cruzata, *Mailman School of Public Health, Columbia University, USA*
Hui-Chen Wu, *Mailman School of Public Health, Columbia University, USA*
Yuyan Liao, *Mailman School of Public Health, Columbia University, USA*
Regina M. Santella, *Mailman School of Public Health, Columbia University, USA*
Mary Beth Terry, *Mailman School of Public Health, Columbia University, USA*
Lambert H. Lumey, *Mailman School of Public Health, Columbia University, USA*

Background and Aims: Levels of DNA methylation can be altered by environmental exposures and have been shown to be important molecular markers in disease etiology. Several methodologies are available to determine genomic DNA methylation including overall genomic DNA methylation and repetitive DNA methylation measurements. It is not clear what the determinants of these methylation measures are in healthy individuals. The aim of this study was to examine whether age, gender, smoking status, and ethnicity are associated with several DNA methylation measurements in white blood cell (WBC) DNA of healthy individuals.
Methods: Individual data from three studies including a total of 1300 healthy subjects were combined. WBC genomic and repetitive element DNA methylation was quantified by three different assays: LUminometric Methylation Assay (LUMA) for genomic DNA methylation levels, and PCR-pyrosequencing (*LINE-1*) and MethyLight (*LINE-1* and *Sat2*) for repetitive element DNA methylation. Demographic and lifestyle characteristics were evaluated in relation to the epigenetic biomarkers.
Results: Smoking status was associated with a decreased in genomic DNA methylation by LUMA. Current smokers had lower levels of DNA methylation than never and former smokers *(*66.3% vs. 68.3%, p=0.0132). No gender or age differences were observed for any of the biomarkers understudy. Repetitive element DNA methylation levels were lower in Caucasian women than other ethnicities (*Sat2:* 38.5% vs. 49.7% (p=0.005) and *LINE-1:* 73.9% vs. 75.2% (p<0.0001). Statistically significant correlations were found for LUMA and *LINE-1* measurements (Spearman coeff=0.11 (p=0.04)), but not *Sat2.*
Conclusions: Genomic DNA methylation levels vary in relation with smoking status and ethnicity. Differential correlation between repetitive sequences and global measurements of DNA methylation suggests contributions of the different biomarkers might be different to global genomic DNA methylation levels. These findings need to be considered in designing epidemiological studies aimed at identifying associations between DNA methylation, disease and environmental exposures.

TRANSPORTION, AIR POLLUTION AND PHYSICAL ACTIVITIES (TAPAS), A 6- CITY INTEGRATED HEALTH RISK ASSESSMENT PROGRAM OF ACTIVE TRAVEL POLICIES: THE PRAGUE CASE STUDY

Hana Brůhová-Foltýnová, *Kolin Institute of Technology,Kolin, Czech Republic; e-mail: bruhova@hotmail.com*
Jan Brůha, *Kolin Institute of Technology, Kolin, Czech Republic*,
Audrey de Nazelle, *CREAL, Barcelona*

Background and Aims: The aim of the paper is to introduce one of the case studies of the international project "TAPAS", which will take place in Prague. Prague is a city with a low share of cycling in the modal split, and a high share of cars. It also suffers from worse death rate indicators in comparison with cities in Western Europe.
Methods: We collected data on active travel, health and environmental conditions. We also met individually with different stakeholders. Further, we proposed a number of policy scenarios to be assessed by the model. Our Institute is also responsible for a statistical analysis of impacts of active transport indicators and policies on public health.
Results:Prague, capital of the Czech Republic, has 1.25 mil. inhabitants and area of 496 km2. The dominant mode of transport is public transport (43%) and cars (33%), while walking contributes to modal split by 23%, and cycling by 1%. To support cycling, several measures have been implemented at the city level since 2004, above all construction of cycling infrastructure (from 245 km in 2003 to 518 km in 2009), and promotion campaigns (maps of cycling routes, information brochures). Safety of cyclists has increased (from 159 registered accidents of cyclists in 2003 to 70 in 2009). Most of the pollution in Prague is caused by traffic (approx. 80-90% of total emissions of NO2, benzene, and CO, more than 90% of PM). Average annual concentration of PM10 was 25.3 μg/m3, PM2.5 20.7 μg/m3 and NO2 29.1 μg/m3 in 2009. Relevant identified policies to be assessed include: 1) construction of cycling infrastructure, 2) building of a new parking system, 3) traffic calming.
Conclusion: Prague seems to be an interesting case as physical inactivity and air pollution from traffic are one of the most serious problems. Further support of active transport could improve these challenges.

OCCUPATIONAL AND ENVIRONMENTAL FACTORS RELATED TO THE INCIDENCE OF MALIGNANT MESOTHELIOMA IN THE URBAN AREA OF ROME, 2001-2009

Elisa Romeo *Department of Epidemiology, Regional Health Service, Latium, Rome Italy*

Patrizia Compagnucci *Department of Epidemiology, Regional Health Service, Latium, Rome Italy*
Letizia Gasperini *Local Health Unit Viterbo, Laboratory of Industrial Hygiene, National Health Service, Civita Castellana, Italy*
Marina Davoli *Department of Epidemiology, Regional Health Service, Latium, Rome Italy*
Francesco Forastiere *Department of Epidemiology, Regional Health Service, Latium, Rome Italy*

Background and Aims: The occurrence of malignant mesothelioma (MM) reflects past asbestos exposure at population level, both in the occupational and in the environmental settings. Our aim was to examine incidence rates of MM in Rome (2.8 million inhabitants) and in the surrounding Lazio region (5.6 million inhabitants), during the period 2001-2009, to identify etiologically relevant occupational and environmental asbestos exposures.
Methods: A population MM register has been collecting data for the period 2001-2009. Incidence rates (per 100,000) of MM in Rome and in the rest of the region were estimated. The possible asbestos exposure was also investigated by standardized interviews.
Results: We recorded 327 MM cases in Rome (219 men and 108 women) and 269 cases in the region (206 men and 63 women). Similar incidence rates were found among men in Rome (1.89; IC95% 1.66-2.16) and outside Rome (1.84 IC95% 1.60-2.11). Among women, the rate was higher in Rome (0.68, IC95% 0.56-0.82) than in the region (0.47, IC95% 0.36-0.60). Asbestos exposure was identified in 54% of the subjects (251 men and 78 women). Occupational exposure was found in 62% of men and 13% of women in Rome, in 82% of men and 3% of women in the rest of the region. The exposure was unknown in 32% of men and 74% of women in Rome and in 15% of men and in 83% of women in the region.
Conclusions: The incidence rates of MM in Rome and in the rest of the region were similar for men and higher for women. Since Rome has only a tertiary productive system, while the rest of the region had industrial complexes with occupational exposure, we suggest that the occurrence of MM in the population of Rome could be related to several occupational exposures and to unrecognized domestic and environmental conditions.

CLIMATE CHANGE, WATER AND HEALTH

Georgios Kamizoulis, *World Health Organization, Coordinating Unit for the Mediterranean Action Plan, Greece*

The climate change inevitably leads to changes in weather conditions in affected regions. Extreme weather events, that are manifested with severe droughts and floods represent risks that may adversely affect public health through impact on water quality, availability and efficiency of water supply and sanitation system.
Water shortage due to droughts is already noticed in the Mediterranean, involving mostly the northern African countries, the eastern Mediterranean and the southern regions of the European countries. The increased demand for water, of about 20% in 2025, due to population growth, according to Blue Plan Centre coupled by the decreased amount of affordable water will lead to the deterioration of the water quality. The health impacts, are related to increase of lake and river surface water temperatures, reduced water flows, heavy effects on drinking-water quality as a consequence of decrease of pollutants dilution and unsuitability of water for drinking and agriculture purposes as a consequence of saline intrusion. In addition, extremely intense rainfall and river flooding that affect the sanitation system efficiency are characterized by a primary risk for public safety. Uncontrolled surcharges may introduce microbial and chemical pollutants to water resources that are difficult to handle through the usual treatment systems.
It is undoubtadly significant to decrease the effects of extreme weather effects by applying precationary measures and especially to implement adaptation activities to climate change.
The Mediterranean Countries, Contracting Parties to the Barcelona Convention, in their five year programme, 2009-2014, included a number of activities that underpin the adaptation to climate change, including water and health. Furthermore the European countries, including the Mediterranean ones, signatories to the Protocol on Water and Health, address the water and health issues related to climate change in a very distinctive way.

THE EXPOSOME APPROACH FOR ASSESSING THE RISKS IMPOSED BY SELECTED VOLATILE CONTAMINANTS OF ENVIRONMENTAL TOBACCO SMOKE (ETS)

Dimosthenis A. Sarigiannis, *Aristotle University of Thessaloniki, Greece; European Commission, Joint Research Centre, Italy*
Spyros P. Karakitsios, *European Commission, Joint Research Centre, Italy*
Alberto Gotti, *Centre for Research and Technology Hellas, Greece*

Background and Aims: Characterization of ETS exposure and the associated risks are subject to misclassification bias, caused by responses such as “exposure to ETS perception”, or “living with a smoker” in questionnaire-based surveys, affecting epidemiologically derived exposure risk functions. This study aims at the development of a methodological framework for assessing mechanistically the risks imposed by ETS, by evaluating biomonitoring data, internal dose modeling and Biology Based Dose Response (BBDR) modeling for three organic contaminants, namely 4-(N-nitrosomethylamino)-1-(3-pyridyl)-1-butanone, benzene and formaldehyde, related to lung cancer, leukemia and nasopharyngeal cancer respectively.
Methods: A nicotine-cotinine PBPK model was developed, allowing the use of biomarkers such as urinary cotinine and nail nicotine for short and long term exposure through reverse modeling. Exposure scenarios reconstruction are fed forward to BBDR models coupling PBPK/D with mechanistic pathology modeling for each carcinogenic contaminant. Genetic polymorphisms linking variation of human susceptibility to xenobiotics were explicitly accounted for. Extrapolation to the wider population through hierarchical population modeling incorporated all variabilities and uncertainties governing exposure and response to xenobiotics from ETS.
Results: Individual risks estimated for lung cancer, leukemia and nasopharyngeal cancer ranged within a magnitude of order 10^{-5}, 10^{-7} and 10^{-9} respectively. Exposure duration had a non-linear effect on lung cancer, while the limited variability of formaldehyde exposure was compensated by the strongly non-linear mechanism governing formaldehyde-DNA adduct formation. Considering that benzene toxicity relies upon the presence of its toxic metabolites, polymorphism variability among gene variants of CYP2E1 and NQO1 was found to be determinant for overall risk assessment.
Conclusions: A multi-tiered approach is proposed here as a valid alternative to classic epidemiological approaches. According to the proposed methodology exposure burden is estimated based on actual biomonitoring data, individual risk is estimated using models with a strong biological underpinning and extrapolation to the wider population is done probabilistically.

IS ECONOMIC PROGRESS MAKING CHILDREN SICK?

Marko Ogorevc, *Institute for Economic Research, Slovenia*
Valentina P. Rupel, *Ministry of Health, Slovenia*

Background and Aims: In recent years Slovenia has seen a growth in hospitalization rates of children under age of 14 due to respiratory problems. Since 2002 when 6 per 1000 children were hospitalized due to five most common respiratory diseases, a number has surged to almost 8 in 2008. In this paper we investigate the relationship between hospitalization and air pollution, which is based on yearly exhausts from industrial plants, while we are aware that "the quality of exposure measurement is often the most critical determinant of the validity of an environmental epidemiological study" (Rothman et. Al, 2008, pp.600)
Methods: To estimate the effects of industrial plants on children's hospitalization rates, while accounting for socio-economic status, we use a SARAR model specification of a Cliff and Ord-type (Kelejian and Prucha, 1998), which simultaneously allows for spatial lag in the dependent variable as well as lag in disturbances. We further allow for processes where the innovations in the disturbance process are assumed to be heteroskedastic of unknown form.
Results: Our results indicate that socio-economic status is important with respect to explaining the children's hospitalization rates. We find that average wage rate has little or no effect, while the social inequality, measured as a standard deviation of wages, is accompanied with increased prevalence. Education on the other hand has a negative effect on hospitalization. We also find some evidence that hospitalization rates are higher where reported exhausts for industrial plants are higher.
Conclusion: Further investigation on correlation between socio economic status and illnesses caused by means of industrial progress and their impact on environmental pollution are recommended in order to enable us to better predict the effects of development on health care expenditures. A special stress should be given to chronic diseases that can be a consequence of environmental pollution as those are the ones that take over the role of main drivers of health care expenditures.

CUMULATED INTERNAL DOSE OF METALS AND PULMONARY FUNCTION AMONG METAL EXPOSED WORKERS

Rocío Capelo, *Universidad de Huelva, Spain*
Miguel Ángel García, *Universidad de Huelva, Spain*
María Díaz-Santos, *Universidad de Huelva, Spain*
Rocío Jara, *Universidad de Huelva, Spain*
Antonio Pereira, *Hospital Juan Ramón Jiménez, Spain*
Jose Antonio Maldonado, *Hospital juan Ramón Jiménez, Spain*
Amanda Gago, *Universidad de Huelva, Spain*
Tamara García, *Universidad de Huelva, Spain*
Jose Luis Gómez-Ariza, *Universidad de Huelva, Spain*
Juan Alguacil, *Universidad de Huelva, Spain*

Background: Inhalation of metals might be toxic to the respiratory system. Metal/chemical industries are important sources of exposure to metals via direct inhalation to the lungs. We studied the relationship between cumulative internal dose of metals and pulmonary function (spirometry) among a group of workers exposed to metals.
Methods: We obtained results of toenails metal levels and spirometry in 55 volunteer workers from the chemical/metal industry and 42 unexposed service workers. Forced vital capacity (FVC), forced expiratory volume in one second (FEV1), peak expiratory flow (PEF), and forced expiratory flow at 25-75% of forced vital capacity (FEF25-75) were measured with a portable spirometer. Toenail metal levels were measured by multielemental analysis with emission spectroscopy by ICP-MS. Comparison of the median of metal levels between two categories of qualitative variables was tested using by the U Mann-Whitney test. The correlation between each metal and the spirometry parameters was estimated with the Spearman's rho.
Results: Molybdenum levels correlated inversely with the percentages of VEF1 (p=0.015), PEF (p=0.009), FEF25-75 (p=0.008), and the FEV1/FVC ratio (p=0.032). Vanadium levels correlated inversely with the percentages of PEF (p=0.001), and FEF25-75 (p=0.019), and with the FEV1/FVC ratio (p=0.019); while manganese also correlated inversely with the percentage of PEF (p=0.039). Cumulative internal dose of vanadium were associated with the presence of an obstructive pattern (p=0.002), with a FEV1 percentage lower than 80% (p=0.008), with a FEV1/FVC ratio lower than 70% (p=0.0001), and with a percentage of FEF25-75 lower than 60% (p=0.011). Similar associations were observed for manganese, molybdenum and cobalt. Chromium levels were associated to a lesser extend with the same parameters, and resulted also associated with the lack of presence of a restrictive pattern (p=0.048).
Conclusions: We observed individual associations between the cumulative internal dose of vanadium, molybdenum, manganese, cadmium, lead and cobalt, and pulmonary function.

Mobile phone use and early-childhood neurodevelopment at 2 years of age

Pei-Hsuan Wu, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University College of Public Health, Taipei, Taiwan*

Ching-Chun LIN, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University College of Public Health, Taipei, Taiwan*

Hua-Fang Liao, *School and Graduate Institute of Physical Therapy, National Taiwan University College of Medicine, Taipei, Taiwan*

Pau-Chung Chen, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University College of Public Health, Taipei, Taiwan*

Background and aims : This study was to examine the association between prenatal and postnatal mobile phone use exposure and early-childhood neurodevelopment in two-year-old children from the general population in Taipei, Taiwan.

Methods: The study was a part of the Taiwan Birth Panel Study. A total of 150 pairs of parents and their singleton child were selected into this study. We used the Comprehensive Developmental Inventory for Infants and Toddlers (CDIIT) to assess child neurodevelopment at two years of age. The CDIIT was used to assess development in the areas of cognition, language, motor (including gross motor and fine motor), social, and self-help of children. Exposure to mobile phone was reported on a questionnaire. Regression model was used to estimate the association between mobile phone exposure and children's neurodevelopment.

Results: In logistic regression models, there aren't any significant associations in all the eight domains of the CDIIT. The adjusted OR was 1.1 (95% CI: 0.3-3.5) for motor during 7 months of gestation to birth, and the adjusted OR for gross motor and fine motor were 1.2 (95%CI: 0.4-3.6) and 0.7 (95%CI: 0.1-3.6), respectively in the early-childhood neurodevelopment at 2 years.

Conclusions: In this study, we didn't find any significant association between prenatal and postnatal mobile phone use exposure and early-childhood neurodevelopment in two-year-old children. However, research on the negative effect of mobile phone use and neurodevelopment is still scanty. Therefore, the further association of mobile phone use and neurodevelopment is needed to explore.

A SURVEILLANCE PROGRAM ON AIR POLLUTION EFFECTS: THE ITALIAN EPIAIR PROJECT

Ennio Cadum, *Epidemiology and Environmental Health, Regional Environmental Protection Agency, Piedmont, Grugliasco (TO), Italy*
Francesco Forastiere, *Department of Epidemiology, Rome E Health Authority, Rome, Italy*
EpiAir Collaborative Group

Background and Aims: Air pollution levels are critical in many urban areas in Italy. The objective of this presentation is to describe the methodology and the main results of the Italian "Air pollution and Health:Epidemiological Surveillance and Primary Prevention – EpiAir- project".
Methods: The EpiAir project, funded by the Centre for Disease Control and Prevention of the ItalianMinistry of Health, was designed to provide methods and criteria for epidemiological surveillance of the health effects of air pollution in large Italian cities. A network of public institutions in the field of environmental control and public health participated in the project. The main elements of the project are: -Evaluation of the short-term health effects (mortality, hospital admissions) of air pollution in large Italian cities, using a standardized methodology (case-crossover approach). –Evaluation of factors (socio-demographic characteristics, co-morbidities) that can confer a higher susceptibility to the effects of air pollution. -Collection of information on the mobility policies recently implemented by local administrations.
Results: The first phase of the project (2001-2005) involved ten Italian cities (Turin, Milan, Mestre, Bologna, Florence, Pisa, Rome, Taranto, Palermo,Cagliari); statistically significant effects of all pollutants (PM10, NO2, Ozone) were observed for natural and cardio-respiratory mortality. Exposure to PM10 and NO2 was found strongly associated with hospital admissions for selected respiratory and cardiac diseases. Several pre-existing chronic conditions appear to confer a higher susceptibility to the adverse effects of NO2. The second phase of the project (2006-2010) is on going; it follows the same methodology while involving a larger number of cities (including also Ancona,Bari,Genoa,and Trieste); in this second phase we will also analyse PM2.5 data, as well as data on admissions to Emergency Departments for selected disorders.
Conclusions: A long-term surveillance program has been implemented in order to evaluate the effects of potential future preventive programs.

IMPACT OF MATERNAL OBESITY ON NEURAL TUBE DEFECTS AND CARDIOVASCULAR ANOMALIES: ABSOLUTE RISK AND TEMPORAL TRENDS

Tennant, Peter, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, England, UK*
Rankin, Judith, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, England, UK AND Regional Maternity Survey Office, Newcastle upon Tyne, England, UK*
Bell, Ruth, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, England, UK AND Regional Maternity Survey Office, Newcastle upon Tyne, England, UK*

Background and Aims: UK guidelines advocate that obese pregnant women (body mass index, BMI≥30kg/m^2) be made aware of the increased risks to them and their offspring. This study pooled data from several sources to derive estimates of the absolute and attributable risks of neural tube defects and cardiovascular anomalies for obese women in England, and predict changes in prevalence resulting from trends in BMI.

Methods: The BMI profile of the maternal population of England and of the prevalence of each outcome were obtained from nationally representative sources. Trends in BMI were modelled by logistic regression. Risk ratios for neural tube defect and cardiovascular anomaly were derived from Stothard *et al*. Absolute risks, attributable risks, and future prevalence were estimated.

Results: The estimated absolute risks of a neural tube defect or cardiovascular anomaly for an obese pregnant woman in England are 19 (95% confidence interval, CI=1.6-2.2) and 75 (95% confidence interval, CI=66-84) per 10,000 births respectively, compared to 10 (95% CI=9.5-11.4) and 60 (95% CI=67-63) per 10,000 births respectively for women of recommended BMI (25-29kg/m^2). An estimated 9.8% (95% CI=5.6-14.1) of neural tube defects and 3.0% (95% CI=0.5-5.4) of cardiovascular anomalies in England are attributable to maternal obesity.

If trends in maternal BMI continue, 24.0% (95% CI=22.1-25.9) of the maternal population of England will be obese by 2020. This is predicted to result in increases of 6.5% and 4.3% respectively in the prevalences of neural tube defects and cardiovascular anomalies compared with the prevalence in 2010.

Conclusions: This study provides estimates of the individual risk and population burden of neural tube defects and cardiovascular anomalies in England resulting from maternal obesity. The results have implications for public health planning and for providing clear information to obese women about their pregnancy-related risks.

LONG-TERM TRENDS OF POPs IN HUMAN MILK IN CZECH REPUBLIC & APPLICATION FOR HUMAN HEALTH RISK ASSESSMENT

Pavel Cupr, *Masaryk University, Research Centre for Toxic Compounds in the Environment, Kamenice 126/3, 625 00 Brno, Czech Republic*
Ondrej Mikes, *Masaryk University, Research Centre for Toxic Compounds in the Environment, Brno, Czech Republic*
Andrea Krskova, *National Institute of Public Health (NIPH), Šrobárova 48, 100 42, Praha 10, Czech Republic*
Milena Cerna, *National Institute of Public Health (NIPH), Šrobárova 48, 100 42, Praha 10, Czech Republic*

Background and Aims: Human biomonitoring of persistent organic pollutants (POPs) concentrations in breast milk in Czech Republic is carried out since 1994 (by **National Institute of Public Health** - NIPH). The main aim of this study was to evaluate long-term trends of selected POPs in human milk in Czech Republic – as background levels for central Europe for use in the project ArcRisk (http://www.arcrisk.eu/).

Methods: All milk samples are obtained under the **Environmental Health Monitoring System in the Czech Republic**. The human milk samples are analyzed for a number of chlorinated organic chemicals including polychlorinated biphenyls (PCB28, PCB52, PCB101, PCB118, PCB138, PCB153, PCB180, PCB170) and selected chlorinated pesticides (OCPs: HCB, alfa-HCH, beta-HCH, gama-HCH, ppDDD, opDDE, ppDDE, opDDT, ppDDT).

Results: More then 4600 breast milk samples were collected and analysed from 9 sites in the years 1994 – 2009 (about 50-200 samples/region/year). Exposure factors that may influence these levels were investigated using a questionnaire according to the WHO protocol (age of mothers, BMI – body mass index, medication, occupational exposure and lifestyle habits, above all smoking). Backward predictions of the internal total POPs exposure doses from human milk concentrations were computed. These dangerous organic substances (neurotoxicity, carcinogenicity and endocrine disrupting effects) are widespread throughout the environment, persisting for decades. They accumulate in the fatty tissue, entering the human body through the food-chain.

Conclusions: Human biomonitoring is a useful tool to evaluate internal exposure of humans with different chemical substances. The next aim of this work will to predict of human health risks by using of slope factor and RfD (reference doses) approach with a spatial GIS visualisation. Relationships between exposure factors from questionnaires will be also investigated. The research was supported by the CETOCOEN project from the European Regional Development Fund (No. CZ.1.05/2.1.00/01.0001) and by the ArcRisk European Community 7th Framework Programme Project (226534).

CUMULATED INTERNAL DOSE OF NATURAL URANIUM IN WORKERS OF AN INDUSTRIAL AREA NEAR A FERTILIZER PRODUCTION PLANT

Background: Natural uranium is a low radioactive element that decays slowly by emitting an alpha particle. If absorbed, uranium can damage human health. Working nearby and at a fertilizer production plant might be an important source of exposure to natural uranium. We compared cumulative dose of uranium between workers from a fertilizer plant, chemical/metal workers from the same industrial park, chemical/metal workers from industrial parks of other regions, and workers unexposed to metals.
Methods: Cross-sectional epidemiological study design. We obtained satisfactory results of uranium-238 levels in toenails of 5 workers of a fertilizer production plant, 44 workers of the chemical/metal industry at the same industrial park, 24 workers of the chemical/metal industry from industrial parks of other regions, and of 43 workers unexposed to metals from the service sector. Internal dose of uranium-238 was measured by emission spectroscopy by ICP-MS with collision cells.
Results: The median of the cumulated dose of uranium-238 among the group including all 63 chemical/metal industry workers was 4.9 ppb; and 3.5 ppb in the group of the 43 unexposed workers ($p<0.001$; U Mann-Whitney test). The median of uranium-238 in the group of fertilizer plant workers was 6.5 ppb; 4.9 ppb among chemical/metal industry workers from the same industrial park, and 4.5 ppb among chemical/metal industry workers from industrial parks without fertilizer plants from other regions ($p=0.056$; Median test).
Conclusions: Our results suggest that occupational activity on the chemical/metal industry is related to accumulation of natural uranium, mostly among workers from fertilizing plants.

APPLICATION OF CLIMATE INDICATORS TO US CHILD POPULATION: TRENDS IN TEMPERATURE VARIABILITY

Suril Mehta, *Environmental Protection Agency, USA*
Jennifer Parker, *Centers for Disease Control and Prevention, USA*
Raghu Murtugudde, *University of Maryland, College Park, USA*
Amir Sapkota, *University of Maryland, College Park, USA*

Background and Aims: Children may be particularly susceptible to climatic change, including extreme temperature. Childhood exposure and health effects of recent temperature extremes remain largely unknown. We highlight the development and initial evaluation of multiple climate indicators and their evaluation through linkage to child population counts to identify childhood exposure trends.
Methods: County-level daily maximum and minimum temperature records from ~8,000 national weather stations (National Climatic Data Center) were geospatially and temporally-linked to US Census annual child population estimates (ages 0-17 years) for 2,311 US counties (~xx% of children). Indicators were developed by: (1) Defining a reference period, 1977-1987; (2) calculating 99th and 1st percentile thresholds of MAX and MIN temperature values for each month/county over the 11-year period; and (3) tabulating the days which exceeded hot and cold thresholds for our study period (1988-2008). Trends in childhood exposure to extreme temperature were stratified by month, season, year, and region.
Results: Days exceeding the 99th percentile hot threshold varied greatly by month, decade, and region, with January experiencing the greatest increase in extreme heat days by decade and region (excluding Western US). Median number of days exceeding the 1st percentile cold threshold dramatically decreased by 85% from the 1980s to 2000s, even when stratified by season and region. There was a 26% increase in percentage of children from 1988-2008 exposed to heat exceeding the 99th percentile of reference period, and a decreased percentage of children exposed to unusually cold days.
Conclusions: Since 1988, US children have been exposed to an increasing number of unusually hot days. Implications for short and long-term child health effects remain to be investigated. Application of climate indicators to national health databases (e.g. National Health Interview Survey) will further investigate children's health implications of extreme temperature.

EFFECTS OF LEAD AND CADMIUM ON BIRTH WEIGHT IN A COHORT OF PREGNANT WOMEN IN CALI - COLOMBIA

Authors: Diana María Caicedo, Javier Fonseca, Miguel Peña, Cecilia Aguilar, Mildrey Mosquera, Cristina Araujo, Genny Martínez, Daniel Cuartas, Fabián Méndez – *Universidad del Valle, Cali, Colombia.*

Background and aims: Population's exposure to heavy metals may affect foetal growth. Studies in Cali show presence of heavy metals in the environment and plausible routes of exposure among vulnerable population. This study aims to evaluate the association between maternal exposure to lead and cadmium and the occurrence of LBW and IUGR.

Methodology: A prospective cohort study was developed. The enrolment of pregnant women was carried out at 11-13 weeks of gestation. Follow-up from admission to delivery included three ultrasounds, clinical evaluations, and determining maternal blood levels of lead and cadmium during the first and third trimesters of pregnancy. Surveys were used to characterize risk behaviours and habits of mothers and their partners. At birth, an anthropometric evaluation was performed on the newborn.

Results: 386 pregnant women were included. Among them, 50% were 18-22 years old; 43%, black; 77%, housewives; and 34% have no social security. At first trimester median lead and cadmium levels were 1.01(0.00-16.1), and 0.11ug/dl(0.01-4.2), correspondingly; while at third trimester were 0.84(0.00-27.95) and 0.04ug/l(0.01-7.08). 47% of women live with people handling Pb/Cd (at job or at home), 35% live close to commercial sources of Pb/Cd, and 48.3% are near a large municipal dump. The incidence of LBW is 7.87% and IUGR is 4.7%. Lead levels ≥5ug/dl at first trimester were associated with an increased risk of LBW (RR: 3.65; CI95% 0.97-13.69; p=0.054).

Conclusions: Women are exposed to several sources of heavy metals during the first trimester of pregnancy, and presented an increased risk of LBW. This knowledge is useful for implementing preventive actions by identification of risk factors of exposure.

UNDERSTANDING THE COMMON EXPOSURE TO TRANSPORTATION NOISE AND AIR POLLUTION AND THEIR POTENTIAL COMMON HEALTH ENDPOINTS

Georgios Grivas, *National Technical University of Athens, School of Chemical Engineering, Heroon Polytechniou 9, GR-15780 Zografos, Athens, Greece*

Background and Aims: Epidemiological studies have shown that air pollution exposure is associated with cardio-pulmonary health outcomes and noise exposure is associated with cardiovascular outcomes. The main source of both exposures is, to a large extent, vehicle traffic. Typically in studies of one exposure the other one is not adjusted for. Investigations of long-term effects are usually based on modeled exposures, using common predictors, which result in (possibly partially artificial) spatially correlated estimates. For short-term exposure variations, there is no evidence on their potential mutual confounding. In this presentation, data from Athens are shown to illustrate the problems and indicate future pathways for distinguishing the effects of the two environmental stressors.
Methods: 1) Within the HYENA study, long-term noise and air pollution (PM_{10} and NO_2) exposure was estimated for 780 subjects living near Athens Airport. Air pollution estimates were derived from the APMoSPHERE project and were also modeled using AERMOD; 2) Continuous measurements for PM and noise were performed in 2 typical Athens apartments for one week using a real time noise analyzer and a real time aerosol monitor for different PM fractions.
Results: AERMOD PM_{10} concentrations originating from vehicle traffic were highly correlated to road traffic noise (r=0.76) but moderately correlated to aircraft noise (r=0.23). Correlations of the APMoSPHERE estimates for PM_{10} & NO_2 and aircraft noise were 0.11 and 0.56 and 0.06 and 0.24 for road traffic noise respectively.
Conclusions: The magnitude of the spatial correlations depends on the way exposures were modeled. Further investigation is needed to better understand the determinants of the resulting estimates. In the time scale, air pollution depends on road traffic load as well as on meteorological conditions, in contrast to noise which is also determined by other local noise sources and is modified by meteorology to a much lesser extent.

QUALITY OF LIFE IN BRAZILIAN WOMEN WITH BREAST CANCER – ASSOCIATION WITH THE SOCIAL ENVIRONMENT

Daniele Bittencourt Ferreira, *National School of Public Health, Oswaldo Cruz Foundation, Brazil*
Anke Bergmann, *National Cancer Institute, Brazil*
Rosalina Jorge Koifman, *National School of Public Health, Oswaldo Cruz Foundation, Brazil*

Background and Aims: The incidence of breast cancer is increasing in Brazil, constituting a major cause of morbidity and mortality with major social and epidemiological impact. The aim of this study is to evaluate the association between social support before the treatment of breast cancer and quality of life (QOL) six months after starting treatment.
Methods: Eligible participants were women with no history of cancer and who were treated for breast cancer in National Cancer Institute of June/2009-March/2010. The evaluation of the social support was performed before the oncology treatment. EORTC QLQ-C30 was used to measure quality of life. Medical Outcomes Survey-Social Support Survey was used to assess social support. The bivariate analysis of dichotomous variables and odds ratio with confidence interval 95% were analyzed.
Results: 195 women were evaluated and it was observed that good emotional support is a protective factor for overall health (OR=0.42 95% CI 0.23-0.79) and scale functionality (OR=0.36 95% 0, 18-0.71). The information support was associated with better global health (OR=0.41 95% CI 0.22-0.76), functionality (OR=0.35 95% CI 0.18-0.70) and symptoms scale (OR=0.38 95% CI 0.18-0.77). Women who reported good emotional support showed reduced of 70% to have general health problems after six months of treatment (95% CI 0.13-0.65).
Conclusions: The results of this study suggest that a good social environment in which these women are inserted prior to treatment showed a positive association with the better quality of life six months after surgery in women with breast cancer, underscoring the importance of environmental assessment of the social in these patients.

THE EFFECT OF AIR POLLUTION ON MORTALITY: META-ANALYSIS RESULTS FROM THE ESCALA PROJECT

Luis Cifuentes, *Pontificia Universidad Católica de Chile*
Nelson Gouveia, *Universidade de São Paulo, Brazil*
Magali Hurtado-Díaz, *Instituto Nacional de Salud Pública, México*
Antonio Ponce de Leon, *Universidade Estadual do Rio de Janeiro, Brazil*
Washington Junger, *Universidade Estadual do Rio de Janeiro, Brazil*
Jeanette Vera, *Pontificia Universidad Católica de Chile*
Victor Miranda, *Instituto Nacional de Salud Pública, México*
Isabelle Romieu, *Instituto Nacional de Salud Pública, México*

Background and Aims: The ESCALA project investigated the association between PM10 and Ozone and premature mortality in nine Latinamerican cities: São Paulo, Porto Alegre and Rio de Janeiro in Brazil; Concepción, Temuco and Santiago, in Chile; and Mexico City, Monterrey and Toluca in Mexico, from 1997 to 2005. The project used a common methodological framework to estimate city specific effects, providing a comparable set of results. So, the aim of this work is estimating the overall effect of air pollution on mortality in nine Latinamerican cities.
Methods: Unipollutant distributed lag models were fitted in each city using the same controls for temporal and meteorological effects. Fixed and random effects were estimated for six causes of death for all ages and for older than 65 years. Heterogeneity was assessed using Cochran Q test and the I2 percentage.
Results: Most of the results showed heterogeneity among cities, so we report the random effects estimates, as the percentage change in risk for 10 ug/m3 increment of 24hr PM10 or 8hr Ozone levels. For PM10, all causes, all ages estimate the RR is 0.77% (95%CI:0.60-1.00). For RSP a 1.39% (95%CI:1.0-1.8) for all ages and 1.64% (95%CI:1.0,-2.3). For CPM, 0.94% (95%CI:0.84-1.05) for all ages, and 1.15% (95%CI:0.93-1.37) for elder. The highest risk was for COPD, all ages: 2.44% (95%CI:1.36-3.59). Results for O3 showed more variability, with most of the random effects estimates non-significant. The excess risk of death for all causes in all ages was 0.05% (95%CI:-0.24;-0.33). The higher risk was for CPM, 65+ years: 0.28% (95%CI:0.09-0.46).
Conclusions: PM10 was associated with increased mortality in most cities for all and specific causes of death. Higher effects were observed in the elderly (65+ years old) and for respiratory causes. The effects were somewhat higher than those reported in other multi-city studies. Ozone effects were less consistent.

ASSESSMENT OF THE HEALTH BENEFITS OF THE IMPROVEMENT OF WATER SUPPLY AND SANITATION SERVICES IN TANGIER (2004-2009)

Lucie Lambolez, *Veolia Environnement Research & Innovation, Rueil-Malmaison, France*
Hélène Morin, *Veolia Environnement Research & Innovation, Rueil-Malmaison, France*
Catherine Arfi, *Consultant in environmental and occupational Health, Issy Les Moulineaux, France*

Abdenbi Attou, *Veolia Water Morocco, Tangier, Morocco*
Mahmoud Berrahal, *Veolia Water Morocco, Tangier, Morocco*

Background and Aims Access to water and sanitation are major issues of Public Health. A very large works program to improve drinking water supply and sanitation was conducted since 2002 in the metropolitan Tangier (750,000 inhabitants) in Morocco. To assess the benefit of the works on the population health, an epidemiological study with a pre-post methodology was achieved between 2004 and 2009.
Methods An epidemiological register was implemented in 17 health facilities in order to follow the incidence of three water-related diseases: diarrhoea in children under 5, conjunctivitis and skin diseases in the overall population. At the same time, surveys were conducted in two-pilot districts which had no water supply other than wells/fountains nor wastewater systems, at the beginning of the study. Twice-yearly, 70 households (≈400 people) were questioned to qualify water use, hygiene practices, health outcomes (diarrhoea, conjunctivitis, skin diseases). Samples of the water they consumed were collected for microbiological analysis. Works progress and sea water quality were assessed during the five-year period (WHO/UNICEF 2008 Esrey 1985, Esrey 1986, Esrey 1991, Fewtrell 2005).
Results In the pilot districts, the incidence of diarrhoea in children (-20%) and conjunctivitis (-34%) decreased in parallel with the improvement of the quality of the water consumed by households (correlated with improved access to drinking water and the reduction of storage practices). On the macroscopic scale of the city, the health indicators remain stable. Different non controlled parameters may explain this result. With the improvement of sanitation at the Tangier level, the quality of sea water in summer was significantly improved and since 2007 all beaches meet the Moroccan standards, for the indicators followed.
Conclusions The originality of the project relies on its two-scale approach and its size: a 5-year health monitoring of the population of a large city on the Mediterranean coast. Results interpretation faces difficulties in estimating the population growth Tangier. An individualized monitoring methodology permits to exclude some confounding factors.

Juan Alguacil, *Universidad de Huelva, Spain*

Background: Diet and living near to chemical/metal industries are a potential source of environmental exposure to metals such as lead, mercury and arsenic, which are recognized causes of neurological disorders in children. Our objective was to explore the relationship between urinary levels of arsenic, lead and mercury, and neurobehavioral performance (subclinical effect) in children aged 9-11.
Methods: Spot urine samples were obtained from 79 children recruited from cities representative of five different environmental scenarios in Andalusia (Spain): 14 from urban/residential, 34 from urban/industrialized, 7 from mining, 14 from rural, and 10 from rural/industrialized. Neurobehavioral performance was satisfactorily assessed in 37 boys and 36 girls by the Behavioral Assessment and Research System (BARS) using Spanish instructions. Multielemental ICP-MS was used to quantify urinary levels of arsenic, lead and mercury. General linear models were used including age, gender, social class, global physical activity, and shore fish consumption as covariates, plus the exposure variable (log transformed urinary levels of each metal separately) to predict each of 14 neurobehavioral outcome variables.
Results: Higher levels of mercury were associated with a worse performance of the Alternate Hand Finger Tapping (AHFT) test (measures “coordination”) (p=0.03), of the Digit Span Forward test (measuring “attention”) (p=0.08) and of the Errors on Simple Reaction test (measures “response speed”) (p=0.02); and with better performance of the Continuous Performance Hit Latency test (measures “attention”) (p=0.001). Children with higher arsenic levels scored better on the Continuous Performance False Alarm Latency test (p=0.08), and tended to score worse on the AHFT test (p=0.10). No statistically significant associations were observed for urinary lead, although children with higher levels tended to perform better with the AHFT test (p=0.09), and worse with the Continuous Performance Correct Rejections test (p=0.15).
Conclusions: Our results suggest that urinary levels of mercury are related with poorer neurobehavioral performance among children.

PBDE 153 AND THYROID FUNTION IN HEALTHY PREGNANT WOMEN

***Megan Horton**, Columbia University, Mailman School of Public Health USA*
***Andreas Sjodin**, Centers for Disease Control and Prevention, USA*
***Sabine Bouslieman**, Columbia University, Obstetrics and Gynocology, USA*
***Ronald Wapner**, Columbia University, Obstetrics and Gynocology, USA*
***Robin Whyatt**, Columbia University, Mailman School of Public Health, USA*
***Pam Factor-Litvak**, Columbia University, Mailman School of Public Health, USA*

Background and Aims: Prenatal exposure to environmentally relevant levels of PBDEs may impair normal brain development by interfering with adequate maternal thyroid function, which is essential to fetal brain development.[1, 2] Our objective was to examine the relationship between prenatal exposure to PBDEs and maternal thyroid function among a cohort of women with normal thyroid function.
Methods: We recruited 314 pregnant women from prenatal clinics in New York City. Eligible subjects were free from clinical thyroid disorders and reported no history of thyroid cancer. We measured concentrations of 12 PBDEs congeners, free thyroxine (FT4) and thyroid stimulating hormone (TSH) in maternal blood samples collected in the first and second trimester of pregnancy (range 5-23 weeks gestation). The association between maternal thyroid function and prenatal exposure to PBDEs was evaluatedusing linear and logistic models controlling for potential confounders including parity, maternal age, education, income and gestational age at thyroid function testing.
Results: The majority of women (81%) demonstrated normal thyroid function, 9% of women had subclinical hypothyroid (elevated TSH, normal FT4), 7% hypothyroxinemia (normal TSH) and 3% overt thyroid disease. All 12 PBDE congeners were detected in maternal plasma (detection frequencies ranged from 6.7% to 98.4%). Congeners 47, 100, 99 and 153 were detected with the greatest frequencies (99%, 91%, 83% and 98.4%, respectively). PBDE 47, 99 and 100 were highly correlated with each other ($r > 0.8$, $p < 0.05$). PBDE 153 was not correlated with any other congeners. Though not statistically significant, PBDE 153 was inversely associated with the FT4 levels dichotomized at the lowest 5%, OR (95%) CI 1.44 (0.89 to 2.32) $p = 0.13$ after adjustment for lipids, triglycerides, parity and gestational age at thyroid function testing. No other PBDE congeners were associated with maternal FT4 or TSH levels.
Conclusions: Our results suggest prenatal exposure to PBDE 153 may be inversely associated with circulating FT4.

Background: Diet and working in the chemical, mining and metal industries are important sources of exposure to metals such as lead, mercury and arsenic, which are recognized causes of neurological disorders, among other human diseases. Our objective was to explore the relationship between cumulative exposure of arsenic, lead and mercury and neurobehavioral performance (subclinical effect) in a group of workers exposed to metals, and a group of workers unexposed to metals.
Methods: We obtained results of cumulated metal levels in toenails and neurobehavioral test in 56 chemical/metal industry workers and 38 service workers unexposed to metals. A neurobehavioral battery consisting of 14 tests was administered. Multielemental ICP-MS was used to quantify toenails levels of arsenic, lead and mercury. General linear models were used including age, gender, and worker exposure group as covariates, plus the metal levels variable (log transformed toenail levels for each metal separately) to predict each of 14 neurobehavioral outcome variables.
Results: We found a suggestion of an association between increased toenails levels of arsenic with a worse performance of the “Tapping with Alternating Hands” test (measures “coordination”) (p=0.17), and of the “Symbol Digit” test (related with “mental function) (p=0.11). Also, a suggestion of worse performance was observed between lead and the “Symbol Digit” test (p=0.087), the “Tapping with the Preferred Hand” test (related to “coordination”) (p=0.17), and the “Digit Span Reverse” test (related with “attention”) (p=0.126). Mercury levels were associated with a worse performance of the “Simple Reaction Time Total Error” test (related with “response speed”) (p=0.04), and showed a suggestion of an association with a better performance of the “Continuous Performance False Alarm Latency” test (p=0.13).
Conclusions: Our results suggest that cumulated exposure to mercury, and to a lesser extend arsenic and lead, are related with poorer neurobehavioral performance among exposed workers.

Long-range Transported Air Pollution from Wild-fires and Cardiorespiratory Hospitalisations

Timo Lanki, *National Institute for Health and Welfare (THL), Kuopio, Finland*
Jarkko V. Niemi, *Helsinki Region Environmental Services Authority (HSY), Finland*
Pekka Tiittanen, *National Institute for Health and Welfare (THL), Kuopio, Finland*
Tarja Yli-Tuomi, *National Institute for Health and Welfare (THL), Kuopio, Finland*
Raimo O. Salonen, *National Institute for Health and Welfare (THL), Kuopio, Finland*

Background and aims: Large amounts of particulate air pollution (PM) are emitted yearly from wild-fires around the globe. Previous studies suggest that acute exposure to PM from wild-fires is associated with respiratory symptoms and even hospitalizations. However, litte is known about possible cardiovascular effects of long-range transported wild-fire smoke. Our aim was to evaluate the association of fine particles (PM2.5; diameter <2.5 µm) measured during episodes of long-range transported wild-fire smoke with cardiovascular and respiratory hospitalizations.
Methods: Data on total cardiovascular and respiratory hospitalisations was obtained for the Helsinki Metropolitan Area (around 1 million inhabitants) from the national hospital discharge register. Outdoor PM2.5 was measured at an urban background and a rural measurement station. Days when PM2.5 levels were simultaneously elevated (>25 µg/m3) at both stations were categorized as episode days of long-range transportation. Episodes were further divided between episodes from wild-fires and other sources based on backward air mass trajectories, remote sensing of fire hot spots, and dispersion modeling of smoke. Case-crossover study design and logistic regression models were used to analyse the data. Models were adjusted for temperature, relative humidity, coarse particles, influenza, and pollen. Control days were selected for each individual as the same weekdays within the same month as the event day.
Results: There were 14 episode days linked with long-range transported wild-fire smoke in 2001–2005. The smoke typically originated from large fires in Eastern Europe. Daily mean PM2.5 concentrations were 7.9 and 26 µg/m3 during non-episode and episode days, respectively. Risk of cardiovascular hospitalization was increased 33 % (95 % confidence intervals 0.1%-77%) per 10 µg/m3 increase in PM2.5 during wild-fire episode (1-day lag). PM2.5 from wild-fires was also associated with 39% (-2%-96%) increase in same-day respiratory hospitalisations.
Conclusions: During and right after episodes of long-range transported air pollution from open biomass-burning both respiratory and cardiovascular hospitalizations seem to be increased. Therefore, adverse health effects of wild-fires on populations are not limited to the immediate vicinity of fire areas.

INVESTIGATING COLD EFFECT IN TEMPERATURE-MORTALITY ASSOCIATION STUDY

Ho Kim, *Graduate school of public health, Seoul National University, South Korea*
Clara Tammy Kim, *Graduate school of public health, Seoul National University, South Korea*

Background and Aims: Numerous epidemiological studies have been conducted on the impact of temperature to health. However, distinguishing between the seasonal and temperature effects on mortality are controversial. The objective of this study is to investigate whether these effects influence the daily mortality in major cities at South Korea.
Methods: We used daily death counts and meteorological data, from 1992 to 2009, of 4 major cities in Korea; Seoul, Daegu, Busan, and Incheon. Then, we compared the local-weighted scatterplot smoothing models (Lowess/Loess) and generalized additive models (GAM) to analyse the association between the daily mean temperature and mortality. For controlling for time trends, we gave the number of observation years for degrees of freedom. We adjusted the effects of secular trends and other cyclical factors, day of the week, humidity, and air pressure. To separate the two effects: temperature and seasonal effects, we stratified the data sets by seasons, 12 months and examining the data. For our analysis, we used the R statistical software.
Results: The year-controlled and crude models revealed different features. We observed a V-shaped smoothing spline curves on the crude models of the four major cities. In the year-controlled models, however, the V-shaped curves disappeared and mortality linearly increased with temperature. Seasonal stratified data in the LOESS model indicated a higher mortality during the winter. In contrast, the GAM model had no relative relationship with mortality and temperature during the winter. Monthly stratified model presented a strong positive temperature-mortality relationship in July and August. On the other hand, the curves during the winter months showed inconsistent results of the four cities.
Conclusions: When we controlled the year and season, the temperature effects disappeared during the winter months. However, our month-specific analysis showed dissonant patterns in each city. We need to consider both local and regional effects for further investigation.

SULFITES CONCENTRATION LEVELS COMPARED TO ALCOHOL AS A BASIS TO ESTIMATE THE MAXIMUM RECOMMENDED DAILY INGESTION OF WHITE WINE

Jose Fernando Hidalgo, *Servicio Andaluz de Salud, Spain*
Juan Alguacil, *Universidad de Huelva, Spain*
Rocío Capelo, *Universidad de Huelva, Spain*
Piedad Martín, *Escuela Andaluza de Salud Pública, Spain*

Background: The WHO recommendation for daily alcohol consumption is 40 grs in men and 32 grs in women. For total daily sulfites, the corresponding figure for both sexes is 49 mg. The maximum concentration of sulfites allowed in white wine is 210mg/L. To date, most health professionals recommend a maximum amount of white wine intake based on its alcohol concentration, however, depending on the amount of alcohol and sulfites levels of wine beverages, the maximum recommended amount of wine to be ingested might depend on the sulfite concentration instead of that of alcohol.
Methods: One hundred and forty one randomly selected samples of white wine from the quality monitoring process of the 'Condado de Huelva' appellation vineyards (campaign 2006/7) were measured for sulfite concentration levels using the Ripper assay. Each sample was obtained from a different container with at least 500L of wine intended to be bottled for public consumption under the 'young wine' category of the 'Condado de Huelva' appellation, which requests a volume percentage of alcohol between 10-12%, and a maximum 20ºC temperature during the aging process.
Results: The median of sulfite concentration in the 141 samples was 105mg/L (5-95 percentiles: 66-244mg/L). Assuming a scenario were all daily alcohol ingestion is due to white wine with 12% of alcohol, the recommended maximum ingestion of white wine results in 290mL in women and 363mL in men. The concentration of sulfites in white wine that would provide 49mg of sufites/day drinking 290mL/day and 363mL/day are 172mg/L and 137mg/L, respectively. Both of such concentrations are below the maximum allowed 210mg/L of sulfites in white wine. 30% of the samples analyzed had sulfites levels above 137mg/L, and 20% above 172mg/L.
Conclusions: Sulfites concentrations below the current allowed limit should be taken into account for maximum white wine daily intake recommendation.

THE ROLE OF SCIENTIFIC EXPERTS IN ASSESSING UNCERTAIN RISKS

Pita Spruijt, *Utrecht University, The Netherlands*
Erik Lebret, *National Institute for Public Health and the Environment (RIVM), The Netherlands*
Anne Knol, *National Institute for Public Health and the Environment (RIVM), The Netherlands*
René Torenvlied, *Utrecht University, The Netherlands*

Background and Aims Environmental health problems are often complex, large-scale and uncertain. Examples of such "systemic risks" are electromagnetic fields (EMF) and ultra fine particles. The uncertainties inherent in systemic risks provide leeway for different appraisal of risks. This raises the question how experts interpret uncertainty and how this affects their policy advice. Research on different expert perspectives has remained largely theoretical. We present a preliminary study which explores whether specific expert roles exist in practice and how these compare to ideal typical ones proposed by Weiss and by Pielke. We explored this for the areas of EMF and particulate matter.
Methods Q methodology was used to evaluate two typologies on different expert roles. Data collection was conducted with the web-based program FlashQ, among scientific experts in the Netherlands. For EMF, 26 experts participated, and for particulate matter 21 experts. Experts ranked 48 statements. Responses were analyzed using factor analysis in the PQMethod program.
Results The experts perceive EMF as a relatively certain risk and particulate matter as an uncertain risk. Three different expert roles are tentatively identified for each sub-domain. For EMF these roles are: The Autonomous Scientist, The Realist and The *Laissez-faire* Expert. For particulate matter, these are: The Engaged Expert, The Instrumental Expert and The Deliberator. These roles are considered hybrids of the expert roles by Pielke and Weiss.
Conclusions The preliminary results of this study indicate that different expert roles exist among scientists who provide policy advice on environmental health issues. These results will be further elaborated in order to identify and deal with the effects of the personal attitudes of scientists, policy makers and other stakeholders on the way they, respectively, advise on, develop and act on policy interventions.

HAVE SHORT-TERM EFFECTS OF ENVIRONMENTAL EXPOSURE ON PNEUMONIA MORTALITY BEEN UNDER-ESTIMATED BECAUSE HOSPITALISATION IS IGNORED?

Matthew Gittins, University of Manchester, UK

Background & Aims: Short-term associations have been demonstrated between air pollution and respiratory mortality including pneumonia. Studies typically assume exposure depends only on place of residence, yet many are in hospital prior to death. This study explores lag length and test the hypothesis that the effect of 'black smoke' is greater when restricted to pneumonia deaths in the community - Community Acquired Pneumonia (CAP).

Methods: A case-crossover design using conditional logistic regression estimated the daily percent increase in risk for pneumonia mortality in relation to 'black smoke' in the previous 30 days. Cases were pneumonia deaths in Edinburgh 1981-1996. Multiple 'control' periods, were defined using the same weekdays for the same month as the case death. Lag structure was investigated by stratified lag model with five 6-day periods and by distributed lag models. Hospital admissions data, defined a CAP death as being someone who had not been in hospital in the 30 days before.

Results: Of 14,346 subjects who died from Pneumonia, 7,536 were CAP subjects. Larger estimated increases in risks were seen in the CAP group for all lag periods. Both stratified and distributed lag methods suggested positive effect estimates for 18 days and negative thereafter; the average percent increase per day across the 18 days was 0.70% (95% C.I. 0.29-1.14) for CAP subjects and 0.30% (95% C.I. 0.03-0.59) for all subjects.

Conclusion: Studies which fail to adjust for hospitalised subjects may underestimate exposure effects as stronger pollution effects on mortality were evident in community based subjects

LEAD AND CADMIUM EXPOSURE AMONG A COHORT OF PREGNANT WOMEN IN CALI-COLOMBIA: THE GEMA STUDY

Authors: Diana María Caicedo, Javier Fonseca, Miguel Peña, Cecilia Aguilar, Mildrey Mosquera, Cristina Araujo, Genny Martinez, Nathalie Abrahams, Daniel Cuartas, Fabián Méndez. Universidad del Valle, Cali, Colombia

Background and aims: Industrialization and inadequate waste disposal have increased exposure to heavy metals. Our studies in Cali-Colombia show that women of low socioeconomic position are exposed to heavy metals during reproductive age. This study aims to characterize high-risk exposure behaviors and its relationship to blood cadmium and lead levels in pregnant women of urban Cali.

Methods: An ongoing prospective cohort study is developed. We included 386 pregnant women between 18-35 years of age, living at one of the poorest areas of Cali. Patients were recruited at 11-13 weeks of gestational age and answered a questionnaire on sociodemographic characteristics, parents' occupational history, smoking habits and other risk behaviors of exposure to lead and cadmium. Additionally, concentrations of lead and cadmium in maternal blood were determined by using atomic absorption spectrometry coupled to graphite furnace.

Results: 386 blood samples were evaluated at enrollment. Medians of cadmium and lead were 0.115ug/dl(<0.014-4.26) and 1.013ug/dl(<0.002-16.18), respectively. Among pregnant women 32.9% had Cd levels ≥0.4ug/l and 4.15% had Pb levels ≥5ug/dl(CDC recommendations). Only 7(1.8%) of pregnant women showed high levels of both lead and cadmium, but 129(33.4%) had at least one blood metal concentration above recommended levels. We evaluated several practices and exposure sources, and determined an increased risk of lead levels ≥5ugl/dl for those women living <4km of the Navarro dump(OR:6.2; CI95%1.7-21.7) and those living <2 blocks away of battery-handling commercial sites(OR:8,33;CI95%1.01-82.8). An increased risk of cadmium levels >0.4ug/l was also observed among women living <4km of the dump, but it was not significant(OR:2.1;CI95%0,63-7.5). Individual risk practices were also identified.

Conclusion: A third of these pregnant women are exposed to significant levels of heavy metals in blood. We evaluated several sources of exposure and found that residence near a former waste disposal site and battery-handling sites were independently associated with maternal blood lead levels

SPATIAL RELATIONSHIPS BETWEEN AIR POLLUTION AND TRAFFIC NOISE FROM ROAD AND RAIL IN OSLO, NORWAY

Bente Oftedal, *Norwegian Institute of Public Health, Norway*
Gunn Marit Aasvang, *Norwegian Institute of Public Health, Norway*
Christian Madsen, *Norwegian Institute of Public Health, Norway*
Per E. Schwarze, *Norwegian Institute of Public Health, Norway*
Sam-Erik Walker, *Norwegian Institute for Air Research, Norway*
Erik Aune, *Municipality of Oslo, Norway*
Per Nafstad, *Institute of General Practice and Community Medicine, University of Oslo, Norway*

Background and Aims: Epidemiological studies have reported associations between cardiovascular outcomes and traffic-related air pollution and noise, but correlation between these pollutants may lead to mutual confounding of associations. We evaluated the spatial relationships between residential air pollution and noise at most and least noise exposed façade, separately for road and rail traffic noise.
Methods: Addresses of the participants in "The Oslo Health Study" (HUBRO) were assigned residential road traffic noise (N=13 764), rail noise (N=3 475) and nitrogen dioxide (NO_2) levels. The noise indicators L_{den} (A-weighted day-evening-night noise level) and L_{night} were calculated using the Nordic Prediction Method for Road and Railway Noise, on 5 x 5 m^2 grid. NO_2 was calculated by the EPISODE dispersion model on 1 km^2 grid and at receptor points representing a higher exposed subpopulation (N=2 599 for road traffic and N=901 for railway noise).
Results: All pollutants have large spatial variation. The correlation between road traffic noise and NO_2 was 0.4 at most exposed and 0.1 at least exposed façade, with similar correlations in the higher exposed subpopulation. In the rail noise population, these correlations were 0.5 and 0.0, respectively, and 0.2 between rail noise and NO_2. The rail noise levels were on average 9 dB(A) lower than the road noise levels.
Conclusions: The moderate correlation between road traffic noise at the most exposed façade and NO_2 suggests a potential to separate their cardiovascular effects. Despite the weak correlation between rail noise and NO_2, road traffic noise dominates this population, and rail noise may not contribute additionally to disentangle effects of traffic-related air pollution and noise in our urban population. The negligible correlations at the least noise exposed façade, which is often the bedroom's façade, may aid in separating effects of night-time noise from air pollution.

EVALUATING ENVIRONMENTAL RISKS IN CHILDREN DIAGNOSED WITH SOLID TUMORS: SINGLE INSTITUTION STUDY

Robin Rohrer, *University of Pittsburgh*, USA

Background and aims: The determination of impact of environmental exposures in the epidemiology of childhood cancers is especially challenging but crucial in the twenty first century. Although cure rates in children's cancers are rising (particularly those of acute lymphoblastic leukemia) there are several pediatric cancers such as brain tumors, neuroblastoma and acute myelogenous leukemia which are only 50% curable or less. Especially alarming is fact that the diagnosis of childhood cancers is slightly increasing and that proportionally hard to treat tumors of the central nervous system are rising in numbers. This study examines the incidence of possible toxic environmental exposures in a cohort of children diagnosed with a solid tumor at the Children's Hospital of Pittsburgh from 1995-2010.
Method: The author used oral interview with families/caregivers to examine preconception, in utero and early childhood exposures to pesticides, other chemical exposures, non ionizing and ionizing radiation including medical radiation, electro magnetic fields and proximity to nuclear power installations.
Results: The caregiver interviews yielded that there were multiple exposures particularly in utero and in early childhood. Highest among these exposures were to pesticides and medical radiation as part of diagnostic workups.
Conclusions: The study reports that there were multiple exposures to possible carcinogens in this cohort of children diagnosed with solid tumors including tumors of the central nervous system. Further study of the results and the extension of the study to previous decades (1970-1995) would enable the author to better link these exposures to diagnosed children retrospectively.

RACIAL/ETHNIC DISPARITIES IN AIR POLLUTION EXPOSURE AND ASTHMA OUTCOMES

Christina Lombardi, *UCLA Center for Health Policy Research, USA*
Ying-Ying Meng, *UCLA Center for Health Policy Research, USA*
Michelle Wilhelm, *Department of Epidemiology, University of California, Los Angeles, USA*

Background and Aims: In the U.S. asthma disproportionately affects those with low socioeconomic status, such as racial/ethnic minorities. For example African Americans often have higher emergency department visits for asthma than whites. Using California Health Interview Survey (CHIS) data, which is representative of California's non-institutionalized population, we aim to determine whether racial and ethnic minorities have higher air pollution exposures and whether air pollution exposures might contribute to disparities in asthma outcomes.
Methods: We mapped CHIS 2003 residential addresses for all respondents and calculated criteria air pollutant and traffic density exposures for each respondent using statewide traffic and air monitoring data. We examined levels of pollution exposure and prevalence of asthma outcomes such as emergency department (ED) visits, daily/weekly asthma symptoms, and daily medication by race and ethnicity. We also ran logistic regression models to test for associations between air pollutant measures and asthma outcomes while controlling for other potential confounders.
Results: Rates of ED visits were higher for Hispanic and African-American children and adults than whites. African American adults and all minority children except Asians are more likely to take daily medication to control their asthma. Mean traffic density appears to be higher for Hispanic, African American, Asian, and multi-race children and adults than white children and adults. Annual average pollutant exposures for traffic-related pollutants, such as NO_2 and PM, appear to be higher for minorities than whites. Additionally, higher pollutant exposures, such as higher traffic density near homes, increase the odds of ER visits after adjusting for age, gender, race/ethnicity and income level.
Conclusions: In California's population racial/ethnic minorities are more highly exposed to air pollution and traffic, which may help explain the disparities found in asthma outcomes. Efforts to reduce pollutant exposures in low socioeconomic communities may help address existing asthma disparities.

CELL PHONE USE AND RELATED SYMPTOMS AMONG ADOLESCENTS: A SURVEY OF 2150 STUDENTS IN IZMIR, TURKEY

Raika Durusoy, *Department of Public Health, Faculty of Medicine, Ege University, Turkey*
Hür Hassoy, *Department of Public Health, Faculty of Medicine, Ege University, Turkey*
Ali Osman Karababa, *Department of Public Health, Faculty of Medicine, Ege University, Turkey*
Ahmet Özkurt, *Department of Electric and Electronic Engineering, Dokuz Eylül University, Turkey*

Background and Aims: There is no large community-based study on cell phone (CP) use and symptom frequency in Turkey. Adolescents are an important risk group (Heinrich et al 2011). The aim of this study was to find out the CP use patterns and related symptom frequencies of high school students in Bornova.
Methods: All high school students in Bornova (20,493 students in 26 schools) comprised the target group of the survey. A sample size of 2530 students was calculated with p=50%, d=3%, design-effect=2 and 20% non-response. Systematic random sampling was applied to choose 87 classes out of 704, to obtain a cluster sample stratified according to schools. A 77-item questionnaire was applied. SAR values were obtained according to the model and brand of CP. 2150 students were included in the analyses. EMF magnitudes were measured at each school.
Results: The mean age of the participants was 15.6±1.3 and 52.2% were female. Among participants, 92.8%(n=1991) were using CP and 91.5%(n=1954) had his/her own CP. The ratio of CP users and owners significantly increased with increasing school grade (X^2 trend p<0.001 both). 14.0% had CPs with SAR>1.00W/kg, 53.9% had 1-4 calls/day, 4.6% had over 10 calls/day, the total duration of calls/day were <5min. for 29.0% and >30min for 11.7%, 27.3% sent/received ≥200 sms/day, 10.8% connected to the internet, 71.8% were registered to promotional campaigns. They were unaware of their CPs' SAR values and 64.1% never used earphones. Among the 23 symptoms surveyed, 21 increased with increasing call durations, 14 with number of calls, 13 with number of instant messages, 6 with increasing SAR values (X^2 trend p<0.05). Registration to campaigns significantly increased the presence of 12 symptoms (X^2 p<0.05).
Conclusions: CP ownership rate was high. Students mostly used their CPs for sms, a less risky attitude in terms of EMF exposure. Some students frequently spoke on their CPs. The use of earphones and other protective attitudes must be improved.

Background and Aims: Biomonitoring urinary excretion of benzene, we inquired into factors affecting benzene uptake in a general population sample living nearby a petrochemical plant.
Methods: Our study population included a random sample of 143 subjects: 33 workers of a petrochemical plant (W), 30 residents within 2 km from the plant (2kmR) and 26 residents from 2 to 4 km from the plant (4kmR), and 54 large city residents 25 km apart (25kmR). Exposure to benzene was evaluated by personal air sampling and urinary benzene (BEN-U) monitoring (specimens collected before and at the end of air sampling).
Results: Median air benzene exposure was 25, 9, 7 and 6 $\mu g/m^3$ benzene among W, 2kmR, 4KmR, and 25kmR respectively, with the highest levels in W and no difference among the other groups. Median BEN-U was 3 to 10-fold higher in smokers compared to non-smokers; among non-smokers BEN-U was the highest in W (median 236 ng/L), and lower in 2kmR (48 ng/L) and 4kmR (63 ng/L) than in 25kmR (120 ng/L). Among non-smoking general population individuals the inverse association between BEN-U and distance of residence from the petrochemical plant was significant ($p<0.001$), and possibly related to urban traffic increasing with the distance from the plant. A multiple linear regression analysis performed among non-occupationally exposed subjects showed that up to 73% of BEN-U variability was accounted for by active smoking, air benzene, urinary creatinine and distance from the plant (for each $p\leq0.002$); marginal influences of personal characteristics and environmental tobacco smoking were also observed ($p\leq0.074$).
Conclusions: Our study showed that benzene uptake is the highest among petrochemical workers. Among subjects non-occupationally exposed, smoking and urban traffic currently contribute to benzene exposure more than living in the proximity of a petrochemical plant.

PROSPECTIVE INTEGRATED ASSESSMENT OF CANCER RISK ATTRIBUTABLE TO PESTICIDES IN EUROPE

Dimosthenis A. Sarigiannis, *Aristotle University of Thessaloniki, Greece*
Periklis Kontoroupis, *Centre for Research and Tecnhnology Hellas, Greece*
Ermioni Solomou, *Centre for Research and Technology Hellas, Greece*
Peter Fantke, *University of Stuttgart, Germany*
Oleg Travnikov, *MSC-East, Russia*
Spyridoula Nikolaki, *Centre for Research and Technology Hellas, Greece*
Susanne Wagner, *University of Stuttgart, Germany*
Alberto Gotti, *Centre for Research and Technology Hellas, Greece*
Anastasios J. Karabelas, *Centre for Research and Technology Hellas, Greece*

Background and Aims: The main climate change policy expected to influence agricultural patterns and, consequently, the need for pesticide use in Europe is the introduction of bio-energy in the domestic energy production mix. Over the next 40 years this will depend on land availability and the need to curb C emissions. Two different scenarios for climate change up to 2050 (a BAU based on 2000 trends and an aggressive emissions abatement scenario limiting temperature change to 2 C) have been assumed.
Methods: The changes in agricultural land use patterns and productivity have been estimated combining CORINE land cover/use data, Eurostat agricultural statistics and the IMAGE and ATEAM models to account for climate change impact on agriculture. The result was mapped on a 50x50 km grid. Using Monte Carlo the changes in land use were distributed stochastically within the grid cells. The areas dedicated to energy crops were calculated taking into account the current state of knowledge regarding yield and the energy demand assumed to be fulfilled by energy crops by the TIMES energy-economic model.
Results: Pesticide use maps were prepared at the same resolution and aggregated at the country level accounting for the spatial allocation of agricultural land for food and energy production. Gradual substitution of active substances with less toxic ones was modeled based on the last twenty years trend and the current regulatory framework. Dietary, inhalation and dermal intake were considered. For inhalation, both long-range transport of pesticides and short-distance exposure due to direct application were accounted for.
Conclusions: Results showed that dietary ingestion is the main route of exposure to pesticides; short-distance inhalation exposure affects primarily farm workers and bystanders. Thus, spatial cancer risk analysis has been undertaken at a finer (100x100 m) resolution, showing significant variations across Europe even within agricultural areas of the same country.

ROAD TRAFFIC NOISE, AIR POLLUTION AND HYPERTENSION IN OSLO, NORWAY

Bente Oftedal,, *Norwegian Institute of Public Health, Norway*
Per Nafstad, *Institute of General Practice and Community Medicine, University of Oslo, Norway*
Per E. Schwarze, *Norwegian Institute of Public Health, Norway* **,**
Gunn Marit Aasvang, *Norwegian Institute of Public Health, Norway*

Background and Aims: Epidemiological studies have reported associations between aircraft noise and hypertension, whereas the relationship between road traffic noise and hypertension is more uncertain. Road traffic is the main source of noise and air pollution, and air pollution has also been linked to cardiovascular outcomes. However, the knowledge about the relative importance of noise and air pollution in developing cardiovascular diseases is limited. We investigated the relationship between residential road traffic noise, air pollution and hypertension.
Methods: We identified hypertension as measured systolic blood pressure above 140 mmHg, measured diastolic blood pressure above 90 mmHg or self-reported use of antihypertensive medication in the population-based "Oslo Health Study" (N=8,921). The participants were assigned residential road traffic noise at most exposed façade and NO_2 levels. L_{den} (A-weighted day-evening-night noise level) and L_{night} were calculated on 5 x 5 m^2 grid, using The Nordic Prediction Method. NO_2 was calculated by the EPISODE dispersion model mainly on 1 km^2 grid
Results: The correlation between road traffic noise and NO_2 was 0.4. Preliminary results showed an odds ratio (OR) of 1.03 for hypertension [95% confidence interval (CI): 0.97-1.09] per interquartile range (IQR) higher level of traffic noise (L_{night}) adjusted for age, gender, body mass index and education. We found no associations between NO_2 and hypertension. Adjusting for NO_2 did not change the OR of traffic noise. In men we found an OR of 1.06 [95% CI: 0.97-1.15] per IQR increase of traffic noise (L_{night}), and OR=0.99 [95% CI: 0.91-1.08] in women.
Conclusions: Residential road traffic noise may not be related to hypertension among participants in "Oslo Health Study". The association was somewhat stronger in men than women, but did not reach statistical significance. These associations are probably not affected by traffic-related air pollution in Oslo.

For a designated ethics discussion session on EMF exposure

Benefits and Barriers to Sharing Electromagnetic Field (EMF) Exposure Research Findings with Participants

On one side of the debate, some studies have supported exposure to electromagnetic fields (EMF) and association with cancers (such as childhood leukemia), reproductive dysfunction, neurological disorders, birth defects and Alzheimer's disease. For example, for the power line issue, results have fueled debate in communities with calls for closing of schools in proximity to power lines. On the other side of the debate, some studies have not found evidence of an association of exposure to EMF and health effects which has provided support for some utility companies to claim that the science is insufficient to confirm an association and no action is warranted.

Given the often equivocal findings in environmental studies, investigators have to weigh the benefits and costs to share study results with study participants. Institutional requirements, typically from the Institutional Review Board (IRB), can cost the investigator considerable time and resources which may not have been considered in the budget. Sharing study results with participants can encourage their continued interest in research by giving them something back. However what does the data mean at the individual level? EMF exposure at the individual level, particularly from insidious exposures, does not have clear toxic cut points. Consequently, explaining results of estimated exposure levels with participants without definitive answers regarding risk is challenging. These issues as well as other benefits and costs of sharing study results with study participants have ethical implications that will be explored among the session participants.

Introducing urban street configuration for improvements in air pollution land use regression models, using 3D building data

Authors: Marloes Eeftens[1], Johan Beekhuizen[1], Rob Beelen[1], Roel Vermeulen[1], Anke Huss[1], Gerard Hoek[1]

1 IRAS Institute for Risk Assessment Sciences, Utrecht, The Netherlands

Word count: 293

Background and aims

Land use regression (LUR) has become a valuable tool to estimate spatial variability of air pollutants within cities. However, in many urban built-up areas, tall buildings along narrow streets obstruct the free flow of air, resulting in higher pollution levels, which are difficult to predict by current LUR models. We describe an approach to calculate indicators of the urban canyon effect for improvement of spatially resolved LUR models using 3-dimensional building data.

Methods

Concentrations of NO_2 and NO_X were measured at 68 sites in the Netherlands, and LUR models were computed for both components using predictors such as population density, land-use and nearby traffic intensity. We used ArcGis10 and python scripting to calculate two indicators for canyon effects at each site: (1) the maximum aspect ratio (building height/width of the street) between buildings on opposite sides of the street, and (2) the mean building angle, which is the angle between the horizontal street level and the line of sight to the top of the nearest building. For each site, we calculated 360 building angles in 1-degree steps centered horizontally around the site, and these angles were then averaged. We evaluated whether the two indicators added to the explained variance of the LUR models.

Results

Explained variance of the original models was 89% for NO_2 and 83% for NO_X. A higher mean building angle was associated with an increase in NO_2 and NO_X concentration and improved the explained variance of both the NO_2 and NO_X LUR model (to 91% and 85%, respectively). The maximum aspect ratio did not significantly improve the models.

Conclusion

Original LUR models explained large percentages of spatial variability in NO_2 and NO_X. Preliminary results suggest that performance of LUR models can be further improved by taking into account buildings obstructing free air flow.

Sequential exposure to biological and chemical contaminants: a new *in vitro* model on human respiratory cells

Christopher Leleu, *Laboratoire de Parasitologie-Mycologie, EA3520, Université Paris Diderot, Paris, France*
Charles Persoz, *Laboratoire de Santé Publique, EA4064,Université Paris Descartes, Paris, France*
Jean Menotti, *Laboratoire de Parasitologie-Mycologie, EA3520, Université Paris Diderot, Paris, France*
Magali Fasseu, *Centre de Recherche Bichat-Baujon, U773, Inserm, Paris, France*
Sophie Achard, *Laboratoire de Santé Publique, EA4064, Université Paris Descartes, Paris, France*
Pascale Meneceur, *Laboratoire de Parasitologie-Mycologie, EA3520, Université Paris Diderot, Paris, France*

Francis Derouin, *Laboratoire de Parasitologie-Mycologie, EA3520, Université Paris Diderot, Paris, France*

Background and Aims:
Humans are permanently exposed to numerous pollutants of different types. The effects of the association between chemical and biological compounds on human respiratory health, and especially asthma, are still unclear. In order to clarify these effects, toxicological evidence is needed in addition to epidemiological observations.
Our aim was to develop an *in vitro* model of exposure using two types of pollutants. The individual or combined *in vitro* effects of a chemical pollutant and a biological contaminant, known to be found in domestic environment and deleterious to respiratory health, were assessed *in vitro* on epithelial respiratory cells using a unique exposure device and stringent conditions of exposure.

Methods:
Human alveolar epithelial cells (A549) were sequentially exposed during 30 min, each at the air-liquid interface in an Vitrocell exposure module to FA at an environmental level (50µg/m^3) then to viable spores of Asp (8.10^8 spores/m^3, sampled at the inflow level). Controls comprised sequential exposures to each agent alone or to ambient filtered air. After 10h post-incubation, cellular viability (XTT and LDH assays) was assessed. Biomarkers of local inflammation, IL-8 and MCP-1 were assayed by ELISA in the medium removed from apical face of cells, and their mRNA expression was quantified by RT-PCR.

Results:
Using this protocol, sequential exposure to air, FA or Asp did not impact cellular viability. Single exposure to FA or Asp and sequential exposure to FA then air did not induce significant changes of production or expression of inflammatory cytokines. However, sequential exposure to air then Asp tended to induce IL-8 production and expression. When combined, FA followed by Asp exposure increased IL-8 production and MCP-1 expression.

Conclusions:
These results show that a combined exposure to different types of environmental pollutants can be modelled in vitro.

LOCAL AND REGIONAL SOURCES OF UFP IN URBAN STREETS

Jan Theunis, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*
Roland O'Donoghue, *University of Birmingham, School of Geography, Earth and Environmental Sciences,UK*
Martine Van Poppel, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*
Vinit Mishra, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*
Patrick Berghmans, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*

Background and Aims: Ultrafine particle (UFP) numbers show large short-term and small scale variation, making strategies to assess personal exposure to UFP in urban environment potentially very costly. Better insight in the role of local and regional processes, can give rise to methods to estimate UFP using correlated pollutants and regional indicators (Can et al 2011).
Methods: UFP and NOx were measured simultaneously in Antwerp (Belgium) at three locations in a single street in Summer 2009, and in four different streets in a 1 km grid in Winter 2010. Different size fractions were compared to traffic counts and meteorological data. Regional contributions to various size fractions were assessed using night time number concentrations and air mass back-trajectory techniques.
Results: In-street spatial variability of total particle number was rather low. UFP concentrations in four different streets showed a remarkably similar temporal trend on top of which the local component is added.
Total particle number correlated poorly with traffic intensity. Mainly the 20 – 50 nm fractions are correlated with traffic intensity. The morning traffic peak leads to a distinct peak in total particle number, but this is not the case for the afternoon rush hour. Analysis of diurnal UFP concentrations for different size bins shows that both processes of agglomeration and condensation and meteorological conditions explain this decoupling of traffic and total particle number. Elevated total night-time UFP was mainly related to larger size fractions (50 - 100 nm). Higher concentrations of the larger size bins were associated with slow moving air masses.
Conclusions: Although short-term variation in UFP number counts at urban traffic locations largely depends on local sources, similar temporal trends result both from regional processes and similar underlying traffic patterns. This study illustrates the potential to extrapolate measured UFP concentrations to similar locations using correlated pollutants and regional indicators.

EXPOSURE AND RISK ASSESSMENT OF VOLATILE ORGANIC COMPOUNDS AND CARBONYLS IN INDOOR ENVIRONMENTS IN EUROPE

Dimosthenis A. Sarigiannis, *Aristotle University of Thessaloniki, Dept. of Chemical Engineering, Thessaloniki, Greece*
Spyros P. Karakitsios, *European Commission, Joint Research Centre (JRC), Ispra (VA), Italy*
Alberto Gotti, *Centre for Research and Technology Hellas, Chemical Process Engineering Research Institute, Thermi, Greece*

Background and Aims: The study paper summarizes the existing cancer and non-cancer risks posed by indoor exposure in dwellings and public buildings in European Union (EU) countries, due to the occurrence of major organic compounds (benzene, toluene, xylenes, styrene, acetaldehyde, formaldehyde, naphthalene, limonene, α-pinene and ammonia, classified by the European Commission's INDEX strategy report as the priority pollutants to be regulated).
Methods: The indoor air quality data used in the study where obtained from the literature of the last decade, including the results of large-scale European projects (e.g. EXPOLIS, AIRMEX), as well as the ones from individual investigator groups. Cancer potency factors and exposure limits (for estimating cancer risks and Margin of Safety respectively) where obtained from different regulatory bodies (EPA-IRIS, OEHHA), aiming to identify the differences in pollutants prioritization imposed by the relevant approaches.
Results: The review process indicated that significant differences in indoor air quality exist within and among the countries where data were available, indicating corresponding differences in sources and emission strength of airborne chemicals, identified or not. Conservative exposure limits were not exceeded for non-carcinogenic effects, except for formaldehyde; for carcinogenic agents the estimated risks were up to three orders of magnitude higher than the one (10^{-6}) proposed as acceptable by risk management bodies. Prioritization between formaldehyde and benzene depends more on the cancer potency factors assumed than the levels of existing concentrations.
Conclusions: The risk assessment evaluation process faces crucial difficulties, either due to the relative paucity of indoor air quality measurements in many EU countries, or by the lack of sampling consistency in the already existing studies, indicating the need for additional measurements of indoor air quality following a harmonized sampling protocol. Additionally, uncertainties embodied in the cancer potency factors and exposure limit values impose further difficulties in substance prioritization and risk management.

FUTURE RE-EMERGENCE OF INFECTIOUS DISEASE DISTRIBUTION IN THE MEDITERRANEAN AREA: HOW LIKELY THEY ARE?

Xavier Rodó, ICREA -*Institut Català de Ciències del Clima (IC3) Barcelona,Spain*
Menno J. Bouma, *Institut Català de Ciències del Clima (IC3) Barcelona,Spain - London School of Hygiene and Tropical Medicine, London, UK*

There is currently a long list of climate-sensitive diseases potentially capable of re-emerging in the Mediterranean areas under ongoing and future global warming. But, how likely those scenarios and projections are? Answering such an important question for our people and societies in the region, requires of an integrated approach to this complex issue, far from the simple risk assessment exercises that have recently steered reasonable public debates on their degree of validity.
Directions of projected changes for the Mediterranean region are quite clear, at least for the next decades and despite reasonable associated uncertainties. What it is not so clear is how, the facilitating effect of climate can play a role in approaching the sylvatic cycles of some of those highly relevant diseases, to the human cycles in a sense that the spill out or leakage of the former can represent a serious threat to the amplification of disease incidence in humans. The role of climate in all this interplay, will be weighed against other sources of changes, perhaps more important than climate itself, such as land-use and land-cover changes, population changes and policies developed by country stakeholders.
Understanding the underlying mechanisms mediating those associations reveals key to derive sound and useful results that may be used as tools for developing early-warning systems for some of the most relevant diseases in the region. An example for cutaneous leishmaniasis will be used to highlight important aspects of this controversial topic, that might be of use also for a whole range of other serious diseases which may be imported to the region.

THE FREQUENCY OF METHEMOGLOBINEMIA IN CHILDREN AND THE CONTEXT OF ITS OCURRENCE

Sorin N. Dinescu, *University of Medicine and Pharmacy of Craiova, Epidemiology Department, Craiova, Romania*
Venera Dinescu, *University of Medicine and Pharmacy of Craiova, Hygiene-Environmental Health Department, Craiova, Romania*
Elena Catalina Bica, *University of Medicine and Pharmacy of Craiova, Pediatrics Department, Craiova, Romania*
Florin Pietrariu, *University of Medicine and Pharmacy "Gr. T. Popa" Iasi, Hygiene-Environmental Health Department, Iasi, Romania*
Marinela Madan, *Olt County Public Health Authority, Slatina, Romania*

Background and Aims: Starting from the premise there is a higher rate of methemoglobinemia in some regions of Romania, the aim of the study was to identify the frequency of methemoglonimenia and context of its occurrence.
Methods: Were included diagnosed cases with methemoglobinemia in children under 1 year age from Olt county during 2005-2009 (N = 90).
Results: The number of cases was decrease from 29 cases in 2005 to 4 cases in 2009. Most of the cases was formula (47 cases) and mixed (42 cases) feed. The age average was 2,7 months.
A significant impact was noted for collective wells (22.22%), but most residents and ensuring water from own fountains. Only one was provided with protection, 95% being located closer than 10 m from latrines. In over half (14/20) of them depth was below than 10 m., and only one had a depth over 20 meters. Of the individual wells, 18.84% are provided with protection, 15.71% being located at a distance over 10 m. from latrines, and 15.71% had over 20m. depth.
Theoretically, depth brings less risk of nitrate poisoning and increase the safety of drinking water, but in our study we observed high concentrations in deep wells. In all samples collected from wells with depth over 20 m. the nitrate concentrations was above 100 mg / l, unlike samples from wells with depth 10-20m, where concentrations above 100 mg / l. were identified only in 79.43% of the samples, respectively 69.23% of samples from wells with a depth below 10m.
Conclusions: Although, a clear decrease of frequency of methemogloinemia was noted, they remain a public health problem. Major problems remain the age, artificial feeding, collective wells, and in areas with heavy pollution, the well depth does not have the guarantee of safe water.

HEALTH IMPACT ASSESSMENT OF INDOOR AIR POLLUTION FROM COMBUSTION SOURCES IN HOMES

Fintan Hurley, *Institute of Occupational Medicine, Edinburgh, UK*
Amy Shafrir, *Institute of Occupational Medicine, Edinburgh, UK*
Araceli Sanchez Jimenez, *Institute of Occupational Medicine, Edinburgh, UK*
Hilary Cowie, *Institute of Occupational Medicine, Edinburgh, UK*
Karen Galea, *Institute of Occupational Medicine, Edinburgh, UK*
Marie Coggins, *National University of Ireland, Galway, Ireland*
Sean Semple, *University of Aberdeen, UK*

Background and Aims: In a large European study (HEIMTSA) and a local study (IAPAH) based in Ireland and Scotland, we developed and applied methods for estimating the health impact of indoor air pollution from combustion sources in homes. We considered two approaches: using a simple binary exposure (presence/absence of the indoor combustion source) or using exposure to $PM_{2.5}$.
Methods: Both approaches involved linking exposure estimates with demographic data, health risk functions and background rates of morbidity to estimate total health burden attributable to combustion-derived air pollution from indoor sources. IAPAH included one 24-hour measurement of $PM_{2.5}$ in each of 100 homes selected for different types of biomass fuel (wood, peat, coal, gas), or environmental tobacco smoke (ETS). Information regarding household and occupant activities was also collected. These and other published data were used to derive estimates of average annual $PM_{2.5}$ exposures, by exposure source. Assessment of ETS used both approaches; biomass combustion used exposure to $PM_{2.5}$ only. Risk functions in $PM_{2.5}$ (for ETS and biomass) were derived from relationships for outdoor air pollution, by scaling functions in background concentrations for use with personal exposures. The ETS binary approach used risks from epidemiological studies of "living with a smoker".
Results: Preliminary results suggest that (i) using binary exposures, the greatest health burden from ETS is from coronary heart disease in adults and (ii) ETS concentrations of $PM_{2.5}$ greatly exceed those from biomass fuel. Health burdens from ETS and biomass, in terms of $PM_{2.5}$, will be presented and, for ETS, compared with impacts using the binary approach.
Conclusions: Discussion will consider strengths and weaknesses of the two approaches, for burden of disease and for evaluating impacts of policies; and the public health implications of the various domestic sources, especially ETS in homes, whose estimated impact is substantial.

LEAD EXPOSURE AND TELOMERE LENGTH IN ELDERLY MEN: THE NORMATIVE AGING STUDY

Kelly Bakulski, *University of Michigan, USA*
Sung Kyun Park, *University of Michigan, USA*
Howard Hu, *University of Michigan, USA*
Huiling Nie, *Purdue University, USA*
David Sparrow, *Veteran's Affairs Boston Healthcare System, USA*
Andrea Baccarelli, *Harvard University, USA*
Joel Schwartz, *Harvard University, USA*

Background and Aims: Telomeres, repeated DNA sequences at the ends of chromosomes, are important for genomic stability. Telomere shortening has emerged as a marker of cellular aging and increased risk of early mortality. Recently, exposure to traffic pollution has been associated with shortened telomeres.
This study examined the associations between measures of lead exposure and telomere length in a cohort of aging men.
Methods: In the Veteran's Affairs Normative Aging Study, cumulative baseline lead exposure was measured by K-Shell X-Ray Fluorescence microscopy of tibia and patella bones between 1991-2002 ($n_{subjects}$ = 589) and acute blood lead exposure by GFAAS ($n_{subjects}$=701). Telomere length was determined at up to four repeated study visits between 1999-2007 (n_{visits} = 1183) by the ratio of telomere sequence repeat to single copy gene (T/S ratio) from real time PCR of whole blood DNA. The first visit cross-sectional effect of lead and other exposures on log(T/S ratio) was determined by generalized additive modeling. Mixed models with repeated telomere measurements and fixed effects of lead were also generated. Potential confounders included smoking, alcohol ingestion and metabolic parameters.
Results: Median telomere T/S ratio at the first visit (aged 55-100) was 1.22 (IQR: 0.503) and at the fourth visit was 1.07 (IQR: 0.712). Lead exposure measured by tibia, patella, and blood lead had no relationship with telomeres cross-sectionally, but was associated with longer telomeres in repeated measures mixed effects models. Telomere measures were inversely associated with age (p-value <0.0001), current smoking status, ischemic heart disease status and body mass index. Higher attained education was associated with longer telomeres.
Conclusions: Telomere length shortens in elderly men with age. The degree of shortening is influenced by smoking status, body mass index, education level, and ischemic heart disease diagnosis. In contrast to previous research on traffic exposure and telomere length, lead exposure was associated with longer telomeres. Possible explanations will be discussed.

ASSOCIATION BETWEEN SERUM CHOLESTEROL AND PLASMA PFOA AND PFOS LEVELS IN A MIDDLE-AGED DANISH POPULATION

Kirsten Thorup Eriksen, *Institute of Cancer Epidemiology, Danish Cancer Society, Denmark*
Ole Raaschou-Nielsen, *Institute of Cancer Epidemiology, Danish Cancer Society, Denmark*
Joseph K. McLaughlin, *International Epidemiology Institute, Rockville, Maryland, United States*
Loren Lipworth, *International Epidemiology Institute, Rockville, Maryland, United States*
Anne Tjønneland, *Institute of Cancer Epidemiology, Danish Cancer Society, Denmark*
Kim Overvad, *School of Public Health, Aarhus University, Denmark*
Mette Sørensen, *Institute of Cancer Epidemiology, Danish Cancer Society, Denmark*

Background:
Perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS) are used in a variety of industrial and consumer products and have been detected worldwide in human blood. Recent studies - mostly based on highly exposed populations - have indicated that PFOA and PFOS may affect serum cholesterol levels. Elevated cholesterol levels are associated with increased risk of cardiovascular diseases.

Aims:
The aim of the present study is to investigate the association between serum cholesterol and plasma PFOA and PFOS levels in a middle-aged Danish population.

Methods:
The study population is 724 individuals (635 men and 89 women) from the Danish Diet, Cancer and Health cohort. Blood samples were donated by the cohort members at the time of enrolment between 1993 and 1997 and stored in a biobank at -150°C. For the study group plasma levels of PFOA and PFOS and serum levels of cholesterol have been determined. None of the 724 individuals takes cholesterol reducing medication. The association between PFOA and PFOS plasma levels and serum cholesterol levels will be analysed by regression techniques. The regression analyses will be adjusted for potential confounders. Also, we will investigate whether gender, body mass index and prevalent diabetes modifies the association between cholesterol and PFOA and PFOS.

Results
The study population of 724 individuals is 50-65 years of age with a mean serum cholesterol level of 231.5 mg/dL. Mean plasma PFOA and PFOS level are 7.1 ng/mL and 35.9 ng/mL, respectively. Results of the regression analyses will be obtained in spring 2011 and will be presented at the ISEE conference in September 2011.

Conclusions: Conclusions will be presented at the ISEE conference in September 2011.

EXPOSURE TO PARTICULATE MATTER AND ITS RELATIVE EFFECT ON HEART RATE VARIABILITY FOR DIFFERING PHYSIOLOGICAL STATES WITH IMPLICATIONS FOR COMMUTER MODAL CHOICE

Marguerite Nyhan, *Trinity College Dublin, Ireland*

Background and Aims: Links between particulate matter (PM) exposure and decreased heart rate variability (HRV) have been documented in studies of older, susceptible individuals, those with existing cardiovascular conditions (Gold et al 2000; Brook et al 2010) and also in young healthy adults (Vallejo et al 2006). HRV is a marker of the risk of sudden death from cardiac events in humans and $PM_{2.5}$ has been shown to be a cause of sudden death in humans. The objectives of the study comprises the measurement of HRV and personal exposure to $PM_{2.5}$ in cyclists, pedestrian, private car commuters and public transport commuters in Dublin City. This will assess the relative variation in HRV with particulate matter (PM) exposure of these groups performing differing levels of physical activity and having differing physiological states.
Methods: Healthy individuals who commuted to and from work or college during peak traffic times were studied. HRV was continuously monitored in subjects using an Actiheart unit over 24 hours. PM exposure over the same time period was measured using an ambulatory device.
Results: The uptake of pollutants was higher for cyclists due to higher breathing rates. This higher uptake led to larger decreases in heart rate variability indices in comparison to subjects using other modes of transport.
Conclusions: Exposure to PM was found to be linked to decreased HRV among healthy subjects. Differing modes of transport, these in turn leading to differing physiological states, led to varying percentage decreases in heart rate variability in response to PM exposure. The results of this study have definite implications for commuter modal choice.

COULD ENDOCRINE DISRUPTING CHEMICALS ALTER PARTNER PREFERENCE IN HUMAN? A DEBATE FOR BISPHENOL A

Banu Sarer Yurekli, *Ege University Faculty of Medicine, Department of Endocrinology and Metabolism, Turkey*
Raika Durusoy, *Ege University Faculty of Medicine, Department of Public Health, Turkey*

Background and Aims: The higher and increasing rate of men who sex with men in industrialized countries might be due to industrialization per se, in parallel to the increase in the production volume of endocrine-disrupting plastics. We hypothesize that endocrine disruptors like bisphenol A (BPA) might alter partner preference of men.
Methods: We searched the literature related to the effects of BPA as endocrine disruptors.
Results: There is a critical period in development during which testosterone or its metabolites organize both the brain and behavior of male rats. Testosterone can have its effects by acting directly on the androgen receptor, or by being metabolized into dihydrotestosterone by 5α-reductase and into estradiol by aromatase. Sexually dimorphic nucleus (SDN), is believed to be related to sexual behavior in animals. It is a cluster of cells located in the preoptic area of hypothalamus of the brain. The volume of SDN in medial preoptic area is modified by hormones, among which testosterone is proved to be of much importance. The larger volume of male SDN is correlated to the higher concentration of fetal testosterone level in males than in females. Also, there is evidence that testosterone acts during specific prenatal period to organize the development of aromatase-expressing neurons into the male-typical SDN. There is extensive evidence that BPA is an estrogen-mimicking chemical, although recent findings have revealed that BPA is a selective estrogen receptor modulator (SERM), since BPA and the potent endogenous estrogen 17 beta-estradiol (E2) do not always show identical effects, and in some studies BPA has been shown to antagonize the activity of E2.
Conclusions: Considering the wide and increasing use of plastics in our daily lives, we hypothesize that endocrine disruptors like BPA might alter partner preference of men by acting on the preoptic area in hypothalamus in men and by acting as SERM.

CHARACTERIZATION OF PREGNANT WOMEN EXPOSURE TO CD AND PB IN TAP WATER AND FRESH-FOOD IN CALI - COLOMBIA

Genny Virginia Martínez Puentes, *Universidad del Valle, Colombia*
Fabián Méndez, *Universidad del Valle, Colombia*
Miguel R. Peña, *Universidad del Valle, Colombia*

Background/aims: Previous studies have suggested that heavy metals could be associated with perinatal health effects among pregnant women in Cali-Colombia. Among pregnant women we characterized concentrations of Cd and Pb in water and local foods.
Methods: A sample of 60 women was selected out of 385 pregnant women included in a cohort study designed to evaluate the effects of environmental exposures on fetal growth. Tap water samples were monthly collected from the drinking water network and at women households during 11 months. Food samples were collected according to the frequency of consumption during the first and third trimesters of pregnancy for a group of local foods with potential bio-accumulation capacity: fresh-vegetables eaten raw (lettuce and cabbage), fish and some cow entrails (liver and kidney). In-sample Cd and Pb concentrations were determined with Atomic Absorption spectrometry coupled to Graphite Furnace. The Hazard Quotient (HQ) to estimate non-carcinogenic risk was calculated with data of height, weight and frequency of consumption collected via a questionnaire.
Results: Cd or Pb were detected in > 90% of 66 water samples, and 11% of them had lead levels above WHO limits. Among 122 food samples, 6% had Cd; and 27%, Pb. Among them, 67% and 28% exceeded FAO Limits for Cd and Pb, respectively. HQ estimations for Cd and Pb, in both water and food, were sometimes >1, suggesting risk of adverse effects in this population.
Conclusions: Our findings show that this population of pregnant women in southeastern Cali is exposed to Cd and Pb in water and food, and sometimes concentrations exceed the recommended EPA and FAO limits. This non-carcinogenic risk may affect fetus development.

A TIERED APPROACH FOR AGGREGATE EXPOSURE ASSESSMENT

Dimosthenis A. Sarigiannis, *Aristotle University of Thessaloniki, Thessaloniki, Greece*
Alberto Gotti, *Centre for Research and Technology Hellas, Thessaloniki, Greece*
Spyros Karakitsios, *Centre for Research and Technology Hellas, Thessaloniki, Greece*
Rudi Torfs, *VITO, Mol, Belgium*
Christa Cornelis, *VITO, Mol, Belgium*
John Cherrie, *Institute for Occupational Medicine, Edinburgh, United Kingdom*
Martie van Tongeren, *Institute for Occupational Medicine, Edinburgh, United Kingdom*

Background and Aims: The study describes the tiered aggregate exposure assessment methodology followed in the TAGS project, as a response to CEFIC-LRI call regarding the issue of realistic estimation of exposure to substances from multiple sources.
Methods: The overall developed methodology focuses on the development of guidance and criteria to inform when an aggregate assessment is triggered, the identification of data types/data gaps and quality required, exposure determinants and modifiers identification, development of strategies so that a verification of the models is possible and the completion of a range of case studies. The approach initially lies on a deliberate and extensive review of existing data, models and methodologies, aiming to compile a new overall methodology, adding the necessary elements for an as much realistic exposure assessment. The tructured methodology is built upon a computational platform that links existing (e.g. EUSES, SHEDS) and additional in house developed aggregate exposure models, to databases (e.g. Expofacts, EXPOLIS), aiming to exposure assessment refinement and data assimilation.
Results: Elevation from lower tiers to the higher ones is based on the Risk Characterization Ratio (RCR) derived in each tier; If RCR is higher than one, a refinement of the assessment is required, imposing the use of more refined data (e.g. contamination levels distributions than worst case estimates), models (probabilistic assessments, use of more accurate environmental fate models), as well as assimilation of complex data (e.g biomarkers data and use of toxicokinetic models).
Conclusions: A crucial stage of the refinement is the minimization of uncertainties embodied in the several stages of the full chain assessment, Bayesian Hierarchical modeling being an imperative tool for the exposure assessor. The applicability of the overall methodology is tested in three distinguished case studies, dealing with classical (benzene) and emerging pollutants (PBDE and BPA).

CLIMATE CHANGE AND PUBLIC HEALTH ADAPTATION PROGRAM: CANADIAN PERSPECTIVE

Manon Fleury, *Public Health Agency of Canada, Guelph, Canada*
Stephen Parker, *Public Health Agency of Canada, Guelph, Canada*

Background : The impacts of climate change can place significant demand on health, particularly among vulnerable populations and regions. The need for adaptation strategies to prepare for, and address, the risks and impacts of a changing climate has been widely recognized. Public health professionals play an essential role in knowledge translation and transfer of science-based information and development of integrated education, surveillance and response systems to reduce health risks. This project will address gaps and identify public health adaptation strategies to address the impacts of climate change on vector-borne and water-borne infectious diseases in Canada.
Methods: The climate change and adaptation program consists of two components: university research and community/regional based pilot projects. The university research projects are developing tools to assess community vulnerability to water-borne and/or vector-borne diseases. The community/regional based pilot projects have undertaken activities to examine infectious disease risks and adaptation associated with climate change in their regions. .
Results: Tools for public health (i.e. risk maps, forecasting models), resulting from the university research, are being produced to identify the predicted risk of water-borne and vector-borne (specifically Lyme disease and West Nile virus) diseases now and in the future with from a changing climate. From the pilot projects a synthesis report of the findings, lessons learned and “best practices” was created to provide information on how health regions and departments in Canada can prepare for and adapt to infectious disease threats from a changing climate based on the experience and activities of the pilot regions.
Conclusions: Through tool development by academic research and knowledge translation and transfer, public health capacity to anticipate and respond to emerging vector-borne and/or water-borne infectious diseases will be increased through the development of appropriate adaptation strategies.

Title: Exposure Assessment to Air Pollution of Children Living in the High Risk Area of Milazzo – Valle del Mela (Sicily): a Bayesian Kriging Approach.

Authors:

Ana M. Vicedo-Cabrera[1,2], **Dolores Catelan**[2,3], **Franca Rusconi**[4], **Riccardo Pistelli**[5], **Fabio Barbone**[6], **Annibale Biggeri**[2,3]

5 School of Respiratory Medicine, Sacro Cuore University, Rome, Italy
6 Institutes of Hygiene and Epidemiology, DPMSC, University of Udine, Italy

Background and aim: To estimate the exposure to ambient gaseous air pollutants at individual residential addresses by a Bayesian kriging approach to be used in studying the relationship between lung function and air pollution in asthmatic subjects living in the high risk area of Milazzo – Valle del Mela (Sicily, Italy).

Methods: ISAAC questionnaire was administered to parents of all 2,506 children attending primary schools of the Milazzo – Valle del Mela area. 154 children that scored positives for any asthmatic symptoms were enrolled in a panel study. The study period was from November 2007 to April 2008. Every two weeks respiratory function and bronchial inflammation was assessed, while parents filled in a diary with daily activities, symptoms and drugs taken by the child during follow-up.
Ambient gaseous air pollutants (SO_2, NO_2, BTX) concentrations were measured by passive dosimeters located at 21 sites at each school-yard during the week preceding each examination (weekly averages). Children's residential addresses were geo-referenced and Bayesian kriging was used to obtain an estimate of pollutants concentration at children's home for each week of monitoring. Exposure assessment was completed by time-activity patterns obtained from daily diaries.

Results: A large geographical heterogeneity in air quality was recorded suggesting complex exposure patterns. In some locations we recorded higher levels of sulphur dioxide (with one or more weekly averages over 20 mcg/cm) and some others showed higher level of NO_2 (with an overall weekly average in the study period over 40 mcg/cm). The spatial distribution of SO_2 concentrations showed the typical shape of a point source with a plume effect. The areas at higher exposure are located along the prevalent wind line. For the period 2007-2008, official data confirmed episodes of SO_2 concentration above 100 mcg/cm.

Conclusions: Our findings suggest that Bayesian kriging may provide better estimates than monitoring values alone since it accounts for the spatial heterogeneity of individual-level exposures.

QUALITY OF LIFE AND THE RELATIONSHIP WITH EARLY COMPLICATIONS OF BREAST CANCER TREATMENT IN BRAZILIAN WOMEN

Daniele Bittencourt Ferreira, *National School of Public Health, Oswaldo Cruz Foundation, Brazil*
Rosalina Jorge Koifman, *National School of Public Health, Oswaldo Cruz Foundation, Brazil*
Anke Bergmann, *National Cancer Institute, Brazil*

Background and Aims: The assessment of quality of life (QOL) in women with breast cancer before treatment allows a more comprehensive assessment these patients. Some initial complications are a major cause of morbidity in the postoperative period. The aim of this study was to evaluate the association between quality of life before treatment of breast cancer and early complications in National Cancer Institute-Brazil (INCA).
Methods: Participants were women with unilateral breast cancer, requiring oncological attention in INCA between June/2009 and March/2010. To assess quality of life before treatment was used EORTC QLQ-C30 and the BR23 module. Information about early changes (axillary web syndrome, pain and subjective symptoms related to early edema in the upper limbs) were obtained by physical examination 30 days after surgery and were collected in a standardized form of the medical records. Bivariate analysis of dichotomous variables and independent variables and the odds ratio, with CI 95%, were analyzed.
Results181 women were evaluate and were observed that women who reported good health overall, showed a protection of 57% for early subjective edema (OR=0.43 95% CI 0.20 -0.96). Symptoms scale of BR23 is negatively associated with pain (OR=0.11 95% CI 0.21-0.73). Patients with good functionality-C30 showed protection of 66% (OR=0.34 95% CI 0.15-0.75) for pain. Were not found statistically significant results when evaluating axillary web syndrome and does not indicate the presence of association.
Conclusions: These results suggest that good quality of life is predictor to evaluated early complications in women with breast cancer in the period before starting cancer treatment.

RESIDENTIAL EXPOSURE TO POLYBROMINATED DIPHENYL ETHERS (PBDE) AND RISK OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

Stephen Rappaport, *School of Public Health, University of California, Berkeley, CA*
Patricia A. Buffler, *School of Public Health, University of California, Berkeley, CA*

Background: Residential dust can be a major source of exposure to PBDEs, which are often found at high levels in U.S. homes, particularly in California. Limited evidence suggests that PBDEs may cause perturbations of the immune system. We estimated the risk of childhood acute lymphoblastic leukemia (ALL) in relation to PBDEs using levels in carpet dust as exposure indicators.
Methods: We studied 167 ALL cases 0-7 years of age and 214 birth certificate controls matched on age, sex, and race/ethnicity from the California Childhood Leukemia Study in 2000-2006. We sampled carpets in the room where the child spent the most time using a high volume surface sampler (HVS3), or we took dust from the home vacuum. We measured concentrations (ng/g) of 14 PBDE congeners that we grouped by Penta- (28, 47, 99, 100, 153, 154), Octa- (183, 196, 197, 203) and Deca-BDE (206-209) formulations. Odds ratios (ORs) were calculated using logistic regression adjusting for demographics, year of dust collection, and sampling method.
Results: BDE-47, 99, and 209 were the congeners found at the highest concentrations in homes (median [ng/g], interquartile range [IQR]: 1173, IQR 473-2175; 1579, IQR 633-3358; 938, IQR 531-1682, respectively). Comparing the highest to the lowest quartile, we found no association with ALL risk for the sum of BDE congeners in the Penta- (OR=0.7, 95% confidence interval [CI] 0.4-1.3), Octa- (OR=1.0, 95% CI 0.6-1.9), or Deca-formulations (OR=1.0, 95% CI 0.6-1.8). However, comparing homes in the highest tertile to those with no detections, we observed significantly increased risks for BDE196 (OR=2.1, 95% CI 1.1-3.8), 203 (OR=2.0, 95% CI 1.1-3.6), and 207 (OR=2.0, 95% CI 1.0-3.8).
Conclusion: We found no association with ALL for most common BDEs in residential dust, but observed positive associations for specific octa- and nona-BDEs. Additional studies with repeated sampling and biological measures will be informative.

MULTIPARAMETRIC ASSESSMENT OF AMBIENT AIR PM IMPACT ON RESPIRATORY HEALTH

Dimosthenis A. Sarigiannis, *Aristotle University of Thessaloniki, Thessaloniki, Greece*
Spyros P. Karakitsios, *European Commission - Joint Research Centre, Ispra (VA), Italy*
Alberto Gotti, *Centre for Research and Technology Hellas, Thessaloniki, Greece*
Pavlos Kalabokas, *Academy of Athens, Athens, Greece*

Background and aims: The present study aims at examining the relationship between green areas and health in four EU cities, investigated the association between air pollution, meteorological conditions and daily respiratory hospitalization for the population of Athens (Greece) from 2003 to 2005.
Methods: To this aim we applied two different statistical approaches: one that makes use of General Linearized Models (GLM) and one based on Artificial Neural Networks (ANN). For both we used time series data for the followings covariates: ozone, PM10, nitrogen dioxide sulphur dioxide, carbon monoxide, temperature, humidity wind speed, wind direction and a dummy variable to account for the seasonality.
Results: Results showed that both models performed adequately with consistent outcomes: PM is the dominant parameter related to hospital admissions, followed by O_3 and the other atmospheric pollutants (CO, NO_2 and SO_2). Meteorological parameters also play a decisive role in the formation of air pollutant levels affecting public health. ANN, in particular, gave a higher contribution to the meteorological parameters, capturing more efficiently the combined effect of chemical (air pollution) and physical (temperature and humidity) stressors on health outcome and so showing a better adaptation in complicate environmental issues results in improved modelling predictions compared to the GLMs.
Conclusions: A major finding of the study regards the flexibility and the adaptation of the methodological approach for assessing non-linear problems and specifically the effect of non-linear parameters, such as air temperature. Thus, the mathematical tool we developed successfully captures the direct impact of the meteorological parameters (temperature and humidity) to health outcomes. Besides the assessment of the significance of the environmental stressors affecting hospital admissions, the ANN approach demonstrated its higher capacity in predicting days with higher morbidity risk. This feature of the model makes it a valid policy-maker tool to support decisions on preventive measures.

OBESITY AND METABOLIC SYNDROME: RISK FACTORS FOR AIR POLLUTION RELATED ASTHMA HOSPITAL ADMISSIONS

Kevin Cromar, *New York University School of Medicine, United States*
Kaz Ito, *New York University School of Medicine, United States*
Robert Silverman, *Long Island Jewish Medical Center, United States*
George Thurston, *New York University School of Medicine, United States*

Background and Aims: Obesity has been shown to be associated with the presence of asthma in children and, to a lesser extent, adults. Additionally, acute exposure to elevated ambient air pollution has been demonstrated to increase the risk of respiratory hospital admission. However, the effect modification of obesity and metabolic syndrome on the association between air pollution and asthma hospital admissions has yet to be determined.
Methods: Data for unscheduled hospital admissions in New York City with a primary diagnosis of asthma was obtained for the years 2003-2006. A poisson generalized linear model was used to determine the association of a distributed lag model of ambient air pollution exposure with asthma hospital admissions for children (under 18), adults (18-64) and older adults (over 65). Additional analyses were conducted for children with a secondary diagnosis of obesity and adults with multiple secondary diagnoses corresponding with metabolic syndrome (i.e. hypertension, diabetes, hyperlipidemia, and obesity).
Results: After controlling for meteorological variables, temporal trends, and other possible confounders, short-term changes in ambient fine particle, nitrogen dioxide, and ozone concentrations were significantly associated with an increased risk of asthma hospital admissions in all age groups. A significant increase in risk of asthma hospitalization due to elevated pollutant concentrations was also observed in children with a secondary diagnosis of obesity, as compared to non-obese children. Also, a significant increase in risk of hospitalization was observed in adults and older adults with at least three of the secondary diagnoses that constitute metabolic syndrome as compared those individuals without metabolic syndrome.
Conclusions: Obesity in children and metabolic syndrome in adults are significant risk factors for air pollution related asthma hospital admissions. The identification of this susceptible subpopulation indicates an ongoing public health risk due to the increasing prevalence rates of both child obesity and metabolic syndrome in adults.

INTERACTION BETWEEN ARSENIC CONCENTRATION IN DRINKING WATER AND GSTT1 GENE POLYMORPHISM IN TOENAIL ARSENIC CONCENTRATION OF CHILDREN

Hyunok Choi, *State University of New York at Albany, Albany, USA*
Elaine Hoffman, *Harvard School of Public Health, Boston, USA*
Quazi Quamruzzaman, *Dhaka Community Hospital, Dhaka, Bangladesh*
Mahmuder Rahman, *Dhaka Community Hospital, Dhaka, Bangladesh*
Golam Mahiuddin, *Dhaka Community Hospital, Dhaka, Bangladesh*
Molly Kile, *Harvard School of Public Health, Boston, USA*
David C. Christiani, *Harvard School of Public Health, Boston, USA*

Background and Aims: Chronic arsenic (As) exposure through drinking water might pose a greater risk of various cancers in children. However, relationship between drinking water As exposure and the internal dose has never been clarified in healthy children. Thus, we aimed: 1) to quantify the dose-response relationship between As exposure through drinking water in children and adolescents; 2) to test interaction of drinking water As and toenail As concentration by *GSTT1, GSTP1*, and *GSTM1* genotypes.
Methods: In Pabna, Bangladesh, a prospective longitudinal biomonitoring study of As exposure was conducted among individuals with no symptoms of arsenic-induced diseases. Among 248 participants, children and adolescents • 18 of age (n = 59) are included in the present analysis. A baseline demographic questionnaire and blood sample was collected. Subsequently, samples of urine, toenail, and water samples were collected once every 3 months.
Results: Mean daily As intake ranged from <1 to 449 μg. Both tubewell water concentration and estimated daily dose in the children remained stable over the 4 year study period (both intraclass correlation coefficients > 0.95). In a multivariate regression model, 10% increase in As intake from the home tubewell drinking water was associated with 2.4 % increase in toenail As concentration (95% CI, 1.8 – 3.0%). At baseline, adolescents (age 14 – 18) had a 0.2% (95% CI, 0.0 – 0.3 %) higher level of As in their toenails, compared to the pre-adolescent children (age • 13 yrs). However, those with a *GSTT1-null* genotype had a 1.4 % lower toenail As concentration (95% CI, -2.8 – -0.1%) compared to those with *GSTT1-wild type* per same unit exposure in drinking water As exposure.
Conclusions: Despite lower range of exposure, children appear to be more sensitive to As exposure from drinking water than the adults. In particular, the children who have *GSTT1-null* genotype metabolize As differently from the adults.

2010's HOT SUMMER AND MORTALITU IN THE RUSSIA'S EUROPE: PREMILIMINARY ASSESMENT

Boris Revich, *Institute of Forecasting Russian Academy of Science, Moscow, Russia*

revich@ecfor.ru

Background and Aims: In 2010 European Russia experienced extreme heat in summer: high temperature for over 1,5 months exceeding the established long-term average norm by more than 5ºC in 43 regions. Moscow, for example, experienced an unprecedented wave of continuous heat for 53 consecutive days, during extreme heat, maximum concentration CO up to 30mg/m^3 and PM_{10} - 1 500 µg /m^3, daily average PM_{10} levels reached 431-906 µg /m^3.

Methods: Based on official monthly governmental reports, a preliminary assessment of the phenomenon in European Russia can be undertaken.

Results: Now the analysis shows that cumulative excess mortality in July and August of 2010 was 54 thou deaths in the regions affected by extreme heat, compared to the same period in 2009. The relative increase in monthly total mortality rates was 50-60% in some regions. The greatest increase in cause-specific mortality was considered to be a result of cardiovascular (31,500 additional deaths), respiratory (1,500) and some external (1,700) causes.

In Moscow yet in July and August of 2010 it increased by 11,000 deaths (60% to that of 2009). It included 5,951 deaths from cardio-vascular diseases, and 339 deaths from respiratory diseases. In August these became the greatest increase of respiratory cases, that could be attributed to the forest and peat fires. All external causes increased mortality by 1,100 cases, including 101 suicides (a relative increase of 77%); mortality from infectious diseases increased by 61,5%, and mortality from cancer increased by 70.2%, possibly due to postponed surgical interventions, and lack of air conditioning in post-operation rooms. A time-series analysis of daily data on cause-specific mortality will be available only in end 2011.

DAILY CHANGES IN AIR POLLUTION AND LUNG FUNCTION IN THE FRESNO ASTHMATIC CHILDREN'S ENVIRONMENT STUDY: USE OF INDIVIDUAL-LEVEL EXPOSURE ESTIMATES OF AIR POLLUTANT CONCENTRATIONS

Jennifer Mann, *UC Berkeley, School of Public Health, Berkeley, CA, USA*
Boriana Pratt, *UC Berkeley, School of Public Health, Berkeley, CA, USA*
Fred Lurmann, *Sonoma Technology, Inc., Petaluma, CA, USA*
Ira Tager, *UC Berkeley, School of Public Health, Berkeley, CA, USA*

Background/Aims: Exposure measurement error should be reduced when estimates of ambient air pollutant exposures account for spatiotemporal variations in concentrations and time/location/activity. We investigated the relationship of daily concentrations of nitrogen dioxide (NO2), nitrate (NO3), ozone, elemental carbon, PM2.5, coarse fraction of PM10, and both FEV_1 and $FEF_{25-75,}$ in a cohort of 315 asthmatic children in Fresno, CA, followed from 2000 to 2008.
Methods: Pollutants were estimated using measurements at a USEPA supersite (SC) within 20 kilometers of all households. Individual estimates of daily ambient exposure (IEADE) were modeled based on concentrations at the supersite, measurements at schools and homes, and a time/location/activity sub-study Pulmonary function was measured each morning with a programmable spirometer (EasyOne®, ndd, Zurich, Switzerland) for 14 days, up to 3 times a year. Effects of 0- to 7-day lags and 2- to 7 day moving averages for a change in interquartile range were investigated.
Results: After adjustment for height cubed, African American race and asthma diagnosis before the age of 2, NO2 was the only pollutant associated with declines in pulmonary function (both FEV1 and FEF25-75), when SC were used to estimate exposure. However, with IEADE, both NO2 and NO3 were associated with decrements in FEF_{25-75}. NO2 lag 1 was associated with a 43.2 ml/s decline in FEF_{25-75} (95 CI=10.3-76.1 ml/s declines for a 12ppb increase) with SC and a 69.5 ml/s decline in FEF25-75 IEADE (95% CI= 14.3 to 125 ml/s decline, 4.2 ppb increase). For NO3 lag 1, declines increased from 9.2 to 107.3 ml/s with use of IEADE (95% CI=-23.2 to 4.8, for a 5.1 µg/m3 increase in SC and -14.3 to 125 ml/s for a 0.9 µg/m3 increase in IEADE respectively.
Conclusion: IIEADE were associated with greater impacts on pulmonary function in asthmatic children, possibly due to reduction of exposure measurement error.

THE MODIFYING EFFECT OF SOCIOECONOMIC STATUS ON THE ASSOCIATION BETWEEN HOSPITALIZATIONS FOR ACUTE MYOCARDIAL INFARCTION AND AIR POLLUTION IN SANTIAGO, CHILE

Jeanette Vera, *Universidad de Chile and Pontificia Universidad Católica de Chile, Chile.*

Background and Aims: Many studies have reported the association between acute myocardial infarction (AMI) and air pollution, but has been little explored the modifying effect of socioeconomic status (SES) on Chilean morbidity data. Thus, the objective study was to examine whether the association between hospitalizations for acute myocardial infarction and air pollution (PM10, PM2.5 and O3) is modified by SES.

Methods: Daily counts of hospitalizations for acute myocardial infarction (ICD-10: I21-I22) from Santiago, Chile (years 2002-2006) were considered. Patients were grouped into the following age ranges: All, 18-64, 65-74 and ≥75 years old. To study the association between AMI and air pollution (PM10, PM2.5 and O3), a time-stratified case-crossover approach was applied, controlling for temperature and dew point, using natural splines. Separate analyses by SES were performed by income groups, according to individual health insurance: private (higher-SES), and public (low-SES) and within this, by four sub-groups: no income; minimum-wage workers, low-income, and medium income. Lags 0-7 and moving averages were evaluated.

Results: 9,665 AIM records with 8,446 by SES were available (mean 64 years old). Means for PM10, PM2.5 and O3 were 69.9 µg/m3, 32.2 µg/m3, and 33.2 ppb, respectively. A significant association ($p<0.05$) was observed in adults 18-64 years old only (hospitalizations increased by 3.1%(0.48-5-79%), per 10 µg/m3 PM2.5, lag2). According to analysis by SES was observed an association for adults 18-64 years old belonging to low-income (hospitalizations increased by 6.4%(0.45-12.7%) PM2.5, lag 0, with increased risk for lag2), medium-income groups (15.8%(1-32.8%), per 10 ppb of O3, with increased risk for lag4), and for higher-SES people (6.28%(0.43-12.5%), PM2.5, lag2; and besides for people 65-74 years old at 28%(6.1-55.4%), O3, lag0). The figures for PM10 were qualitatively similar for PM2.5

Conclusions: This analysis suggests that socioeconomic status modifies the association between AIM hospitalizations and air pollution in Santiago, Chile.

THE ASSOCIATION BETWEEN SOCIAL ENVIRONMENT AND EARLY COMPLICATIONS IN WOMEN WITH BREAST CANCER IN A REFERENCE CENTER IN BRAZIL

Daniele Bittencourt Ferreira, *National School of Public Health, Oswaldo Cruz Foundation, Brazil*
Rosalina Jorge Koifman, *National School of Public Health, Oswaldo Cruz Foundation, Brazil*
Anke Bergmann, *National Cancer Institute, Brazil*

Background and Aims: The social environment in which each individual is inserted may be represented for the social support. Studies suggest that the presence of good social support have association with lower complications of treatment in patients with breast cancer. The aim of this study is to evaluate the association between social support prior to oncology treatment and early complications after surgery (pain and subjective symptoms related to early edema in the upper limbs) in women with breast cancer.

Methods: The participants were women with breast cancer and that demanding attention at the Brazilian National Cancer Institute between June/2009 for March/2010. Medical Outcomes Study-Social Support Survey was used to assessment of social support before the oncology treatment. The information about early complications was obtained by physical examination 30 days after surgery and was collected in a standardized form for medical register. Bivariate analysis between dichotomous outcome and selected independent variables and relative risks, with CI 95%, were ascertained.

Results: 181 eligible women were evaluated and revealing that those with good emotional and affective support showed reduction of 76% (OR= 0.24 95% CI 0.10-0.57) and 62% (OR=0.38 95% CI 0.12-0.64) in pain, respective. The better material support reduced in 73% the pain (OR= 0.27 95% CI 0.11-0.623). Were not found statistically significant results when evaluating early edema.

Conclusions: The results suggest that social support would be a predictor of early complications after surgery in patients with breast cancer. This study suggests that the good social environment of the patients would act as a protection factor for the development of those complications.

A NEW COMPUTATIONAL PARADIGM FOR ASSESSING ENVIRONMENTAL HEALTH IMPACT OF POLICIES

Dimosthenis Sarigiannis, *Aristotle University of Thessaloniki, Thessaloniki, Greece*
Vittorio Reina, *European Commission - Joint Research Centre,Ispra (VA), Italy*
Alberto Gotti, *Centre for Research and Technology Hellas, Thessaloniki, Greece*
Clive Sabel, *University of Exeter, Department of Geography, United Kingdom*
Barry Evans, *University of Exeter, Department of Geography, United Kingdom*
Volker Klotz, *University of Stuttgart, Stuttgart, Germany*

Background and aims: Present problems in assessing the environmental health impact of policies include the multitude and complexity of exposure pathways, data paucity and mechanistic understanding of the interactions across the chain from policy down to health impact and economic costs associated. Many models of different complexity exist. They are currently applied to address parts of the full-chain but their full integration in a single comprehensive system poses additional difficulties.
Methods: This work introduces the concept of a multi-layered distributed computational platform consisting of an integrated set of stand-alone ('loosely-coupled') modules, designed to be linked together seamlessly, in order to demonstrate the impact of a range of policies on health. It covers emissions of all relevant substances into air, water and soil with multi-media modeling capabilities to capture the fate of chemicals across environmental media and micro-environments that could significantly alter actual exposure profiles to toxicants. Combining the information from environmental fate modeling, biokinetics/dynamics and epidemiologically-derived data the impact on human health could be estimated. Linking the latter to the societal economic cost through the introduction of DALYs and/or monetary valuation functions the societal cost of the policy measures considered is reckoned.
Results: The system harnesses the power of cloud computing through a distributed architecture in order to maintain a high level of precision in results and the necessary sophistication of the models employed. Thus the models addressing each part of the full-chain are operated as a seamlessly interoperable system, even though they are spread all over Europe. The individual modules are linked via fast internet based data exchange protocols.
Conclusions: This integrated assessment system allows for a full exploration of trade-offs and synergies of individual policy options. The paper concludes by giving specific examples of successful implementation of the complexity analysis paradigm delineated above.

A PREDICTION MODEL OF THE DISTRIBUTION OF NO2 THROUGH THE LAND COVER, TRAFFIC, AND OTHER EVIRONMENTAL VARIABLES

Pablo Sánchez-Villegas, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Antonio Daponte, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Piedad Martín-Olmedo, *Andalusian School for Public Health. Granada (SPAIN)*

Pilar Rueda, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Virginia Ballesteros, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Background And Aims: The geographic distribution of air pollutants can not always be measured directly, so it is necessary to create models that approximate its distribution. On the other hand, variables linked to land cover, traffic, the perception of people about their own exposure to pollution, among others might be readily available. The aim of this study was to make a prediction of NO2 pollution through such variables in the city of Seville, capital of the region of Andalusia, southern Spain

Methods: We considered the census tract as the unit of analysis. Through a campaign of passive diffusive samplers (measuring NO2), values were interpolated spatially by a krigging technique and assigned to each census tract the average estimated value. Predictors considered were land cover variables (percentage of soil built, percentage of vegetation, etc), distance to traffic infrastructures (according to different traffic intensities) and perception variables form the Spanish Census (perception of levels of contamination, noise, odors, etc). To these independent variables was applied a factor analysis to reduce the number of variables to consider. We created a linear regression model. We compared the actual NO2 values (kriging) with those estimated by the model

Results: The components of factor analysis were: distance to main roads, perception of environment, land cover and other ecological characteristics of the residence area. The model had an adjusted R2 of 0.34 and the percentage of model error was about 3% (sMAP)

Conclusions: Given the difficulty of obtaining measurements in space geographically sufficient to characterize pollution levels, other available variables may be used; from our study, the use of estimates as described in this paper combining self-perception variables with land use and traffic might approximate valid air pollution distribution

EVALUATING THE IMPACT OF GPs SURVEILLANCE ACTIVITY ON SUMMER MORTALITY AMONG ELDERLY IN ROME

Anna Maria Bargagli *Department of Epidemiology, Lazio Regional Health Service, Italy*
Claudia Marino *Department of Epidemiology, Lazio Regional Health Service, Italy*
Giovanna Cappai *Department of Epidemiology, Lazio Regional Health Service, Italy*
Patrizia Schifano *Department of Epidemiology, Lazio Regional Health Service, Italy*
Manuela De Sario *Department of Epidemiology, Lazio Regional Health Service, Italy*
Simona Vecchi *Department of Epidemiology, Lazio Regional Health Service, Italy*
Paola Michelozzi *Department of Epidemiology, Lazio Regional Health Service, Italy*

Background and aim: Since 2006, a heat prevention program has been operating in Rome; the main component is the active surveillance of at risk population subgroups by General Practitioners (GPs). Regional guidelines recommend GPs to monitor patients a priori classified at medium/high risk through an indicator based on administrative data. GPs surveillance activities during summer include telephone calls and home visits.
The study evaluates the impact of GPs surveillance on summer mortality among elderly (65+ years) residing in Rome in the period 2007-2010.
Methods: Data on all-cause mortality were obtained from the Municipal Mortality Registry. A Poisson regression model was applied to estimate the Relative Risk (RR) of dying during heat wave days among subjects included and not included in the surveillance program stratifying by level of the susceptibility indicator.
Results: Out of 2550 GPs working in Rome, 19% in 2007 and 14% in the following four years participated in the program. GPs monitored about 11,000 patients each summer, 2% of residents. Among patients included in the surveillance the proportion classified at medium/high risk was low throughout the four-years (about 20%). Among medium/high risk subjects, an excess mortality during heat-waves was observed in those not included in the programme in 2007 and 2008 (+32% and +34% respectively), whereas no excess was observed among surveilled patients. In summer 2009, no reduction in mortality among patients under surveillance was observed. An updated mortality analysis will be presented including summer 2010 and stratifying by urban heat island.
Conclusions: Preliminary results showed temporal heterogeneity in the impact of the GPs programme on elderly mortality. Since GPs surveillance represents a challenging and resource-consuming activity, the evaluation of its effectiveness for the prevention of heat-health effects represents a relevant public health issue. Results will be discussed considering specific characteristics of both the programme and subjects included.

Background and aims: The purpose of this work was to describe PON1 activity in a group of Brazilian subjects, analyze its phenotype distribution, to compare PON1 activities between groups of subjects with different lipid profiles, search for associations between these profiles and paraoxonase activity; and to investigate whether diet and lifestyle might affect this activity.

Methods: Subjects groups included a total of 94 volunteers, age range of 18-60. Variables studied included basal and salt stimulated PON1 activity and arylesterase activity according to Eckerson's method. Serum cholesterol, HDL, LDL, VLDL and triglycerides were also analyzed. Other variables such as energy consumption and nutrients intakes were assessed from a validated food consumption frequency questionnaire. Lifestyle variables were also assessed. Correlation analysis, T test and ANOVA were used for statistical analysis.

Results: Results indicated that three variables were important to show differences between normal and dislipidemic groups: PON1 salt stimulated activity, % of stimulation of PON1 activity and PON1/arilesterase ratio. Our results also show that whenever we compared B phenotype with other phenotype group (even in combination A + AB) it was demonstrated significant or closely significant differences between groups in relation to HDL and LDL levels. Increased LDL levels in B phenotype group and a reversed relationship concerning HDL levels were observed.

Conclusions: PON1 activity may be an important biomarker to assess risk of diseases associated with individual lipid status and diet may also affect PON1 activity. Our results also point out the need of more studies concerning paraoxonase polymorphism since little is known about environmental interactions with PON1 gene polymorphism in the multiethnic Brazilian population.

PHTHALATES IN BREASTMILK OF WOMEN EXPOSED DURING INVASIVE MEDICAL PROCEDURES

Bustamante-Montes LP, *UAEM ,México*
Hernández-Valero MA, *MD Anderson Cancer Center, USA*
Karam-Calderón MA, *UAEM, México*
Borja-Aburto VH, IMSS, México
Borja-Bustamante P, *Clínica Especializada Condesa GDF, México*
García Fábila MM, *UAEM, México*

Background: Phthalates are a group of chemicals distributed ubiquitously in the environment potentially harmful for children. Maternal exposure during medical procedures could also expose the newborn via human milk elimination. We measured four primary phthalates metabolites (FMHE, FME, FMB and the FMO) in breast milk of women who underwent different medical procedures.
Methods: The study was conducted in an obstetrics hospital located in the city of Toluca, Mexico. Milk samples were obtained from two groups of women: (1) 30 women hospitalized in the intensive care unit (ICU) and (2) 30 women with uncomplicated delivery. Milk samples were collected two days after birth, and processed by GC-MS.
Results: Concentrations of all the studied phthalate metabolites were higher in women hospitalized in the neonatal ICU (means total phthalates = 0.193 mg/l) than those from the women with uncomplicated deliveries (means total phthalates =0.082mg/l). Kruskal Wallis test for the difference between the total of metabolites was $p = 0.06$
Conclusions: This study is the first of its kind conducted in Mexico. Although, differences in concentration levels were found between groups, these were not statistically significant, and the reasons may be due to the sample size. Also, the unexposed population has medical interventions that contain phthalates (IV access).

CLEARSKY: ESTIMATING CO AND PM2.5 EXPOSURE VARIATIONS FROM TRAFFIC SENSORS

Edmund Seto, *University of California, Berkeley, School of Public Health, Berkeley, CA, 94720, USA*

Background and Aims: Traffic sensors are pervasive in urban environments. Used to monitor traffic congestion, roadway sensors can be re-purposed for opportunistic sensing of roadway air pollution emissions. Further integration of emissions with meteorological systems and dispersion models can allow for real-time estimates of air pollutant concentrations near major roadways. In development of the ClearSky project, we demonstrated near real-time and historical exposure assessment based on traffic sensing in the San Francisco Bay Area in California, United States. We discuss the role of ClearSky in informing equity for health impact assessments related to land use and transportation planning.

Methods: For ClearSky, an information system was developed that integrated data from roadway traffic sensors (PEMS), mobile emissions factors (EMFAC), meteorology (Weather Underground), and line source dispersion model (CALINE) to estimate CO and PM2.5 concentrations near major roadways in Alameda County, CA. As a demonstration, the system was used to document the variability in exposures over a 2-day live trial period. Concentrations were assigned to census blocks to assess the relationships between exposure variation and several vulnerability factors, such as age, poverty, and race/ethnicity.

Results: The demonstration illustrated data quality and computational challenges that needed to be overcome to make the system publically available. In the region, 20% of the population lives within 500m of a freeway. The initial trial, illustrated disparities in exposure, particularly for low income populations and populations of color, for which more than a quarter of the population lived in areas with the highest quartile exposures. While no disparities in exposure were found by age, roughly a quarter of children in the county lived in the highest quartile exposure.

Conclusions: The ClearSky project demonstrated both challenges and opportunities for integrating sensing and information systems to inform equity-focused health impact assessments of land use and transportation projects.

ONSET AND CESSATION LAGS FOR THE EFFECT OF $PM_{2.5}$ ON MORTALITY - A REVIEW

Heather Walton, *Science Policy Group, Environmental Research Group, MRC-HPA Centre for Environment and Health, King's College London, UK*

Background and Aims: The choice of lag times is crucial for quantifying the benefits of reducing long-term exposure to fine particles. This is difficult to study given everyone is exposed to some degree, there is no clear start and finish to exposure and past and current exposures are correlated. There is a need to make use of evidence from a range of studies and to consider mechanistic data and inference from other fields.
Methods: References were collected from searches on PubMed on particulate matter, mortality and long-term, chronic or cohort and on key authors in the field. Further publications were obtained from reference lists. The scope was limited to $PM_{2.5}$ and all-cause mortality, the effect most often used in health impact calculations. A PubMed search was also done on smoking cessation. This was supplemented with information on cause-specific mortality and from review papers on mechanisims.
Results: A range of lags were suggested from the effect mostly occurring within the first year (e.g. Laden et al 2006) through to around 40% in the first 5 years with the remainder tailing out to 30 years and beyond (analogy with smoking cessation literature). The 'average' of the suggested lags had around 60% of the effect in the first 5 years, 90% by 20 years and the remaining 10% spread up to and beyond 30 years (Walton, 2010). This pattern had a greater proportion of the effect at longer lags than the pattern suggested by the EPA (EPA 2010). This 'average' has no extra validity – it is based on very different options. This uncertainty can be represented by a range from lags from 0 to 30 years around the 'average'. Mechanistic evidence was compatible with either short or long lags.
Conclusions: A reasonable proportion of the effect occurs within 5 years but there may be a long tail to at least 30 years. An 'average' pattern can be used supplemented by sensitivity analysis from 0 to 30 years.

Núria Malats, *Genetic & Molecular Epidemiology Group, Spanish National Cancer Research Centre (CNIO), Spain*

Background and Aims: Limitations in knowledge on the etiology of exocrine pancreatic cancer (EPC) hamper primary prevention interventions. Although scarce, there is some evidence supporting associations between trace elements and EPC. The aim was to evaluate the association between concentrations of twelve trace elements in toenails and EPC risk.
Methods: We studied 118 EPC cases and 399 hospital controls with available toenail samples. Levels of trace elements were determined by inductively coupled plasma - mass spectrometry. Odds ratios (OR) and 95% confidence intervals (CIs) were calculated using logistic regression, adjusting for potential confounders.
Results: Significantly increased risks of EPC were observed among subjects presenting the highest concentrations of arsenic ($OR_{upper\ quartile}$ = 1.90, 95%CI 1.02-3.53; P-trend = 0.015), cadmium ($OR_{upper\ quartile}$ = 3.43, 95%CI 1.79-6.57; P-trend = $6x10^{-6}$) and lead ($OR_{upper\ quartile}$ = 6.17, 95%CI 2.67-14.27; Ptrend = $5x10^{-5}$). Higher concentrations of selenium ($OR_{upper\ quartile}$ = 0.05, 95%CI 0.02-0.14; P-trend = $3x10^{-11}$) and nickel ($OR_{upper\ quartile}$ = 0.26, 95%CI 0.12-0.56; P-trend = $2x10^{-4}$) were inversely associated with EPC risk.
Conclusions: These novel findings, if replicated in independent studies, suggest an important role of trace elements in EPC risk and pancreas carcinogenesis, and the potential benefits of policies aimed at decreasing population exposure to arsenic, cadmium and lead.

EVOLUTION OF TESTING AND ASSESSMENT METHODS IN CHEMICALS POLICY PROGRAMS AND IMPLICATIONS FOR EPIDEMIOLOGY AND CHILDREN'S HEALTH

Amy D. Kyle, *School of Public Health, University of California, Berkeley, California. USA*

Background and aims: Policies for safety of industrial chemicals and chemicals used in products are receiving attention. The European Union (EU) is implementing its comprehensive chemicals management program, known as REACH. The United Nations is coordinating the Globally Harmonized System for labeling and classification. In the United States (US), the Congress has debated amending the Toxic Substances Control Act, and many states have enacted elements of chemicals policy reform. With this discussion is increased scrutiny of methods for chemicals testing and assessment. Both the US and the EU are engaged in processes to move chemicals testing and assessment from methods largely based on the use of animal models and epidemiology to methods based largely on assays and "high throughput" methods. The US National Academy of Sciences recommended such approaches in 2007. This is an analysis of the trajectory of this process and its implications.

Methods: The documentation for testing and assessment requirements for REACH, the GHS, and US programs was reviewed with regard to hazard traits. Literature regarding the development and evolution of new methods available from the US Environmental Protection Agency (US EPA), the National Institute of Environmental Health Sciences (NIEHS), and REACH was reviewed.

Results: The US and European processes are evolving differently, with the EU focused on substitution of new methods for older methods and the US focused on mechanisms of toxicity and markers. Neither has defined a set of goals that would encompass significant concerns for children, particularly developmental neurotoxicity, immune effects, or lung development. Though the management regimes refer to use of epidemiological data, the approaches to new methods do not seem to be incorporating epidemiology into validation or verification approaches. Methods for interpretation of data in policy contexts are also not yet well developed.

Conclusions: Additional attention is needed in these areas.

THE NIEHS/EPA CHILDREN'S ENVIRONMENTAL HEALTH AND DISEASE PREVENTION RESEARCH CENTERS: MORE THAN A DECADE OF INNOVATIVE RESEARCH ON IMPORTANT CHALLENGES IN ENVIRONMENTAL EPIDEMIOLOGY

Richard Callan, *U.S. Environmental Protection Agency, United States*
Nica Louie, *U.S. Environmental Protection Agency, United States*
Kimberly Gray, *National Institute of Environmental Health Sciences, United States*

Background and Aims: The US Environmental Protection Agency (EPA) and the National Institute of Environmental Health Sciences (NIEHS) have supported the Children's Environmental Health and Disease Prevention Research Centers (Children's Centers) program since 1998, forming a successful and collaborative research network.
Methods: These multidisciplinary, translational research centers are investigating the role of environmental exposures such as air pollutants from traffic, pesticides, endocrine disruptors and social factors in adverse birth and health outcomes including asthma, autism, developmental delay and childhood leukemia and are using approaches such as epigenetics to find novel biomarkers of exposure, early developmental and pubertal effects. Community engagement is an important part of the program.
Results: Findings include: (1) Higher levels of organophosphate (OP) pesticide metabolites in mothers' urine during pregnancy are associated with attention problems in children; (2) Children with certain polymorphisms in the PON1 gene may be at higher risk from exposure to OPs; (3) Children with high prenatal exposure to PAHs from traffic-related air pollution had lower cognitive development tests at age 3 and lower IQ scores at age 5; (4) Research shows an association between increased prenatal LMW phthalates and poorer parental rating of childhood behavioral domains; (5) Children living within 75 meters of a major roadway have an increased risk of developing asthma; (6) variation in several genes in the nitric oxide (NO) synthesis and inflammatory pathways are associated with exhaled NO and asthma and children with variants of glutathione regulation genes may be protected from increased asthma risk; (7) Children with autism have a high incidence of mitochondrial dysfunction, which may affect developing brain cells.
Conclusion: Research from the NIEHS/EPA Children's Centers program is having a significant impact on the field of children's environmental health and provides a foundation for studies such as the US National Children's Study.

ASSOCIATION OF PLASMA CHOLINE AND BETAINE WITH ARSENIC METHYLATION

Megan Hall, *(Columbia University, USA)*
Xinhua Liu, *(Columbia University, USA*
Vesna Slavkovich, *(Columbia University, USA)*
Vesna Ilievski, *(Columbia University, USA)*
A Siddiquie, *(Columbia University Arsenic Project in Bangladesh, Bangladesh)*
Joseph Graziano, (*Columbia University, USA)*
Mary Gamble, *(Columbia University, USA)*

Background and Aims: Roughly 140 million people worldwide are exposed to arsenic (As)-contaminated drinking water at concentrations exceeding the WHO standard of 10 µg/L. Metabolism of inorganic As (InAs), which facilitates urinary excretion, involves two methylation steps; both utilize S-adenosylmethionine (SAM) as the methyl donor. SAM biosynthesis relies on B vitamins including folate, but other nutrients, including choline and betaine, also contribute to the methyl pool. Folate and betaine are interdependent; they are the two complementary methyl donors used in the remethylation of homocysteine to methionine, a crucial step in SAM production. Betaine is obtained from the diet or produced endogenously from choline oxidation. The aim of this study was to investigate the associations of plasma choline and betaine with the methylation of As and to determine whether these associations differed by folate status.
Methods: We conducted a cross-sectional study of 378 Bangladeshi adults between the ages of 23 and 60 who were exposed to a wide range of As concentrations in drinking water. Plasma choline and betaine were measured using liquid chromatography tandem mass spectrometry (LC-MS/MS). Total As and As metabolites were measured in urine and blood.
Results: There were no statistically significant associations between plasma betaine or choline and urinary As metabolites among the folate-sufficient participants (n=266). Among the folate-deficient (n=112), plasma betaine and choline were inversely associated with the proportions of total urinary As excreted as InAs (betaine: • = -0.16, p=0.05, choline: • = -0.02, p=0.0004) and monomethylarsonic acid (betaine: • = -3.11, p=0.03, choline: • = -0.39, p=0.005), and positively associated with the proportion excreted as dimethylarsinic acid (betaine: • =5.75, p=0.01, choline: • =0.80, p=0.0004). Similar patterns of association were observed with blood As metabolites.
Conclusions: These findings suggest that two nutrients, choline and betaine, are favorably associated with As methylation, particularly among folate-deficient individuals.

FUZZY SET IN VECTORIAL ANALYSIS OF BODY IMPEDANCE

Bruna Bronhara, *Department of Epidemiology, School of Public Health, University of Sao Paulo*
Rosangela Toledo Kulcsar, *Faculty of Technology of Carapicuíba (FATEC)*
Júlio Cesar Rodrigues Pereira, *Department of Epidemiology, School of Public Health, University of Sao Paulo*

Background and aims: Vectorial analysis of body bioimpedance suggests patterns of body composition (Piccoli et al. 2002). However, limits defining these patterns are uncertain and Fuzzy Logic Theory (Zadeh, 1965) has shown to be adequate for dealing with uncertainty inherent to this complex phenomena. The aim is to create hypothetical linguistic model based on fuzzy rules for studying human body composition.
Methods: Fuzzy rules were defined by experts on body composition using Nhanes III dataset as a guide for checking the biological plausibility. Input variables were resistance/height and reactance/height. Output variables were edema, dehydration, caquexia, athletics, thinness, obesity, eutrophic and each of them presented five categories of intensity (from 0.10 – definitely not - until 1.00 – definitely yes). Fuzzy rule base was composed by fuzzy propositions as "if reactance high and resistance high, then dehydration is definitely yes, athletics uncertain, thinness uncertain and so on. Takagi-Sugeno was the inference method. An individual presenting 207 Ω/m resistance/height and 39Ω/m reactance/height was selected for applying the linguistic model.
Results: Fuzzy model produced seven superficial graphics, which corresponded to each pattern of body composition. Membership degrees of individual selected for dehydration, athletics, thinness, eutrophic, obesity, caquexia and edema were, respectively, 0,27; 0,53; 0,16; 0,59; 0,88; 0,30 e 0,61. The highest category of intensity was obesity, which bests represented his current body composition. As an additional contribution provided by a fuzzy model, information about intensity of edema was also important for choosing a better therapeutic strategic, for example. In addition, fuzzy model allows quantifying the intensity of each patter for individuals, which were made, until now, by visual inspection of vectorial graphic.
Conclusions: Potential of fuzzy approach in expanding knowledge of body composition of individuals was presented. Overcoming binary classifications as yes/no pertain to a group may be reviewed in health science as strategy for expanding scientific knowledge**.**

AIR POLLUTION AND REPEATED ULTRASOUND MEASURES OF FETAL GROWTH IN MEXICO CITY

Marie S. O'Neill, *University of Michigan, Ann Arbor, USA*
Brisa N. Sánchez, *University of Michigan, Ann Arbor, USA*
Luis O. Rivera-González, *University of Michigan, Ann Arbor, USA*
Jorge Beltrán Montoya, *Universidad Nacional Autónoma de México, México City, México*
Nayeli Martínez, *Universidad Nacional Autónoma de México, México City, México*
Felipe Vadillo Ortega, *Universidad Nacional Autónoma de México, México City, México*

Background and Aims: Fetal growth may be affected by maternal air pollution exposure. Among a cohort of pregnant women in Mexico City, we obtained repeated fetal biometry ultrasound data to examine associations between maternal air pollution exposure in early pregnancy and changes in fetal growth.
Methods: Information on factors known to impair fetal growth was collected by physical exams and questionnaires in 2010. Repeated ultrasound scans during gestation were performed to measure biometric parameters of the developing fetus [head circumference (HC), abdominal circumference (AC), femur length (FL), and biparietal diameter (BPD)]. Gestational age was estimated from these ultrasound measurements. Using 2009-2010 air pollution data from the city's atmospheric monitoring network, first trimester citywide averages of $PM_{2.5}$ were calculated for each individual. We applied linear regression to calculate individual-specific slopes for the four growth parameters. These slopes were used as the outcome in four multivariate linear models with predictors being individual-specific first trimester concentrations of $PM_{2.5}$; mother's age and education, and fetal sex.
Results: Data were analyzed for 42 women. The average (SD) rates of increase (centimeters/gestational week (cm/wk) for fetal parameters (HC, AC, FL, and BPD) were: 1.01 (0.08), 1.04 (.12), 0.25 (0.02), and 0.28 (0.03) respectively. Point estimates for the association were positive for both HC (.083 cm/wk, p = 0.17, per 10 $\mu g/m^3$ increment in exposure) and FL (.014 cm/wk, p = 0.43). Reductions of -.005 cm/wk for BPD (p = 0.82) and -.170 cm/wk for AC (p = .06) per 10 $\mu g/m^3$ were observed.
Conclusions: Fetal parameters may respond to maternal air pollution exposures uniquely, and this response may vary by pollutant and timing of gestational exposure. This analysis of repeated ultrasound measures and first trimester $PM_{2.5}$ concentrations supports the need for further work examining changes in fetal parameters associated with other pollutant exposures.

WORKING CONDITIONS AND PSICOSOCIAL EFFECTS OF MUSCULOSKELETAL DISORDERS IN A CALL CENTER AND NURSES IN COSTA RICA

Marianela Rojas (1), Patricia Monge (1), Freddy Brenes (2), Sarah Felknor (3)

Background and aims

Musculoskeletal disorders in upper and lower limbs affect many workers and represents important working and economic losses. Its relation with repetitive motions and psychosocial conditions at work are being suggested as risk factors. We report preliminary results from a survey performed in Costa Rica in two working populations: call center operators (C-C) and nurses. This study belongs to a multicenter study of Southampton Hospital.

Methods

A sample of call center workers (N=237) and nurses from the social security service (N=250) were assess through a questionnaire, with personal data, current working conditions, health status, upper and/or lower limb discomfort during last 12 months and past month, and was applied to both populations. Psychosocial conditions at work were assessed by ISTAS-21: psychological demands, active performance, employer' social support and compensation. Data was analyzed separately by department, location of disability for both populations.

Results

Women represented 64% in both populations. Media of age was 25 years for both populations. Women report more limbs`disabilities and also more years of continuance in the organization in both populations. Repetitive motions are reported frequently in both genders and populations (64 and 65%). Possibility on assignment of own tasks were reported in 48% (C-C); and 20% (nurses), impossibility for decision on own recesses: 44% and 80% respectively. Hand and wrist disabilities were reported more frequently among youngers, while shoulder and elbow in older workers in C-C. Back and shoulder disabilities were reported more frequently among young nurses, while back and knee problems were more frequent among older nurses. Results on psychosocial effects and comparison of other variables between both populations are in process and will be presented.

Conclusions

Prevalence of disabilities is more frequently reported in women, which could be related to longer continuity on work organization and cumulative exposures. Analysis of extra-work (family) factors is needed.

ASSOCIATION OF FINE AND COARSE PARTICLES WITH EMERGENCY HOSPITAL ADMISSIONS FOR RESPIRATORY DISEASES IN CANARY ISLAND

Olga Costa, *Dirección General de Salud Pública. Gobierno de Canarias. Center for Research on Public Health (CSISP),Valencia, Spain Institution*
Elena López-Villarrubia, *Dirección General de Salud Pública. Gobierno de Canarias. CIBER en epidemiología y salud pública (CIBERESP), Spain*
Carmen Iñiguez, *Center for Research on Public Health (CSISP), Valencia, Spain. CIBER en epidemiología y salud pública (CIBERESP) , Spain. Departament d'Infermeria, Universitat de València, Valencia, Spain.*
Ferran Ballester, *Departament d'Infermeria, Universitat de València,Valencia, Spain. Center for Research on Public Health (CSISP) Valencia, Spain. CIBER en epidemiología y salud pública (CIBERESP) , Spain.*

Background and Aims: Most of the studies differentiating the effect of PM sized fractions have been carried out in cities where fine particles ($PM_{2.5}$) levels were higher than coarse particles ($PM_{10-2.5}$). These studies have shown the effect of $PM_{2.5}$ on health, but there is limited evidence that $PM_{10-2.5}$ is associated independently with health. The citizens of the Canary Islands are exposed to particulate matter highly influenced by mineral dust ($PM_{10-2.5}$ levels are higher than $PM_{2.5}$) because their proximity to the African Continent. Our objective is to assess the short term association between $PM_{2.5}$ and $PM_{10-2.5}$ and hospital admission for respiratory diseases.
Methods: From 2001 to 2005 the association between daily changes in each of PM sized fraction and daily emergency hospital admissions for respiratory diseases was assessed using Generalized Additive Poisson models, controlled for potential confounders. Unconstrained distributed lag models (DLM) (lags 0 to 5) were estimated.
Results: An increase of 10 $\mu g/m^3$ in $PM_{2.5}$ levels was associated with a 11.4% (5.5, 17.7%) and a 3.6%(-2.5, 10.11) increase in risk of respiratory admissions in Santa Cruz de Tenerife and Las Palmas de Gran Canaria respectively, across concurrent and subsequent 5 days. A 5.0% (-0.0, 10.4) and a -2.0%(-6.9, 3.0) increase of admissions were associated with $PM_{10-2.5}$ in these cities.
Conclusions: We found a robust short term impact of $PM_{2.5}$ on emergency hospital admissions for respiratory diseases in Canary cities along with the evidence that these associations spread over several successive days. $PM_{10-2.5}$ may play a relevant role in harmful particulate effect on respiratory mortality. These findings suggest that it may be necessary to establish new air quality standards for coarse particles.

EFFECTS OF PRENATAL AND POSTNATAL TOBACCO SMOKE EXPOSURE ON THE DEVELOPMENT OF ASTHMA AND WHEEZING: A POPULATION-BASED SIX-YEAR COHORT STUDY

Jouni J.K. Jaakkola, *Center for Environmental and Respiratory Health Research, University of Oulu*
Laura R. Jarman, *Institute of Occupational and Environmental Medicine, University of Birmingham, Birmingham*

Background: Exposure to tobacco smoke products has been associated with many harmful effects in children. Previous studies have suggested that maternal smoking during pregnancy has stronger impact on a child's respiratory health than postnatal tobacco exposure, but few studies have assessed potential synergistic effects. This study aimed to assess the independent and joint effects of maternal smoking during pregnancy and postnatal exposure to tobacco smoke on doctor-diagnosed asthma and wheeze in children.
Methods: A six-year population-based cohort study was conducted in Espoo, Finland. The study population included 1984 children. Information was collected using parent-completed postal questionnaires at baseline and follow-up on the child's personal characteristics, environmental exposures (including tobacco smoke) and respiratory health. The health outcomes were current asthma, new asthma and current wheeze at follow-up. Adjusted odds ratios were used as measures of effect.
Results: Maternal smoking during pregnancy had the strongest effect on current asthma at the follow-up (adjusted OR 1.76, 95% CI 1.02-3.04), new asthma (adjusted OR 1.74, 95% CI 1.00-3.03) and current wheeze (adjusted OR 2.19, 95% CI 1.05-4.56). The effects of postnatal exposure to second-hand smoke (SHS) and the joint effect of prenatal and postnatal exposure to tobacco smoke were weaker.
Conclusions: The adverse effects of tobacco smoke exposure on asthma and wheeze are strongest when a child is exposed to tobacco in the prenatal period. The effects of postnatal exposure to SHS on asthma and wheeze are weaker, but such exposure is clearly harmful.

DISTRIBUTION OF AIR POLLUTION IN A HIGHLY INDUSTRIALIZED AREA

Pablo Sánchez-Villegas, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Antonio Daponte, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Pilar Rueda, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Virginia Ballesteros, *Andalusian Observatory of Health and Environment (OSMAN). Andalusian School for Public Health. Granada (SPAIN)*

Piedad Martín-Olmedo, *Andalusian School for Public Health. Granada (SPAIN)*

Background And Aims: The area of Campo de Gibraltar (1528,6 km2 southern Spain) is a highly industrialized area, where PM10 have a high concentration of heavy metals. It consists of 7 municipalities, whose population is 264,620 inhabitants. The aim of this study is to characterize air pollution (PM10) in that area

Methods: Data were collected daily from 5 automatic stations measuring PM10 concentration, in addition to daily wind speed and direction at a meteorological station in the same area

Results: The nearest stations to the industries are showing higher mean values of PM10 concentrations (46.3 µg/m3 95%CI = [45.29-47.3] and 41.00 µg/m3 95%CI=[40.12-41.9]), while further away had the lowest (33.96 95%CI=[32.84-35.07] and 34.39 95%CI=[33.26 to 35.52]). Except for one case, the threshold of 50 µg/m3 was exceeded more than 35 times a year (all years and stations). Moreover, more frequent winds in the area are easterly winds followed by westerly winds. The frequency of other wind directions is very low. For all stations, PM10 concentrations are higher when the wind is blowing from East. The number of exceedances of the threshold value (50 ug/m3) is more than double when the wind blows from East than when blows from West (all stations considered)

Conclusions: PM10 concentration is higher near of the industries. Regardless the location, the pattern of PM10 concentration in the study area depends of the wind direction

INTEGRATING ENVIRONMENTAL HEALTH EQUITY CONSIDERATIONS IN RISK BASED DECISION MAKING: CHALLENGES AND OPPORUNITIES

Onyemaechi Nweke[1], Abdel Kadry[2], Devon Payne-Sturges[2], Rosanna Beltre[1]
[1]Office of Environmental Justice, US Environmental Protection Agency, Washington DC
[2]Office of Research and Development, US Environmental Protection Agency, Washington DC

Background

The United States (US) presidential Executive Order No. 12898 mandates each Federal agency to make achieving Environmental Justice (EJ) part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its actions on low-income populations and minority populations in the United States. A 2005 US Government Accounting Office report noted that implementation of the executive order was limited in the development of air regulations. This study investigates the opportunities and challenges of integrating equity in risk based decision-making within the context of rule-making.

Methods

We developed an equity-focused risk-based decision-making framework, which includes the application of disproportionality functions to assess for social group disparities in environmental health (EH) outcomes. We subsequently demonstrated the application of the equity-focused framework to hypothetical regulatory analyses reflective of a sample of EPA regulations that are based on risk.

Results

Our study demonstrates that equity can be integrated into risk-based rule-making. To assess for disparities in EH outcomes, a variety of approaches can be applied. The choice of method depends on the data characteristics and the framing of analytical questions. A notable limitation of the equity-focused framework is the constrained applicability of analytical results to the policy decision given the statutory constructs of some of EPA's regulations.

Conclusions

The equity-focused decision-making framework allows for successful integration of equity in all steps of many risk-based EPA rule-making decisions. Continued collaborative efforts amongst risk assessors and managers are necessary to further advance the development of additional methods, to facilitate greater consideration of concepts such as cumulative risk disparities.

EXPOSURE TO HEAVY METALS IN A HIGHLY INDUSTRIALIZED AREA

Antonio Daponte, *Andalusian Observatory of Health and Environment (OSMAN), Andalusian School of Public Health, Granada (SPAIN)*

Pablo Sánchez-Villegas, *Andalusian Observatory of Health and Environment (OSMAN), Andalusian School of Public Health, Granada (SPAIN)*

Piedad Martín-Olmedo, *Andalusian School of Public Health, Granada (SPAIN)*

Pilar Rueda, *Andalusian Observatory of Health and Environment (OSMAN), Andalusian School of Public Health, Granada (SPAIN)*

Virginia Ballesteros, *Andalusian Observatory of Health and Environment (OSMAN), Andalusian School of Public Health, Granada (SPAIN)*

Background and aims
The area under study is one of the more heavily industrialized in southern Spain, with a population of almost 250.000 people. Particularly, cadmium, nickel, and chromium are present in the industrial emissions particulate matter. Also, surveys show that population in the area perceives that is being strongly affected by the industrial activity. Moreover, this area is within a cluster of Spanish provinces showing systematically higher mortality rates

Methods
Subjects were a random representative sample of the 5 to 69 years old individuals residents in this area. A total of 432 subjects selected were residents in the different municipalities and neighbourhoods of the area, which are at different distances of industrial complexes. A urine sample was collected from participants as well as questionnaires for diet, socio-demographic characteristics, occupational exposures, and other individual level characteristics behaviors. Other variables considered were wind direction and speed, distance to industries, and distribution of air pollutants in the area, according to automatic monitoring stations and to diffusive passive samplers

Results
Urine concentrations (μg/ g de creatinine) ranged from 0,67-0,82 for nickel, 0,42-0,82 for nickel, and 0,33-0,35 for chromium. There were significant differences for Cd and Ni, but not for Cr. Also, no significant differences were found when using the 95th percentile. Several individual factors were associated with significantly higher urine concentrations of metals. Also, the effect of ecological variables were explored in the analysis, such as wind direction, distance to industrial sources, and other

Conclusions
Explanation for results are that differences in environmental exposures between areas are small, not homogeneously distributed according to time or space, and some individual characteristics may be not well assessed by the methodology employed. Environmental exposure to selected chemicals in the study area were of low magnitude and not different to urban settings in the region

ASSOCIATION BETWEEN STAPHYLOCOCCUS AUREUS IN THE HOME EVIRONMENT AND DECREASED LUNG FUNCTION IN ASTHMATIC CHILDREN IN BARBADOS

Greg Diette, *Johns Hopkins School of Medicine, Baltimore, Maryland USA*
Meredith McCormack, *Johns Hopkins School of Medicine, Baltimore, Maryland USA*

Background and Aims. *Staphylococcus aureus,* a gram-positive bacterium, can survive in the environment for weeks to months. While asthma is a known risk factor for nasal colonization with methicillin-resistant *Staphylococcus aureus* (MRSA), less is understood about potential associations between *S. aureus* environmental exposure and asthma symptoms. We adapted culture methods for MRSA and methicillin-susceptible *S. aureus* (MSSA) to the household setting and estimated associations between measures of lung function in asthmatic children and household *S. aureus* environmental positivity.
Methods. We sampled surface dust from a subgroup of 19 children enrolled in a pilot childhood asthma study in Barbados during July 2010. Children and their families recorded twice-daily FEV_1 measures using a personal PIKO instrument for five days. Concurrently, we sampled a common room surface and the child's pillow in each home using sterilized dry electrostatic cloths, which we cultured using single-enrichment (MSSA) and double-enrichment (MRSA) protocols. We confirmed suspect *S. aureus* colonies by real-time PCR methods for *femA* (MSSA), and *mecA* (MRSA) gene presence.
Results. Eight of 19 households (42%) were positive for MSSA (4) or MRSA (4). Pillows were the location most often positive (7 of 8 households). Average child age was 11 years (range: 6-17). Mean FEV_1 was 1.60 [95%CI: 1.15-2.06], accounting for within-child correlation. *S. aureus* household positivity was associated with a 0.43 unit decrease in log FEV_1 measures in asthmatic children, controlling for within-child correlation of measurements over time ($p=0.02$). Age was a significant confounder and attenuated the estimate to a 0.20 unit decrease ($p=0.07$).
Conclusions. Among children with asthma in Barbados, *S. aureus* in the home environment was associated with lower lung function. While this study did not assess *S aureus* nasal colonization in asthmatic children, future research using a larger cohort to investigate the link between *S. aureus* exposure and asthma outcomes is warranted.

META-ANALYSIS OF EXCESS MORTALITY DURING HEAT WAVES AND COLD SPELLS IN FOUR CITIES IN RUSSIAN SUBARCTIC REGION

Boris Revich[1], Dmitry Shaposhnikov[1], Zanna Varakina[2] *Institute of Forecasting Russian Academy of Science, Moscow,* [2] *North Medicine University, Archangelsk, Russia*

revich@ecfor.ru

Background and Aims: Circumpolar region presents particular interest for epidemiologists because it will experience the greatest climatic changes. Epidemiological study in a small town is difficult for a statistician because the daily mortality counts are small; they are not normally distributed and do not fit the independence assumption. We accounted for these difficulties and assessed the impacts of extreme temperature events on mortality rates in four sites within Russian subarctic region: Archangelsk, Murmansk, Yakutsk and Magadan), and then conducted a meta-analysis.

Methods: Long-term distributions of daily mean temperatures were analyzed for identification of heat waves and cold spells during the study period of 1999-2007 at each location. We investigated daily mortality from all non-accidental causes, coronary heart disease, strokes, respiratory diseases and all external causes among age groups 30-64 and 65+. Statistical analysis was done in two steps. In Step 1, site-specific estimates of relative increases in mortality were obtained. At each location, separately estimated mortality risks for 'short' waves (5 to 7 days) and 'long' waves (8 days and longer). During Step 2, we obtained pooled estimates of cause- and age-specific mortality risks, and conducted meta-analysis of all site-specific information.

Results: The relationship between cold and mortality is stronger than between heat and mortality. Greater increases in mortality were observed during long cold waves than during short cold waves, but for heat waves the opposite was true. Age group 65+ was more vulnerable to cold than age group 30-64; but no age-specific differences were observed during heat waves. All increase in non-accidental mortality during cold waves was attributed to cardiovascular causes. Relative increases in mortality from all external causes during heat waves were commensurable with these from brain strokes. The proposed methodology can give fairly robust results only in towns with populations greater than approximately 100,000.

EFFECT OF HEXAVALENT CHROMIUM ON PULMONARY FUNCTION IN CHILDREN

Papadimitriou E. MD[1], Priftis K. MD PhD[3], Pililitsis L. MD[1], Kouroutou P. MD[1], Riza E. PhD[1], Papasaranti E MS[1], Veloudaki A. MA[1,2], Linos A. MD MPH PhD[1,2]

1. Athens Medical School, 75 Mikras Asias Street, Athens, Greece
2. Prolepsis Institute of Preventive Environmental and Occupational Medicine, 7 Fragoklissias Str, Maroussi, Athens, Greece
3. 3rd Department Athens Attikon Hospital, Chaidari, Athens, Greece

Background and aims: CrVI (Hexavalent chromium) is a known carcinogen when inhaled. Little information is available on its possible association with PEFR (Peak Expiratory Flow Rate), FVC (Forced Vital Capacity), FEV_1 (Forced Expiratory Volume in 1 sec) and asthma related symptoms in children. The study aims to examine the association between children residing in Oinofyta, an industrial, highly contaminated with CrVI, region in Greece and asthma. The role of additional risk factors will be examined and quantified. Children in Oinofyta, could be exposed to CrVI through inhalation, oral consumption, bathing or contact with contaminated ground.

Methods: Two socioeconomically comparable cohorts of children (150 children each), one exposed to CrVI and a control group will be studied. Aspirometry will be performed in all members of the cohorts. PEFR, FVC and FEV_1 will be measured and cohorts' parents will be interviewed concerning children's respiratory health, demographic and household characteristics, parental occupation and indoor air pollutants (including smoking). The study has been approved by the University Ethics Committee and the Ministry of Education. All parents are asked to sign an informed consent.

Results: So far, 66 parents have been approached and all agreed to participate. 66 children were examined, 14 out of which (21%) had a subnormal spirometry, as demonstrated by reduced PEFR, FVC and FEV_1, while the prevalence of asthma in Greece has been recently reported to be 5-10%. Furthermore, 12 from the 56 (21%) parents that completed the interview stated that their children had at some point obstructive airway symptoms. These results represent only a small part of the study. We expect to complete examinations and interviews in both cohorts by July 2011.

Conclusion: So far, it appears that exposure to CrVI influences pulmonary function and causes asthma related symptoms in children.

UNDERSTANDING INTRA-NEIGHBORHOOD PATTERNS IN FINE PARTICULATE AIR POLLUTION USING MOBILE MONITORING IN BRADDOCK, PA

Background and Aims: Braddock, Pennsylvania, in the eastern suburbs of Pittsburgh, lies in a valley adjacent to the Monongahela River. An economically distressed area, Braddock is home to the Edgar Thomson Steel Works, one of the few remaining active steel mills in Pittsburgh. Braddock exceeds both the average annual (>15 µg/m3) and daily (>35 µg/m^3) National Ambient Air Quality Standards (NAAQS) for particulate matter ($PM_{2.5}$), and is situated in a federal $PM_{2.5}$ non-attainment area.

Methods: A mobile monitoring design was used to explore the within-neighborhood spatial and temporal (within-day and between-day) variability in $PM_{2.5}$ and PM_{10}. Our sampling route consisting of 25 designated stops, of 3- to 5-minute intervals, sampled in summer and winter months, during morning and afternoon hours, in 2010-2011. Ambient weather data was obtained from Pittsburgh International Airport, and examined to identify inversion events.

Results: The $PM_{2.5}$ and PM_{10} mobile monitoring data display some spatial variation between stops, and substantial temporal variations across days. Concentrations also differed substantiailly between morning and afternoon runs. The $PM_{2.5}$/ PM_{10} ratio was generally high (0.8 to 1), suggesting a predominance of fresh combustion particles in our sampling area. For morning sampling runs, mean $PM_{2.5}$ concentrations ranged from 31 to 55 µg/m^3 (SD = 1.53 and 4.92 µg/m^3, respectively), and mean PM_{10} concentrations ranged from 30 to 70 µg/m^3 (SD = 1.64 and 7.68 µg/m^3, respectively). During summer months, afternoon concentrations were significantly lower than in the morning for both $PM_{2.5}$ and PM_{10}, owing to morning inversions in the river valley. During the winter, concentrations were generally lower than during summer, but showed lesser diurnal variability, with no inversion events.

Conclusions: These pilot data reveal significant diurnal and spatial variability in both $PM_{2.5}$ and PM_{10} concentrations within Braddock. Results will inform the design of a stationary monitoring network, to be implemented and maintained as part of a longitudinal study on childhood asthma exacerbation in Braddock.

DIFFERENCES IN AIR QUALITY PERCEPTION PATTERN BETWEEN INDUSTRIALISED AND URBAN AREAS IN SOUTHERN SPAIN, AND ITS RELATIONSHIP TO MODELLED AMBIENT NITROGEN DIOXIDE

Piedad Martín-Olmedo, *Andalusian School for Public Health. Cuesta del Observatorio 4. 18080 Granada (SPAIN)*

Pablo Sánchez-Villegas, *OSMAN. Andalusian School for Public Health. Granada (SPAIN)*

Antonio Daponte, *OSMAN. Andalusian School for Public Health. Granada (SPAIN)*

Pilar Rueda, *OSMAN. Andalusian School for Public Health. Granada (SPAIN)*

Virginia Ballesteros, *OSMAN. Andalusian School for Public Health. Granada (SPAIN)*

Background and aims: Annoyance due to environmental stressors impairs well-being, and is being recognised as an adverse health effect itself. This impact is meant to be greater in highly industrialised areas where the issue of outdoor air quality generates ongoing controversial debates. However, individual perception has not being always consistently related to actual central site measurements of air pollution. The objective of this study is to describe spatial pattern of public perception of air quality attending to characteristics of local settings (industrialised versus urban area), certain individual and social determinants, and its relationship to a GIS-based kriging nitrogen dioxide (NO_2) measurement.
Methods: Annoyance scores were extracted from a community health survey undertaken at the industrialised area of Gibraltar's surroundings (GS), based in population from Algeciras, La Línea, San Roque y Los Barrios (total n=360), and at the city of Seville (n=650). Respondents' exposure to NO_2 was estimated using a GIS-based kriging approach built over a passive diffusion tubes campaign. The associations were examined using multivariate logistic regression.
Results: The concentration (mean, standard deviation) of NO_2 in the GS (29.55, 5.39 $\mu g/m^3$) was significantly ($p< 0.05$) higher than in the city of Seville (28.29, 2.53 $\mu g/m^3$). Similar trend showed findings related to public air quality perception, with significantly ($p< 0.05$) greater concern among citizens from GS (71.35%) than those from Seville (30.05%). However, the relationship between public perception scores and NO_2 levels showed a very different pattern in the urban area of Seville (positively related) than in the industrialised setting of GC.
Conclusions: Personal and socio-demographic determinants of public air quality perception needs to be addressed independently depending on the local settings characteristics.

PRINCIPLES OF COMMUNITY- BASED PARTICIPATORY RESEARCH IN ENVIRONMENTAL CHILDHOOD RURAL ASTHMA INTERVENTION

Tomas Tamulis, *Kent State University College of Public Health, Kent, Ohio, USA*
Dmitry Krupitsky, *Asthma Control Program, Hawaii State Department of Health, Honolulu, Hawaii, USA*

Background: The community groups served by Hawaii's Community Health Centers (CHCs) closely reflect the socio-demographic profile of those adversely affected by asthma in the state of Hawaii.
Methods: CDC-funded Childhood Rural Asthma Project, Phase V, coordinated by Hawaii Department of Health and Hawaii Primary Care Association, covered administrative district areas of Koolauloa and Waianae on Oahu, and Kona on Big Island, Hawaii. The total number of 89 children, with previous physician diagnosed asthma (ICD-9 493.00-493.99), were recruited by local CHCs in 2009-2010. The standardized logic program evaluation model based on one-group pre- and post-assessment of longitudinal in-home environmental and educational interventions was used to develop and to measure the program performance and outcome indicators.
Results: The data analysis revealed statistically significant change in pre- and post program outcome indicators, including increased competency, knowledge and skills on environmental triggers, clinical symptoms and treatment, and self-management of asthma; and reduced number of asthma symptoms, asthma-related physician and ER visits, and missed school days.
Conclusions: Sustainable long-term partnership between local community health organizations and community is a core element of community-based participatory research designed to address current health disparities and also to reduce the burden of childhood asthma in the state of Hawaii.

ESTIMATION OF THE OVERALL EFFECT OF PM10 ON HOSPITAL ADMISSIONS FOR RESPIRATORY DISEASES IN NINE CITIES IN THE METROPOLITAN REGION OF SÃO PAULO (MRSP), BRAZIL

Clarice Umbelino Freitas,: *Epidemiological Surveillace Center, Department of Health, São Paulo,Brazil.*
Washington Junger,: *Universidade Estadual do Rio de Janeiro, Rio de Janeiro, Brasil*
Antonio Ponce De Leon,: *Universidade Estadual do Rio de Janeiro, Rio de Janeiro, Brasil*
Gouveia, Nelson: *Universidade de São Paulo, São Paulo, Brasil*
Mirta Alcira Ferro Rodrigues Silva,: *Epidemiological Surveillace Center, Department of Health, São Paulo,Brazil*
Rogerio Araujo Christensen,: *Epidemiological Surveillace Center, Department of Health, São Paulo,Brazil*

Background and aims: The MRSP has 39 municipalities in an area of 7.9 km2 and a population of 19.7 million inhabitants. This area has 22 air monitoring stations of air quality that measures PM10 across 9 cities. In these cities was conducted time series study to evaluate the impact of PM10 on hospital admissions for respiratory diseases and meta-analysis was performed for overall risk assessment for PM10 in the region to estimate the global risk.
Methods: Cities specific analyses were carried out using a common framework. The library ARES developed for R application was used to analyze the relation between admissions for respiratory illnesses and PM10. This analysis was done in generalized additive models Poisson regression. The models accounted for seasonality, secular trends and climate in the analysis of each city. City specific estimates were summarized by means of a meta-analysis.
Results: It was found positive and significant association between respiratory disease and PM10 in seven cities. The random effect estimates for respiratory disease and PM10 for the nine cities was 1.33% [95%IC 0.53; 2.14] change for 10 $\mu g/m^3$.
Conclusions: It was found overall significant risk for respiratory diseases and PM10 in the selected municipalities of the MRSP.

ENVIRONMENTAL FACTORS AND NON-HODGKIN'S LYMPHOMA IN DOGS: a survey.

Katia Cristina Kimura, *Department of Pathology, School of Veterinary Medicine and Animal Science, University of Sao Paulo, Brazil*

Ricardo Augusto Dias, *Department of Pathology, School of Veterinary Medicine and Animal Science, University of Sao Paulo, Brazil*.
Maria Lucia Zaidan Dagli, *Department of Pathology, School of Veterinary Medicine and Animal Science, University of Sao Paulo, Brazil*.

Background and Aims: Lymphomas are hematopoietic malignancies originating from lymphoid cells. According to literature, lymphoma in dogs is similar to non-Hodgkin lymphoma in humans. Some studies show that environmental factors increase the risk of developing lymphoma. This study investigated the correlation between environmental factors and the risk of developing lymphoma in dogs through an epidemiological survey applied to their owners.
Methods: An epidemiological survey was applied to 167 dog owners, corresponding to 84 control cases and 83 dogs diagnosed with Non-Hodgkin lymphoma. Cases and controls were collected in 5 different veterinary hospitals in the city of São Paulo, Brazil. The survey retrieved information about possible environmental contaminants such as passive smoking, contact with pesticides and herbicides and physical, chemical and biological contaminants in water, air and soil.
Results: Statistical analysis showed that dogs with a defined breed had a higher number of representatives with lymphoma when compared to mongrel dogs; multicentric form and stage 4 were the most observed and there was no sexual predisposition. Animals weighing more than 10 kg, living outdoors and close to an important avenue in the city of São Paulo (10 to 20 thousand vehicles and 1 to 1.3 thousand motorcycle per hour) had a higher risk for disease development (OR: 3.8, 95% CI: 1.8 - 8.0, $p < 0.001$ / OR : 3.7, 95% CI: 1.7 - 8.0, $p = 0.001$, respectively).
Conclusions: These results suggest that environmental factors, such as air pollution, may increase the risk for developing canine lymphoma. Further studies are necessary to quantify pollutants in the environment and biomarkers in dogs, in order to better answer this hypothesis.

CHARACTERIZATION OF CHILDHOOD ASTHMA IN BARBADOS FROM A PILOT STUDY OF ENVIRONMENTAL RISK FACTORS

Sonali Bose MD MPH, *The Johns Hopkins University*
Linnea M. Smith-Waters BS,*The Johns Hopkins University*
Selvi Jeyaseelan PhD,I ,*The University of the West Indies*
an R. Hambleton PhD, ,*The University of the West Indies*
Angela Jennings MBBS, *Queen Elizabeth Hospital*
Gregory B. Diette, MD MHS,*The Johns Hopkins University*
Meredith McCormack MD MHS, *The Johns Hopkins University*

Background and Aims: Recent global climate changes have been accompanied by an increase in asthma prevalence in Barbados, particularly among children. While changes in air quality and lifestyle likely contribute to disease burden, there is little published data about the asthma health of this population. We characterized the respiratory health of children with asthma in Barbados with the aim of relating their morbidity to potential environmental risks.
Methods: Twenty-six children with physician-diagnosed asthma were enrolled in a study investigating the impact of air quality on asthma health. Validated questionnaires (adapted from pediatric ATAQ, CHSA, PAQLQ) to measure asthma control, asthma-specific health status and quality of life were administered. Daily activity and symptom diaries were also completed.
Results: The mean age of subjects was 10 years (range 5-16) and the majority were boys (20/26). Although most children were on controller therapy with inhaled corticosteroids (23/26), subjects reported a median of 2.5 days (IQR 0-6) of respiratory symptoms (wheeze, cough, chest tightness), and 2.0 nights (IQR 1-2) of symptoms in the last 2 weeks. Symptoms of cough, in the absence of a cold, occurred for 2 out of 14 days. In this cohort, health care utilization was predominated by acute care facilities, with 46% reporting A&E visits and 39% needing overnight hospitalizations in a 3 month period; in contrast, only 15% sought care at a physician's office. Children were found to spend most of their day indoors; however second-hand smoke exposure was noted to be very rare.
Conclusions: Barbadian children suffer significant morbidity from their asthma, requiring frequent visits to acute care facilities, despite the use of controller medications. Future work is needed to identify triggers in the indoor and outdoor environments that could contribute to high disease burden and ways to shift acute care visits to the primary care setting.

Background:

Knowledge of health risks associated to transport (air pollution, noise, injuries and physical inactivity) indicates that substantial health co-benefits are expected from low-carbon transport policies.

There is dearth of comparative analyses of health co-benefits from policies currently prescribed to reduce climate change in transport.

This limits policy makers' ability to chose among options benefiting health most, and of research bodies to extend knowledge in this domain.

Methods

WHO reviewed evidence on health impacts of recommendations on climate change mitigation for transport in the IPCC .Fourth Assessment Report, including:

- modified vehicles and fuels;
- land use factors;
- non-motorized transport or public transport.

Health impacts from those policies were classified as negative, insignificant or positive. The strength of evidence used in this analysis was judged as weak, strong or no evidence.

Results

When health is considered, the best transport interventions reviewed by the IPCC are travel mode shifts. This differs from the present emphasis on technological improvements in vehicles and fuels provided in the IPCC report.

There is also emerging evidence on how transport policies improve physical activity and related health outcomes:

- Active travel policies were associated with increased physical activity, reduced obesity and BMI.
- Public transport was associated with increased physical activity, less obesity and lower risk of road traffic injury.
- Increased car use was associated with less physical activity and more obesity.

Discussion

There is emerging research into the health impacts of actual transport interventions. Results from these studies allow health actors to advise on which transport policy options (among those being considered by panels such as the IPCC) are best for health. A new research agenda is proposed, directed at assessing the health performance of interventions in transport to mitigate climate change.

Gestational Mutations and Carcinogenesis

Rafael Meza, *University of British Columbia Centre for Disease Control, Canada*
E. Georg Luebeck, *Fred Hutchinson Cancer Research Center, USA*
Suresh H. Moolgavkar, *Fred Hutchinson Cancer Research Center, USA*

Background and Aims: We present a mathematical formulation to evaluate the effects of gestational mutations on cancer risk.
Methods: The hazard or incidence function of cancer is expressed in terms of the Probability Generating Function (PGF) of the number of normal and mutated cells at birth. Using Filtered Poisson Process Theory, we obtain the PGF for several mechanistic models for the accumulation of gestational mutations. In particular, we develop expressions for the hazard function when one or two successive mutations could occur during gestation. We also calculate the hazard when the background gestational mutation rates are increased due to exposure to mutagens, such as prenatal radiation.
Results: To illustrate the use of our models, we apply them to colorectal cancer in the SEER database. We find that the proportion of cancer risk attributable to developmental mutations depends on age and that it could be quite significant when gestational mutation rates are high. The analysis of the SEER data also shows that gestational mutations could contribute to inter-individual variations in colorectal cancer risk.
Conclusions: Gestational mutations could have substantial impact on cancer risk if mutation rates are significant. Spontaneous mutations during gestation may be responsible for some of the heterogeneity of cancer risk in human populations. Our methodology can be used to estimate the effects of mutagen exposure during gestation on cancer risk. For adult onset cancers the largest risk of gestational exposure to mutagens appears to be conferred by exposure late during pregnancy.

VALIDATION METHODOLOGY TO DETERMINE ETILENTIOUREA IN FILTER-PAPER DRIED UREA SPOT

Rodríguez-Reyes J, *Laboratory of Experimental Immunology, National Institute of Pediatrics*
Castillo-Cruz RA, *Laboratory of Experimental Immunology, National Institute of Pediatrics*
Ibarra-González I, *Genetics, Nutrition Research Institute Biomedical (UNAM)*
Fernández-Lainez C, *Genetics of Nutrition, National Institute of Pediatrics. Mexico*
Rojo Callejas F, *Chemistry Faculty (UNAM)*
Vela-Amieva M*,* *Genetics of Nutrition, National Institute of Pediatrics. Mexico*

Background and Aims: Ethylenebisdithiocarbamates (EBDTCs) is used to eliminate pelages in the agriculture. Nevertheless, it is mixed with its metabolite Ethylenethiourea (ETU). The International Agency for Research in Cancer has evaluated the carcinogenic risk of ethylene thiourea
(ETU) to man and classified it as an antithyroid substance and as a suspect carcinogen, since this type of substance is believed to induce thyroid tumours through the suppression of thyroxin synthesis leading to hyperplasia of the thyroid gland.The methods utilized in its determination have high cost and monitored is restrictive; because is necessary major volume of sample, transport and storage. So is necessary to adapt a method for diagnostic more efficient.
To validity a methodology for the detection of ETU in sample in filter-paper dried urea spot.
Methods: 5 ml test tube with 2mL of urine adds 1 ml of water. The sample is keep ultrasonic-treated in water-bath for 60 min Later is mixed for 20 min a shaker it is filtered, evaporated to dryness and reconstituted with 100µL to water and injected to the chromatograph of liquids
Results: The limit of detection in samples liquidate (water and urine) was of 10µg/ml, we established curve of calibration with the concentrations 10, 20, 50, and 100µg/ml, of that one was obtained r2=0.94 of in water, and r2 = 0.87, in urine. The second phase is to embed samples of 2 ml of urine on filter paper to do the same extraction procedure in the process
Conclusion: The methodology in sample of desiccated in paper filter, resulted more efficient in the detection of ETU in urine human. Because, it methodology dimities cost and volume of sample. It assay could be used as environmental screening infantile, for detection of pesticides and it evaluate as endocrine disruptor and probable effect risk to the health.

THE ASSOCIATION BETWEEN EXPOSURE TO FINE PARTICULATE MATTER ($PM_{2.5}$) AND ADMISSIONS FOR ACUTE MYOCARDIAL INFARCTION IS MODIFIED BY COMORBID CONDITIONS IN SANTIAGO, CHILE

Jeanette Vera, *Universidad de Chile and Pontificia Universidad Católica de Chile, Chile*
Marcela Ferrada, *Pontificia Universidad Católica de Chile, Chile*
Pabla Campos, *Hospital de Urgencia Asistencia Pública, Chile*
Patricio Yovaniniz, *Hospital Barros Luco Trudeau, Chile*
Patricio Sanhueza, *Hospital San Juan de Dios, Chile*
Ramón Corbalán, *Pontificia Universidad Católica de Chile, Chile*
Gregory Wellenius, *Brown University, Boston, United States of America.*
Carolina Nazzal, Facultad de Medicina, *Universidad de Chile, Chile*
On Behalf of the National Registry of Myocardial Infarction (GEMI) group.

Background and Aims: The association between acute myocardial infarction (MI) and particulate matter fine (PM2.5) is well-documented. However, it is interesting to understand better the role of comorbid conditions on susceptibility to MI. Thus, the study aim was to assess whether the association between exposure to PM2.5 and MI is modified by comorbid conditions such as diabetes mellitus, hypertension, hyperlipidemia, or obesity..

Methods: Medical records of MI patients were obtained from four hospitals of the GEMI Registry in Santiago, Chile (2002-2007). PM2.5 and meteorological variables were obtained from the MACAM monitoring network. A time-stratified case-crossover design was used to examine the association between PM2.5 and MI, controlling for temperature and dew point using natural splines. We estimated the effect separately among patients with comorbid (diabetes mellitus, hypertension, hyperlipidemia, and obesity) or total cholesterol level on admission (stratified by high ≥200mg/dL, and normal <200mg/dL). Lag and moving averages were considered.

Results: 3,176 MI patients were included (62 ± 13 years old). A 10 µg/m3 increase in PM2.5 levels was associated with increased admissions of MI patients with *diabetes mellitus* (9.0% (95%CI: 0.9-17.7%), 1-day moving average), with *hyperlipidemia* (9.1% (95%CI:0.7-18.1%), 3-day moving average to a 9.7% (95%CI:0.8-19.5%), 4-day moving average), with both *diabetes mellitus and hyperlipidemia* (18.2% (95%CI: 5.6-32.2%), 0-day lag), with *high-cholesterol levels* (11.1% (95%CI:1.3-21.7%), 4-day moving average to a 12.0% (95%CI:0.2-25.1%), 7-day moving average); and with both *hyperlipidemia and high-cholesterol levels* (13.5% (95%CI:0.3-28.5%), 3-day moving average to a 16.1% (95%CI:1.3-32.9%), 4-day moving average). No significant association was observed for MI patients with hypertension or obesity or normal cholesterol.

Conclusions: These results suggest that the association between exposure to PM2.5 and admissions for MI, is modified by comorbid conditions. Those at greater risk are patients with diabetes mellitus, hyperlipidemia or with high-cholesterol levels, thus are especially susceptible groups in Santiago, Chile.

PREVALENCE OF RESPIRATORY DISEASES AND ENVIRONMENTAL FACTORS IN THE CHILDREN IN CUIABÁ, SOUTHERN BRAZILIAN AMAZON

Rosa Antonia Maria, *University of State of Mato Grosso, Brazil*

Eliane Ignotti, *University of State of Mato Grosso/ Federal University of Mato Grosso, Brazil*

Sandra de Souza Hacon, *FIOCRUZ-Brasil*

Background and aim: Respiratory diseases are the main causes of child morbidity and mortality. The aim of this study is to analyze the prevalence of respiratory diseases, as well to identify domiciliary environmental risk factors in younger than 5 years, residents in Cuiabá, Brazilian Amazon.
Methods: Cross-sectional study was carried out by 700 children sampled in the 653 territorial divisions by census tracts in Cuiabá. This city is located in the Brazilian Amazon and presents an important seasonal variation of humidity and high levels of exposure to air pollutants and temperature. The study includes variables on the children's health and socio economic status, characteristics of pregnancy and birth. The dependent variable included children with presence of respiratory symptoms during two weeks before the interview that represents the current moment.
Results: The prevalence of respiratory diseases represents 57% in the study group. The maternal alcoholism (CAGE positive) shoed to be statistically associated with the occurrence de respiratory diseases ($\rho = 0.06$). The size of house smaller than 30 m² was associated to the prevalence of respiratory diseases ($\rho = 0.00$). Children with normal ($\rho = 0.049$) or precarious ($\rho = 0.008$) hygiene of the home environment showed higher probability to have symptoms of respiratory diseases.
Conclusion: The prevalence of respiratory diseases was approximately 2/3 of the children living in Cuiabá, which are associated to the conditions of the domiciliary environment.
Keywords: Respiratory Diseases, Prevalence, Environmental Factors

SOME APPROACHES TO MULTI-POLLUTANT EPIDEMIOLOGY: PRODUCTS OF COAL COMBUSTION AND SMELTER OPERATION, PRODUCTS OF INTERNAL COMBUSTION ENGINES, AND SOURCE CATEGORY CONTRIBUTIONS

William E. Wilson, Jr., *123 Providence Glen Drive, Chapel Hill, NC 27514; email: wandgwilson@aol.com*

Background and Aims: Due to current interest in multi-pollutant approaches to various aspects of air pollution, pollutant concentrations in Phoenix, AZ (1995-1998) have been analyzed for associations with cardiovascular mortality. Both the ability to determine accurately the independent effects of single pollutants and to estimate the joint effects of groups of pollutants are considered.
Methods: A priori regression models were used based on previous analyses conducted in Phoenix. Subsequent sensitivity analyses give changes in beta from varying model parameters and thus an indication of the reliability of model results.
Results: As, Se, Hg, and Sulfate are poorly correlated at the Phoenix measurement site. The joint effect (by including concentrations of all pollutants in a joint statistical model) gives a total beta very close to the sum of the individual pollutant betas. Therefore, betas for individual pollutants are meaningful and relative toxicities can be estimated. NO2, CO, and EC are highly correlated. The sum of the betas from a joint model is about equal to the largest single pollutant beta. Thus, it is difficult to obtain reliable betas for individual pollutants, only for their joint effect. Because of the high correlation between many pollutants, statistical models were used to produce poorly correlated factors which can often be associated with source categories (Source Category Models). Individual and joint results for factors from two such models are reported in interquartile range (IQR) units.
Conclusions: It is difficult to estimate individual for highly correlated pollutants. Regression models using poorly correlated factors from Source Category Models (each factor including multiple pollutants) provide suggestions regarding the relative toxicity of source categories. Joint models using source categories yield an indication of the total effects of all identifiedsources acting jointly. (In making this presentation, Dr. Wilson is representing himself.)

EXPOSURE TO HERBICIDES IN HOUSE DUST AND RISK OF CHILDHOOD LEUKEMIA

Helen D. Reed, *University of California, Berkeley, USA*,
Catherine Metayer, *University of California, Berkeley, USA*
Joanne Colt, *National Cancer Institute, Bethesda, MD USA*
Patricia A. Buffler, *University of California, Berkeley, USA*
Steve Selvin, *University of California, Berkeley, USA*
Mary H. Ward, *National Cancer Institute, Bethesda, MD USA*

Background and Aims: Previous studies investigating the risk of childhood leukemia in relation to self-reported use of herbicides have produced mixed results. We measured herbicide concentrations in house dust–a reservoir for household chemicals--to estimate the association of childhood acute lymphoblastic leukemia (ALL) with exposure to these compounds.

Methods: A total of 269 ALL cases and 333 healthy controls (<8 years of age at diagnosis/reference date and residentially stable) from a case-control study in California (2001-2007) received a second interview with collection of carpet dust samples. Dust samples were obtained using a high-volume surface sampler or from the household vacuum cleaner. Herbicides were selected for analysis based on frequency of use in California and feasibility of laboratory quantification and included agricultural herbicides (alachlor, bromoxynil, simazine, and pendimethalin) and lawn and garden herbicides (trifluralin, MCPA, MCPP, 2,4-D, dacthal, and dicamba). Odds ratios (OR) and 95% confidence intervals (CI) were estimated using logistic regression. Models included log-transformed concentrations for herbicides detected in at least 50% of homes or binary variables (detect/non-detect) for herbicides detected in 5% to <50% of homes. All models included child's age, sex, race/ethnicity, household income, year and season of dust sampling, residence location (urban, suburban, rural), and residence type.

Results: Simazine, 2,4-D, and MCPP were the most prevalent herbicides (84%, 84%, and 73% detections, respectively). Dacthal was detected in 40% of case homes vs. 31% of control homes (OR=1.47, 95% CI 1.01, 2.14). Increasing dacthal concentrations were associated with a positive trend in risk among non-Hispanics but not other racial/ethnic groups. No other herbicides were associated with ALL risk.

Conclusions: In non-Hispanics, we observed increased risk of ALL associated with household exposure to dacthal, but no associations for other herbicides. A strength of this study is the use of household dust samples to estimate exposure to specific herbicides rather than self-reports.

THE OCCURENCE OF RESIDUAL ORGANOCHLORINE AND ORGANOPHOSPHORUS PESTICIDES IN THE AGRICULTURAL REGION OF TALTIZAPÁN, MORELOS IN MÉXICO

Antonio Velasco, *Centro Nacional de Investigación y Capacitación Ambiental-Instituto Nacional de Ecología*
Jorge Rodríguez, *Instituto Nacional de Pediatría, Laboratorio de Inmunología Experimental*
Rocio Castillo-Cruz, *Instituto Nacional de Pediatría, Laboratorio de Inmunología Experimental*
Irmene Ortíz, *Departamento de Procesos y Tecnología, Universidad Autónoma Metropolitana- Cuajimalpa*

Background and Aims: The presence of residual organochlorine and organophosphorus pesticides in agricultural soil and water samples from Tlaltizapan, state of Morelos, México at different periods of the sugar cane cultivation cycle was evaluated.
Methods: There were performed three monitoring of soil and water samples within an area of approximately of 63 Km ², the sampling were conducted in November 2208, November 2009 and April 2010.
Results The metabolite p,p´-DDE, γ-HCH, p,p-DDD and heptachlor were found in more of 95% of the sampling zones in the three monitoring performed along 2 years. The highest concentration detected (129.6 µg kg-1dry soil) was for α-HCH but its frequency of detection was ~5%. The low-detection frequency of α-HCH and the high-concentration values of γ-HCH indicate the repeated use of technical-grade HCH and Lindane (γ-HCH) in the region. Among the organophosphorus pesticides, the ethyl parathion was the compound with the highest soil concentration, ~2000 µg kg-1dry soil in first monitoring. However, this compound was detected in the second monitoring in a concentration of ~4 µg kg-1dry soil and it was not detected in the third one, indicating that is not accumulated in the environment. The heptachlor was the compound most commonly found in all water samples, in a range of 0.45-1.25 ng L-1.
Conclusions: The presence of this organochlorine compound in water samples indicates a possible migration from soil to water bodies due to soil erosion. There was not detected the presence of organophosphorus compounds in water samples; this can be attributed to the moderate persistence of these compounds and their consequent degradation before arriving the water bodies.

HIERARCHICAL APPROACH OF FACTORS RELATED TO INCOME, HOME ENVIRONMENT AND OCCURRENCE OF ASTHMA IN ALTA FLORESTA – BRAZILIAN AMAZON

Rosa Antonia Maria, *University of State of Mato Grosso, Brazil*
Eliane Ignotti, *University of State of Mato Grosso/ Federal University of Mato Grosso, Brazil*
Sandra de Souza Hacon*, FIOCRUZ-Brazil*

Background and aim: Asthma is the most prevalent chronic disease in childhood. The aim of this study is to analyze the influence of factors related to income, home environment and occurrence of asthma among students.
Method: Cross-sectional study using hierarchical approach of determinants of asthma among students residents in Alta Floresta, Brazilian Amazon. A questionnaire with information about the socio economic level, the living conditions and the health status was applied. Questions of the International Study of Asthma and Allergies in Childhood were applied. The variables were clustered in three levels: distal (socio economic variables), intermediate (smoking and the parent's educational level) and proximal (the student's characteristics).
Results: After the adjustment to the distal level the following variables presented statistically significance: Students living in houses with only one room (OR = 3.68; CI 95%: 1.34-10.10) and with missing waste disposal (OR = 2.43; CI 95%: 1.26-4.67). On the intermediate level mothers smoking during pregnancy (OR = 3.58; IC 95%: 1.47-11.30), even after the adjustment by variables of the distal level.
Conclusion: The occurence of asthma among children living in Alta Floresta is associated to the characteristics of the home environment and the environmental conditions to which the children are exposed.

DISTANCE TO ROADWAY AND LONG-TERM SURVIVAL FROM ACUTE MYOCARDIAL INFARCTION

Joshua I Rosenbloom, *Beth Israel Deaconess Medical Center, USA*
Elissa H Wilker, *Beth Israel Deaconess Medical Center, USA*
Murray A Mittleman, *Beth Israel Deaconess Medical Center, USA*

Background and Aims: The relationship between exposure to traffic-related air pollution and long-term survival from myocardial infarction (MI) has not been thoroughly investigated. We investigated the association between distance between residence and major roadway and 10-year all-cause mortality after MI in the Determinants of MI Onset Study (Onset Study), hypothesizing that living closer to a major roadway at the time of MI would be associated with increased risk of mortality.
Methods: The Onset Study enrolled 3886 individuals hospitalized for MI in 64 centers across the United States from 1989-1996. Institutionalized patients, those providing only Post Office Boxes, and those whose addresses could not be geocoded were excluded, leaving 3263 patients eligible for analysis. Addresses were geocoded and the distance to the nearest A1/A2 roadway was assigned and dichotomized to > 100m or ≤100m, based on previous studies. All patients were followed for mortality through 2007. We used Cox regression to calculate hazard ratios (HRs) after 10 years of follow-up, adjusting for personal characteristics (age, sex, race, educational attainment, marital status, smoking, body mass index, comorbidities, medications), neighborhood-level characteristics derived from US Census block group data (median income, education, urbanicity), and clinical characteristics at the time of MI (thrombolysis, peak CK, development of CHF and/or ventricular tachycardia).
Results: There were 941 deaths at 10 years of follow-up. In crude analyses, living within 100m of a major roadway was associated with an HR of 1.35 (95% confidence interval [CI] 1.07, 1.70). In fully adjusted analyses the HR was 1.26 (95% CI 0.99, 1.60).
Conclusions: In this group of survivors of acute MI from across the United States, living close to a major roadway at the time of MI was associated with increased risk of all-cause 10-year mortality; this relationship persisted but lost statistical significance even after adjusting for individual and neighborhood-level covariates.

Title: BREAST CANCER INCIDENCE IS RELATED TO URANIUM PARTICULATE EXPOSURE IN A POPOULATION LIVING NEAR A URANIUM REFINERY

Susan M. Pinney, *Dept. of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH, USA*

Robert Wones, *Dept. of Internal Medicine, University of Cincinnati College of Medicine, Cincinnati, OH, USA*

Background and Aims: Ionizing radiation has been recognized as a risk factor for breast cancer in humans, but recently studies of mammary cell lines have noted that the heavy metals cadmium and uranium seem to exhibit estrogenic activity. We examined data from a longitudinal cohort to determine if breast cancer incidence was related to exposure to uranium and radiation in a population residing around the Feed Materials Production Center (FMPC), a uranium refinery in Fernald, Ohio.
Methods: The FMPC was part of the US Department of Energy (DOE) nuclear weapons complex, and produced uranium metal products from 1952-1989, with releases of soluble and insoluble uranium and ionizing radiation. The US Centers for Disease Control and Prevention (CDC) developed dose estimation models for exposures to individuals who lived within a 5-mile radius from the perimeter of the plant. We used these algorithms to estimate exposure for 4823 women enrolled in the Fernald Medical Monitoring Program (FMMP), of whom 184 were diagnosed with breast cancer during the 18 year tenure of the FMMP (1990–2008), and conducted life-table analyses, with appropriate covariates (age, family history of breast cancer, parity, age at first birth), to determine the relationship between uranium/radiation exposure and breast cancer incidence.
Results: The mean value of the uranium particulate exposure (ug/m^3-years) for women in the three exposure groups was 0.086, 0.354, 1.596, and for cases was 0.738 vs. 0.614 for controls. The risk of breast cancer in the highest exposure group compared to baseline was significantly elevated (HR=1.55, 95% CI 1.12, 2.15). In the subgroup with age at first exposure ≤15 years the HR for the highest exposure group was 4.56 (1.93, 10.77).
Conclusions: For women living within five miles of a uranium processing plant, degree of exposure to uranium particulates was related to risk of incident breast cancer.

Support for this project provided by the Fernald Medical Monitoring Program and the National Institute for Environmental Health Sciences, through the University of Cincinnati Center for Environmental Genetics (P30-ES06096).

THE PARTICIPATORY DESIGN OF EXPOSURE ASSESSMENT APPARATUS

David Holstius, *University of California, Berkeley*

Background and Aims: Sensor-equipped phones, handheld monitors, and instrumented bicycles are just three examples of the diverse forms of personal and microenvironmental monitoring equipment that could emerge from advances in increasingly affordable, digital, and real-time measurement technologies. Who participates in the design of this emerging set of technologies, how, and what effect does it have on exposure assessment and environmental health? What benefits could emerge from involving research participants more extensively in the design of instrumentation, as well as its staging and operation? What systematic approaches can guide broader participation in this activity? We present a process-oriented framework and method for eliciting and thinking through these problems as well as reflections and lessons learned.
Methods and Materials: We review the Participatory Design (PD) framework, a well-established tradition of theory and method for the user-centered design of persuasive digital technologies (Davis 2009), as well as recent case studies in community-oriented PD (DiSalvo 2008) and citizen sensing (Willett 2010, Dutta 2009). We extend the contributions of this work by describing an iterative, workshop-oriented approach for the participatory design of exposure assessment apparatus. Relying on small-group sketching and description, as well as intensive rapid prototyping, the method results in the construction of functioning artefacts as well as stories and demonstrations.
Results: Using commercially available, open-source components, we were able to construct several artefacts within a series of six workshops spread over three months. We identified four areas for future work to streamline and increase the value of such activity for exposure assessment stakeholders: (1) benchmarking and response characterization of low-cost, off-the shelf sensors; (2) modularization of components identified and described in multiple artefacts; (3) curricula and analytical techniques guiding the use and interpretation of measurements obtained from such artefacts; and (4) collaboration with the emerging maker and hacker subculture, from whom we drew examples, materials, and inspiration.
Conclusions: Low-cost and do-it-yourself (DIY) sensing platforms may offer innovative ways for professionals and non-professionals to expand participation by cooperating on the design of exposure assessment instrumentation. Workshop methods are time-intensive and require dedicated involvement from scientists, designers, and engineers; however, this might be ameliorated. Further exploration of the potential for Participatory Design methods in exposure assessment is warranted.

CHLORINATION DISINFECTION BY-PRODUCTS IN CANADIAN DRINKING WATER AND BRAIN CANCER RISK

Kenneth C Johnson, *Public Health Agency of Canada, Canada*
Will King, *Queen's University, Canada*
Saiyi Pan, *Public Health Agency of Canada, Canada*
Yang Mao, *Public Health Agency of Canada, Canada*

Background and Aims: The etiology of brain cancers remains poorly understood. The studyof brain cancer and chlorination disinfection by-products (CDBPs) in drinking water with the best exposure assessment suggested increased risk of brain cancer associated with long-term exposure to CDBPs. Our aim was to replicate this high-quality study in Canada.
Methods: We conducted a population-based case-control study of 1009 incident cases of primary brain cancer and 5039 controls in eight Canadian provinces to assess the impact of chlorination disinfection by-products in Canadian drinking water on brain cancer risk. Mailed questionnaires were used to collect a lifetime residential history, source of drinking water, and other risk factors. We estimated the exposure to chlorination by-products in drinking water by combining questionnaire data with historical data on by-products levels for more than 600 water treatment plants. We included 684 cases and 3805 controls in the analysiswho had exposure information for at least 70% of the period 5 to 45 years period prior to interview.
Results: Risk was not related to lifetime average trihalomethane (THM) levels or years of exposure to THMs or to higher levels or longer duration of exposure to bromodichloromethane (BDCM). We observed no association with more years of exposure to THM at 3 levels: THM>20, >40 and >60 µg/l. The results for women and men were similar to that for both genders combined. Stratified analyses by histology subtype of brain cancer did not demonstrate any consistent relationship of brain cancer risk with either exposure to higher levels of THM or DBCM, or longer years of exposure to THM or DBCM, although increased risk was observed for some categories of exposure years for glioblastoma and astrocytoma tumors.
Conclusions: Our study does not support the hypothesis that chlorination disinfection by-products play a significant role in the etiology of brain cancer.

ASSOCIACTION BETWEEN AIRBORNE POLLEN AND ASTHMA EMERGENCY ROOM ADMISSIONS DURING SAHARAN DUST INTRUSIONS

Aurelio Tobías, *Institute of Environmental Assessment and Water Research, Spanish Council for Scientific Research, Spain*

Jorge Pey, *Institute of Environmental Assessment and Water Research, Spanish Council for Scientific Research, Spain*
Andrés Alastuey, *Institute of Environmental Assessment and Water Research, Spanish Council for Scientific Research, Spain*
Xavier Querol, *Institute of Environmental Assessment and Water Research, Spanish Council for Scientific Research, Spain*

Background and Aims: A previous study reported larger mortality risk during Saharan dust days compared to non-Saharan dust days in Barcelona, Spain (Perez et al. 2008). No studies are available of potential interaction effects of Saharan dust with other environmental risk factors of natural origin on human health. Our objective is to investigate if the risk of asthma morbidity due to airborne pollen concentrations increases during Saharan dust outbreaks.
Methods: Data were collected on the daily number of asthma emergency room admissions, mean daily concentrations of the major pollen types with allergenic capacity: *Olea*, *Plantago*, Poaceae and Urticaceae, and Saharan dust intrusions from 2005 to 2007. Changes of effects between Saharan and non-Saharan dust days were assessed using Poisson regression models, adjusting for trend and seasonality and meteorological variables.
Results: During non-Saharan days the strongest associations for pollen types ranged from a lag of 2 to 6 days and showing risks of asthma lower than 2.5%, for an increase of 1 pollen grain/m^3. In the course of Saharan outbreaks the lagged effect of pollen types was shorter, of 1 day for all pollen types, and the risk of asthma much higher: 6% for Urticaceae, 13% for Poaceae, 16% for *Olea*, and 35% for *Plantago*, although estimates were only statistically significant ($p<0.05$) for Poaceae and *Plantago*.
Conclusions: Saharan dust outbreaks have strong acute respiratory effects. Further investigations are needed to understand the mechanisms that explain these observations.

Andrés Alastuey, *Institute of Environmental Assessment and Water Research, Spanish Council for Scientific Research, Spain*
Xavier Querol, *Institute of Environmental Assessment and Water Research, Spanish Council for Scientific Research, Spain*

Background and Aims: Winds from the Sahara desert transport large amounts of dust to Spain. The presence of high dust concentrations for long periods of time, and the interaction between dust and air pollution, raise concerns about adverse health effects and appropriate interventions by health authorities.
Methods: We investigated the short-term effects of particles (PM2.5 and coarse fraction (PM10-PM2.5)) on cause-specific daily mortality (circulatory, respiratory and cerebrovascular causes) in the city of Madrid (Spain), during days with and without Saharan dust intrusions, between January 2003 and December 2005. Changes of effects between Saharan and non-Saharan dust days were assessed using a time-stratified case-crossover design.
Results: During Saharan dust intrusion days an increase of 10 µg/m3 in the coarse fraction increased daily mortality by respiratory causes by 7.5% (95% confidence interval = 0.1% to 15%), with a lag of 3 days. In contrast, during non-Saharan dust intrusion days an increase of 10 µg/m3 in PM2.5 increased daily mortality for circulatory causes by 3.5% (0.1% to 7%) with a lag of 2 days. No effects of particles were found for cerebrovascular mortality.
Conclusions: Saharan dust outbreaks may have adverse health effects. Further investigation is needed to understand the role of fine particles and the mechanism by which Saharan dust could increase respiratory-specific mortality. In spite of that current air guidelines should be revised for Mediterranean cities with Saharan dust intrusions.

INDOOR PARTICULATE MATTER CONCENTRATIONS ARE HIGHER DURING AFRICAN DUST SEASON IN HOMES OF CHILDREN WITH ASTHMA IN BARBADOS

D'Ann Williams, *Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland USA*
Selvi Jeyaseelan, *The University of the West Indies, Cavehill, Barbados*
Ian Hambleton, *Chronic Disease Research Centre, Tropical Medicine Research Institute, The University of the West Indies, Cavehill, Barbados WI*
Meghan F. Davis, *Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland USA*
Angela Jennings, *School of Clinical Medicine and Research, The University of the West Indies, Queen Elizabeth Hospital, Bridgetown, Barbados WI*
Greg Diette, *Johns Hopkins School of Medicine, Baltimore, Maryland USA*
Patrick Breysse, *Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland USA*
Meredith McCormack, *Johns Hopkins School of Medicine, Baltimore, Maryland USA*

Background and Aims: Childhood asthma is a significant public health problem in Barbados and air quality may be a contributing factor. Ambient particulate matter (PM) concentrations in Barbados are influenced by seasonal global transport of African dust plumes. Ambient and indoor concentrations can negatively impact respiratory health in susceptible populations. In a panel study to demonstrate feasibility of assessing asthma and the relationship to African dust exposure, PM was measured in homes of asthmatic children in Barbados during 2 seasons: low African dust (season 1) and high African dust (season 2).
Methods: Twenty-six asthmatic children in Barbados were studied for 5 days, January-February 2010 (season 1), and 19 children completed a second 5-day monitoring period in July 2010 (season 2). Home indoor environmental monitoring set-ups collected integrated PM samples and passive second-hand smoke/nicotine (SHS) for 5 days. Children completed daily lung function testing during the study period.
Results: Indoor $PM_{2.5}$ and PM_{10} concentrations were 26 and 21% higher during season 2 than season 1 (8.3 ± 3.2 versus 11.2 ± 5.7 ug/m^3, p=0.04 for $PM_{2.5}$ and 26.5 ± 10.0 versus 33.0 ± 11.4 ug/m^3, p=0.03 for PM_{10}, respectively). Increases in log$PM_{2.5}$ and logPM_{10} tended to be associated with decreases in percent-predicted FEV_1 (p=0.06 and p=0.16 respectively). Most SHS samples (78%) were below the LOD; those >LOD were low concentrations (0.007 - 0.1 ug/m^3).
Conclusions: To our knowledge, this is the first study to measure the relationship between African dust and indoor home environments in Barbados. Indoor PM concentrations in homes of asthmatic children were significantly higher during the African dust season and increases in PM were linked to decreased percent-predicted FEV_1. The findings of this pilot study support the need for research investigating effects of global transport of African dust on respiratory health in Barbados and other affected geographic locations.

LONG-TERM EXPOSURE TO AIR POLLUTION FROM TRAFFIC IN EUROPEAN CITIES IN RELATION TO PREGNANCY OUTCOME AS WELL AS AIRWAY DISEASE AND COGNITIVE FUNCTION IN CHILDREN: THE ESCAPE STUDY

Göran Pershagen, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden
Olena Gruzieva, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden
Manolis Kogevinas, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain
Rémy Slama, Inserm and University J. Fourier Grenoble, Grenoble, France
Raymond Agius, Centre for Occupational and Environmental Health, School of Community Based Medicine, University of Manchester, Manchester, UK
Joachim Heinrich, Institute of Epidemiology, Helmholtz Zentrum München, Neuherberg, Germany
Jordi Sunyer, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain
Rob Beelen, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands
Bert Brunekreef, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands

Background and Aims: Work package 3 of the European multicenter ESCAPE project focuses on quantitative assessment of the impact of ambient air pollution on adverse pregnancy outcomes (aim 1), development of asthma, sensitization, lung function and respiratory infections in children during the first twelve years of life (aim 2), and cognitive function development in children up to five years of age (aim 3). Biomarkers are used to assess some phenotypes, particularly with regard to allergy and sensitization.
Methods: A total of 18 birth cohorts are included from different parts of Europe, as well as Taiwan and Australia. All participating cohorts assessed the spatial variability of specific air pollution components within their communities based on the ESCAPE exposure protocol. City-specific analyses with subsequent combined analyses are performed as well as pooled analyses for some outcomes.
Results: A different set of cohorts is included for each specific aim. Thirteen cohorts contribute to aim 1 with 77,600 participants, 13 cohorts to aim 2 with 54,600 participants, and 6 cohorts to aim 3 with 18,500 participants. For aim 2 separate analyses are performed in the five oldest birth cohorts, including more than 18,000 children, and results will be presented at the ISEE conference.
Conclusions: The project adds to the existing knowledge on the impact of ambient air pollution on adverse pregnancy outcomes, childhood airway disease and cognitive function development. In particular, it is envisaged that the results will serve as a basis for estimation of exposure-response relationships and contribute to an understanding of the role of specific air pollution components.

PARTICIPANT EXPERIENCE IN THE U.S. NATIONAL CHILDREN'S STUDY, SALT LAKE COUNTY VANGUARD CENTER

Pamela A. Silberman, *University of Utah, USA*
Carol Sweeney, *University of Utah, USA*
Sean D. Firth, *University of Utah, USA*
M. Janice Gilliland, *University of Utah, USA*
Leslie E. Palmer, *University of Utah, USA*
Edward B. Clark, *University of Utah, USA*

Background and Aims: Participant retention is important to the success of the population-based U.S. National Children's Study (NCS). In order to determine motivators and barriers to participation, participants are asked to complete a self-administered questionnaire about experience in the study. We report on responses from English- and Spanish-speaking participants in Salt Lake County Vanguard Center.
Methods: Study data collection visits to participants' homes occurred during the 1st and 3rd trimesters of pregnancy, and included biological and environmental sample collection, anthropometrics and questionnaires. We summarized results of self-administered Participant Evaluation Questionnaires on which women were asked to rate the importance of factors in their decision to take part in the study and to describe their study experience on a scale from mostly negative to mostly positive.
Results : In-home study visits with multiple modes of data collection typically were 2 to 3 hours duration in the Vanguard phase of the NCS. Among early participants who had completed two study visits, factors rated highest as contributors to a decision to take part in the study included "feeling as if I can help children now and in the future," identified as very important by 62 of 69 (93%), and "helping doctors and researchers learn more about children and their health," rated as very important by 64 of 69 (96%). 55 of 69 (83%) participants rated their experience with the National Children's Study as mostly positive. When asked which study activities participants liked the most, 23 participants mentioned an ultrasound.
Conclusions: Despite the significant time commitment, study participants who complete a first study visit are very likely to be retained in the study through the second and subsequent visits. A high proportion of participants reported motivating factors that align well with the goals of the study, i.e. helping children and learning about their health.

LONGITUDINAL FOLLOW-UP OF COAST GUARD DEEPWATER HORIZON RESPONDERS

Jennifer Rusiecki, *Uniformed Services University, USA*

Erica Schwartz, *United States Coast Guard, USA*

Laura Weems, *United States Coast Guard, USA*

Lawrence Engel, *University of North Carolina, Chapel Hill, USA*

Background: Little is known about health effects from oil spills on response workers, despite the frequency of these events worldwide. The Deepwater Horizon (DWH) disaster was the largest oil spill in U.S. history. The response, led by the U.S. Coast Guard, involved over 7,000 Coast Guard workers, who carried out a wide range of clean-up activities. Of the few studies that have evaluated the human health consequences of oil spills, most have been cross-sectional. Respiratory symptoms, including cough and shortness of breath, and neurological, hematologic, psychological, genotoxic and endocrine effects have been reported. Benzene, a major component of crude oil, is a known hematotoxin and carcinogen, even at low exposure levels.
Methods: We have designed a study to follow up the cohort of Coast Guard DWH responders to elucidate the health consequences of oil spill exposures by capitalizing on existing, detailed data. The key sources of these data include an exit survey completed by each responder, which provides self-reported task, location, exposure, and health data; personal monitoring data on a subset of responders; and pre- and post-deployment clinical data from Coast Guard electronic health records and ICD-9 coded diagnostic data. The objective of our study is to identify clinical and subclinical health effects among Coast Guard DWH responders by analyzing the clinical and self-reported data and comparing pre- and post-deployment disease rates. This study will also lay the groundwork for future nested studies of selected outcomes and for targeted studies of biomarkers of adverse biological effect using banked pre- and post-spill serial serum samples available for all responders. By carefully following up this cohort, we may help to mitigate long-term health consequences among these workers and provide much-needed insight into the health effects from oil spills.

ASTHMATIC CHILDREN PERSONAL EXPOSURE AND INHALED DOSE OF AIR POLLUTANTS

Joana Valente, *CESAM & Departamento de Ambiente e Ordenamento, Universidade de Aveiro, Aveiro, Portugal*
Pedro Martins, *CEDOC, Departamento de Fisiopatologia, Faculdade de Ciências Médicas (FCM), Universidade Nova de Lisboa, Lisbon, Portugal and Serviço de Imunoalergologia, Hospital de Dona Estefânia, Centro Hospitalar de Lisboa Central, EPE, Lisbon, Portugal*
Myriam Lopes, *CESAM & Departamento de Ambiente e Ordenamento, Universidade de Aveiro, Aveiro, Portugal*
Nuno Neuparth, *CEDOC, Departamento de Fisiopatologia, Faculdade de Ciências Médicas (FCM), Universidade Nova de Lisboa, Lisbon, Portugal and Serviço de Imunoalergologia, Hospital de Dona Estefânia, Centro Hospitalar de Lisboa Central, EPE, Lisbon, Portugal*
Ana Isabel Miranda, *CESAM & Departamento de Ambiente e Ordenamento, Universidade de Aveiro, Aveiro, Portugal*
Carlos Borrego, *CESAM & Departamento de Ambiente e Ordenamento, Universidade de Aveiro, Aveiro, Portugal*

Background and Aims: The study presented focus on the determination of personal exposure and inhaled dose of air pollutants (PM, O3, NO2, BTEX and formaldehyde) in asthmatic children in Portugal. Association between exposure and dose of air pollutants and the respiratory health of children was investigated.
Methods: The ISAAC questionnaire has been applied to identify 60 asthmatic children that participated in the study. Personal exposure was calculated using a microenvironmental approach and inhaled dose was estimated according to different ventilation rates for each child, in each moment. Daily activity profiles for each child were established through personal questionnaires to parents and children and allowed the identification of the microenvironments (ME) frequented by those children and the activity level and time spent in each one. The air quality characterization of different ME (outdoor and indoor) was performed combining measurements and air quality modelling techniques.
Results: Results show significant differences in the contribution of the various ME to exposure and dose. Although exposure in ME where children have high activity levels may be low, the mass of pollutant inhaled there is high. Statistical association between health and air pollution data shows that children that have higher contact with air pollution have respiratory exams indicating lower health condition.
Conclusions: This study allowed the estimation of weekly personal exposures and inhaled doses of a set of pollutants, for summer and winter conditions. It reveals the importance of advancing in the chain of events that relate air pollution and health, showing that similar exposures can lead to quite different inhaled doses. The findings indicate the importance of controlling air quality in indoor sport facilities; children do not spend significant time in those environments, but it results in high inhaled doses.

METHOD VALIDATION BY GC-MS TO DETERMINE PYRETHROIDS METABOLITES IN URINE

Isabel SIlva, *MACstudent REQUIMTE, Instituto Superior de Engenharia do Porto, Portugal and CESPU, Portugal*
Valentina F. Domingues, *REQUIMTE, Instituto Superior de Engenharia do Porto, Portugal*
Begoña Criado, *CESPU, Portugal*
***Cristina Delerue-Matos**, REQUIMTE, Instituto Superior de Engenharia do Porto, Portugal*

Background and Aims: Pyrethroids (PYRs) Pesticides are synthesized from prototype pyrethrins (naturally occurring toxin) derived from the flowers of *Tanacetum cinerariaefolium*, in order to increase their environmental stability and selective insecticidal properties. PYRS are widely used in agriculture, forestry, veterinary, nurseries, in textile industry, and in public health programs worldwide. PYRs are one of the most frequently and widely used class of insecticides.
The exposure to this classes of pesticides can increase the probability of developing Parkinson's disease[1], some of these PRYs may be endocrine disruptors and they have been listed as such by the Environmental Protection Agency (EPA) [2].
Human exposure to PYRs can occur via food intake, inhalation and dermal absorption[1]. Proper usage of PYRS is enforced, in part, by periodic monitoring PYRs in food samples in spite of their short life time [3] but more important monitoring PYRs organism. Can be assessed by measuring intact compounds or their metabolites in urine or blood, but due of rapid metabolism, urine analyses is more efficient [4].
The aims of this work were development of a reliable health risk assessment through the analysis metabolites of PYR pesticides in the population and development and validation method for analysis of metabolites of PRYs in urine samples by Gas Chromatography Mass Spectrometry (GC-MS).
Methods: Solid phase extraction (SPE) with Strata X cartridges, followed derivatization with 1,1,1,3,3,3-Hexafluor-2-propanol (HFIP) and N',N'-Diisopropycarbodiimid (DIIC) and finally quantification method with Termo GC ultra GC-MS equipped with a column ZB.XLB (30×0,25mm ID 0.25µm film thickness Phenomenex).
Results: Concentrations ranging from 0.5 to 10µg/L in studied urine previous spiked with 3 phenoxybenzoic acid (3PBA) and 2 Phenoxybenzoic acid (2PBA) as an internal standard. The quantification ions are: 135, 141,169,196,197 and finally 364. With this method were obtained a calibration curve with R=0,992.
Conclusions:
This method is a reliable method for detection of PYRs metabolites in urine samples

DETERMINATIONS OF ENDOCRINE DISRUPTORS IN ENVIRONMENTAL USING SPE AND GAS CHROMATOGRAPHY- TANDEM MASS SPECTROMETRY

José Vera, *REQUIMTE,* Faculdade *de* Ciências *da Universidade do* Porto*, Portugal and REQUIMTE, Instituto Superior de Engenharia do Porto, Portugal*
Valentina F. Domingues, *REQUIMTE, Instituto Superior de Engenharia do Porto, Portugal*
Cristina Delerue-Matos, *REQUIMTE, Instituto Superior de Engenharia do Porto, Portugal*

Background and Aims: Endocrine disrupting compounds (EDCs) include a wide variety of pollutants, namely substances of different sources of contamination: domestic, industrial and agricultural e.g. pesticides estrogens, heavy metals and plasticizers. The ECDs are present in the environment at low levels of concentration and they can only be determined by using a preconcentration technique[1]. Gas chromatography/mass spectrometry (GC-MS) is commonly accepted as one of the most powerful techniques for the separation, identification and quantification of EDCs, even in the nanogram range[2].
Methods: Chromatographic analyses were carried out in a Thermo GC ULTRA Gas Chromatograph Mass Spectrometer equipped with a ZB-XLB. High-purity helium at a constant flow rate of 1.3mL/min was used as carrier gas. An AI/AS 3000 auto injector was used. Injections (1µL) were made in the split/splitless mode. Samples were analyzed using the following oven temperature programme: initial temperature 60 C (held for 1 min), increased by 20 C/min to 200 C (held for 1 min), increased again by 5°C/min to 245°C and held at this temperature for 40 min.
Results: We have optimized the method by determining the following ECDs; Atrazine-desethyl, HCB, Atrazine-deuterated, Atrazine, Simazine, Lindane, Vinclozoline, Alaclhor, Malathion, Aldrin, α-Endosulfan, p.p`-DDE, Dieldrin, DDD, Endrin, o.p`-DDT, β-Endosulfan, Methoxychlor, Bifentrhin, Fenpropatrhin, Iprodione, λ-Cyhalothrin, Permethrin, β-Cyfluthrin, Cypermethrin, Fenvalerate and Deltamethrine all present good linearity.
Conclusions: The limit of detection achieved allows the determination above the legal limits.

EVALUATION OF DIFFERENT QUECHERS FOR DETERMINATION ORGANOCHLORINE PESTICIDES IN CARROT

L. Correia de Sá, *MAC Student, FCNAUP, University of Porto, Portugal.*
V. C. Fernandes, *REQUIMTE, ISEP, PORTO, Portugal and Investigation Centre (CIQ), FCUP, Portugal*
C. Calhau, *FMUP, University of Porto, Portugal*
V. F. Domingues, *REQUIMTE, ISEP, PORTO, Portugal*
C. Delerue-Matos, *REQUIMTE, ISEP, PORTO, Portugal*

Background and Aims: The Organochlorine Pesticides (OCPs) due to their extensive use in agriculture and also because of their chemical stability and slow biodegradation became ubiquitous pollutants. Overall use has been restricted since the late 1970s[1]. However these biologically hazardous chemicals still persist and move throughout the biosphere[2].
Most of the OCPs are therefore included in the organic persistent pollutants which are characterized by exceeding long half-lifes in the environment[3] and to have potential biomagnification capacity through food chain[4].
To OCPs has been associated a range of both acute and chronic health effects, such as cancer, birth defects, neurological damage and in addition they are suspected to act as endocrine disruptors[5]
The aim of this study was to develop a method to evaluate OCPs in carrots**.**
Methods: The analyzed compounds include: HCH (α,β,δ), HCB, lindane, aldrin, 4.4'-DCBP, α-endosulfan, dieldrin, *p-p'*-DDE, endrin, β-endosulfan *p-p'*-DDD, *o-p'*-DDT and methoxychlor. The extraction was performed with QuEChERS. Gas chromatography with ECD was employed for the determination of pesticides.
Results: Five types of QuEChERS with different compositions were also tested. The chosen QuEChERS was composed of 4g MgSO4, 1g NaCl, 1g Na3Citrate 2H2O, and 0,5g Na2HCitrate 1 ½ H_2O.
With the chosen QuEChERS linear calibration curves were obtained for the 14 pesticides and the internal standard (IS). Concentrations ranging from 5 to 70µg/kg in carrots were studied**.**
Conclusions: The samples homogenization influences the results reproducibility therefore it can be a crucial step for the analysis.
The sample preparation procedures, QuEChERS, can be applied to carrots for OCPs analysis.

IN UTERO EXPOSURE TO PERSISTANT ORGANIC POLLUTANTS (POPS) IN GIRLS: RELATIONSHIPS TO GROWTH, PUBERTAL DEVELOPMENT AND REPRODUCTIVE SUCCESS: NEW DATA

Michele Marcus, *CDC, Emory University and Kaiser Permanente, Atlanta, GA*
Mildred Maisonet, *CDC and Emory University, Atlanta, GA*
Krista Christensen, *Emory University, Atlanta, GA.*
ChanleySmall, *Emory University, Atlanta, GA*
MetreciaTerrell, *Emory University, Atlanta, GA*
Carol Rubin, *CDC, Atlanta, GA*
Antonia Calafat, *CDC, Atlanta, GA*

Background and Aims: POPs have been shown to affect the endocrine system, particularly during critical windows of development. We examined the effect of *in utero* exposure to two different classes of POPs, polyfluoroalkylcompounds (PFCs) and brominated flame retardants (BFRs) on girls' childhood growth and pubertal development. The study of BFRs includes follow-up into the reproductive years.
Methods: The study of PFCs is a nested case control study within the Avon Longitudinal Study of Parents and Children (ALSPAC). Serum samples collected during pregnancy from mothers of earlier-maturing girls (n=218) and later-maturing girls (n=230) were assayed for PFCs by solid-phase extraction coupled to isotope dilution high-performance liquid chromatography-tandem mass spectrometry. The study of BFRs is a cohort study of Michigan residents who consumed contaminated meat and dairy products as a result of an industrial accident. Serum samples from women were assayed for BFRs by gas chromatography with electron capture detection. Their female offspring were followed prospectively (n=327).
Results: In the ALSPAC study PFC concentrations were associated with more rapid postnatal growth. A 1-unit increase in log-transformed PFCs was associated with a 0.02 increase in the rate of growth per month (weight-for-age SD score). Previously published work in this population found PFCs associated with increased odds of earlier menarche (OR=1.3), however, this increase did not reach statistical significance (Christensen et al, 2011). The study of BFR previously found earlier pubertal development among girls with high exposure in utero and through breastfeeding (Blanck et al, 2000). Continued follow-up has revealed a dose-related increase in the risk of spontaneous abortion among these, now adult, women.
Conclusions: Exposure to POPs during critical periods of endocrine development may have substantial long-term consequences.

Title: EFFECT MODIFICATION BY INFLUENZA ON THE ACUTE RELATIONSHIP BETWEEN COLD TEMPERATURE AND CARDIOVASCULAR MORTALITY IN 67 U.S. CITIES

Rebecca Gluskin *New York University, Department of Environmental Medicine, U.S.A.*
George Thurston *New York University, Department of Environmental Medicine, U.S.A.*
Kazuhiko Ito *New York University, Department of Environmental Medicine, U.S.A.*

Background: A better understanding of the effects of temperature on human health is needed to improve estimates of the health effects of climate change. Cardiovascular mortality (CVD) has been associated with periods of cold temperature and influenza epidemics. However, the manner in which these two exposures interact on the outcome of CVD has yet to be determined. We investigated a potential role of the intensity of influenza-like illness (ILI) on the relationship between cold temperatures on daily cardiovascular death.

Methods: The data available for this study includes 67 United States metropolitan areas from the fall of 2003 through the end of 2006. We used a Poisson time-series regression model to estimate the effects of temperature at its lowest quintile in each city in each year during the cold season (October – March) at lag 0 through 3 days, adjusting for temporal trends and day of week. In a second-stage random effects model, we included the annual ILI mean intensity for each city and each year, as well as other potential predictors such as average annual temperature, population density, and the percent of population over age 65.

Results: Of the effect lags considered, the 2-day laggedcoldest quintile of temperature showed the strongest and most significant association with increased CVD mortality, with an excess risk of 3.9% (95% confidence interval: 0.16, 7.70%). We found a significant
effect modification of the temperature effect by the influenza intensity, with an inter-quartile range increasing the excess risk by 31%.

Conclusions: These findings suggest that ILI rates may modify cold temperature effects on CVD mortality.

REGIONAL DIFFERENCE OF INDOOR ACTIVITY PATTERNS IN KOREA.

Kiyoung Lee, *Department of Environmental Health, Graduate School of Public Health, Seoul National University*
Wonho Yang, Department of Occupational Health, Catholic University of Daegu

Background and Aims: The information about time spent in microenvironments plays a critical role for personal exposure to environmental pollutants. While there are several large scale activity pattern studies in Western countries, comprehensive time activity pattern research for exposure assessment has not been readily available in Korea.
Methods: We analyzed residential indoor and transportation times of Korean population over 10 years old. The population based study collected time activity pattern of 31,634 Korean for two consecutive days. Impact of sociodemographic factors on time activity has been assessed using multiple linear regression models.
Results: The residential indoor times were 14.23 hours in weekday and 16.13 hours in weekend and shorter than those in Western countries. The transportation times were 1.75 hours in weekday and 1.68 hours in weekend. The residential indoor times were significantly longer in weekend than in weekday ($p < 0.000$). However, transportation distributions of weekday and weekend were similar. Korean population spent less time at home after the working hours. The time spent in residential indoor at 6 PM and 10 PM were about 37% and 75%, respectively. These residential indoor time were different from the results of about 67% (6 PM) and 90% (10 PM) in USA. The most significant factors on residential indoor time were employment status, age, monthly income and gender in weekday and employment status and gender in weekend. The factors on transportation were gender, employment status and monthly income in weekday and gender, employment status, age and marriage status in weekend.
Conclusions: Since there are substantial difference of Korean population activity pattern, this information can be critical for exposure assessment in Korea. Determinants of time activity pattern need to be taken into account in exposure assessment, epidemiological analyses, exposure simulations, as well as in the development of preventive strategies.

NON-HODGKIN LYMPHOMA MORTALITY TIME TRENDS IN BRAZIL, 1980-2008

Patricia Boccolini, *IESC/Universidade Federal do Rio de Janeiro, Brasil*
Crisgtiano Boccolini, *ENSP/Fundação Oswaldo Cruz, Brasil*
Ubirani Otero, CONPREV/ Instituto Nacional do Câncer, Brasil
Armando Meyer, *IESC/Universidade Federal do Rio de Janeiro, Brasil*

Background and AIMS: Non-Hodgkin Lymphomas (NHL) are part of a heterogeneous group of hematologic cancer originated at the lymphoid tissue, and represent more than 3% of cancer incidence worldwide. In Brazil there are few epidemiological studies on incidence and mortality of this neoplasmin the population. This paper aims to analyze the NHL mortality time trend in South and Southeast in Brazil, between 1980 and 2008.
Methodology: Information on NHL deaths was obtained from the Brazilian Mortality Information System, from 1980 to 2008, according the ICD 9 and 10. The total population and the stratification by age and sex were obtained from the Brazilian Institute of Geography and Statistics (IBGE), and the age-standardized death rates was obtained employing the 2000 world population standard. The joinpoint log-linear model, using Poisson regression, was employed to identify points where trend lines change significantly in magnitude/direction to verify trends, with a Confidence Interval of 95%.
Results: The Average Annual Percent Change (AAPC) in age-adjusted death rates due to NHL showed an statistically significant increasing trend in six of seven South and Southeast Brazilian States studied, ranging from 1,2% (Minas Gerais State) to 5.0% (Rio Grande do Sul State) per year from 1980 to 2008. The exception was Rio de Janeiro State, with no trends in the period. São Paulo State was the only one with an AAPC decrease trend of 2,21% per year, considering the 2000-2008 period. Considering the trends stratified by sex, the women had an higher AAPC increase than men.
Conclusions: NHL Mortality has been increasing worldwide and results of this research suggest that the same occurs in the South and Southeastern Brazil, but more analytical studies are needed.

EXPOSURE ASSESSMENT APPROACHES FOR ARSENIC IN DRINKING WATER

Background and Aims

Accurate retrospective exposure assessment is a major challenge in conducting epidemiologic studies of environmental factors and diseases with long latency, such as cancer. For example, bladder cancer is typically diagnosed clinically late in life, but has an etiological relevant exposure period of decades. The aim of this study is to compare and contrast exposure assessment methodologies in recent cancer studies which attempted to classify lifetime exposure of arsenic.

Methods

Two studies were in the USA, and the third in Eastern Europe. Case/control ascertainment was from 11 counties in Michigan, 3 states in New England (NEBCS), and from parts of the countries Hungary, Romania, and Slovakia (ASHRAM). Methods for locating residences of the study population prior to diagnosis inside and out of the ascertainment areas, for linking these residences to their drinking water supply, and for predicting the level of arsenic in their supply over a lifetime exposure period are compared in this presentation.

Results

Arsenic concentration specific to residential water supplies were estimated for 99%, 95%, and 80% of the cumulative exposure periods across all study participants in the Michigan study (64,040 Exposure-Years), NEBCS (173,361 E-Y), and ASHRAM (94,008 E-Y), respectively. Average residential mobility was approximately 9 residences over the exposure period in the Michigan study, 7 in NEBCS, and not reported in ASHRAM. Concentrations varied widely across the locations of current and past residences in all studies, especially in terms of water supply source: private wells versus public supply (only reported in USA studies).

Conclusions

Accurately locating past residences in epidemiological studies concerning waterborne contaminants and diseases with long latency is critical to exposure assessment. Recent cancer studies demonstrate achievement of this step allows for estimating contaminant concentrations over much of the exposure period, thus accounting for exposure misclassification that could result from study population mobility.

EMERGING METHODOLOGIES FOR EXAMINING ENVIRONMENTAL INFLUENCES ON CHILDREN'S EXPOSURE TO AIR POLLUTION

Jason Gilliland, *University of Western Ontario, Canada*
Matthew J Maltby, *University of Western Ontario, Canada*
Janet Loebach, *University of Western Ontario, Canada*
Xiaohong Xu, *University of Windsor, Canada*
Alex Mates, *University of Windsor, Canada*
Isaac Luginaah, *University of Western Ontario, Canada*

Background and Aims: Air pollution is a critical environmental and public health issue. Children are especially vulnerable to air pollution in their surroundings as they have higher ventilation rates, spend more time outdoors, and are more constrained in their mobility than adults. Most research relating health-related outcomes (e.g., asthma) to environmental factors (e.g., land uses) identifies correlations, but stops short of understanding how individuals interact with their surroundings. For example, PM2.5 is traditionally assessed using fixed or 'passive' monitors which assume homogeneity in pollution distribution over large areas, and have consistently under-reported actual personal exposure.
Methods: We address methodological shortcomings by providing a fuller understanding of the daily spatial and temporal routines of children in the spaces they inhabit. Using an innovative suite of portable, high-precision, personal monitoring tools (air pollution monitors, accelerometers, and GPS) we are able to combine 'active' measurements of PM2.5 exposure, energy expenditure, and geographic location at 1-second intervals throughout a child's day; in turn, we can identify environmental influences on children's activities and exposure to PM2.5. These tools were used to continuously monitor 36 children in a Canadian city (London) for one week; time-activity diaries, questionnaires, and interviews were used to provide additional context. GIS was used to visualize and analyze spatial-temporal patterns.
Results: This presentation will describe the innovative protocol and preliminary findings on how variations in children's levels of exposure to PM2.5 varies in relation to spatio-temporal variations in their activities and characteristics of their everyday environments (e.g., land use patterns, greenspace).
Conclusions: This study highlights the importance of 'active' versus 'passive' monitoring for more accurate assessments of exposure to air pollution. A better understanding of the spatial and temporal aspects of children's exposure to air pollution and the environmental context provides necessary evidence for formulating interventions to promote the health of children.

INFLUENCE OF THE BUILT ENVIRONMENT ON PERSONAL EXPOSURE TO FINE PARTICULATE MATTER IN CYCLISTS DURING THE MORNING COMMUTE IN A CANADIAN CITY

Matthew J Maltby, *University of Western Ontario, Canada*
Jason Gilliland, *University of Western Ontario, Canada*

Background and Aims: The health impacts of exposure to fine particulate matter air pollution ($PM_{2.5}$) conflict with the health benefits of commuting by active transport. This is of special concern to commuting cyclists as they are often near air pollution generating traffic and respiring at an elevated rate. Long-term and short-term exposure to $PM_{2.5}$ has been implicated epidemiologically in numerous cardiovascular and respiratory ailments. Personal exposure studies are critical as single-site ambient monitors do not adequately capture environmental variations and consistently report lower pollution measurements.
Methods: Participants were equipped with a GPS and a portable device which measures $PM_{2.5}$ both recording at one second intervals. Five routes totalling approximately 50km were cycled during the morning commute for 5 days across the city bicycle network in a midsized Canadian city (London, ON). GIS was employed to spatially analyze over one hundred thousand pollution data points.
Results: This study found that mean individual exposure of 22.8µg/m^3 was significantly greater than mean hourly ambient measures of 12.88µg/m^3 ($p = 0.03$). Although atmospheric conditions such as wind direction ($r = 0.72$) were found to correlate with daily personal exposure to $PM_{2.5}$, intraurban variation was still present in the data normalized to control for temporal meteorological effects.
Conclusions: This study aims to be the first to incorporate elements of the built environment, such as the presence of street trees, traffic volume, traffic speed, urban morphology (e.g. block length, distance to nearest intersection), and land uses into a regression model in order to account for the variation and hotspots of $PM_{2.5}$.

Prolonged Respiratory Effect of Oil Spill Exposure on Children

Woo-Chul Jeong *Taean Institute of Environmental Health*
Kyung-Mook Kim, *Department of Internal Medicine, College of Medicine, Dankook University,Korea*
Suk-Chul Jung, *Department of Occupational and Environmental Medicine, College of Medicine, Dankook University,*
Sang-Chul Roh *Department of Occupational and Environmental Medicine, College of Medicine, Dankook University*
Jong-Il Hur, *Taean Institute of Environmental Health*
Young-Koo Jee[1] *Department of Internal Medicine, College of Medicine, Dankook University,Korea*

Background and Aims: : The aim of this study was to evaluate the effect of oil spill on pulmonary function and prevalence of asthma of children living close to oil spill area in the Yellow Coast of South Korea.
Methods: Of 662 eligible children, 436 (65.9%) subjects, who completed a questionnaire and finally agreed to participate in the study, were enrolled on June 2009. Modified International Study of Asthma and Allergies in Childhood (ISSAC) questionnaire (Korean version) was used as a questionnaire, and health examination included skin prick test, pulmonary function test, and methacholine bronchial provocation test. Study subjects were divided into high and low exposure group according to exposure level to oil spill.
Results: (Arial, 8pt, bold)
There were no statistically significant differences in characteristics such as age, sex, height, weight, and family history of asthma between high and low exposure group. FEV_1 was significantly lower in high exposure group than in low exposure group (high *versus* low exposure group; 82.6±10.8% versus 85.3±10.4%, P=0.011). Prevalence of asthma based on a questionnaire was significantly higher in high exposure group than in low exposure group (high *versus* low exposure group; 31.4% versus 19.5%, P=0.005). Prevalence of asthma based on a methacholine bronchial provocation test was also significantly higher in high exposure group than in low exposure group (high *versus* low exposure group; 18.2% versus 7.9%, P=0.001). In a binary logistic regression analysis, male gender, family history of asthma, and high exposure to oil spill were significant risk factors for asthma (Gender[Male/Female]; OR 2.54, 95% CI 1.31-4.91, P=0.006, Family history of asthma [Yes/No]; OR 3,77, 95% CI 1.83-7.75, P=0.00, Exposure group[High/Low]; OR 2.43, 95% CI 1.27-4.65, P=0.007)
. **Conclusions** This study suggests that exposure to oil spill can be a risk factor for development of asthma in children. Future longitudinal study will be needed to determine the relationship between oil spill exposure and asthma and should include biologic markers related to airway inflammation to reveal the mechanism about how oil spill exposure affects lung function and bronchial hyperreacitivity.

.

CAPITALIZING ON AVAILABLE MONITORING DATA TO INFORM EXPOSURE ASSESSMENT IN THE GULF STUDY

Lawrence Engel, *National Institute of Environmental Health Sciences*
Mark Stenzel, *Exposure Assessment Applications, LLC*
Patricia Stewart, *Stewart Exposure Assessments, LLC*
Richard Kwok, *National Institute of Environmental Health Sciences*
Aubrey Miller, *National Institute of Environmental Health Sciences*
Aaron Blair, *National Cancer Institute*
Dale Sandler, *National Institute of Environmental Health Sciences*

Background and Aims: The Deepwater Horizon disaster, which released approximately 5 million barrels of oil into the Gulf of Mexico, is the largest oil spill in United States history. Over 100,000 workers participated in clean-up efforts. These workers may have been exposed to a number of agents during clean-up activities, including volatile organic compounds such as benzene, toluene, ethyl benzene, and xylene (BTEX); semi-volatile compounds such as polycyclic aromatic hydrocarbons; 2-butoxyethanol; propylene glycol; particulate matter; and oil mist. The duration of the spill and subsequent clean-up operation, as well as the large number of workers involved, enabled collection of a large amount of monitoring data, including over 20,000 observations of workers or work areas. These data were collected primarily by BP contractors and government agencies. They will be used, together with other data, to estimate exposures for each job group/location/time scenario defined in the GuLF STUDY, a large, prospective study currently being conducted by the US National Institute of Environmental Health Sciences to investigate the health effects of clean-up related exposures among these workers. The majority of measurements were reported to be below the limits of detection; however, interpretation of these data are complicated by the large number of job group/location/time scenarios, differences in analytical methods and instrumentation employed, use of compliance-based rather than research-based sampling strategies, and severe and varied working conditions.

Methods: Exposure distributions will be examined across, and descriptive statistics presented for, various job group/location/time scenarios. Important exposure determinants will be identified and reported. Results will be interpreted in light of the sampling strategies and analytic methods/instrumentation used.

Conclusions: Despite their limitations, the monitoring data available for Deepwater Horizon clean-up workers provide a rare opportunity to clarify exposure scenarios and their determinants for this spill and may help inform monitoring and exposure mitigation efforts in future spills.

A HEALTH SURVEY FROM ARSENIASIS-ENDEMIC AREAS IN SOUTHWESTERN TAIWAN

Tzu-Chieh Huang, *Department of Public Health ,China Medical University, Taichung, 404, Taiwan*

Chih-Ching Yeh *School of Public Health, Taipei Medical University, Taipei 110, Taiwan*

Ling-Ling Hsieh, *Department of Public Health, Chang Gung University, Tao-Yuan 333, Taiwan*

Background and Aims: Epidemiological studies shows that chronic exposure to arsenic in groundwater has associated with elevated risks for cardiovascular disease. This study investigated the prevalence of hypertension, hyperlipidemia, hyperglycemia, as well as biochemical indices in the Arseniasis-endemic areas in southwestern Taiwan.

Methods: Health screening survey was applied to the residents aged over 40 in the Beimen and Xuejia in Tainan County since July, 1997 to 2000. 1,963 out of 5,844 qualified residents from the 13 villages in the Beimen and from the 5 villages in Xuejia joined the survey.

Results: The prevalence of hypertension was 52.6% in Beimen, and 44.2% in Xuejia according to a systolic blood pressure ≧140 mm Hg and a diastolic blood pressure ≧ 90 mm Hg. The prevalence of hyperglycemia was 20.0% in Beimen and 17.4% in Xuejia. The abnormality rate of cholesterol, triglycerides and HDL in Beimen was 25.8%,20.9%, and 4.0%, respectively, while the same rate in Xuejia was 11.4%, 24.2%, and 0.7%, respectively. The positive rate of urine glucose, and urine protein was 7.7% and 25.7% in Beimen and 9.6% and 14.4% in Xuejia. The hematuria (blood in the urine) positive rate was 38.9% and 37.6% in Beimen and Xuejia respectively. The positive rate of HBs-Ag (the surface antigen of the hepatitis-B Virus) was 25.7% and 17.2% in Beimen and Xuejia. We find that the prevalence of hypertension, the abnormality rate of cholesterol, and HDL were significantly higher in Beimei than in Syuejia.

Conclusions: Data suggested that hyptertension, hyperlipidemia, and hyperglycemia in arseniasis-endemic area may have correlation with arsenic exposure.

PHTHALATES IN RELATION TO AUTISM AND DEVELOPMENTAL DELAY: EXPLORATORY ANALYSES FROM THE CHARGE STUDY

Irva Hertz-Picciotto, *MS1C, Dept PHS, One Shields Ave., UC Davis*
Deborah H. Bennett, *Division of Environmental and Occupational Health, Department of Public Health Sciences, University of California, Davis*
Huei-An Chu, *Division of Environmental and Occupational Health, Department of Public Health Sciences, University of California, Davis*

Background and Aims: Phthalates are used as plasticizers, solvents, and stabilizers common in household products with PVC plastic (toys, food containers, vinyl flooring) and in personal care products (fragrances, shampoo, lotion). Animal studies demonstrate developmental toxicity and endocrine disruption. Human research has linked phthalates to ADHD and behavior problems. Larsson et al. (2009) observed an association between autism and vinyl flooring.
Methods: Participants were 104 children from the CHARGE (Childhood Autism Risk from Genetics and Environment) Study, a case-control investigation of children aged 2-5 years with clinically confirmed autism/autism spectrum disorder (AU/ASD), developmental delay (DD) and typical development (TD). House dust was collected and analyzed for five phthalate compounds DMP (dimethyl phthalate), DEP (diethyl phthalate), DBP (dibutyl phthalate), BBP (benzyl butyl phthalate), and DEHP (di(2-ethylhexyl)). Multinomial logistic regression models were used to examine the association between phthalate concentrations in house dust and autism. Multiple linear regression was used to evaluate phthalates in relation to the Mullen's Scales of Early Learning, a test of cognitive skills. Mother's education was controlled in both analyses. We calculated 90% confidence intervals, in recognition of the exploratory nature of this project.
Results: Compared with TD controls, AU/ASD children tended to have higher household BBP (for each 1 unit increase in log[microgram/g dust], (OR=1.41 [90% CI 1.05-1.91]); and DEHP (OR=1.73 [90% CI 1.07-2.82]). Similarly, DD households, compared with those of TDs, had higher DEP (OR=2.42 [90% CI 1.23-4.76]). Concentrations of phthalates in house dust were also negatively correlated with cognitive scores: excluding those with DD and controlling for diagnosis (ASD vs. TD), DEP was associated with lower scores (beta=-0.04, p-value=0.07).
Conclusions: House dust represents a long-term reservoir for chemicals from products in the home. The higher phthalate levels in households of children affected by ASD and DD suggest that these compounds may interfere with CNS development.
Key Words: Phthalates, autism, autistic spectrum disorder, developmental delay, cognitive deficit, dust, exposure

HEALTH, WEALTH, DISASTERS AND ECOLOGIC FOOTPRINTS: TECHNOLOGIC FATIGUE?

Elihu Richter, *Hebrew University, Jerusalem, Israel*

Y Stein, *Hebrew University, Jerusalem, Israel*

Background and Aims: The catastrophic effects of the Japanese nuclear disaster in 2011 and the British Petroleum disaster in the Gulf of Mexico raise two questions: 1. When does the quest for more energy jeopardize health and wealth? 2. Is a role for epidemiologists in prediction and prevention of such disasters sufficient in the light of the concept of the ecologic footprint**?**
Methods: We review the lessons learned from these disasters as to the role and adequacy of epidemiologists in prediction, prevention and precaution and protection in the light of the concept of the ecologic footprint**.**
Results: These disasters, like all others, were rare, but not random, and had their warning signs, including ignoring worker complaints, lessons from past failures and anticipating linked probabilities from multiple failures. Both Japan and the USA are in the upper quartile of countries in measures of wealth, public health and quality of life as measured by the Human Development Index. But their ecologic footprints are also high. (4 gha per person and 9.5 gha per person).
Conclusions: The catastrophic effects of the British Petroleum and Japanese nuclear disasters underscore the case for an obligatory role for epidemiologists and other public health experts in (1) assessing the potential impacts for mass disasters of new technologies and (2) assessing the operation of existing tecnologies. Fail safe systems presuppose an epidemiologic approach based on risk assessment and sentinel early warning signs. Even so, wealthy and relatively healthy countries energy hungry countries (e.g. Japan and US) with very high ecologic footprints may be unsustainable. We ask: does the ever growing world need for cheap energy create driving forces and pressures and high ecologic footprints of disasters which undermine health and wealth?

POPULATION IMPACT OF CHLORINATION BY-PRODUCTS EXPOSURE ON INTRA-UTERINE GROWTH RETARDATION OCCURENCE

Patrick Levallois, Suzanne Gingras, *Institut national de santé publique, Québec, Québec, Canada*
Manuel Rodriguez, *Université Laval, Québec, Québec, Canada*
Robert Tardif, *Université de Montréal, Montréal, Canada*

Background and Aims: Chlorination By-Products (CBPs) exposure during pregnancy has been associated with intra-uterine growth retardation (IUGR). The objective of this study was to estimate the potential population attributable risk of CBPs in comparison to that of well proved causal factor, e.g. maternal smoking.
Methods: We conducted a population based case-control study in the Quebec City (Canada) metropolitan area. Five hundred and sixty seven term newborns with birthweight <10th percentile (small-for-gestational age- SGA) were compared with 1911 term controls with birthweight ≥ 10th percentile. The quality of drinking water serving the mother residences was monitored regularly for trihalomethanes (THMs) and haloacetic acids (HAAs) during the study. A phone interview of the mother was completed within three months after childbirth to evaluate maternal lifestyles, water consumption and risk factors for IUGR. Adjusted Odds Ratios (OR) of SGA according to different levels of CBPs were evaluated by means of an unconditional logistic regression with control of all potential confounders. Population attributable risk (PAR) was calculated using OR as an estimation of RR and the proportion of exposed among controls.
Results: The adjusted OR of SGA for a concentration of total THMs>80µg/l or the five main HAAs>60µg/l at the tap, during last trimester of pregnancy, was 1.30 (95% Confidence Intervals (CI): 1.03-1.65). The proportion of controls exposed to high levels of CBPs was 19.4% and the corresponding PAR for such CBPs exposure was estimated at 5.5%. In comparison, the OR of maternal smoking during the last pregnancy trimester was 2.07 (95%CI:1.56-2.74). The proportion of controls exposed to tobacco smoke was 9.8% and the corresponding PAR for maternal smoking was estimated at 9.6%.
Conclusions: If the relationship between CBPs exposure and SGA is causal, its impact on the occurrence of IUGR in this population would be non-negligible but lower that of maternal smoking.

Genome-Wide Interaction Study on occupational hazards and asthma, the European Community Respiratory Health Survey (ECRHS)

M Kogevinas, A Espinosa, JR Gonzalez, M Bustamante, JP Zock, E Bouzigon, D Jarvis

Dr Debbie Jarvis
Respiratory Epidemiology and Public Health Group

Imperial College
London

Dr Emmanuelle Bouzigon
INSERM Unité 794, Paris

Background and aims. Very few studies have addressed gene-environment (GxE) interactions in asthma at the genome-wide level and none in the context of occupational hazards. Our objective was to detect GxE interactions for asthma and job exposure in a population–based cohort.

Methods. Occupational exposures for 2205 adults from the ECRHS were assessed through job histories, an asthma-specific JEM and expert assessment. We performed a genome-wide interaction analysis for asthma as a whole and adult onset asthma by using 582,892 single nucleotide polymorphisms (SNP) and work exposure to high-molecular weight agents (HMW) and latex. Two analytical strategies were used to detect GxE interactions: 1) a global genome-wide analysis and 2) a two-stage approach.

Results. In the global analysis, a single SNP with marginal genome-wide significance (p-val<1.E-07) emerged to interact with latex for adult onset asthma. In the two-stage approach, SNPs associated with exposure (p-val<1.E-05) at the first step were then tested for association with outcomes at the second step. In this approach, two SNPs were detected to interact with HMW and four SNPs with latex for adult onset asthma (p-val<0.05). These SNPs were not among the top 30 SNPs in the global analysis. No interactions were found for asthma genes identified in a recently published large GWAS on asthma.

Conclusions. We found very few clues on GxE interactions. Results depended not only on exposure and outcome definitions, with slightly lower p-values for the more specific definitions (adult onset, latex) but also on the analytical strategy followed. Replication of these findings will be presented using two additional studies (EGEA and Sapaldia). With the exception of the evaluation of few prevalent exposures such as smoking, most studies evaluating GxE interactions are likely to be underpowered.

EXPOSURE ASSESSMENT APPROACHES FOR NITRATE INGESTION

Mary H. Ward[1], John R Nuckols[2], Sonya Heltshe[1], Briseis Aschebrook-Kilfoy[1], Curt Dellavalle[1], Peter Weyer[3], Bernard T. Nolan[4], Charles Lynch[3]
[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, DHHS; Bethesda, MD, USA; [2]Dept. of Radiological and Environmental Health Sciences, Colorado State University, Ft. Collins, CO, USA; [3]University of Iowa, Iowa City, IA, USA; [4]U.S. Geological Survey, Reston, VA, USA

N-nitroso compounds, formed endogenously from drinking water and dietary sources of nitrate and nitrite, are potent animal carcinogens that cause tumors at numerous anatomic sites. Exposure to nitrate via drinking water occurs mostly in agricultural areas and levels are often highest in private wells. In the United States, private wells are not regulated; therefore, monitoring data are scarce making exposure assessment challenging. We describe exposure assessment approaches for nitrate in drinking water sources for two epidemiologic studies: a cohort of Old Order Amish in three counties in Pennsylvania and the Agricultural Health Study (AHS), a cohort of pesticide applicators and their spouses in Iowa and North Carolina. In Pennsylvania, we used well measurements (n=386) from the U.S. Geological Survey (USGS) to develop a standard linear mixed effects model that included variables for aquifer type, geology, transmissivity, and karst density using the well recharge area as the modeling unit. We evaluated the model by comparing predicted and observed nitrate concentrations on a separate dataset of well measurements (n=96). In the AHS, we have information on water source (public supply, private well, other), well depth, and whether the well ever tested high (above the maximum contaminant level of 10 mg/L nitrate-nitrogen). We are linking residence locations on public supplies (40% of participants) to public monitoring databases for nitrate. For residences with private wells, we will use available measurement data to develop regression models that include information about well depth, whether the well tested high, hydrogeologic characteristics of the well, and land use information. Ingestion of nitrate and nitrite from dietary sources can be estimated from food frequency questionnaires; exposure estimates from several studies will be presented. We will also discuss the importance of considering factors affecting endogenous nitrosation in the exposure assessment and data analysis stages of epidemiologic studies.

Medical exposure to ionizing radiation and brain tumour risk – analyses of data from five Interphone countries

Bosch de Basea M [1], **Sadetzki S** [2], **Armstrong B** [3], **Hours M** [4], **Krewski D** [5], **McBride M** [6], **Parent ME** [7], **Siemiatycki J** [8], **Vrijheid M** [1], **Woodward A** [9], **Cardis E** [1]

[6] *BC Cancer Research Centre, Canada*
[7] *INRS - Institut Armand-Frappier, Laval, Canada*
[8] *Université de Montreal, Canada*
[9] *Massey University, New Zealand*

Background and Aims: Medical ionizing radiation represents an indispensable tool in modern medicine and it is the largest human-made source of radiation exposure. At moderate to high doses, ionising radiation is however a known risk factor for cancer and it is the only well established risk factor for brain tumours (UNSCEAR, 2008). Despite extensive knowledge of radiation risks gained through epidemiologic investigations and mechanistic considerations the health effects of low-level radiation exposure are still poorly understood (1). We therefore evaluated the risk of brain tumours in relation to reported medical radiation exposure.

Methods: This analysis is based on pooled datasets from five Interphone countries (Australia, Canada, France, Israel and New Zealand) information on all medical procedures involving ionizing radiation exposure during participant's lifetime was obtained by questionnaire, including year, anatomical region exposed and reason for examination or treatment for radiotherapy. Estimated dose to the brain was calculated for each procedure based on time and country specific average dose levels available in publications of the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR)(2). Analyses are based on unconditional logistic regression, stratified on age, sex, country/region. All analyses are adjusted for socio-economic status.

Results: The analyses included 905 cases of glioma, 916 cases of meningioma, 423 cases of acoustic neuroma and 6840 controls. Odds ratios (ORs) and 95% CI (confidence intervals) will be presented by cumulative estimated level of medical radiation for each of these tumour types

Conclusions: Results from these analyses will contribute to the body of evidence on potential health effects of low level medical exposure to ionising radiation.

Background and Aims: Brain tumours are the second most common neoplasms in young people. Apart from exposure to ionizing radiation and genetic predispositions, little is known about risk factors for these tumours. Mobi-Kids will study effects of environmental factors on brain tumour risk in young people, with particular focus on electromagnetic fields from mobile phones and other communication technologies.
Methods: Mobi-Kids is a collaborative case-control study starting in 12 countries (Austria, Australia, Canada, France, Germany, Greece, India, Israel, Italy, Spain, Taiwan, The Netherland)s using a common core protocol. Cases are 10-24 years old patients newly diagnosed with a brain tumour. Controls are patients hospitalized for appendicitis within the participating regions, individually matched to cases on age, sex and region of residence. A face-to-face interview will be held with participants and their parents to assess lifestyle, residential and school history, use of communication technologies, exposure to environmental risk factors, medical history and family history of cancer. Particular attention will be paid to issues of potential selection bias related to the low response rates of population-based controls (by selecting hospitalised controls) and potential recall errors (by validating questionnaire responses on mobile phone use with user data from network operators). Improved exposure indices for RF will be derived taking into account spatial distribution of energy in the brain at different ages; ELF from the phones will also be considered, as well as other important sources of EMF and chemical exposures in the general environment of young people.
Results: Data collection has started in most participating countries.. The study is expected to include nearly 2000 brain tumour cases and twice as many controls during a 2.5-year study period.
Conclusion: MOBI-KIDS will generate novel insights in brain tumour aetiology among young people. In particular it will address the association with information technology.

THE GULF STUDY: METHODOLOGIC CONSIDERATIONS IN USING EXISTING ENVIRONMENTAL AND PERSONAL MEASUREMENTS FOR EXPOSURE ASSESSMENT USING QUESTIONNAIRE DATA

Background and Aims: The Gulf Long-term Follow-up Study (GuLF STUDY) is investigating the potential short- and long-term health effects associated with clean-up activities following the Deepwater Horizon disaster in the Gulf of Mexico. The GuLF STUDY is characterizing workers' potential exposures to a number of chemical and physical agents associated with crude oil, dispersants, and other chemical and physical hazards arising from the spill or the clean-up work. Potential exposures varied not only by job task, but also spatially across the Gulf region and temporally. Reliable and valid exposure assessment is essential to evaluate and accurately characterize exposure-disease relationships. **Methods:** We have developed exposure scenarios for groups of workers who had potentially similar exposure distributions and performed similar tasks. To classify individuals into exposure scenarios, we are using a telephone interview to ascertain the tasks, locations, times, and work characteristics such as use of personal protective equipment and practices. We are using a variety of exposure assessment techniques that incorporate individual and environmental monitoring data, which include a large amount of censored data and cover a wide geographic area. **Results:** Data collected from the first six months of GuLF STUDY telephone interviews will be presented. Characteristics of different exposure scenarios and participant reporting will be presented to illustrate exposure reconstruction methods and estimation of exposures among the study participants. **Conclusions:** Robust exposure assessment requires accounting for the variety and quality of the environmental and industrial hygiene data and descriptive data collected during the oil spill clean-up response. Careful synthesis and analysis of these data will be critical for the correct interpretation of any epidemiologic findings.

USING CROSS-SECTIONAL BIOMONITORING STUDIES TO EXPLORE THE RELATIONSHIP BETWEEN HUMAN BODY BURDEN AND AGE

Cristina L. Quinn, *Department of Physical and Environmental Sciences, University of Toronto Scarborough, 1265 Military Trail, Toronto, Ontario, Canada M1C 1A4.*
Frank Wania, *Department of Physical and Environmental Sciences, University of Toronto Scarborough, Toronto, Canada*

Background and Aims: Cross-sectional data sets are a compilation of different individuals whereas the longitudinal body burden trends are for only one individual over their entire lifetime. Numerous studies have reported cross-sectional biomonitoring data of polychlorinated biphenyls (PCBs) with human body burdens increasing continuously into old age. This relationship has been previously interpreted to indicate the role of age on bioaccumulation. We propose that what has been interpreted as an increase in body burden with age is actually a result of the temporal relationship between the sampling period and the peak in emissions. The purpose of this research was to investigate which factors control the concentration versus age relationship.
Methods: Population cross-sections were generated from longitudinal calculations using the mechanistic model CoZMoMAN that links emissions to the environment with human body burdens. Body burden-age trends were generated from the longitudinal body burden calculations for human exposure to hypothetical chemicals with various partitioning and degradation properties. The influence of model assumptions and emissions peakedness are also examined.
Results: The temporal relationship between the emissions scenario time trend and the biomonitoring sample collection period is the most influential factor controlling the shape of concentration-age trends for population cross-sections. For chemicals with degradation half-lives of 1 year or less, the relative concentration-age trend is always the same. Published biomonitoring studies for PCBs and PBDEs are interpreted in the context of the relationship between emissions and metabolic degradation.
Conclusions: Bioaccumulation does not monotonically increase with age. The main predictors of cross-sectional body burden trends with age are the amount of time elapsed after emissions peaked and the chemical degradation rate.

CANCER RISK FROM *IN UTERO* EXPOSURE TO CHERNOBYL FALLOUT IN UKRAINE

Maureen Hatch, *U.S. National Cancer Institute, Division of Cancer Epidemiology and Genetics, Radiation Epidemiology Branch, †6120 Executive Boulevard, Rockville, Maryland 20852, USA*
Alina Brenner, *U.S. National Cancer Institute, Division of Cancer Epidemiology and Genetics, Radiation Epidemiology Branch, USA*
Evgenia Ostroumova, *U.S. National Cancer Institute, Division of Cancer Epidemiology and Genetics, Radiation Epidemiology Branch, USA*

Background and Aims: - Iodine-131 (I-131), the major component of Chernobyl fallout and an isotope readily absorbed by the thyroid gland, has been clearly linked to a subsequent increase in thyroid cancer among those exposed in early childhood. The embryo/fetus could also be vulnerable given the small size of the gland, the proliferative activity of fetal thyroid cells, and the high rate of radioiodine accumulation from the maternal circulation after 12 weeks gestation. We evaluated risk of thyroid cancer from *in utero* exposure to I-131 and also explored the incidence of non-thyroid cancers.
Methods: We identified 2,582 mother-child pairs from the northern region of Ukraine in which the mother was pregnant at the time of the Chernobyl accident or the two months following when I-131 fallout was still present. Individual fetal thyroid I-131 doses were estimated from I-131 activity in the mother's thyroid (mean dose=72 mGy; range 0-3,230 mGy). From 2003-2006, the *in utero* cohort was screened using an in-depth, standardized clinical examination. To evaluate incidence of other cancers, we linked the cohort to the Ukrainian National Cancer Registry (UNCR) for the period 1997 (the earliest year for which electronic records were available throughout the study area) and 2008, and estimated the standardized incidence ratio (SIR).
Results: Seven cases of thyroid carcinoma and one case of Hurthle cell neoplasm were identified at the time of screening. The estimated excess odds ratio per Gray for thyroid carcinoma was markedly elevated (EOR/Gy=11.9) although not significantly so (P=0.12). Preliminary results of record linkage with the UNCR identified 6 cases of non-thyroid cancer, including 2 brain gliomas, 3 cases of Hodgkin disease, and 1 choriocarcinoma. The SIRs were 0.9 for males (95% confidence interval (CI): 0.11, 3.28) and 1.8 for females (95% CI: 0.49, 4.66). A subsequent linkage is currently underway.
Conclusions*:* The data suggest that *in utero* exposure to I-131 in Ukraine may have increased the risk of thyroid carcinoma 20 years after the Chernobyl accident. Given the young age of the cohort, the results for cancer incidence at other sites are based on small numbers and should be interpreted cautiously.

MORTALITY CAUSED BY HEAT EXPOSURE IN EUROPEAN CITIES AND THE IMPACT OF UHI MITIGATION POLICIES

Kollanus, V., *National Institute for Health and Welfare, Finland - University of Kuopio, Finland,*
Huynen, M., *University of Maastricht, the Netherlands*
Torras Ortiz, S., *University of Stuttgart, Germany*
Tuomisto, J.T., *National Institute for Health and Welfare, Finland*

The objective was to evaluate current and future mortality caused by ambient heat exposure in densely populated metropolitan areas in Europe, and to assess the effectiveness of urban heat island (UHI) mitigation policies in reducing it. The evaluated policies were: 1) increasing urban vegetation by planting trees on open grassy areas and street curbsides, and 2) increasing city albedo by replacing impervious roof and street surfaces by light coloured surfaces. Heat exposure in cities was assessed based on EMEP grid data on urban population and weather conditions derived from hourly temperature and dew point data modelled with the Max Planck Institute for Meteorology Regional Model (REMO). Future exposure was evaluated for IPCC climate scenarios A1B and B1. The impact of UHI mitigation policies was modelled based on percentages of city surface area that could be redeveloped from one surface cover type to another and the unit cooling effects of these changes. Meta-analytical exposure-response functions for the effect of short-term heat exposure on natural mortality in European cities were used in quantifying the mortality impacts. Currently, almost 15000 deaths were estimated to be attributable to heat exposure in the European cities annually. By 2050, deaths were assessed to increase by 440% in the IPCC climate scenario A1B and 220% in B1. This increase is due to both warmer climate and aging population. The UHI mitigation policies were estimated to result in thousands of averted heat related deaths annually. Overall, vegetation policy reduced annual deaths by 4% and albedo policy by 11%. There are various uncertainties in the assessment. However, the simple methodology used does provide valuable insight into the potential magnitude of the health impacts of heat exposure in Europe and the effectiveness of different policies aimed at reducing them.

INVESTIGATING INTERGENERATIONAL DIFFERENCES IN HUMAN PCB EXPOSURE DUE TO VARIABLE EMISSIONS AND REPRODUCTIVE BEHAVIOURS

Cristina L. Quinn, *Department of Physical and Environmental Sciences, University of Toronto Scarborough, 1265 Military Trail, Toronto, Ontario, Canada*
Frank Wania, *Department of Physical and Environmental Sciences, University of Toronto Scarborough, Toronto, Canada*
Gertje Czub, *Swedish Chemicals Agency, Sundbyberg, Sweden.*
Knut Breivik[*] *Norwegian Institute for Air Research, Kjeller, Norway and University of Oslo, Department of Chemistry, Oslo, Norway*

Background and Aims: The atmospheric emissions of polychlorinated biphenyls (PCBs) have varied greatly since their introduction in the 1930s. Female reproductive characteristics have changed over the same time frame. Since both environmental chemical exposure and reproductive characteristics are expected to influence the human body burden, these concurrent trends may produce and/or enhance intergenerational differences in human PCB exposure. The objectives of this study were to determine the extent of prenatal, postnatal, and lifetime exposure of different generations and to evaluate the impact of reproductive characteristic on intergenerational differences in exposure.
Methods: The non-steady state mechanistic model CoZMoMAN was used to calculate human bioaccumulation of PCBs assuming both hypothetical constant and realistic time-variant emissions. The influence of age of childbearing, parity, and breast-feeding prevalence was evaluated for three epidemiological exposure endpoints (prenatal, postnatal, and lifetime exposure).
Results: The main determinant of exposure is an individual's year of birth relative to the emission history of PCBs. Reproductive characteristics can have a significant impact but this relationship also depends on the temporal relationship with contaminant emissions. All calculations indicated that the generation born around 1980 was exposed prenatally and postnatally to more PCBs than any other generation while the generation born in 1960 experienced the greatest cumulative lifetime exposure.
Conclusions: The reproductive characteristics of the mother had a greater influence on the prenatal and postnatal exposure of her infant than on her own cumulative lifetime exposure. Therefore, despite the production and use of PCBs being banned for over 40 years, the health repercussions can be expected to persist for several decades.

UNSUSPECTED DISCOVERY OF MERCURY POISONING IN BARBADOS

Olivia Drescher, *Centre de Recherche CHUQ, Québec, Canada*
Eric Dewailly, *CHUQ Research Center, University Laval in Québec, Canada*
Michael Krimholtz, *Queen Elizabeth Hospital, Barbados*
Jonathan Rutchik*, Division of Occupational Medicine, University of California at San Francisco*

Background : One remaining mercury exposure source of concern for humans is through the consumption of contaminated fish. Among populations of the world depending on fish as a major food source, Caribbean people are at risk of exposure. We measured mercury body-burden, in 46 individuals working in the fisheries in Barbados. The average hair mercury concentration was 4.65 µg/g. However, among the 20 women participants, 4 cases of exceptionally high hair mercury levels were unveiled: 361.08, 1404.21, 4012.04, and 5616.85 µg/g.
Objectives: The primary objective was to determine the source of exposure which led to the 4 cases of mercury poisoning. The secondary target was to assess mercury body-burden through urine analysis and conduct clinical neurologic assessment.
Methods: Spot urine specimens were collected from the 4 participants with elevated hair mercury levels. They were offered free clinical evaluation. Information sessions and open-discussions were organized for the concerned participants in the hope to discover the exposure source and increase public awareness about the health effects of mercury.
Results: Spot urine samples, for the 4 outliers (females aged 39-54) with hair levels: 361.08, 1404.21, 4012.04, and 5616.85 µg/g, revealed elevated urine mercury levels, respectively: 310, 350, 26, and 110 nmol/L. Mercury-containing skin-lightening creams were identified as the source of exposure. Of these, a bleaching cream manufactured in Jamaica contained 30,000 ppm of ammoniated mercury.
Conclusions: The high hair and urine mercury levels indicate that the use of mercury-containing cosmetics represent a significant exposure. Although the use of mercury in cosmetics is banned in many developed countries, no similar regulations exist in developing countries. Unsuspecting users might be at risk of health effects from dermal application of these creams. This study brings forth crucial information for public health policy makers to ban cosmetics containing mercury and for the promotion of public awareness aimed at dark skinned people.

INTEROCC STUDY: SOCIAL CLASS AND THE RISK OF GLIOMA BRAIN TUMOURS

Jack Siemiatycki, *Université de Montréal Hospital Research Centre (CRCHUM), 3850 Saint Urbain Street, Montreal, Canada*
Lesley Richardson, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Laurel Kincl, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Klaus Schlaefer, *German Cancer Research Center (DFKZ), Heidelberg, Germany*
Elisabeth Cardis, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
For the INTEROCC Study Group

Background and Aims: The etiology of glioma remains unexplained. There is inconsistent evidence as to whether social class influences risk of this brain tumour. In the context of a large international case-control study of brain cancer, we investigated the possible relationship between social class and glioma.
Methods: A set of case-control studies was carried out in seven countries. Overall, 1717 cases of glioma and 5099 controls were interviewed. Information was collected on highest attained education and lifetime occupational history. Different socioeconomic status (SES) measures were investigated, two based on highest attained educational level (of the subject and maximum of the subject and spouse) and two with the occupational history transformed to a prestige scale and income scale. These were assessed as possible risk factors for glioma, adjusting for age, sex, and study centre.
Results: None of the SES indices was associated with glioma in any consistent fashion. In the highest category of the education based SES the OR was 0.94 (95%CI 0.82 – 1.08).
Conclusion: There was no relationship between these SES indices and glioma. This could indicate that exposure variables associated with SES do not play a role in glioma etiology, or that different exposure variables associated with SES play countervailing roles whose net effect is null.

INTEROCC STUDY: SOCIAL CLASS AND THE RISK OF MENINGIOMA BRAIN TUMOURS

Jack Siemiatycki, *Université de Montréal Hospital Research Centre (CRCHUM), Montreal, Canada*
Lesley Richardson, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Laurel Kincl, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Klaus Schlaefer, *German Cancer Research Center (DFKZ), Heidelberg, Germany*
Elisabeth Cardis, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
For the INTEROCC Study Group

Background and Aims: The etiology of meningioma remains unexplained. There is inconsistent evidence as to whether social class influences risk of this brain tumour. In the context of a large international case-control study of brain cancer, we investigated the possible relationship between social class and meningioma.
Methods: A set of case-control studies was carried out in seven countries. Overall, 1591 cases of meningioma and 4710 controls were interviewed. Information was collected on highest attained education and lifetime occupational history. Different socioeconomic status (SES) measures were investigated, two based on highest attained educational level (of the subject and maximum of the subject and spouse) and two with the occupational history transformed to a prestige scale and income scale. These were assessed as possible risk factors for meningioma, adjusting for age, sex, and study centre.
Results: The two education-based SES indices led to similar findings as did the pair of occupational-based indices. The lowest risks were seen among subjects in the highest education category (OR 0.71, 95% CI 0.61, 0.82) and among subjects in the highest occupational prestige category (OR 0.72, 95% CI 0.6, 0.85). When both education and occupation based SES indices were included in the same model, the relationships with risk persisted for both indices.
Conclusion
Risk of meningioma was related to both education-based and occupation prestige-based SES indices, with lowest risks among those in high SES categories. These risks may reflect the impact of lifestyle and occupational factors.

ADDRESSING THE CHALLENGES OF CLIMATE CHANGE TO NUTRITION SECURITY

Tirado M.C, *University of California-Los Angeles School of Public Health, Los Angeles, CA,, USA - Public Health Institute, Center for Public Health and Climate Change, Oakland, CA, USA*
Herman D, *University of California-Los Angeles School of Public Health, Los Angeles, CA,, USA*
Crahay P, *Action Against Hunger, Food Security Department, Paris, France.*
Cohen M, Oxfam America, Climate Change and Humanitarian Department, Washington, DC.

Background/Aim: More than one billion people are suffering malnutrition. Food and nutrition security have deteriorated and reductions in child malnutrition are proceeding too slowly to meet the Millennium Development Goal (MDG) target of halving hunger by 2015. Three major challenges threaten current and future efforts to overcome food and nutrition insecurity: climate change, the growing use of food crops as a source of fuel and the soaring food prices.
Methods: The analysis of the impacts of climate change of climate change and bioenergy on health, food and nutrition security is based on the four-dimensional food security framework defined by FAO's Food Insecurity and Vulnerability Information and Mapping Systems (FIVIMS) combined with a nutrition security framework which includes environmental health, house hold food access and maternal and child care practices. The paper provides a cross sectoral analysis of the adaptation strategies and policies to address climate change and bioenergy challenges.
Results: Climate change is projected to affect the health status of millions of people through increases in malnutrition. Climate change and variability exacerbates climate-sensitive impediments to sustainable development faced by developing countries particularly in Africa and SE Asia. Two case studies in Ethiopia and Bangladesh suggest that to address these challenges requires integrated approaches for adaptation, mitigation and sustainable development. Strategies include measures that would simultaneously reduce pressures on biodiversity and food and nutrition security and contribute to carbon sequestration.
Conclusion: Agriculture, health, and nutrition security policies need to be integrated onto national and international climate change agendas, in order to devise effective and pro-poor policies.
Efforts to improve food and nutrition security in the face of challenges, including climate change and bioenergy production should to place the achievement of the MDGs at the centre of human endeavour. In particular, it remains essential to accelerate progress in reducing poverty and malnutrition while protecting the environment in Sub-Saharan Africa and SE Asia.

CLIMATE CHANGE AND "ONE HEALTH": A CASE STUDY IN CALIFORNIA's GREEN ECONOMY

Tirado von der Pahlen M, *University of California-Los Angeles School of Public Health, Los Angeles, CA,, USA - Public Health Institute, Center for Public Health and Climate Change, Oakland, CA, USA*
Dora C, *World Health Organization, Geneva, Switzerland.*
Fletcher E, *World Health Organization, Geneva, Switzerland.*
Salsburg R, *Public Health Institute, Center for Public Health and Climate Change, Oakland, CA, USA*

Background/Aim : Climate Change has an impact on critical components of "One Health" such as human health, animal health, plant health and environmental health. Climate and environmental change also affects socio-economic determinants of "One Health" such as development, demographics, agriculture, animal production, global trade, food prices, poverty etc. The study aims to provide an analysis of the impacts of climate change on "One Health" and identify adaptation and mitigation strategies to address these impacts.
Methods: The analysis of the impacts of climate change and variability on "One Health" integrates the WHO Health Impact Assessment methodology with the FAO Biosecurity framework which includes human health (food safety), animal health, plant health and environmental health. The study provides a cross-sectoral analysis of the adaptation and mitigation strategies and policies to address climate change and variability challenges to "One Health" focusing in a case study in California's green economy.
Results: There are multiple pathways through which climate change may impact "One Health" including: changes in temperature and precipitation patterns, increased frequency and intensity of extreme weather events, ocean warming and acidification, changes in complex contaminants' transport pathways, and socio-economic and demographic factors among others. To address the challenges of climate change and variability to One Health is complex and requires trade-offs in a green economy framework. The case study in California addressing agriculture and environment sectors in show that decisions made in the agricultural sector impact environment, health and social factors and that health impact assessments are critical for policy change.
Conclusion: To address the impacts of climate and environmental change One Health in a green economy it is necessary to develop inter-sectoral adaptation and mitigation strategies that are integrated in resilient climate development plans. Approaches such as health promoting agriculture policies and green chemistry are critical to mainstream health across sectors in California's green economy. In this context health impact assessments facilitate decision-making and policy changes in a green economy since address socio-economic and development aspects.

NEIGHBORHOOD PERCEPTIONS, ACCESS TO RESOURCES AND PSYCOSOCIAL INFLUENCES ON PHYSICAL ACTIVITY: OPPORTUNITIES FOR IMPROVING THE BUILT ENVIRONMENT

Kristen Malecki, *University of Wisconsin, Madison, Department of Population Health Sciences, Middleton, USA*
Marjory Givens, *University of Wisconsin, Madison Department of Population Health Sciences, USA*
Matt Walsh, *University of Wisconsin, Madison Department of Population Health Sciences, USA*
Julstin Lo, *University of Wisconsin, Madison Department of Population Health Sciences, USA*
Nieto, *University of Wisconsin, Madison Department of Population Health Sciences, USA*

Background and Aims:
Physical activity can play an important role in prevention and management of disease. Many previous studies have looked at the role of the built environment in increasing physical activity but fewer studies have looked at psychosocial determinants and their relationship to physical activity levels. The goal of this study was to examine psychosocial influences on individual perceptions of neighborhood characteristics and resources within walking distance on physical activity levels in a general population sample.
Methods: The Survey of the Health of Wisconsin (SHOW) is an annual survey of representative samples of adult (21-74 years old) residents in Wisconsin. Modeled after the National Health and Nutrition Exam survey SHOW provides a unique opportunity to conduct multi-level assessments of the built environments impact on physical activity and chronic disease. Households are selected using two-stage cluster sampling; recruitment and initial interviews are done at the household; additional interviews and physical exams (including collection of blood samples) are conducted at permanent or mobile examination centers. Between 2008 and 2010, 1,550 participants have been recruited. Households are geocoded and linked with contextual data including objective audits of the social and built environment.
Results: Positive neighborhood resources are more predictive of physical activity than individual's perception of their neighborhoods as a place to be physically active. Depression, age and obesity modify these relationships. The percentage of SHOW participants reporting some physical activity compared to no physical activity is significantly greater when individuals report having interesting destinations within easy walking access. An estimated 86% report some physical activity when living within less than a 20 minute walk of a park. Similar trends are seen for recreational facilities, walking trails, and elementary schools.
Conclusions: Despite individual perceptions and mental health, increasing neighborhood resources within short walking distances may provide important opportunities to increase physical activity.

EXPOSURE MISCLASSIFICATION BIAS IN ENVIRONMENTAL EPIDEMIOLOGY: WITHIN-HOUSEHOLD RESPONSE CONCORDANCE ON HOUSEHOLD CHARACTERISTICS IN THE 2008-2010 SURVEY OF THE HEALTH OF WISCONSIN (SHOW)

Kristen Malecki, *University of Wisconsin, Madison, Department of Population Health Sciences, Middleton*
Justin Lo, *University of Wisconsin, Madison Department of Population Health Sciences*
Matt Walsh, *University of Wisconsin, Madison Department of Population Health Sciences*
Paul Peppard, *University of Wisconsin, Madison Department of Population Health Sciences*
F. Javier Nieto, *University of Wisconsin, Madison Department of Population Health Sciences*

Background and Aims: Environmental exposure assessment often relies on survey data which can lend itself to misclassification and recall bias that can lead to null associations and unreliable exposure estimates. Large-scale studies such as NHANES randomly choose one participant from each household to obtain information about characteristics of that home. It is assumed that the answers given to basic household characteristic affecting health outcomes would be the same for all residents from that household. The goal of this study was to test the assumption to estimate the extent this leads to discrepant exposure and risk estimates..

Methods: In the SHOW study, the same household characteristic questionnaire was administered to multiple respondents within each household, allowing for analysis of variations in response patterns. The SHOW study consists of a series of annual surveys gathering health-related data on a representative sample of Wisconsin residents age 21-74. A total of 1,043 households have been enrolled in SHOW; of these, 494 households had two or more respondents.

Results: For this analysis, we focused on the following household characteristics (percent discrepant between respondents within household): report of peeling paint outside the house (24.6%), recent indoor pesticide use (21.6%), past radon testing (21.4%), black grout or caulk (19.4%), use of water filtration system (19.2%), mildew or mold odors (19.1%), outdoor weed killer/insecticide use (18.0%), water stains on walls or ceilings (17.4%), household smoking policy (16.1%), peeling paint in the home (13.4%), and source of water supply (4.0%).

Conclusions: Preliminary analysis indicates that agreement within households may be associated with concordance of individual education (p-value=0.03) and income levels (p-value=0.04) among respondents. For studies designed to look at household characteristics, these results indicate the need to rely on more than one respondent or the potential benefit of external verification of responses to improve exposure estimates.

Abstract ISSE2011, Barcelona

BICYCLIST BLACK CARBON EXPOSURE AND THE IMPACT OF ROUTES CHOICE AND BIKING FACILITIES, A SPATIAL ANALYSIS

Luc Dekoninck, Ghent University, department of Information Technology, St-Pietersnieuwstraat 41, 9000 Ghent, Belgium

Prof. dr. Ir Dick Botteldooren, Ghent University, department of Information Technology, St-Pietersnieuwstraat 41, 9000 Ghent, Belgium

Luc Int Panis, Flemish Institute for Technological Research (VITO), Boeretang 200, Mol, Belgium and Transportation Research Institute Hasselt University, Wetenschapspark 5 bus 6, Diepenbeek, Belgium

Background and Aims: Personal exposure to Black Carbon is strongly related to activity pattern and more specifically linked to the time spent in traffic related micro-environments. Enhancing bicycle use is a popular policy measure but has a risk of increasing exposure to air pollution.

Methods: A mobile measurement campaign was set up in the city of Ghent, Flanders to explore the spatial and temporal variability of Black Carbon (BC) exposure for bicyclists in urban and suburban areas. More than 100 commuting trips (>= 8 km)were cycled while carrying a micro-aethalometer over a time span of several months.

Results: The focus of the study is on the spatial and temporal variability of BC exposure and we investigate how the variation relates to geographic, meteorological and local traffic volume parameters. This analysis allowed showing that the exposure to BC can be significantly different when specific cycling facilities are used. Although, during the lowest exposure parts of the individual trips, a significant contribution from background concentrations as observed by the national air pollution monitoring network could be shown, our results clearly indicate that local sources are rather important and thus a cyclist can affect its exposure by careful route choice. Of particular interest are BC concentrations in the vicinity of highways where an influence of wind direction and screening by buildings and noise barriers was observed. Increased BC concentrations are also observed while passing through street canyons with high traffic loads, as expected.

Conclusions: The spatial and temporal evaluations are used to identify the potential relevant geographic parameters to build a general exposure model for bicyclists. In most cases stronger variations were found for the black carbon than was expected from known spatial variations of UFP en PM2.5.A geo-statistical analysis is performed to support these preliminary findings.

THE EFFECT O F STATINS ON HOSPITALIZATION OF SUBJECTS WITH INFLUENZA A H1N1: CASE-CONTROL POPULATION BASESTUDY FROM MEXICO

Juan Manuel Mejía –Aranguré, César Gonzalez-Bonilla, Santiago Echavarria-Zuno, Alvaro Mar-Obeso, Concepción Grajales-Muñiz, Victor Borja-Aburto. juan.mejiaa@imss.gob.mx *Instituto Mexicano del Seguro Social, México*

Background and Aims. To assess the effect of consumption of statins in hospitalization of subjects with influenza A H1N1.

Methods. The study included patients with diagnostic of pandemic influenza A H1N1 (pH1N1), who were diagnosed with the disease during the pandemic (July 2009-September 2009) in the Mexican Institute of the Social Security. During this period there were 4233 cases with pH1N1. The cases were all the inpatient subjects above 18 years old for pH1N1 (N=604). The controls were outpatient subjects higher than 18 years old with diagnostic of pH1N1 (N=1812), the controls were matched by state of residence. For this report we just had information of 383 cases and 727 controls. A questionnaire where information about consumption of atorvastatin, simvastatin, pravastatin, lovastatin, rosuvastatin, fluvastatin, cerivastatin and bezafibrate was included; pregnancy and chronic diseases were included too. The logistic regression was realized, odds ratio (OR) with 95% confidence intervals (95%CI) were reported.

Results. The frequency of consumption of pravastatin was of 2.1% and 2.2% for benzafibrate, the others statins had a frequency below of 0.5%. The effect on hospitalization for pH1N1 of pravastatine was of 0.24 (95% CI 0.03,1.97), to bezafibrate was of 0.47 (95% CI 0.06,3.40). The pregnant women had a risk of hospitalization for pH1N1 of 2.91 (95% CI 1.25,6.81) and the subjects with diabetes had a risk of 3.33 (95% CI 1.42, 7.83).

Conclusions These are preliminary results but the consumption of pravastatin and/or bezafibrate would prevent the hospitalization in infected subject for the pH1N1. The project was supported by the Fondo Sectorial de Investigacion en Salud CONACYT.

INTERACTION BETWEEN THE SUSCEPTIBILITY TO DEVELOP ACUTE LEUKEMIA IN CHILDREN AND PATERNAL SMOKING

Juan Manuel Mejia-Arangure, Maria Luisa Perez-Saldivar, Janet Flores, Roberto Bernaldez, María de los A del Campo, Aurora Medina, Miguel A Palomo, Rogelio Paredes, Armando Martínez, Ma Carmen Rodriguez, Jesús Zarco, Roberto Rivera, Hilario Flores, Clara Gorodezky, Fabio Salamanca and Arturo Fajardo-Gutiérrez. (juan.mejiaa@imss.gob.mx; Instituto Mexicano del Seguro Social, Mexico).

Background and Aims. It has been suggested that acute leukemia (AL) can be the result of the interaction between inherited susceptibility to the disease and exposure to different carcinogenic factors. The present study evaluates the interaction between the susceptibility to develop acute leukemia and paternal smoking as a risk factor.
Methods. A Case-control study with selection by the susceptibility was realized; we had two types of cases and controls: 47 children with Down syndrome (DS) and AL who are known to be highly susceptible to develop AL, 423 children with AL without DS from the same population-base, a group of 207 children with DS without AL, and another group of children neither AL nor DS. The interaction was assessed with logistic regression. The results were adjusted by different variables. In our data there was not interaction between susceptibility for developing AL and paternal smoking.
Results. The paternal smoking prior to the conception had an odds ratio (OR) of 5.9 (95% confidence interval, CI, 2.3, 15.8) when entire population was analyzed. In the population with DS the OR was 0.8 (0.4, 1.7) and in the group without SD was 5.4 (1.9, 15.1). With the postnatal paternal smoking the ORs were 2.6 (1.1, 6.5), 0.4 (0.2, 0.8) and 2.6 (1.1, 6.43), for entire population, children with DS and children without DS, respectively.
Conclusions. The results did not show an interaction between the susceptibility for developing AL and paternal smoking. However the risks for paternal smoking before and after the conception were very high in the population without DS. The project was supported by the Fondo Sectorial de Investigacion en Salud CONACYT.

RIESGO DE DESARROLLAR LEUCEMIA AGUDA. INTERACCIÓN ENTRE EL TABAQUISMO DE LOS PADRES Y LA SUSCEPTIBILIDAD A LA ENFERMEDAD. UN MODELO PARA EVALUAR LAS CAUSAS DE LA LEUCEMIA EN NIÑOS. Mejia-Arangure JM, Perez-Saldivar ML, Flores J, Bernaldez R, del Campo MA, Medina A, Palomo MA, Paredes R, Martínez A, Borja VH, Rodriguez MJ, Vargas VM, Zarco J, Rivera R, Flores H, Gorodezky C, Salamanca F and Fajardo-Gutiérrez A. Hospital de Pediatría, Instituto Mexicano del Seguro Social, México, D.F., México.

INTRODUCCION. Se ha sugerido que la leucemia aguda (LA) en los niños es el resultado de la interacción entre la susceptibilidad a la enfermedad y la exposición a diferentes factores cancerígenos.

OBJETIVO. Evaluar la interacción entre la susceptibilidad a desarrollar leucemia aguda y el tabaquismo de los padres como un factor de riesgo.

MATERIAL Y METODOS. Se hizo un estudio de casos y controles seleccionados por la susceptibilidad. Se tuvieron dos tipos de casos y dos tipos de controles: 47 niños con síndrome de Down (SD) y LA que son niños con una susceptibilidad elevada para desarrollar LA, 423 niños con LA y sin SD de la misma base poblacional. Un grupo de 207 niños con SD sin LA y otro grupo de niños sin LA ni SD. La interacción fue evaluada a través de un modelo de regresión logística y los resultados fueron ajustados por diferentes variables potencialmente confusoras.

RESULTADOS. No se encontró interacción entre la susceptibilidad a la leucemia y el tabaquismo de los padres. El tabaquismo paterno previo a la concepción tuvo una razón de momios (RM) de 5.9 (Intervalo de Confianza 95% de 2.3 a 15.8) cuando fue evaluada toda la población. En la población con SD la RM fue de 0.8 (0.4-1.7) y en el grupo sin SD fue de 5.4 (1.9-15.1). Con el tabaquismo post natal la RM fue de 2.6 (1.1-6.5), 0.4 (0.2-0.8) y 2.6 (1.1-6.43) para la población total, los niños con SD y los niños sin SD, respectivamente.

CONCLUSION. Los resultados no mostraron una interacción para desarrollar LA entre la susceptibilidad a la enfermedad y la exposición paterna al tabaco. Sin embargo los riesgos para el tabaquismo paterno antes y después de la concepción fueron muy elevados entre los niños sin SD.

BIOMASS BURNING CONTRIBUTIONS TO URBAN AEROSOLS IN A COASTAL MEDITERRANEAN CITY

Background and Aims: Carbonaceous matter is a major constituent (up to 80%) of atmospheric aerosols in urban areas (Rogee at al., 1993; Pakkanen et al., 2000; Harrison et al., 2004) so that understanding the sources of such material is highly relevant to particulate matter (PM) control strategies. Biomass combustion is one of the main sources, both controlled and from wildfires. Therefore, the objective of the work is to investigate the concentrations in ambient air of biomass combustion tracers, such as levoglucosan, in the urban environment of a south European city, Barcelona (Spain), firstly to check if concentrations are large enough to be analysed, then to compare them with values obtained in urban environments in other geographical areas and, finally, to quantify the contribution of biomass burning to PM levels.
Methods: Measurements were carried out at an urban background monitoring site located in Barcelona (Spain) in the framework of the international DAURE campaign (winter 2009). The biomass burning impact to PM levels was quantified by means of levoglucosan, K^+ and OC concentrations and the receptor model Multilinear Engine 2 (ME-2) introducing the following constraints: upper limits for ammonium and K^+, a lower limit for OC and a target OC/levoglucosan ratio of 6.1±0.3.
Results: The significant correlation between levoglucosan and OC (r^2= 0.77) and K^+ (r^2=0.65), as well as a marked day/night variability of the levoglucosan levels during the DAURE campaign were indicative of the contribution of biomass burning emissions from around Barcelona during night-time for heating purposes (3±1% of $PM_{2.5}$ aerosols). In addition, on specific days (21-22th March), the contribution from regional or long-range transported biomass burning aerosols was detected (6±1% of $PM_{2.5}$). The model Multilinear Engine-2 allowed quantifying the contribution of this source on an annual basis, it accounted for 3% of PM_{10} and 5% of $PM_{2.5}$ and PM_1 in 2009.
Conclusions: The biomass burning impact was detected at an urban background site in Barcelona despite the complexity of the source mixture affecting the air quality of the city, characterised by notable primary and secondary traffic emissions. Two main emissions sources were identified: domestic emissions from heating and regional transported aerosols from forest or agricultural fires. The contribution of biomass burning to PM_{10}, $PM_{2.5}$ and PM_1 levels in winter was much lower than in urban environments in north and central European regions, indicating that heating habits differ widely among EU regions.

COMPLICATIONS OF LABOR AND DELIVERY AMONG US WOMEN WITH ASTHMA, CONSORTIUM ON SAFE LABOR

Pauline Mendola 1, S. Katherine Laughon 1, Una Grew al 1, Jun Zhang 2

1. *Eunice Kennedy Shriver* National Institute for Child Health and Human Development, 6100 Executive Blvd, Rockville, MD 20852, USA.
2. MOE and Shanghai Key Laboratory of Children's Environmental Health, Xinhua Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China

Background/Aims: Pregnant women with asthma may be at particular risk from air pollution exposures because poor pregnancy and infant outcomes have been independently associated with maternal asthma and with air pollutant exposure. We describe the labor and delivery complications from a US nationwide study, the Consortium on Safe Labor and assess differences between women with asthma and those without asthma.

Methods: The Consortium on Safe Labor (CSL) included 12 US clinical centers with a geographic distribution that will allow future analysis of air quality in relation to birth outcomes. A total of 228,668 deliveries with 233,844 newborns between 2002 and 2008 were included in the study. Extensive electronic medical record data on maternal and newborn information was captured. This preliminary analysis is based on the first delivery from each woman in the study (n= 206,969) and we examine the characteristics and labor and delivery complications of women with asthma compared to women without asthma.

Results: In the CSL, 13,716 women (6.6%) had a history of asthma noted in their medical records and 8,305 (4%) had asthma during the prenatal period. Preliminary findings show that women with asthma during pregnancy were more often Non-Hispanic Black or White than other race/ethnicities, generally younger, not married, and had public insurance. No differences in parity were observed. Behavioral and medical risk factors (smoking, alcohol use, obesity, diabetes, hypertension) were all more common among asthmatics. Asthmatic women were more likely to experience preeclampsia (4.3% vs. 3.3%), and less likely to have spontaneous labor (58.7% vs. 60.8%). Infants born to asthmatic mothers were more likely to weigh <2500 grams (12.8% vs. 9.3%).

Conclusions: Preliminary results suggest pregnant women with asthma may constitute a particularly vulnerable subpopulation and further research on the impact of air quality in relation to pregnancy and infant outcomes of asthmatic women is needed.

The role of non-governmental organizations in promoting occupational and environmental carcinogen regulation

Lisette van Vliet, PhD, *Toxics Policy Advisor, Health and Environmental Alliance*

In Europe an estimated 1 in 3 are diagnosed with cancer, and 1 in four will die from cancer. As the overall incidence seems to continue to rise, the contribution of environmental regulations towards cancer prevention becomes increasingly important. Experts recently meeting under the auspices of the World Health Organisation declared that a substantial percentage of all cancers are caused by environmental and occupational exposures, and that primary prevention of such exposures is the single most effective means to prevent cancer.

In the European Union, there is a complicated range of environmental laws and policies that address and control the uses of cancer-related chemicals: the most notable being chemicals (REACH), pesticides and workers protection laws. Others include biocides, outdoor air quality, water quality, toys, cosmetics, and food contact materials.

This talk covers how public interest organisations in general, and the Health and Environment Alliance in particular, work to improve cancer prevention: strengthening the formulation and application of environmental policies by highlighting important science to policy makers at appropriate junctures; running public awareness campaigns to engage citizens and affected groups; and identifying opportunities for policy revisions that can bolster prevention. For example, during the revision of the EU pesticides laws NGOs pointed to the increasing body of evidence on pesticides' impact on vulnerable groups, and insisted on the need to address endocrine disrupting chemicals.
How do NGOs work on the vaunted EU chemicals legislation REACH, what are our experiences so far?
What is the role of NGOs in the new Pesticides laws, with its high water marks prohibiting cancer-related chemicals?
How do NGOs use the epidemiological evidence to initiate and reinforce the policies?
How does Europe fare from an NGO perspective, and what are the main challenges both in particular policy areas, and in horizontal matters?

Doll and Peto Revisited: current knowledge about occupational and environmental causes of cancer

Manolis Kogevinas, *Centre for Research in Environmental Epidemiology, Barcelona, Spain*

In 1981 Doll & Peto provided the most comprehensive, at that time, estimates on the causes of cancer. Occupational exposures were estimated to produce around 4% of all cancers and environmental around 3%. Research in occupational and particularly environmental causes of cancer has dramatically expanded since then. At the same time, exposures were modified: many classical occupational carcinogens were controlled in industrialised countries; others were simply transferred to developing countries, while new exposures occurred. Half of today's recognized occupational carcinogens (IARC group 1) were already recognized as such by 1964; by contrast, > 95% of today's probable and possible occupational carcinogens were not even mentioned in the mid1960s, and about one-third were not mentioned as of 1987. A recent evaluation on occupational carcinogens in the UK provided a similar proportion as that suggested 25 years earlier. Estimates by the WHO on environmental cancer are slightly higher now, compared to those estimated by Doll & Peto. Exposure assessment is among the most important issues today in research on environmental and occupational cancer and should be regarded as the "Achilles heel" for research. Existing cohort studies may not be appropriate for future research that will depend heavily on the use of modern technological approaches such as satellite imaging, GIS, remote sensing and extensive use of biomarkers. The extent to which the use of "omic" technologies will help identify more environmental carcinogens and provide better estimates, is still uncertain. The emerging research model in environmental epidemiology is multidisciplinary, possibly focused more on cross-sectional and prospective cohorts and broadly collaborative.

Role of the ISEE in Evaluating Scientific Evidence and Making Policy Recommendations

Dean Baker, MD, MPH; *Professor and Director*, *Center for Occupational and Environmental Health, University of California, Irvine, USA*

Background: Environmental epidemiology has made major contributions to the scientific basis for establishing environmental health policies. However, the role of epidemiology is less clear as governments and international organizations have given greater emphasis to precautionary, preventive oriented approaches to replace current reactionary approaches to environmental health policy. The ISEE is an international professional society with members from more than 50 countries. The ISEE Executive Council undertook a process to evaluate whether the Society should form a Policy Committee and to determine the mission and scope of such a committee.
Methods: The ISEE Executive Council established an *ad hoc* policy planning committee that recommended the formation of a standing Policy Committee and the conduct of a membership survey to clarify the standing committee's mission and scope. An online membership survey was administered in 2011 that contained questions on policy issues.
Results: This presentation will provide a summary of the *ad hoc* policy committee report and the findings of the membership survey. 394 ISEE members responded to the survey out of 895 current members. There was clear support – "strongly agree" or "agree" – that the ISEE should establish a Policy Committee (67%), that ISEE has a role to play in proactively identifying important policy issues (87%), and that the Policy Committee should provide policy makers and the public with expert opinion on scientific questions (83%). There was less consensus on whether ISEE policies should focus only on issues related to the professional practice of environmental epidemiology (45%) versus those wanting a larger scope (32%) and whether the ISEE should take positions on specific laws and regulations (31%) versus only taking general positions on scientific issues (46%).
Conclusions: The ISEE membership strongly endorsed establishing a Policy Committee, taking policy positions on the professional practice of environmental epidemiology and providing expert opinion on scientific questions related to environmental epidemiology.

Introduction and description of REACH and U.S. President's Cancer Panel

Clapp R, *Boston University and University of Massachusetts - Lowell, USA*

Background: A new approach to regulating chemicals in commerce, called Registration, Evaluation, Authorization and Restriction of Chemical Substances (REACH), was developed in the European Union and adopted in 2007. Its provisions require that chemical manufacturers provide more information to the European Chemicals Agency about health risks and environmental effects than previously required. Certain substances "of very high concern" such as persistent bioaccumulative toxicants, are ultimately to be phased out but will in the interim go through a stringent control and permission process. Certain types of high concern substances will only be permitted if there are no feasible alternatives and overwhelming socio-economic reasons. The U.S. President's Cancer Panel report released in May 2010 reviewed information about occupational and environmental carcinogenic exposures provided by scientists over the period 2008-2009. The Panel and staff identified numerous deficiencies in current U.S. policies and recommended a new regulatory approach that would be more precautionary and prevention oriented. This report received considerable media attention and drew both criticism and praise from a range of U.S. cancer prevention advocates, scientists and organizations. The ISEE was asked to endorse the report in Summer 2010, but currently does not have a mechanism for doing this.
Methods: The European Commission's Environment Department assessed the health impacts and costs to industry of the REACH program. In a 2003 report, the EC projected costs of between 2.8 and 5.2 billion Euros over an eleven to fifteen year implementation period. Health benefits were estimated at 50 billion Euros over the next thirty years. In the U.S., literature on occupational and environmental causes of cancer was reviewed and presented to the President's Cancer Panel by several ISEE members. An eight-page summary table was included as an Appendix to the Panel's 2010 report and will be described.
Results: REACH regulations have gradually been implemented and have made substantial impact on European and North American chemical manufacturers. In 2011, six substances of very high concern were listed as candidates for phase-out. The U.S. President's Cancer Panel report has been cited in support of new chemicals policy legislation, the Safe Chemicals Act of 2011.
Conclusion: Important public health regulations in the EU and proposed legislation in the U.S. have benefited from environmental health and epidemiologic research. ISEE can play a more active organizational role in support of such policies. Endorsement of the U.S. President's Cancer Panel 2010 report should be considered in this context.

The President's Cancer Panel report and future research needs

Francine Laden, *Associate Professor of Environmental Epidemiology, Harvard School of Public Health, Boston MA USA*
Mark Winkler, *Associate Professor of Environmental Epidemiology, Harvard School of Public Health, Boston MA USA*
Catherine Winkler, *Associate Professor of Environmental Epidemiology, Harvard School of Public Health, Boston MA USA*

The US Presidents Cancer Panel is an advisory committee originally established by the National Cancer Act of 1971, charged with reporting to the President on important issues on cancer. In 2010 the current panel, consisting of 2 scientists published the 2008-2009 annual report, focusing specifically on environmental cancer risk, based on testimony from 45 representatives of academia, government, industry, the environmental and cancer advocacy communities and the general public. The overall conclusion from this report was that we do not understand enough about the environmental origins of cancer and that the precautionary principle needs to be employed more when considering the introduction of new chemicals into the general population. They also emphasized the need for more focus on vulnerable populations and periods of life such as *in utero* and early childhood. In this talk I will give an overview of the major findings and conclusions from this report, as well as some of the discussion that followed in the scientific and lay literature after its publication. Specifically, in the context of what we already do know, I will present the environmental risks deemed by the council to be important for further study and their suggestions about future research and policy needs. I will also discuss some of the challenges in studying the environment and cancer, emphasizing the need for new developments in exposure assessment.

HEALTH EFFECTS OF THE LACK OF ORGANIZED WASTE DISPOSAL IN UNRECOGNIZED BEDOUIN VILLAGES IN THE NEGEV AREA OF ISRAEL – IMPLICATIONS FROM MULTI-METHOD STUDIES OF HEALTH STATUS AND WASTE DISPOSAL PATTERNS

Julie Cwikel, *The Center for Women's Health Studies and Promotion, Ben Gurion University of the Negev, Beer Sheva, Israel*,
Ilana Meallem, *Man in the Desert, Social Science Unit, Jacob Blaustein Institute for Desert Research, Sde Boker Campus, Ben Gurion University of the Negev, Israel*
Yaakov Garb, *Man in the Desert, Social Science Unit, Jacob Blaustein Institute for Desert Research, Sde Boker Campus, Ben Gurion University of the Negev, Israel*

Background and aims: The Bedouin of the Negev region of Israel are a formerly nomadic, indigenous, ethnic minority, of which 40% currently live in unrecognized villages without organized, solid waste disposal.
Methods: Findings from two studies, using both quantitative and qualitative methods, explored the health effects of transition from traditional rubbish production and disposal to current uses, the current composition of rubbish, methods of waste disposal, and the extent of exposure to waste-related environmental hazards among Bedouin women of the Negev. The first study based on personal interviews (N=202) and was compared to a comparable survey among Jewish women from the Negev (N=526). The second study was carried out over 6 months in the village of Um Batim and included observations, waste documentation, GSI mapping and personal interviews (N=58).
Results: Bedouin women reported higher rates of urinary tract infections (52.5% vs. 13.9), gynecological problems (18.7% vs. 14.7%), and asthma or respiratory tract infections (13.8% vs. 8.0%) than Jewish women reported. The modern, consumer lifestyle produced both residential, animal and construction waste which was dumped very close to households (range 3-65 meters, average 33). Waste was tended to by women who predominantly used backyard burning for disposal (79%), exposing villagers, predominantly women and children to corrosive, poisonous and dangerously flammable items at these burn sites. Village residents expressed a high level of concern over environmental hazards, yet no organized waste disposal or environmental hazards reduction was implemented.
Conclusions: Excess reported morbidity may be related to exposure to backyard burning of household and animal waste. More direct measurement of exposure to toxins from backyard burning is recommended to validate the exposure-morbidity axis. An on-going program to train women environmental activists and to introduce biogas digesters to handle animal and household organic waste hopes to provide partial solutions to the observed environmental health problems.

AN APPROACH TO MULTI-POLLUTANT ACCOUNTABILITY RESEARCH USING PRINCIPAL STRATIFICATION

Corwin Ziegler, *Harvard School of Public Health, USA*
Francesca Dominici, *Harvard School of Public Health, USA*

Air quality regulations are typically enacted with the goal of improving public health, and large-scale regulations that reduce ambient air pollution are often accompanied by improvements in mortality and morbidity. However, whether observed improvements in health are due to a regulation or to concurrent trends in other risk factors often remains uncertain. Quantifying health effects of actions taken to improve air quality, also known as accountability research, is challenging for large-scale efforts meant to improve air quality and health over a long period of time and over large geographical areas.

In this talk we will introduce a potential-outcomes framework for accountability research that uses a Bayesian MCMC computational strategy. The approach stratifies areas based upon the estimated causal effect of an air quality regulation on ambient air pollution and assesses the causal effect of the regulation on health outcomes within these strata. As regulations may affect concentrations of many interrelated pollutants, we extend the use of principal stratification to a multi-pollutant approach that accommodates a multivariate intermediate response vector. Furthermore, we make use of recent advancements in hierarchical modeling for point-referenced spatial data to capitalize on information contained in the geographic locations of the pollution measurement sites.

Insofar as these methods rely on unobserved potential outcomes, they rely on assumptions regarding associations not identified based on observed data, indicating the importance of sensitivity analyses. We apply our method to examine whether the 1990 Clean Air Act Amendments causally affected Medicare mortality through affecting ambient concentrations of particulate matter and ozone.

EPIDEMIOLOGY AND AIR QUALITY STANDARDS

Bert Brunekreef, PhD
Professor of Environmental Epidemiology
Institute for Risk Assessment Sciences
Utrecht University, The Netherlands

Air quality standards have been driven by epidemiological evidence for a long time. This has the advantage that no extrapolations are needed from high to low dose, or from animal to human. The disadvantage is that, due to the observational nature of epidemiology, causality of associations between air pollution and ill health are sometimes difficult to establish. As a consequence, fierce debates sometimes erupt about the epidemiology database for regulation.

In the US and the EU, slightly different approaches to setting air quality standards are being used, and implementation of standards is also slightly different. In the presentation, air quality standards for NO_2 and airborne particulate matter will be compared, and the use of epidemiological data in support of standard setting will be highlighted.

MAINTAINING THE RELEVANCE OF EPIDEMIOLOGY: ADDRESSING THE FULL SCALE FROM EXPOSURE TO POLICY WITHIN AN INTERACTIVE ENVIRONMENT

Klea Katsouyanni, *University of Athens Medical School, Greece*
Evi Samoli, *University of Athens Medical School, Greece*
Antonis Analitis, *University of Athens Medical School, Greece*

The wide recognition of air pollution, either at higher or at medium-lower levels of concentrations, as one of the most important public health problems has been a result of extensive and complementary research and of effective communication with stakeholders and decision makers. Today we are faced with questions and challenges to provide better answers for management and preventive strategies which will maximize the benefits for public health worldwide. In exposure assessment, on the one hand looking into greater detail, we need to understand the role of specific particle chemical and physical characteristics for each health outcome. On the other hand, we need to assess the role of mixtures of pollutants and the contribution of sources. For the estimation of exposures in locations with minimal monitoring, the uses of new technologies are explored. Concerning the causality of the pollutant-health outcome associations, studies on the mechanisms of effect using biomarkers of exposure and early effects, as well as epigenetics, both for cancer and cardiovascular endpoints are employed. A very important item in the chain leading to health protection, is the best use of evidence for assessing costs and benefits to result in useful standard setting. In this respect, a view placing air pollution reduction benefits in a more global context involving other environmental factors (which may originate e.g. from the urban environment, from specific life styles, or be related to climate changes), taking advantage of established synergies or seeking to explore other interactions can become very advantageous.

SATELLITE-BASED $PM_{2.5}$ EXPOSURE ASSESSMENT AND ITS IMPLICATIONS FOR EPIDEMIOLOGICAL STUDIES

Hyung Joo Lee and Petros Koutrakis

School of Public Health, Harvard University, Boston MA, USA

Background and Aims: Satellite-based $PM_{2.5}$ air quality monitoring data has been used to complement ground $PM_{2.5}$ monitoring networks, especially for regions with sparsely distributed $PM_{2.5}$ monitors. This study developed a statistical method to predict daily $PM_{2.5}$ concentrations for both retrieval and non-retrieval days.

Methods: AOD data from 2003 MODIS and GOES was used to predict surface-level $PM_{2.5}$ concentrations based on a mixed effects model with random intercepts and slopes, allowing daily calibrations of $PM_{2.5}$-AOD relationships, in the New England region. The model using MODIS AOD was also applied to an extended study period (Years 2000-2008), using daily spatial patterns of $PM_{2.5}$ ground measurements to estimate $PM_{2.5}$ concentrations for non-retrieval days. This model for non-retrieval days took into account the temporal variability of regional $PM_{2.5}$ levels along with a spatial smoothing function of coordinates.

Results: The AOD-derived $PM_{2.5}$ concentrations were compared with the measured $PM_{2.5}$ concentrations, and both 2003 MODIS and GOES AOD predicted ground $PM_{2.5}$ concentrations quite well (CV R^2=0.92 for MODIS; CV R^2=0.89 for GOES). For the entire period of 2000-2008, this model presented high $PM_{2.5}$ predictability for both retrieval (CV R^2=0.88) and non-retrieval (R^2=0.81) days. The spatial pattern of $PM_{2.5}$ for 9 years overlapped quite well with mapping of dense population areas, major interstate highways, and high point emission sources.

Conclusions: This statistical model greatly improved the $PM_{2.5}$ predictability for both retrieval and non-retrieval days (compared to previous methods that did not use daily calibrations), and the predicted $PM_{2.5}$ concentrations may be reliably applied to epidemiological studies. Our study indicates that satellite-based $PM_{2.5}$ exposure assessment can reduce the exposure measurement error which is likely to occur for current epidemiological studies using sparse ground $PM_{2.5}$ monitoring networks.

GLOBAL AIR POLLUTION AND HEALTH: WHAT TO DO WITH NON-LINEAR EXPOSURE-RESPONSE RELATIONSHIPS?

Kirk R. Smith, University of California, Berkeley, USA

Modern epidemiologic studies of combustion particle exposures increasingly find that extreme non-linear exposure-response relationships best fit the data for many important health outcomes. Prominent among these are adult cardiovascular outcomes and child pneumonia, which together are probably responsible for half or more of the global burden of disease from the four major exposure categories – outdoor pollution, environmental tobacco smoke, household pollution from cooking, and active smoking. Although there are physiological mechanisms that could explain such non-linearity, the policy implications are far from clear. As an example, one implication of such non-linearity is that the health benefits of modest exposure reductions in relatively clean cities would be greater than the great changes in exposure that would result in moving smokers to non-smoking status. In addition, it implies that there are important and unexamined interactions among the particle exposure categories, for example for a women living with a smoking husband and cooking over an open fire in a slum of a polluted city. What part of her exposure is the most important? Or is it all equivalent? How do we think of policy strategies to maximize the cost-effectiveness of interventions under such non-linearity? And what are the equity considerations? These issues will be explored in the global context, where the total burden of disease from combustion particles is currently estimated at nearly 8 million premature deaths a year, greater by far than any other environmental risk factor.

BIOLOGICALLY DRIVEN APPROACHES TO THE STUDY OF AIR POLLUTION: THE EXAMPLE OF LUNG CANCER

Paolo Vineis and Christiana Demetriou, MRC-HPA Centre for Environment and Health, Imperial College, London UK

The association between ambient air pollution exposure and lung cancer risk has been evaluated in prospective studies and the results are generally consistent, indicating that long-term exposure to air pollution might be causally related to lung cancer. The contribution of intermediate biomarkers in epidemiological studies will be assessed in our presentation, to ascertain whether biomarkers can reinforce causal reasoning. Using online databases and manual references we have identified papers which evaluated the effects of ambient air pollution using biological measures of dose and/or effect. The cumulative evidence for each biological measure was assessed by us using the Venice criteria which rate a group of studies from A (strong) to C (weak) on amount of evidence, replication of findings, and protection from bias. We consider here biological measures that scored A or B for all three criteria. The biological measures that fulfilled these criteria are: 1-Hydroxypyrene, DNA adducts, chromosomal aberrations, micronuclei, oxidative damage to nucleobases, and methylation changes. These biological measures cover the whole spectrum of progression from external exposure to tumor formation, adding to the plausibility of a causal association between air pollution and lung cancer. As DNA adducts, chromosomal aberrations, micronuclei and 8-oxo-7,8-dihydro-2'-deoxyguanosine have been suggested to be predictive for future cancer risk in some studies, these results support causality of an association between air pollution and lung cancer risk. We will also present results of pilot studies on epigenetics in relation to air pollution, and will discuss the role of epigenetics in lung carcinogenesis.

Overview: emphasizing the critical knowledge gained from the Chernobyl experience

E. Cardis[1] and M. Hatch[2]

1 Centre for Research in Environmental Epidemiology (CREAL), Municipal Institute of Medical Research (IMIM), CIBERESP, Dr Aiguader 88, 08003 Barcelona, Spain, ecardis@creal.cat

2 Radiation Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Building EPS, MS 7238, Rockville, Maryland 20852, United States of America

Background and Aims - Twenty-five years have passed since radioactive releases from the Chernobyl nuclear accident led to exposure of millions of people in Europe. Studies of affected populations have provided important new data on the links between radiation and cancer – particularly the risk of thyroid tumours from exposure to iodine isotopes - that are important not only for a fuller scientific understanding of radiation effects, but also for radiation protection.

Methods – The presentation reviews the epidemiological evidence to date concerning cancer and non-cancer outcomes published in the peer-reviewed international literature and discusses the information which further, well-structured studies of specific exposed populations may provide for the quantification of radiation risks and the protection of persons exposed to low doses of radiation.

Results – It is now well-documented that children and adolescents exposed to radioiodines from Chernobyl fallout have a sizeable dose-related increase in thyroid cancer, with risk greatest in those youngest at exposure and with a suggestion that deficiency in stable iodine may increase the risk. Data on thyroid cancer risks to other age groups are somewhat less definitive. In addition, there have been reported increases in incidence and mortality from non-thyroid cancers and non-cancer endpoints. Although some studies are difficult to interpret because of methodological limitations, recent investigations of Chernobyl clean-up workers ("liquidators") have provided evidence of increased risks of leukaemia and other hematological malignancies and of cataracts, and suggestions of an increase in risk of cardiovascular diseases, following low doses and low dose rates of radiation.

Conclusions – Further careful follow-up of these populations, and the establishment and long-term support of life- span study cohorts, may continue to provide important information for the quantification of radiation risks and the protection of persons exposed to low doses of radiation.

INTELLECTUAL AND PSYCHOSOCIAL FUNCTIONING IN PERSONS EXPOSED IN UTERO TO CHERNOBYL FALLOUT IN BELARUS

Sergey A. Igumnov, M.D., Ph.D.

Belarusian Republican Research and Practical Center of Mental Health, 152, Dolginovsky tract, Minsk 220053, Belarus; tel/fax: +375 17 289 8048; e-mail: Sigumnov67@gmail.com

Background and Aims – Investigation of intellectual and psychosocial development of persons from Belarus exposed *in utero* to radiation following the Chernobyl accident in 1986. Antenatal exposure of the thyroid gland to radioiodine is one of the factors that might impact upon intellectual development.

Methods – Intellectual and psychosocial assessments were performed on 250 persons randomly selected from children exposed to Chernobyl fallout *in utero* recorded in the Belarusian Chernobyl State Registry and 250 controls similar in age drawn from settlements with ^{137}Cs soil levels indicating little radioactive contamination. The mean fetal thyroid doses from ^{131}I intakes by the mother were estimated to be ~ 400 mGy in the exposed group and 40 mGy among controls; mean fetal doses from external exposure were estimated at 10 mGy and 0.2 mGy respectively. Intellectual development was evaluated at ages 6–7, 10–12, and 15–16 years using the Wechsler Intelligence Scale for Children (WISC-III^{UK}) validated for use in adolescents. Psychosocial assessments were based on interviews with subjects and their parents. We used t-tests to analyze continuous variables and χ^2 tests for comparisons of proportions.

Results – At 6–7 years of age, the exposed group had a lower mean full-scale intelligent quotient (*IQ*) compared to controls (89.6±10.2 vs 92.1±10.5, P=0.007). Group differences at 10–12 years (94.3±10.4 vs 95.8±10.9) and 15–16 years (98.2±10.7 vs 99.5±10.5) were not significantly different. Inverse correlations were observed between prenatal exposure dose and *IQ* both for (i) ^{131}I: at 6–7 years (r =-0.11), at 10–12 years (r=-0.21), at 15–16 years (r=-0.29); and (ii) external irradiation: at 6–7 years (r=-0.14), at 10–12 years (r=-0.13), at 15–16 years (r=-0.19) but were not statistically significant. The exposed group had a higher incidence of developmental disorders of speech, language and motor function, and childhood-onset emotional disorders and disorders of social functioning.

Conclusions – Unfavorable social-psychological and social-cultural factors (low parental education level, adaptation difficulties following relocation from contaminated areas) proved to play a significant role in the genesis of borderline intellectual functioning and emotional disorders in *in utero* exposed persons.

Effects Of Exposure Later In Life: Cancer And Cardiovascular Disease Among Chernobyl Cleanup Workers From The Most Affected Countries

Marat Maksyutov[1], Victor K. Ivanov[1], Elisabeth Cardis[2] and Ausrele Kesminiene[3]

1 Medical Radiological Research Center (MRRC), 4 Korolyov street, 249036, Obninsk, Kaluga region, Russia; e-mail: nrer@obninsk.com

2 Centre for Research in Environmental Epidemiology (CREAL), Municipal Institute of Medical Research (IMIM), CIBERESP, Barcelona, Spain

3 International Agency for Research on Cancer (IARC), Lyon, France

Background and Aims. The current presentation summarizes results of studies of radiation risks among Chernobyl emergency workers (liquidators) conducted over the last 25 years and empahizes the importance of future follow-up of this cohort for radiation research.

Methods. Cohort and case-control studies of radiation risks, conducted among liquidators from Russia, Ukraine, Belarus and Baltic countries are reviewed.

Results. Two case-control studies with detailed individual dose reconstruction – one conducted in Belarus, the Russian Federation and the Baltic countries, and the other in Ukraine (in collaboration with the International Agency for Research on Cancer and the National Cancer Institute respectively) – reported similar estimates of leukaemia risk among Chernobyl liquidators: the ERRs for all leukaemia were 4.8/Gy (90% CI: n.d. – 33.1) and 3.44/Gy (95% CI: 0.47 - 9.78), in the IARC and NCI study, respectively. These are slightly higher but statistically compatible with those estimated from A-bomb survivors and recent low-dose-rate studies. A similar case-control study of thyroid cancer was also conducted in Belarus, the Russian Federation and the Baltic countries, suggesting an increased risk of thyroid cancer following low dose-rate exposures to external radiation and I-131 in adults. Follow-up of the cohort of Russian liquidators also suggested an increased risk of mortality from solid cancers ERR/Gy=0.74 (95% CI: 0.03; 1.76) and circulatory system diseases ERR/Gy=0.41 (95% CI: 0.02; 0.86).

Conclusions. Because of the size of the exposed populations (600-800 000 in total from all over the former USSR), the range of doses received, the possibility to obtain or reconstruct individual radiation dose estimates for a large proportion of the population, liquidators cohorts are particularly suited to improve our knowledge on effects of radiation received at low doses and dose rates, thus providing evidence to assess the adequacy of current basis for international radiation protection guidelines.

RESULTS OF UKRAINIAN-AMERICAN PROJECT FOR THE STUDY OF THYROID CANCER IN COHORT EXPOSED TO CHERNOBYL FALLOUT AS CHILDREN OR ADOLESCENTS

[†]Vyshgorodska 69, Kyiv 04114, Ukraine; tel: +(38044) 430-36-94; fax: (38044) 428-19-96; e-mail: m.d.tronko@dccie.kiev.ua

Background and aims – As a result of the accident at the Chernobyl Nuclear Power Plant, millions of residents of Belarus, Russia and Ukraine were exposed to significant doses of radioactive iodine isotopes, mainly I-131. The purpose of the Ukraine-American Thyroid Project is to quantify the risk of thyroid cancer and other thyroid diseases in the framework of a classical cohort study, comprising subjects who were aged up to 18 years at the moment of the accident, had direct measurements of thyroid I-131 activity taken within two months after the accident, and were resident in three heavily contaminated northern regions of Ukraine (Zhytomyr, Kyiv, and Chernihiv oblasts).
Methods - Four two-year screening cycles have been implemented: 13,243 subjects were screened in cycle 1 (1998-2000); 12,419 (93.8%) in cycle 2 (2001-2002); 11,745 (88.7%) in cycle 3 (2003-2004); and 10,186 (76.9%) in cycle 4 of screening. A standardized procedure of clinical examinations included: thyroid palpation, ultrasound examination, blood collection followed by a determination of thyroid hormone levels, urinary iodine content test, and, if indicated, fine needle aspiration. Individual I-131 doses on cohort member's thyroid were assessed from I-131 activity measurement in the subject's thyroid and extended dosimetry interview data (mean dose = 0,79 Gy; dose range - 0 to 40 Gy).
Results - 45 prevalent cases of thyroid carcinoma have been detected in cycle 1 of screening. Thyroid cancer risk based on the first cycle of screening demonstrated a strong approximately linear relationship with the individual thyroid exposure dose ($p < 0.01$); the ERR was estimated to be 5.25 (95% CI: 1.70, 27.5) per Gy. Also, an analysis has been completed, of 65 incident cases of thyroid cancer diagnosed during the screening cycles 2 - 4, and about 73,000 persons/years of observation. The dose dependence was consistent with both linear model of excessive absolute risk (EAR), and that of excessive relative risk (ERR). EAR per 10^4 PY per Gy was estimated to be 2.21 (95% CI: 0.04 - 5.78) and ERR 1.91 per Gy (95% CI: 0.43 - 6.34).
Among 110 cases of thyroid cancer diagnosed in 1998-2008, papillary carcinomas were prevalent - 104 cases (94.5%); in addition, 5 cases (4.6%) of follicular adenoma and one case (4.6%) of medullary carcinoma were diagnosed.
Conclusions - The data obtained demonstrate that for a period of 20 years after the Chernobyl accident thyroid cancer risk still remains reliably significant, which is a weighty argument in favor of a further follow-up of cohort members of the Ukrainian-American Thyroid Project in order to ascertain the dose-effect relationship and determine the time pattern of risk.

Early Exposures and Later Effects in Life: Revisiting the Barker Hypothesis
Professor Brenda Eskenazi

We have all heard the adage that "children are not little adults" but what does it mean for *their* adulthood when fetuses and children become exposed to environmental pollutants. What are the long-term costs and consequences of early exposure? The often-cited Barker hypothesis, which is based on observations of adult cardiovascular disease being related to early life exposure to poor nutrition, will be revisited in terms of the effects of early life exposure to environmental pollutants. How can assessment of early life exposure be incorporated into studies of adult-onset disease?

Environmental Epidemiology in the Context of Translational Science: Lessons from Studies of Air Pollution and Cardiovascular Diseases

Professor Joel Kaufman

"Translational science" is typically conceived in the context of medical sciences: a bridge between basic research discoveries and clinical practice. The archetypal application is pharmaceutical development. This "bench-to-bedside" emphasis now prevails with funding agencies and academic institutions. The concept of translational science can be difficult to apply but is also important in the environmental health arena; instead of influencing treatment, the goals are beneficial interventions and relevant policymaking in the interest of improving public health. Environmental epidemiologists are well-placed to straddle the research-to-practice bridge, free of challenges facing most environmental health "bench" scientists—by avoiding the need to adjust results from animal models to humans and by directly examining exposure concentrations in relevant ranges--but challenges persist. Research over the past twenty years concerning the association between air pollution and cardiovascular disease provides a useful lens to consider the incorporation of translational science concepts into the framework of environmental epidemiology.

Environment and Cancer – research priorities

Professor Christopher Wild

The global burden of cancer is estimated to double in the next 20 years, with a majority of the increase occurring in the low and middle-income countries. These trends are in common with those for other non-communicable diseases, including cardiovascular disease and diabetes. Much could be achieved in terms of prevention based on implementation of current knowledge but at the same time the aetiology of many cancers remains obscure. This implies research into causes must parallel that into prevention; this combination should be one priority in the coming decade.

The majority of cancers have an environmental (broadly defined) aetiology but the precise contribution and interaction with other risk factors is difficult to elucidate. This is at least partially due to limitations in accurately measuring individual exposure, including exposures early in life. Recent advances in laboratory sciences (e.g. "omics" technologies) have been paralleled by an increased understanding of disease mechanisms (e.g. epigenetics). This provides a promising avenue for the improvement of environmental exposure assessment and an understanding of its consequences. In addition, this new generation of biomarkers can help establish the biological plausibility of exposure-disease associations, providing also a bridge from epidemiology to experimental data.

Much remains to be accomplished to provide the evidence-base for public health decisions on cancer prevention. Nevertheless, rapid advances in technology, the fresh understanding of mechanisms and the availability of large prospective cohort studies with associated biobanks provide exciting new opportunities. Prevention strategies based on these foundations demand an interdisciplinary approach whereby the term translational cancer research includes translation from the laboratory to the clinic and to the population. Such a "two-way translation" holds rich promise in combating the projected increases in global cancer burden (Wild CP, Mutagenesis, 24, 117-125, 2008; Wild CP, Environ. Heath, 10, suppl. 1, S15, 2011).

How can toxicology inform environmental epidemiology? A new approach to Environmental Health.

Professor Linda Birnbaum

The disciplines of environmental epidemiology and toxicology must work closely together on the challenges of addressing human relevance to existing experimental models by sharing techniques and approaches to fill relevant data gaps to improve public health. Research from toxicology has (1) provided solid mechanistic evidence to strengthen epidemiologic conclusions, (2) helped inform design of epidemiological studies by identifying windows of susceptibility (3) has led to new methods to identify interim phenotypes related to biological response to environmental exposures, and (4) has provided evidence for more complex dose response relationships that explain why various exposures have differing health effects.

Challenges in environmental health sciences can be met by supporting collaborations among scientists across disciplines, by developing strategies to integrate new methods and technologies, and sharing results with broader audiences. At NIEHS, we have developed several programs and models to foster collaborative efforts between disciplines within extramural, intramural and the National Toxicology Programs.

Transport and Health
Professor Bert Brunekreef

There are many links between transport and public health. Worldwide, death and injury from road traffic accidents are by far the most important, accounting for 1,3 milion deaths and from 20 - 50 million non fatal injuries every year according to a recent WHO report. Some 90% of these occur in low to middle income countries where without proper preventive measures, a further increase is expected with the ongoing increase in road traffic.
Vehicles powered by internal combustion engines produce toxic air pollutants which adversely affect the health of traffic participants, subjects living close to busy roads and the population at large. Engineering controls on vehicles and fuels have mitigated some of these problems in the developed world. Again, the disease burdens are likely to be larger in low to middle income countries which have not yet been able to afford the most technologically advanced pollution controls. However, relatively few studies have been conducted in areas of the world likely to experience the worst problems.
Active modes of transport such as cycling and walking are being promoted in some developed countries as an alternative to driving cars. Although cyclists and pedestrians are at higher risk of inhaled pollutants - because of higher respiration rates - and of traffic accidents than car riders or users of public transport, there is general concensus that the health benefits of physical exercise associated with walking and cycling outweigh the pollution and accident risks.
Transport may also increase health risks of infection as especially in mass transport, transmission may easily occur. Disease vectors may also hitchhike their way to faraway places ("airport malaria"), and in an increasingly global market, foodborne diseases may also be more easily transported elsewhere.
