THE INFLUENCE OF GENETIC POLYMORPHISMS ON THE RISK OF DEVELOPING ASBESTOSIS

Alenka Franko, *Clinical Institute of Occupational Medicine, University Medical Center, Ljubljana, Slovenia*
Vita Dolzan, *Institute of Biochemistry, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*
Niko Arneric, *Clinical Institute of Occupational Medicine, University Medical Center, Ljubljana, Slovenia*
Metoda Dodic-Fikfak, *Clinical Institute of Occupational Medicine, University Medical Center, Ljubljana, Slovenia*

Background and Aims: Relatively little is known about the genetic factors that may influence the development of asbestosis. The aim of this study was to investigate whether common functional polymorphisms in *GSTT1*, *GSTM1*, *GSTP1, MnSOD*, *ECSOD*, *CAT* and *iNOS* genes represent risk factors for developing asbestosis in workers occupationally exposed to asbestos.
Methods: The study included 262 cases with asbestosis and 265 controls with no asbestos-related disease. Data on cumulative asbestos exposure were available for all subjects. PCR based methods were used to genotype *GSTM1*-null, *GSTT1*-null, *GSTP1* Ile105Val and Ala114Val, *MnSOD* Ala –9Val, *ECSOD* Arg213Gly, *CAT* –262C>T and *iNOS* $(CCTTT)_n$ polymorphisms. Logistic regression analysis was used to assess asbestosis risk.
Results: The OR of asbestosis was 3.21 (95%CI 2.43–4.23) for cumulative asbestos exposure, 1.01 (95%CI 0.71–1.43) for *GSTM1*-null; 0.61 (95%CI 0.40–0.94) for *GSTT1*-null; 1.52 (95%CI 1.08–2.15) for *GSTP1* 105Ile/Ile versus 105Ile/Val and 105Val/Val; 0.97 (95%CI 0.64–1.48) for *GSTP1* 114Ala/Ala versus 114Ala/Val and 114Val/Val; 1.50 (95 %CI 1.01–2.24) for *MnSOD* –9Ala/Ala versus Ala/Val and Val/Val; 1.63 (95%CI 0.62–4.27) for *ECSOD* 213Arg/Gly versus Arg/Arg ; 1.36 (95%C 0.70–2.62) for *CAT* –262TT versus CT and CC; and 1.20 (95%CI 0.85–1.69) for *iNOS* LL versus SL and SS. The associations between *MnSOD* Ala –9Val polymorphism and asbestosis risk and between *iNOS* $(CCTTT)_n$ and asbestosis were modified by *CAT* –262C>T polymorphism (p=0.038; p=0.031, respectively).
Conclusions: Our study showed that *GSTP1* 105Ile/Ile and *MnSOD* –9Ala/Ala genotypes significantly increase the risk of developing asbestosis, whereas a protective effect was found for *GSTT1*-null genotype. A strong interaction was observed between *MnSOD* Ala –9Val and *CAT* –262C>T, as well as between *iNOS* $(CCTTT)_n$ and *CAT* –262>T polymorphisms. The findings suggest that in addition to asbestos exposure, genetic factors may also have an important influence on developing asbestosis.

INDOOR AIR POLLUTION AND MYOCARDIAL INFARCTION RISK AMONG WOMEN

Vilija Malinauskiene, *Lithuanian University of Health Sciences, Lithuanian Academy of Physical Education, Lithuania*

Background and aims: Indoor air pollution and health outcomes are under investigation in the recent years. Myocardial infarction risk is associated not only with the traditional ischemic heart disease risk factors, but with toxicants in the living and working environment as well. The aim of our study was to investigate the associations between indoor (gas stoves usage, environmental tobacco smoke) air pollution and first myocardial infarction among 34-61 years old women in Kaunas, Lithuania, taking into account the possible effects from age, the traditional ischemic heart disease risk factors (arterial hypertension, increased body mass index, low physical activity), education level, socioeconomic position, household crowding, perceived stress, sleep disorders, family stress, residential high traffic.
Methods: We conducted the population-based case-control study among 35-61 years old women in Kaunas, the second largest city in Lithuania in 1997-2005. Totally 368 myocardial infarction cases and 725 healthy controls were interviewed, using the standardized questionnaire, containing the information on gas stove usage, environmental tobacco smoke and other risk factors. The logistic regression analysis was used for the calculation of the adjusted OR and 95% CI of age, gas stove usage, environmental tobacco smoke, the traditional ischemic heart disease risk factors (arterial hypertension, increased body mass index, low physical activity), education level, socioeconomic position, household crowding, perceived stress, sleep disorders, family stress, residential high traffic for the first myocardial infarction risk among women.
Results: In the fully adjusted model the OR for gas stove usage was 1.20; 95% CI 0.72-1.98, environmental tobacco smoke 1.28; 95% CI 0.71-1.66.
Conclusions: The study has demonstrated that indoor air pollution exposure might have trace associations with the first myocardial infarction risk among women.

TRAFFIC-RELATED AIR POLLUTION AND ACUTE CHANGES IN HEART RATE VARIABILITY AND RESPIRATORY FUNCTION IN URBAN CYCLISTS

Scott Weichenthal, *Health Canada / University of Montreal, Canada*
Ryan Kulka, *Health Canada, Canada*
Aimee Dubeau,, *Health Canada, Canada*
Christina Martin, *Health Canada, Canada*
Daniel Wang,, *Environment Canada, Canada*
Robert Dales, *Health Canada / University of Ottawa, Canada*

Background and Aims: Few studies have examined the acute health effects of air pollution exposures experienced while cycling in traffic. The aim of this study was to examine the relationship between traffic-related air pollutants and acute changes in heart rate variability, lung function, and exhaled NO in healthy cyclists.
Methods: Forty-two healthy adults (19 to 58 years of age) cycled for 1-hour on high and low-traffic routes as well as indoors. Ultrafine particles (UFPs) (<0.1 um), PM2.5, black carbon, and volatile organic compounds were measured along each cycling route and ambient NO2, SO2, and O3 levels were recorded from a fixed-site monitor. Mixed-effects models were used to examine the relationship between air pollution exposures and changes in baseline health measures adjusted for potential confounders.
Results: An inter-quartile range increase in UFP levels was associated with a 220 ms decrease (95% confidence interval: -386, -53) (approximately 35 %) in high frequency power 4-hours after the start of cycling. Significant inverse relationships were also observed between NO2 and the ratio of low-frequency to high-frequency power and between O3, root mean square of successive differences in adjacent NN intervals (RMSSD), and percentage of adjacent NN intervals differing by more than 50 ms (pNN50). Acute changes in respiratory outcomes were not consistently associated with air pollution levels.
Conclusions: Exposure to traffic-related air pollution may contribute to decreased parasympathetic modulation of the heart in the hours immediately following cycling.

SPATIAL ANALYSIS OF INDOOR AND OUTDOOR POLLUTION AND WORLD ASTHMA MORTALITY RATES USING GEOGRAPHIC INFORMATION SYSTEMS

Komal Shah, BA, *University of Texas School of Public Health, United States of America*
Lu-Yu Hwang, MD, *University of Texas School of Public Health, United States of America*
Thomas F. Reynolds, PhD. *University of Texas School of Public Health, United States of America*

Background: Asthma deaths are an increasing public health problem in lower income countries. Exposure to indoor and outdoor pollution has been known to increase the risk of asthma; by analyzing this association globally, the death rate could be decreased.
Aims: Using Geographic Information System (GIS) analysis, the study objective was to perform an ecological investigation to determine if there is a positive correlation between countries' asthma mortality rates (AMR) and two exposures: indoor and outdoor air pollution. A secondary objective was to compare the strength of the associations between AMR and the two exposures.
Methods: Relevant articles and country data on indoor pollution (percentage of solid fuel usage), outdoor pollution (annual particulate matter less than ten microns), and AMR were researched using PubMed and World Health Organization databases. Exposure data was matched to outcome data and layered on their respective countries using a GIS software tool.
Results: AMR, indoor pollution, and outdoor pollution were highest in Africa and Southeast Asia. Linear regression was used to determine that indoor pollution (r^2=.42, df=170, p=.000) and outdoor pollution (r^2=.04, df=173, p=.011) were significantly associated with AMR, though indoor air pollution had a stronger association.
Conclusions: AMR and indoor pollution percentages were strongly associated and prominent in Africa and Southeast Asia. Further epidemiological studies could focus on hypothesized “social justice” confounders such as lack of proper healthcare or lack of resources in these regions.

RISK FACTORS FOR DIRECT HEAT-RELATED HOSPITALIZATIONS DURING THE 2009 ADELAIDE HEATWAVE

Ying Zhang, *University of Adelaide, Australia*
Monika Nitschke, *South Australian Department of Health, Australia*
Peng Bi, *University of Adelaide, Australia*

Background and Aims: Adelaide experienced an extreme heatwave in the summer of 2009 with six consecutive days over 40ºC. The health impacts of this extreme event included an almost 14-fold increase in direct heat-related hospital admissions. However, risk factors for these extra health burdens have not been investigated. This study aims to identify risk factors for direct heat-related hospitalization during the 2009 Adelaide heatwave in order to reduce future health burdens related to extreme heat events and to provide scientific evidence for improving the current South Australian heatwave emergency response system.
Methods: A case-crossover study was conducted in metropolitan Adelaide to compare the characteristics of patients from heatwave (28 Jan to 1 Feb) and non-heatwave periods before and after (21-25 Jan and 11-15 Feb). Direct heat-related hospitalization was based on ICD-10 codes (X30, T67, E86) from any of the principal and other diagnosis of each patient. Analyzed factors included age, gender, country of birth, marital status, socio-economic status, and number/type of co-existing morbidities, including cardiovascular disease, renal failure and diabetes. Logistic regression was applied to estimate the Odds Ratios and 95% CIs.
Results: Among the 355 patients being admitted during the heatwave period, half of them were female; 70% were over 60 years old; 37% were born overseas, 32% were married and the mean number of co-morbidity was 5.7. The factors significantly included in the Logistic regression model were age (OR=1.02: 1.01-1.02), higher socio-economic status (OR=0.57: 0.35-0.96), number of co-morbidity (OR=0.90: 0.86 -0.94) and renal failure (OR=1.67:1.05- 2.62).
Conclusions: The most vulnerable groups to the heatwave include those who are older, with lower socio-economic status and with renal failure. Public health responses to extreme heat events should give priorities to these vulnerable groups. Patients with more co-morbidity may be less likely to be admitted to a hospital with direct-heat related conditions.

NITRATES IN DRINKING WATER AND THE RISK OF DEATH FROM CHILDHOOD BRAIN TUMORS IN TAIWAN

Hsu-Huei Weng, *Department of Diagnostic Radiology, Chang Gung Memorial Hospital at Chiayi, Chang Gung University College of Medicine, Taiwan.*
Shang-Shyue Tsai, *Department of Health Care Administration, I-Shou University, Kaohsiung County, Taiwan.*
Trong-Neng Wu, *Graduate Institute of Environmental Health, China Medical University, Taichung, Taiwan.*
Fung-Chang Sung, *Department of Public Health, China Medical University, Taichung, Taiwan.*
Chun-Yuh Yang, *Faculty of Public Health, College of Health Sciences, Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background and Aims: The objective of this study was to (1) examine the relationship between nitrate (NO3-N) levels in public water supplies and risk of death from childhood brain tumors (CBT) and (2) determine whether calcium (Ca) and magnesium (Mg) levels in drinking water might modify the effects of NO3-N on development of CBT.
Methods: A matched cancer case-control study was used to investigate the relationship between the risk of death attributed to CBT and exposure to NO3-N in drinking water in Taiwan. All CBT deaths of Taiwan residents from 1999 through 2008 were obtained from the Bureau of Vital Statistics of the Taiwan Provincial Department of Health. Controls were deaths from other causes and were pair-matched to the cases by gender, year-of-birth, and year-of-death. Information on the levels of nitrate-nitrogen (NO3-N), Ca and Mg in drinking water were collected from Taiwan Water Supply Corporation. The municipality of residence for CBT cases and controls was presumed to be the source of the subject's NO3-N, Ca, and Mg exposure via drinking water.
Results: Relative to individuals whose NO3-N exposure level was <0.31 ppm, the adjusted OR (95% CI) for CBT occurrence was 1.4 (1.07-1.84) for individuals who resided in municipalities served by drinking water with a NO3-N exposure > 0.31 ppm. No significant effect modification was observed by Ca and Mg intake via drinking water.
Conclusions: Data suggest that exposure to NO3-N in drinking water is associated with a higher risk of CBT development in Taiwan.

PUBLIC SEWER SYSTEM AND DRAINAGE OF A CITY IN THE NORTH OF MEXICO

Navor González,, *Universidad Autónoma de Chihuahua. México*.
Luis Ojeda, *Universidad Autónoma de Chihuahua. México*.
Cristina Aguirre, *Universidad Autónoma de Chihuahua. México*.
Corral, Alba. *Universidad Autónoma de Ciudad Juárez. México.*
Miguel Rea, *Universidad Autónoma de Querétaro. México*.
Elaine González, *Universidad Autónoma de Chihuahua. México*.

Background and Aims: Owing to the fact that the workers of the sewer system of Chihuahua City are presumably exposed to various risks situations and to environments potentially harmful for their health, and considering that the nature of their activities and the conditions under which those take place have very peculiar characteristics that require to be investigated by reconstructing the various procedures and processes involved in their daily work tasks, and by that, identify the working conditions and the risks that of those tasks come up during the working day. The aims consisted in developing an occupational health diagnosis to identify conditions, insecure acts, risks and demands in the health of this group of workers, and also to support the development of an intervention proposal.
Methods: The reconstruction of the complex diagrams of the work process was realized by the elaboration of a direct observation guide of the squads in their working day, identifying with this the conditions, insecure acts, risks and demands, classifying them according to the social philosophy of work. The data collection was obtained by interviews with administrative personnel, managers, and squad leaders. Using the General Information Warrant of the Company, of the Verifying Questionnaire of Health Diagnose by Dr. Jesus Gabriel Franco.
Results: We can conclude that the workers are exposed to a large amount of risks and demands in their working conditions and to insecure acts. There is a lack of personal protection equipment and there is no safety work and health training program, among other subjets.
Conclusions: It could be determined that there is no conscience about this risks or about the high accidents probability and the health damages. There is no intervention of the Safety Commission or of the authorities.

SOCIAL AND ECOLOGICAL HEALTH EFFECTS FROM LIVING IN A DIOXIN CONTAMINATED NEIGHBORHOOD

Julia (Ky) Gress, *University of Florida, USA*

Background: The Cabot-Koppers wood treatment facility was in operation for nearly 100 years and is located in a densely populated low-income neighborhood with over 4,000 residents in Gainesville, Florida. For decades, residents have been expressing concern about adverse effects associated with exposure to chemicals from Koppers. In 2009, the USEPA confirmed the presence of elevated levels of dioxins in residents' yards. Recent indoor house dust sampling in the area has detected dioxin concentrations up to 700 times above background levels. The goal of this research project was to assess how the social and ecological health indices of this large neighborhood are changing as the nature and extent of dioxin contamination is becoming characterized.

Methods: In July 2009, a door-to-door survey on perceptions of risk associated with living near the Cabot-Koppers Superfund site was administered to 94 residents living within .5 mile of the site. Information about ways in which residents interact with their environment was also collected. Twenty in-depth interviews are currently being conducted with a subset of this original sample to better understand how residents interpret the demographic, social and environmental changes occurring in their neighborhood and how these changes influence their perceptions of risk.

Results: Preliminary analysis of survey data shows that residents' perceptions of risk are not correlated with how knowledgeable they feel about the nature and extent of the dioxin contamination of their yards and homes. Instead, perceptions of risk are correlated with awareness of specific changes occuring in the neighborhood environment that they attribute to the dioxin contamination.

Conclusion: Public knowledge of the contamination of residential properties with dioxin is resulting in changes in the way residents' experience their home environment and neighborhood. Residents' perceptions of risk associated with living in a dioxin contaminated neighborhood are complex and interwoven with concerns about the overall decline in the social and ecological health of their neighborhood.

OCCUPATIONAL SOLVENT EXPOSURE DURING PREGNANCY AND CHILD BEHAVIOR AT AGE TWO IN THE PELAGIE COHORT

Fabienne Pelé, *INSERM, France*
Gina Mukle, *CHUQ Medical Research Center, Québec City, Québec, Canada*
Nathalie Costet, *INSERM, France*
Ronan Garlantézec, *CHU Brest, France*
Christine Monfort, *INSERM, France*
Luc Multigner, *INSERM, France*
Florence Rouget, *CHU Rennes France*
Sylvaine Cordier, *INSERM, France*

Background: Many women work during pregnancy and are exposed to occupational toxicants. The developing central nervous system is highly vulnerable to neurotoxics such as solvents. Although ample evidence shows the neurotoxicity of solvents on adults, very few studies have examined their neurodevelopmental effects in humans following prenatal exposure. Our objective was to analyze the associations between maternal occupational exposure to solvents during pregnancy and child behavior problems (attention deficit/hyperactivity, aggressivity, opposition, and emotionality) at age two.
Methods: Women from the PELAGIE mother-child cohort (including 3005 working women) were recruited in Brittany (France) between 2002 and 2006, at the beginning of pregnancy to document occupational exposure to solvents at that time. Maternal reports (n = 1277) described children's behavior at two years of age. We evaluated the associations between occupational solvent exposure and children's behavior with linear regressions after adjustment for confounders.
Results: 51% of women reported no occupationally exposure to solvents, 21% occasional exposure and 28% regular exposure in early pregnancy. Children prenatally exposed to solvents were more likely to have higher scores for attention deficit/hyperactivity (p for trend = 0.019) and aggressivity (p for trend = 0.014) scores, and dose-response relations were observed.
Conclusions: The dose-response effect and the high prevalence of children potentially exposed to solvents from their mother's workplace exposure underline the public health relevance of this result. Further studies should corroborate our results and explore which particular solvents are most deleterious. Determination of the persistence of these behavioral effects requires long-term follow-up of exposed children.

A POPULATION-BASED CASE-CONTROL STUDY OF RADIOFREQUENCY EXPOSURE IN RELATION TO CHILDHOOD CANCER

Chung-Yi Li, *National Cheng Kung University, Taiwan*
Chih-Ching Liu, *Bureau of Health Promotion, Department of Health, Taiwan*

Background and Aims: The existing epidemiological evidence concerning the putative link between exposure to radiofrequency (RF) electromagnetic fields and cancer risk has been mostly acquired from studies of adult population; the cancer risk associated with RF exposure in children has not been adequately addressed. This study was conducted to investigate the relationship between environmental exposure to RF emitted from mobile phone base stations (MPBS) and risks of all cancers, leukemia, and brain tumors in children.
Methods: This is a population-based case-control study based on Taiwan's National Health Insurance inpatients claims. Cases were incident cases aged 15 or less and admitted in 2003-2007 for all cancers (ICD-9-CM: 140-239) (*n*=2,606) including 939 leukemia cases (204-208) and 394 cases of brain cancer (191). Controls were randomly selected from all non-cancer children insured in the same year of case's first-time admission, with frequency matched on age (+/- 5 years) and with a case/control ratio of 1:30. Annual cumulative power (ACP, watt-year) was calculated for each of the 71,185 MPBS in service between 1998 and 2007. Then the annual power density (APD, watt-year/km^2) of each township (*n*=367) was computed as a ratio of summation of ACP of all MPBS in a township to the area of that particular township. Each study subject's exposure to MPBS emitted RF was indicated by the averaged APD within the 5-year period prior to the cancer diagnosis calculated for the township where he/she lived. For those study subjects aged less than 5 years, the APD was only averaged for the time period between birth and child's age. Unconditional logistic regression model with generalized estimation equation was employed to calculate the relative risk estimates of childhood cancer in relation to RF exposure.
Results: Per 10 watt-years/km^2 increase in 5-year averaged APD was associated with a covariate-adjusted odds ratio (AOR) of 1.02 (95% confidence interval (CI)=0.96-1.08) for all cancers. The corresponding figures for leukemia and brain tumors were also not elevated at 0.97 (0.87-1.08) and 1.09 (0.95-1.25). A higher than median averaged APD (some 168 watt-years/km^2) was significantly associated with an increased AOR for all cancers (1.13; 95% CI=1.01-1.28), but not for leukemia (1.23; 95% CI=0.99-1.52) or brain tumor (1.14, 95% CI=0.83-1.55).
Conclusions: This study noted a positive but weak association between RF exposure to MPBS and risk of all cancers in children. The elevated risk was also seen for leukemia and brain tumors, but further inferences were limited by inadequate statistical power.

TOOLS FOR ADAPTING TO INFECTIOUS DISEASE IMPACTS FROM CLIMATE CHANGE

Jan C. Semenza, *European Centre for Disease Prevention and Control, Sweden*

Background and Aims: Europe will endure differential impacts from climate change with specific vulnerabilities in each bio-geographic region. The dynamics of infectious disease transmission are intricate in their own right but particularly so under climate change scenarios when distribution and transmission patterns are projected to shift.
Methods: The European Centre for Disease Prevention and Control (ECDC) has developed three tools for adapting to these impending challenges.
Results:

1) Knowledge mapping for climate change and food and waterborne diseases (FWD)

Information (key facts) was extracted from peer-reviewed 722 relevant publications for the period 1998 to 2009 and entered into an electronic knowledgebase. Key facts (~ 50,000 words) pertaining to temperature, precipitation, water, food, etc. for 6 selected pathogens were scrutinized, evaluated and compiled according to exposure pathways. Electronic data mining can facilitate management of future threats from infectious diseases.

2) A tool for Quantitative Microbial Risk Assessment (QMRA) for climate change and FWD

ECDC has developed a highly versatile decision support tool to estimate infection risks from climate change. Through QMRA of FWD this tool can assist decision makers in prioritizing different adaptation options. The tool includes a total of 13 QMRA combinations, each existing of consecutively linked modules selected from a total of 22 modules which can be run under current location-specific climate conditions; projected climate; or specific conditions depending on the selected modules.

3) A handbook for vulnerability, impact and adaption assessment of climate change health threats from infectious diseases

ECDC has developed a toolkit with a set of decision-making algorithms to help assess vulnerabilities, impacts and adaptation. Criteria for evaluating health and economic variables and options for monitoring and evaluation are presented to guide prioritisation of adaptation strategies.
Conclusions: These three tools can help public health practitioners allocate scarce resources under climate change conditions.

MAPPING CLIMATE CHANGE VULNERABILITIES FOR INFECTIOUS DISEASES IN EUROPE

Jan C. Semenza, *European Centre for Disease Prevention and Control, Sweden*

Background and Aims: Global climate change can shift the distribution of infectious diseases. Europe has a number of distinct climatic regions with specific climate change vulnerabilities. The quantitative outcome of these impacts on infectious diseases is less than certain.
Methods: Two surveys were conducted, one in 2007 and one from 2009/2010, with national infectious disease experts from 29 EAA countries. The aim was to capture their assessment of the projected epidemiologic situation for vector-, food-, water-, and rodentborne microorganisms under climate change scenarios.
Results: The large majority of experts agreed with the epidemic potential of these pathogens as a result of climate change. The proportion of countries reporting concerns was 83% for vectorborne; 68% for waterborne; 70% for foodborne; and 68% for rodentborne diseases. Specifically, 83% of countries were concerned about borreliosis; 69% about West Nile fever; 63% about tick-borne encephalitis; 62% about leptospirosis and 60% about salmonellosis. Observed changes in geographic distribution, seasonality, altitude and latitude were mapped by country. Planning and preparedness activities were captured as part of the survey along with surveillance activities for these pathogens. A number of shortcomings and deficiencies were identified that lend themselves to adaptation interventions.
Conclusion: In the absence of sufficient scientific data on climate change impacts on infectious diseases we resort here to an expert appraisal of projected changes in disease distribution. We map the landscape of this assessment and conclude that scarce resources can be allocated more effectively by conducting impact, vulnerability and adaptation assessments, on a regional or national scale. Surveillance activities should be tailored to the most appropriate region, season, and pathogen and guide strategic adaptation to climate change.

CHARACTERIZING ULTRAFINE PARTICLE NUMBER REDUCTIONS INSIDE VEHICLES

Hudda Neelakshi, *University of Southern California, USA*
Kostenidou Evangelia, *University of Southern California, USA*
Delfino Ralph, *University of California - Irvine, USA*
Sioutas Constantinos, *University of Southern California, USA*
Fruin Scott, *University of Southern California, USA*

Background and Aims: Time spent in vehicles is an important contributor to ultrafine particle (UFP) exposure, but exposures are difficult to characterize due to the complicated interplay between varying on-road UFP concentrations, particle losses to the ventilation system and cabin interior surfaces, and particle replenishment rates, as reflected by air exchange rate (AER). No study to date has systematically characterized all of these factors under a full range of real-world conditions.
Methods: In this study, six vehicles were chosen to be representative of vehicles up to 10 years old across a full range of driving speeds. Each vehicle was tested at seven AER conditions. UFP losses were determined as a function of particle size at different driving speeds, fan settings, cabin filter loadings, and ventilation conditions (outside air [OA] or recirculation [RC]) for each vehicle. AER was also measured.
Results : AER was determined as the dominant factor affecting inside-to-outside (I/O) UFP concentration ratios. Lower AERs occurred under RC conditions, e.g., <30 air changes per hour (hr^{-1}). Under these conditions, I/O ratios ranged from <0.05 at AER <2hr^{-1} up to 0.40 at AER = 20hr^{-1} and were highly negatively correlated to AER (r^2=0.83). At OA ventilation setting, AERs were an order of magnitude higher, e.g.,20 to 145 hr^{-1}, and I/O ratios were higher, ranging from 0.4 to 0.6. Vehicle cabin filter condition was never a major factor and filtration appeared to play a very small role in UFP removal. Particle losses were lowest in the range of 100 to 200 nm and were roughly constant over the range where on-road UFP size distributions vary the most, i.e., < 50 nm.
Conclusions : UFP concentration reductions inside vehicles are driven primarily by AER, with I/O ratios ranging from nearly zero to above 0.6. Therefore, ventilation setting and AER are necessary to accurately estimate in-vehicle UFP exposure.

DEVELOPMENTAL ORGANOCHLORINE COMPOUND EXPOSURE, THYROID FUNCTION, AND NEUROPSYCHOLOGICAL FUNCTION UP TO AGE 5½ YEARS

Jordi Julvez, *Harvard School of Public Health, Boston, MA, United States*
Frodi Debes, *Faroese Hospital System, Tórshavn, Faroe Islands*
Pal Weihe, *Faroese Hospital System, Tórshavn, Faroe Islands*
Anna L Choi, *Harvard School of Public Health, Boston, MA, United States*
Philippe Grandjean, *Harvard School of Public Health, Boston, MA, United States*

Background and Aims: Exposure to organochlorine compounds can alter thyroid function in humans (Alvarez-Pedrerol et al. 2009), and hypothyroidism during early in life can adversely affect a child's neurodevelopment (Haddow et al. 1999). This study aims to assess the relationship between developmental organochlorine exposures and thyroid function in regard to subsequent neurodevelopment.
Methods: A population-based birth cohort of 182 children was followed annually up to age 66 months. The assessments included organochlorine compound concentrations in maternal pregnancy serum and milk, clinical thyroid function parameters in maternal and cord serum, and subsequent neuropsychological outcomes of the child, along with socio-demographic cofactors.
Results: The findings showed consistent, negative and monotonic associations between organochlorine and resin-triiodothyronine uptake ratio after covariate adjustments. No associations were observed with other thyroid function parameters. Increased resin-triiodothyronine uptake ratio was associated with improved performance on most of the neuropsychological tests. For other thyroid function parameters, the findings were less consistent. The regression coefficients between resin-triiodothyronine uptake ratio and neuropsychological outcomes were slightly increased after adjustment for polychlorinated biphenyl exposure as a covariate, although the latter did not have a clear independent effect.
Conclusions: The results are in accordance with a plausible neurotoxic pathway of organochlorine compound exposures by negatively affecting resin-triiodothyronine uptake ratio during early life. Even minor changes linked to decreases of the resin-triiodothyronine uptake ratio during early life may adversely impact a child's neurodevelopment.

SERUM PERFLUORINATED COMPOUND CONCENTRATION AND ATTENTION DEFICIT/HYPERACTIVITY DISORDER IN CHILDREN AGED 5–18.

Cheryl R Stein, *Mount Sinai School of Medicine, New York, New York, USA*
David A Savitz, *Brown University, Providence, Rhode Island, USA*

Background and Aims: Perfluorinated compounds (PFCs) are ubiquitous, environmental pollutants used to manufacture non-stick cookware and waterproof fabrics. Perfluorooctanoic acid (PFOA) and other PFCs are found in maternal and umbilical cord blood and breast milk. Toxicology studies demonstrate the potential for PFCs to impact human growth and development. Attention Deficit/Hyperactivity Disorder (ADD) is a developmental disorder with suspected environmental and genetic etiology.
Objectives: We examined the cross-sectional association between serum PFC concentration and report of doctor-diagnosed ADD with and without current ADD medication use.
Methods: We used data from the C8 Health Project, a 2005–2006 survey in a Mid-Ohio Valley community highly exposed to PFOA through contaminated drinking water, to examine the association between serum PFC concentration and report of doctor-diagnosed ADD in non-Hispanic white children aged 5–18. This community was highly exposed to PFOA, but exposure to other PFCs reflects typical background levels. Logistic regression models were adjusted for age and gender.
Results: Of the 10,546 eligible children, 12.4% reported ADD, and 5.1% reported ADD plus current ADD medication use. The adjusted odds ratio (OR) for PFOA exposure above the 50th percentile was decreased (OR 0.80, 95% confidence interval (CI) 0.67, 0.95) for ADD plus medication as compared to exposure below the 50th percentile. Conversely, the OR for perfluorohexane sulfonic acid (PFHxS) levels above the 50th percentile was increased (OR 1.33, 95% CI 1.11, 1.59) for ADD plus medication as compared to exposure below the 50th percentile. There were no clear associations between the other PFCs and ADD.
Conclusions: It seems unlikely that PFOA protects against ADD. We suspect that the inverse association between PFOA and ADD reflects a spurious finding related to the geographic determination of PFOA exposure in this population, or to unmeasured behavioral or physiologic correlates of both exposure and outcome.

ASSOCIATION OF DIABETES WITH ARSENIC EXPOSURE, ARSENIC METABOLITES AND AS3MT POLYMORPHISM

Dana Loomis, *University of Nebraska Medical Center, USA*
Luz M. Del Razo, *CINVESTAV-IPN, Mexico*
Gonzalo Garcia-Vargas, *Juarez University, Mexico*
Zuzana Drobna, *University of North Carolina, USA*
Miroslav Styblo, *University of North Carolina, USA*

Background and Aims. Exposure to inorganic arsenic (iAs) is suspected of causing diabetes mellitus and other diseases. This study examined associations of diabetes with exposure to iAs in drinking water, metabolites of iAs in urine and AS3MT polymorphism.
Methods. Participants were adults and children age • 5 years living in Durango-Coahuila and Hidalgo states, Mexico. Information on water used and residential and medical history was obtained by questionnaire and participants provided samples of drinking water and spot urine. Prevalent diabetes was classified by fasting blood glucose (FBG) (≥125 mg/dl), oral glucose tolerance test (OGTT) (≥200 mg/dl) and self-report of diabetes diagnosis or treatment. iAs and its metabolites in urine were analyzed by hydride generation-atomic absorption spectroscopy. Associations between diabetes and iAs and urinary metabolites of iAs were estimated by logistic regression with adjustment for age, sex, hypertension and obesity. Urinary creatinine was evaluated as a covariate in analyses of urinary metabolites of iAs.
Results. Odds ratios (ORs) for diabetes classified by FBG and OGTT were similar. The OR increased about 1% per ppb of As in water (95% CI 1.01-1.02). Diabetes was associated with current iAs exposure, but cumulative arsenic exposure, or with total urinary arsenic concentration or total tri- or pentavalent iAs in urine. However, the OR for urinary dimethyl-As^{III} was 1.07 (95% CI 1.01-1.13) per ng As/ml after adjustment for creatinine (1.05 without adjustment). Neither methyl-As^{III} nor pentavalent methylated arsenicals in urine were associated with diabetes. Met287Thr polymorphism was associated with FBG • 126 mg/dl (OR = 2.36) and OGTT • 200 mg/dl (OR = 2.86), although neither association was statistically significant.
Conclusions. This study links diabetes with exposure to iAs and is the first to suggest that the dimethyl-MAs^{III} may be a marker of risk of developing diabetes.

DETERMINANTS OF URINARY ARSENIC CONCENTRATION IN A MEXICAN POPULATION

Dana Loomis,, *University of Nebraska Medical Center, USA*
Gonzalo Garcia-Vargas, *Juarez University, Mexico*
Luz M. Del Razo, *CINVESTAV-IPN, Mexico*
Zuzana Drobna, *University of North Carolina, USA*
Miroslav Styblo, *University of North Carolina, USA*

Background and Ams. Millions of people worldwide are exposed to inorganic arsenic (iAs), a known carcinogen, in drinking water. This study examined potential predictors of urinary arsenic concentration in two areas in central Mexico with historically high iAs levels in village water supplies.
Methods. Participants were adults and children age • 5 years residing in the La Laguna and Zimapán regions in Durango-Coahuila and Hidalgo states, respectively. Information on residential history and water use was obtained by questionnaire and participants provided samples of drinking water and spot urine. Concentrations of iAs in water and As species in urine, iAs, MAs and DMAs, were determined by hydride-generation atomic absorption spectrometry. Potential predictors of iAs in water and urine were examined using linear regression and linear mixed models on log-transformed concentrations.
Results. The concentration of iAs in water samples was significantly associated with the source of drinking water and place of residence, including the village as well as the region. Interactions of location and water source were significant. Total arsenic (tAs) in urine was significantly associated with iAs concentration in water, source of drinking water and region of residence, as well as with sex and urinary creatinine. Higher urinary tAs concentrations were observed among those drinking municipal tap water rather than bottled water or water from springs or dug wells. Other environmental and personal factors including source of cooking water, length of residence, duration of water use, recent absence from the area, age and obesity were not associated with urinary tAs. Trivalent and pentavalent species of iAs in urine were associated with tAs in urine but not with environmental or personal factors.
Conclusions. The level of tAs is strongly related to the concentration of iAs in drinking water, but sex and factors specific to location also play a role.

WILL WOMEN DIAGNOSED WITH BREAST CANCER PROVIDE BIOLOGICAL SAMPLES FOR FUTURE RESEARCH PURPOSES?

Shelley Harris, , *Cancer Care Ontario, Canada; Dalla Lana School of Public Health, University of Toronto, Canada; Occupational Cancer Research Centre, Canada*
Beatrice Boucher, *Cancer Care Ontario, Canada; Department of Nutritional Sciences, University of Toronto, Canada*
Michelle Cotterchio, *Cancer Care Ontario, Canada; Dalla Lana School of Public Health, University of Toronto, Canada*

Background and Aims: Biological samples are often used to assess exposures in case control studies of cancer risk. Little is known about the response rates for biological sample provision, especially in younger age groups, and how these are affected by other demographic or lifestyle variables. A population based study of breast cancer patients was conducted to estimate these rates and to obtain information on the recruitment of friend/colleague controls.
Methods: Breast cancer cases diagnosed April-May 2010 were recruited to determine the proportion willing to provide biological samples (morning or 24 hour urine, saliva, blood) and contact information for similarly aged women for control recruitment. Cases (n=417) were women 25-74 years of age identified through the Ontario Cancer Registry and 67% (n=278) of those completed a mailed questionnaire.
Results: Women indicated they were willing to provide blood samples, by visiting a clinic (62%) or having a nurse visit the home (61%). They also were willing to provide saliva samples (73%) and morning (66%) or 24-hr urine samples (52%). Compared to older women, younger women (• 45) were consistently more likely to agree to provide any biological samples and were 3.1 times (OR) more likely to report they would collect a morning urine sample (95% CL: 1.15-8.35). Only 26% of cases indicated they would be willing to give contact information for similarly aged women (controls) to provide samples in future studies. Educated women were more likely to agree to provide biological samples, and women who consumed alcohol were more likely to agree to provide contact information than non-drinkers. Ethnicity, income, body mass index, and smoking status did not influence these results.
Conclusions: Reasonable response rates for biological sample collection can be expected in future case controls studies of breast cancer (especially among younger women), however, other methods of control selection must be devised.

COOKING FUEL CHOICES AND INDOOR AIR POLLUTION ACTIVITIES OF ACCRA HOUSEHOLDS: DETERMINING FACTORS AND ASSOCIATIONS WITH BIRTH WEIGHT

Amegah Adeladza Kofi, *University of Cape Coast, Ghana*
Norgbe Gameli Kwame, *University of Ghana, Ghana*
Dzodzomenyo Mawuli, *University of Ghana, Ghana*

Background and Aims: Birth weight is a predictor of infant growth and survival, and an important indicator of health in adulthood. The evidence linking air pollution especially ambient levels with reduced and low birth weight has been accumulating worldwide. The effect of indoor air pollution on birth weight however remains largely unexplored but yet purported as the most important environmental exposure for pregnant women especially in developing countries. This study therefore sought to establish the cooking fuel choices and indoor air pollution activities of Accra households, identify the perpetuating factors, and examine their consequences for birth weight trajectories.
Methods: A cross-sectional design was employed to assess exposure status of 592 mothers accessing postnatal services at the Korle Bu Teaching Hospital located in Accra and to record birth weight of their newborns.
Results: Cooking fuel choices of mothers was dependent on their residential location (p=0.011) and educational level (p=0.000). Mothers residing in middle/upper class neighbourhoods preferred LPG whereas charcoal was most preferred by mothers in low class and slum areas. Primary and junior high educated mothers and mothers with no formal education preferred charcoal whilst tertiary educated mothers liked LPG. Cooking fuel type (p=0.000) and household rubbish burning (p=0.027) was associated with birth weight with charcoal users and mothers present most of the time during rubbish burning sessions delivering smaller babies. Charcoal use was a significant risk factor for LBW (Adjusted OR=3.526, CI=1.732-7.179, p=0.001).
Conclusion: Improving social status and income levels of women residing in deprived areas; scaling up household waste collection to cover all Accra zones; and increasing LPG production facilities, expanding their distribution networks in urban centres, and curbing their competing use in motor vehicles are thus important in reducing maternal exposure to indoor air pollution.

HYPOPLASTIC LEFT HEART SYNDROME AND COARCTATION OF THE AORTA: TOXICOGENOMIC STUDIES SUGGEST AN ENVIRONMENTAL FACTOR

Karen Kuehl, *Children's National Heart Institute, Washington, US*
Christopher Loffredo, *Georgetown University, Washington, US*
Eric Hoffman, *Children's National Medical Center, Washington, US*
Munziba Khan, *Children's National Medical Center, Washington, US*
Richard Jonas, *Children's National Heart Institute, Washington, US*
Dana Barr, *Emory University, Atlanta, US*
Wayman Turner, *Centers for Disease Control, Atlanta, US*
Manhai Long, *University of Aarhus, Denmark*
Eva Bonefeld-Jorgensen, *University of Aarhus, Denmark*

Background : We sought to identify possible gene-environment interactions for congenital heart malformations (hypoplastic left heart (HLH) and coarctation of the aorta (CoAo)). We have previously shown geospatial aggregations of HLH and CoAo, higher maternal solvent exposure, and potential interaction with GST-theta activity.(Loffredo)
Methods: Mother/infant pairs, where infants were < 1yr of age were studied. Cases werei infants undergoing cardiac surgery for HLH or CoAo (N=14 pairs). Controls were unrelated cardiac malformation (N=16 pairs). Bloods were obtained at the time of surgery. Mothers completed a questionnaire about environmental exposures. Blood DNA was genotyped for 14 toxicogenomics loci. Blood concentrations of 37 lipid-adjusted PCB isomers, and 9 pesticides were determined in all pairs. Statistical analyses were made for the sum of total PCBs, dioxin like (DLPCB) and non dioxin like (NDL) PCBs. Blood AhR transactivation was also measured.
Results: Mean infant age was 53 days for cases and 92 days for controls. Total PCBs, DLPCBs, NDLPCB levels were associated with CoAo (*N=7) (P= 0.008 for total PCB), but not with HLH (N=7). Covariates for PCB levels included history of alcohol consumption and maternal age. By non parametric analysis, blood concentrations of summed pesticides were associated with case status (p=0.0034), and separately for HLH and for CoAo specifically (ppDDE and t-NONA). 4 gene loci showed positive associations of low metabolizer alleles with infant cases (ARNT T19, PON1 rs# 662, CAT C26T rs # 1001179and CYP1A2 rs # 726551).
Conclusions: Our data are consistent with gene-environment interactions leading to genospatial clustering of congenital heart malformations. Blood levels of PCBs and pesticides in infants with HLH or CoAo and their mothers were higher than controls. DL and NDL PCB and pesticides were associated with CoAo; DDE and t NONA were associated with both HLH and CoAo. This pilot study should be confirmed in larger cohorts

IMPACT OF ATMOSPHERIC POLLUTION UPON THE HEALTH OF THE POPULATION: SINGULAR EVENTS

Varea, Montse, *Miguel Hernandez University, Spain*
Carolina Chofre, *Miguel Hernandez University, Spain*
Nuria Galindo, *Miguel Hernandez University, Spain*
Juan Gil-Moltó, *Miguel Hernandez University, Spain*
Javier Crespo, *Miguel Hernandez University, Spain*

Background and Aims: Recent studies point out that the association between morbidity and mortality with atmospheric pollution varies depending upon the region, seasonal period and the heterogeneous chemical composition of suspended particulate matter. From the environmental point of view, many studies exist about variations in PM levels, both on their size distribution as well as their chemical composition, according to certain singular events having an either natural or anthropogenic origin, identified by the analysis of the surrounding orographic, meteorological and environmental characteristics.
The objective of this study is to estimate the short-term association between the number of hospital emergency room admissions and atmospheric pollution, evaluated by a lone variable categorized as event.
Methods: Ecological study of temporal series relating hospital emergency room admissions caused by the circulatory apparatus cerebrovascular, total cardiac, total respiratory, asthma and chronic pulmonary obstruction and the atmospheric pollution indicated by the presence or not of a singular event in the city of Elche. The following are considered events: a) Saharan intrusion, contributing mineral dust masses from North Africa; b) Atmospheric stability, high stability situations favoring pollution accumulation; c) Regional accumulation, persistent recirculation of contaminated air masses; d) European episode, the entrance of air masses originating in Europe; e) Smoke or collections of particles resulting from incomplete combustion; and f) Firework displays. The magnitude of association was estimated using Poisson regression.
Results: The increase in atmospheric pollution during periods of atmospheric stability is associated with an increase of 1.64% (IC 95%: 1.30-2.08%) in hospital admissions from respiratory causes, and specifically from asthma (2.55%) or COPD (1.26%), but not statistically significant. On the other hand, a risk of becoming ill due to cardiovascular causes was obtained in both periods of Saharan intrusion as well as atmospheric stability, but they were not significant either.
Conclusions: Singular events are a variable to keep in mind in the study of the impact of atmospheric pollution upon the health of the population. Although these results can only be considered preliminary, as there were only two events – a Saharan intrusion and atmospheric stability – a sufficient number of days did transpire to be studied.

EXPOSURE TO ENVIRONMENTAL LEAD AFFECTS LUNG AGING OF THE GENERAL POPULATION FROM A LARGE INDUSTRIAL COMPLEX

Pak Yun-Suk, *Department of Occupational and Environmental Medicine, School of Public Health and Institute of Health and Environment, Seoul National University, Seoul, Korea*
Oh Aeri, *Department of Occupational and Environmental Medicine, School of Public Health and Institute of Health and Environment, Seoul National University, Seoul, Korea*Young Lim Kho,
Lim Kho Young, *School of Human and Environmental Science, Eulji University, Seongnam, Korea*
Paek Domyung, *Department of Occupational and Environmental Medicine, School of Public Health and Institute of Health and Environment, Seoul National University, Seoul, Korea*

Background and Aims: Lead effects, even from low level exposures, have been implicated in the aging process of several organs including brain. However, effects of lead on the lung aging of general population have not been studied. This study was to ascertain the risk factors of aging on the pulmonary function (PF; forced expiratory volume in 1 second [FEV_1], forced vital capacity [FVC]) of those exposed to lead in the vicinity of industrial complex
Methods: In total, 263 men and women, aged over 30, were recruited from two cities during a 2-year follow-up. Spirometry testing was conducted at yearly cycles I and II. We estimated the change in FVC and FEV_1 during the study period and analyzed the rate of change according to the height, baseline FVC, and FEV_1, after controlling for sex, bronchial hyperresponsiveness, blood lead, urinary cotinine, and 1-hydroxyprene.
Results: The decline of PF progressed with age. More marked decline of FVC was noted for men than women ($p < 0.05$), but the decline of FEV_1 was not. Biological factors, especially height ($p < 0.05$) and pulmonary status ($p < 0.0001$), were associated with the decline of both PFs. Exposure to environmental lead was also significantly associated with the decline of both PFs
Conclusions: Even within a normal range of PF decline from aging, people with a smaller height, lower pulmonary status at baseline, and higher level of BPb were more vulnerable to the decline of PF. Lead accumulated in adult may contribute to rapid aging on pulmonary function.

AN APPROACH TO THE ASSESSMENT OF THE COMBINED IMPACT OF SOME AMBIENT AIR POLLUTANTS ON THE RESPIRATORY SYSTEM OF CHILDREN

Julia I.Kazmer, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*
Anatole N. Varaksin, *Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Russia*
Boris A. Katsnelson, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*

Vladimir G. Panov, *Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Russia*
Vladimir B. Gurvich, *Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Russia*

Background and Aims: Assessment of the type of combined harmful impact produced by the most important ambient air pollutants (NO_2, SO_2, particulate matters) on the respiratory system in a specific environment could allow the uncertainty in risk assessment to be reduced. We approached such assessment based on toxicological concepts ("additivity", "subadditivity, or antagonism", "superadditivity, or synergy") applied to the data of an epidemiological study**.**
Methods: We analyzed the data of a questionnaire-based survey of 5085 primary schoolchildren in 13 areas of 10 Russian townships and the results of a year-long monitoring of ambient air pollution with the above-mentioned substances in these areas. The assessed respiratory response was the presence of cough for at least 3 months during the year. The association of this response with the impact of pollutants was investigated by translating pollutant concentrations into categorical form (below or above the median value), with the effects of the most essential confounders eliminated by means of database restriction. Restriction was carried out for two risk factors: smoking of adults in the presence of the child and the use of gas ovens for home heating and linen drying. Such restriction reduced the dataset to 1965 children, for which two-level charts for cough probability dependence on pollutant levels were constructed, and correlation analysis was carried out.
Results: It has been shown that, at the levels of ambient air pollution which are characteristic of the environmental situation considered, the combined respiratory impact of SO_2 and NO_2 is less than additive, that of SO_2 and PM_{10} is additive, and that of SO_2 and $PM_{2.5}$ is more than additive.
Conclusions: It has been demonstrated that it is possible to estimate the combined impact of ambient air pollutants on the respiratory airways if the effects of other strong potential risk factors are eliminated by means of dataset restriction.

ASSOCIATION BETWEEN VEHICULAR DENSITY AND HOSPITALIZATION BY CARDIOVASCULAR DISEASES IN THE CITY OF SAO PAULO, BRAZIL

Clarice Umbelino Freitas, *Centro de Vigilância Epidemiológica – SES – São Paulo – Brasil*
Maria Regina Alves Cardoso, *Faculdade de Saúde Pública – USP – São Paulo – Brasil*.
Adelaide de Cassia Nardocci, *Faculdade de Saúde Pública – USP – São Paulo – Brasil.*
Helena Ribeiro, *Faculdade de Saúde Pública – USP – São Paulo – Brasil.*

Mirta Alcira Ferro Rodrigues Silva, *Centro de Vigilância Epidemiológica – SES – São Paulo – Brasil*
Agnes Soares Silva, *Faculdade de Saúde Pública – USP – São Paulo – Brasil.*

Background and aims: A cross-sectional study using vehicular density (VD) as an indicator of exposure, calculated for micro-areas of the city of Sao Paulo, was conducted to assess the impact of air pollution on admissions for cardiovascular diseases.
Methods: Hospitalizations for cardiovascular diseases (ICD10: I20-I25.9 and ICD10: I60-I69.8) in adults aged 40 years or more from public and private hospitals of the city in the period 2004-2006 were geocoded by their residence addresses.
Vehicular density, according to the type of fuel, was calculated for micro-areas of 500m2 of the city and used as the indicator of exposure to traffic-related air pollution. The number of resident people and the Human Development Index (HDI) were available for these micro-areas. Admission rates for cardiovascular diseases were calculated and the VD (total and according to type of fuel) and HDI were categorized into quartiles. Multiple logistic regression models with the admission rates as the dichotomous dependent variable (equal or greater than the median) and the VD and the HDI as independent variables were used.
Results: 30,843 admissions by cardiovascular diseases were analyzed in 1,927 micro-areas of the city. Having the first quartile of VD as baseline and allowing for the HDI, the adjusted OR for total VD were: 2.54 (95%CI: 1.93-3.42; 4.49 (95%CI: 3.35-6.01; 4.94 (95%CI: 3.60-6.79). For diesel vehicles the OR were: 2.55 (95%CI: 1.94-3.36): 4.96 (95%CI: 3.06-5.42); 4.09 (95%CI: 3.02-5.56), and for vehicles powered by gasoline and alcohol were: 2.60 (95%CI: 1.97-3.42); 4.70 (95%CI: 3.51-6.30): 4.96 (95%CI: 3.61-6.83). Significant linear trends were observed for cardiovascular diseases and all types of fuel.
Conclusions
A statistically significant association between VD and admissions for cardiovascular diseases was found. This association was not influenced by the type of fuel.

MATERNAL EXPOSURE TO AMBIENT TEMPERATURE AND THE RISK OF PRETERM BIRTH AND STILLBIRTH

Linn Beate Strand, *Queensland University of Technology, Australia*
Adrian G.Barnett, *Queensland University of Technology, Australia*
Shilu Tong, *Queensland University of Technology, Australia*

Background and Aims: Almost 10% of all births are preterm and 2.2% are stillbirths. Recent research has suggested that environmental factors may be a contributory cause to these adverse birth outcomes. We examined the association of preterm birth and stillbirth with ambient temperature in Brisbane, Australia
Methods: We obtained data on meteorological factors, air pollution and births (n = 101,870) in Brisbane, Australia between 2005 and 2009. We used a Cox proportional hazard model to assess the association of preterm birth and stillbirth with ambient temperature. We also examined if there were any periods of the pregnancy particularly vulnerable to high temperatures.
Results: We found an association between maternal exposure to higher ambient temperature and increased risk of stillbirth. With increasing temperatures from 12 °C to 21 °C, the hazard ratio for stillbirth increased by about 70%. The temperature effect was greatest for fetuses of less than 36 weeks of gestation. We also found an association between higher temperatures and shorter gestations and the hazard ratio for live birth increased by about 6% as the mean temperature increased from 15 °C to 25 °C. This effect was greatest at later stages of the pregnancy.
Conclusions: The results provide strong evidence of an association between exposure to higher temperature during pregnancy and increased risk of stillbirth and shorter gestations.

CHILD GROWTH AND DEVELOPMENT FROM BIRTH TO 36 MONTHS OLD BORN TO ADOLESCENT MOTHERS-RESULTS OF THE TAIWAN BIRTH COHORT STUDY

Meng-Chih Lee, *Institute of Medicine, Chung Shan Medical University, Taichung, Taiwan*
Wei-Ya Wu, MD, MS *Institute of Medicine, Chung Shan Medical University,Taichung City, 402, Taiwan*

Background: Adolescent pregnancy carries a higher risk of adverse birth outcomes. So far, there have been very few longitudinal studies on the growth of children born by adolescent Mothers. This study explores birth outcomes and their determinants in adolescent pregnancies, using subjects drawn from the Taiwan Birth Cohort Study (TBCS).

Methods: Using data of Wave I (6months old), II (18 months old) and III (36 months old) of TBCS, a national sample of 19,381 pairs of mothers and their children were included for analysis, including 560 pairs resulting from adolescent mothers. Through completed field interviews with structured questionnaires and surveys with mothers or other family members, and with references to each child's birth certificate and Passport of Well-baby Care, differences in birth outcomes and personal, pregnancy and social profiles of mothers were analyzed.

Results: A total of 560 adolescent mothers (<20 years old) and 18,821 adult mothers (20-34 years old) were included in our study. There was no significant difference between two groups in terms of parameters of the child growth. For development, the numbers (proportions) of failure in milestones at 3 years old for gross motor, fine motor, language and social development of children born to adolescent mothers are 13(2.32%), 34(6.07%), 10(1.79%)and 24(4.29%), respectively; while there are 392(2.08%), 1015(5.39%), 308(1.64%)and 512(2.72%) for those born to adult mothers. The determinants of failure in development are “the mother isn't the night-time caregiver” and “family dysfunction“.

Conclusion: There was no significant difference in both growth and development at 3 years old between children born to adolescent and adult mothers.

THE ASSOCIATION BETWEEN EXPOSURE TO PARTICULATE MATTER DURING PREGNANCY AND BIRTH WEIGHT AND GESTATIONAL AGE: THE UK PAMPER STUDY

Svetlana V Glinianaia, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom*
Rakesh Ghosh, *Department of Public Health Sciences, University of California, Davis, California, USA*
Mark S Pearce, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom*
Judith Rankin, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom*
Steven Rushton, *Institute of Health and Society and Institute for Research in Environment and Sustainability, Newcastle University, Newcastle upon Tyne, United Kingdom*
Tanja Pless-Mulloli, *Institute of Health and Society and Institute for Research in Environment and Sustainability, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background and Aims: Exposure to particulate matter during pregnancy is associated with adverse birth outcomes, but the evidence for some outcomes is inconsistent. The UK Particulate Matter and Perinatal Events Research (PAMPER) study investigated associations between maternal exposure to black smoke (BS) and birth outcomes in Newcastle upon Tyne, an industrial city with stable population, over three decades (1962-1992).
Methods: A two-stage statistical exposure modeling strategy was used, incorporating monitored weekly BS levels and temporally and spatially varying covariates, to estimate weekly BS exposure for each individual pregnancy (88,679 births with complete covariate information) averaged over each trimester and the whole pregnancy period. Regression analyses assessed associations between BS exposure and birth weight, gestational age and birth weight standardized for gestational age and sex.
Results: The median weekly BS exposure estimate across whole pregnancy was 33.8μg/m^3 (IQR 17.2-108.3μg/m^3). The unadjusted linear decrease in birth weight was 3.4g (95% CI 2.9, 3.9) per 10μg/m^3 increase in BS, reducing to 1.7g (95% CI 0.9, 2.4) after adjustment. The exposure-response function was non-linear: birth weight decreased by 70g for an approximately 100μg/m^3 increase in BS from the 1st to 75th percentile, with only 25g decrease for 100μg/m^3 BS increase from the 75th to 95th percentile. Standardized birth weight also reduced with an increase in BS exposure. Associations between BS and gestational age were very small and non-significant. Significant interaction between BS and deprivation on the effect on birth weight and standardized birth weight was observed.
Conclusions: Associations between maternal BS exposure and offspring birth weight were of the same order of magnitude as those reported for passive smoking, and varied across the range of exposure estimates. Based on our findings, we hypothesize that intrauterine growth restriction may be on the causal pathway in the association between exposure to BS and birth weight reduction.

COMPARISON OF EXPOSURE ESTIMATION METHODS FOR AIR POLLUTANTS: AMBIENT MONITORING DATA AND REGIONAL AIR QUALITY SIMULATION

Mercedes Bravo, *Yale University, United States*
Montserrat Fuentes, *North Carolina State University, United States*
Yang Zhang, *North Carolina State University, United States*
Michael Burr, *North Carolina State University, United States*
Michelle Bell, *Yale University, United States*

Background and Aims: Ambient monitors are often used to estimate air pollution exposure for epidemiological studies. This approach is efficient and economical but has limitations, including restricted coverage and resolution. Three-dimensional air quality modeling has potential to address some limitations of monitoring networks. We evaluated application of a regional air quality model to estimate air pollution exposure for epidemiological studies.
Methods: Individual and spatially-aggregated (county-level) exposure estimates for $PM_{2.5}$ and O_3 were calculated for the eastern U.S. in 2002 using simulation results from the Community Multi-scale Air Quality (CMAQ) modeling system and a traditional approach based on ambient monitoring data. Differences in populations included in monitor- versus model-derived exposure estimates were evaluated, and advantages and limitations of exposure estimation approaches were assessed.
Results: Exposure estimates generated from CMAQ provided greater spatial coverage and higher spatial and temporal resolutions compared to estimates from monitor data. The monitoring approach produced estimates for 370 counties for $PM_{2.5}$ and 454 for O_3. Modeled estimates included 1861 counties, covering 50% more population. Populations with and without monitor coverage differed: counties with monitors tended to be more urban, with a higher percentage of black residents, college graduates, young children, and higher median income and modeled pollutant levels. CMAQ slightly overestimated O_3 (annual normalized mean bias [NMB]=4.30%); annual modeled $PM_{2.5}$ estimates were similar to observations (NMB=-2.09%), though bias varied seasonally (e.g., -27.1% in July to 32.0% in November).
Conclusions: Epidemiology may benefit from use of regional air quality models, with improved spatial and temporal resolutions and ability to study populations far from monitors that may differ from those near monitors. However, model performance varied by pollutant, measure of performance, and exposure metric. Appropriateness of using modeled pollutant exposures in health studies depends on the pollutant, acceptable level of uncertainty, population of interest, study design, and other factors.

AIR POLLUTION EXPOSURE DURING PREGNANCY AND MATERNAL AND FETAL C-REACTIVE PROTEIN LEVELS. THE GENERATION R STUDY

Background and Aims Exposure to air pollution has been associated with increased levels of the inflammatory marker C-reactive protein. We investigated the associations of exposure to particulate matter (PM_{10}) and nitrogen dioxide (NO_2) during pregnancy with high-sensitivity C-reactive protein (hs-CRP) levels in mothers in first trimester and neonates in a population-based cohort study among 7339 pregnant women in Rotterdam, the Netherlands.
Methods Air pollution levels were modelled at the home address using a combination of advanced GIS based modelling and hourly monitoring data. For different periods preceding the blood sampling, average exposures to air pollution were assessed. Hs-CRP levels were measured in maternal blood samples collected in early pregnancy and in cord blood samples. Hs-CRP levels were log-transformed and multivariate linear and logistic regression analyses were performed. Models were adjusted for known determinants of CRP levels (maternal age, body mass index, ethnicity, education, parity, folic acid supplementation use, smoking, and alcohol consumption), and for season of conception and road traffic noise exposure.
Results Mean exposure levels during pregnancy were 30.3 • g/m^3 (SD 3.2) for PM_{10} and 39.8 • g/m^3 (SD 4.2) for NO_2. In early pregnancy, higher air pollution exposure levels were not associated with hs-CRP levels. An increase in PM_{10} and NO_2 exposure levels during pregnancy was associated with an increased risk of detecting a hs-CRP level above 1.00 mg/L in neonates (odds ratio 2.37, 95% confidence interval 1.16 to 4.88).
Conclusions Maternal exposure to higher PM_{10} and NO_2 levels during pregnancy was associated with increased fetal hs-CRP levels. In contrast, maternal air pollution exposure was not associated with hs-CRP levels in early pregnancy. Our results suggest that maternal exposure to air pollution during pregnancy may promote the inflammatory process in neonates.

PREVENTING THE CORRUPTION OF A GOVERNMENT RESEARCH PROGRAM

NEUTRA, RAYMOND, *Neutra Consultancy, USA*

Background and Aims: This presentation will explain how staff of a government agency and a stakeholder's advisory committee created procedures to successfully avoid corruption of an extramural research program.
Methods: The presentation will summarize information about the oversight,conduct and attempted corruption of the California Electric and Magnetic Fields Program.
Results: In 1992 the California Public Utilities Commission (PUC) asked the California Department of Health Services(DHS) to oversee an extramural policy-relevant research program. It was to deal with the mix of electric and magnetic exposures (EMFs) from power lines and house wiring. The research was to provide information about sources of exposure, possible risks and policy options for lowering exposure in schools and from power lines. The PUC stipulated that the program be overseen by a stakeholder's advisory committee made up of concerned citizens, electrical worker unions, utility representatives and public interest organizations such as the Parent Teacher's Organization. The committee was charged with developing procedures and transparency to prevent corruption of the conclusions by any of the stakeholders. This committee later additionally requested a risk assessment by the DHS scientists. The stakeholders had to approve the wording of the scope of work in the requests for proposals, the membership of the panels who judged the submitted research proposals. They were directly involved in specifying the options to be considered and the criteria to be used for judging options for dealing with EMFs from power lines and schools. They demanded the formation of a scientific advisory committee to approve the risk evaluation methodology and the risk assessment itself.
Conclusions: Despite several serious but unsuccessful attempts by some stakeholders to sway the results, the final products were judged by all the stakeholders to be corruption-free.

Backgrounds and Aims Although breast milk remains the best source of nutrition for infants, it may represent a potential source of toxicant exposure and a concern for public health, especially in developing countries. The purpose of this study is to investigate the levels of lead and mercury in breast milk in postpartum women in seven cities of China and to explore related determinents.
Methods National surveys were conducted between October and December, 2008 in seven cities in China. A total of 1600 questionnaires were handed out with a response rate of 83.4%. About 10 mL breast milk was obtained from each mother at about 9:00 am 3 to 5 days after delivery. Breast milk samples were fully digested using a microwave protocol and then were analyzed by inductively coupled plasma mass spectrometer (ICP-MS) for lead, zinc (and other trace metals), and by a Direct Mercury Analyzer (DMA80) for mercury.
Results The concentrations of lead varied significantly by region, with overall P25, P50 and P75 values of 2.92• g•L, 5.11• g•L, and 9.14• g•L respectively, and the highest lead concentrations in Xiamen (median 8.76• g•L) . Mercury levels also varied by region, with overallP25, P50 and P75 values of 0.87• g•L, 1.65• g•L, and 3.18• g•L respectively, and the highest levels in Guangzhou(median 3.99• g•L). Results of multivariable linear regression showed that lower educational attainment of fathers (P=0.01), active smoking status of mothers (P=0.00) was associated with a higher level of lead in breast milk. Factors associated with a higher mercury concentration in breast milk included the use of kitchen ventilator (P=0.03), pet bites or scratch injury during pregnancy (P=0.00), higher consumption of fish (P=0.04) and use of milk powder (P=0.02). Zinc concentrations were lower among those with less education (high school or less) .
Conclusions Using microwave digestion-ICP-MS could determine the concentration of multiple elements with minimal samples of breast milk, making it ideal for population surveillance and large sample epidemiological surveys. In general, concentrations of lead and mercury, as well as the nutritional elements iron, selenium, zinc and cooper, were within the acceptable range in breast milk in China. The significant regional variances in lead and mercury concentrations between the seven cities reflected different exposure levels, and most risk factors for higher levels were related to family factors.

Background and Aims: Although future climate is predicted to have more extreme heat conditions, the available evidence on the impact of these conditions on pregnancy is very scarce and inconclusive. This study was aimed to investigate the impact of maternal short-term exposure to extreme ambient heat on the length of pregnancy.
Methods: This study was based on a cohort of births (N=7587) that occurred in a major university hospital in Barcelona during 2001-2005. Three indicators of extreme heat conditions were applied, two based on one day exposure to an unusually high (more than 95^{th} and 99^{th} percentiles of long-term average for the same day) heat-humidity index (perceived temperature) and one based on exposure to unusually hot temperatures persisting for a five-day period. Each mother was assigned the measures made by the closest (aerial distance) of three meteorological stations across the region (101 km^2). A two-stage analysis approach was developed with the first stage separating the monthly trend in gestational age for the study region as a whole from within-region personal variation and the second stage quantifying the risk using a range of covariates together with the predicted regional monthly trend by the first stage model as an offset. The second step was repeated for lags zero (delivery date) to six days.
Results: We detected a five-day (95% confidence interval of 0.5-10.1 days) reduction in gestational age at delivery after maternal lag 1 exposure to unusually high (99^{th} percentile) heat-humidity index. The result for the indicator of persistent heat was not conclusive because of the small number of exposed subjects.
Conclusions: Maternal exposure to extreme heat episodes results in a reduction in gestational age at delivery in lag1 exposure, suggesting an immediate effect of this exposure on pregnant women. Further studies are required to confirm our findings in different settings.

CLIMATE AND BACTERIAL INFECTIONS DURING PREGNANCY; PRESENT IMPLICATIONS AND FUTURE CONCERNS

Payam Dadvand, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Xavier Basagaña, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Francesc Figueras, *University of Barcelona, Spain*

Mark J. Nieuwenhuijsen, *Centre for Research in Environmental Epidemiology (CREAL), Spain*

Background and Aims: Maternal bacterial infections during pregnancy are both frequent and can be associated with serious complications like maternal morbidity and mortality, and life-threatening neonatal infections. The available evidence on the impact of climate on human bacterial infections particularly during pregnancy is very limited. This study was aimed to investigate the impact of climatic factors on maternal group B streptococci (GBS) colonisation during pregnancy.
Methods: This study was based on a cohort of births (N=7976) that occurred in a major university hospital in Barcelona during 2001-2005. Averages of daily temperature, relative humidity, and heat index (perceived temperature) over the weeks 32-36 (one month prior to sampling) of pregnancy measured by the closest (aerial distance) of three meteorological monitors to the maternal residential place were assigned to each subject. Logistic regression models were developed to extract adjusted odds ratios for continuous and categorical (quartiles) exposures.
Results: We detected an increased risk of GBS colonisation due to increase in daily average temperature (adjusted odds ratio (95% confidence interval (CI)) of 1.02 (1.01, 1.03)), relative humidity (1.03, 95% CI (1.01, 1.05)), and heat index (1.01, 95% CI (1.01, 1.02)). Treating exposures as categorical variables resulted in similar findings.
Conclusions: We found elevated risk of maternal GBS colonisation during pregnancy in association with increase in ambient temperature and humidity. If confirmed by future studies, our findings are important as they provide guidance for clinicians and policy makers for providing targeted primary and secondary preventions and in time, it offers a basis for assessing the impact of possible changes in future climate on maternal infections during pregnancy and their consequent complications.

MEASUREMENT ERRORS IN THE ASSESSMENT OF EXPOSURE TO SOLAR ULTRAVIOLET RADIATION AND ITS IMPACT ON RISK ESTIMATES IN EPIDEMIOLOGICAL STUDIES

Payam Dadvand, , *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Xavier Basagaña, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Jose Barrera-Gómez, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Brian Diffey, *Newcastle University, UK.*
Mark J. Nieuwenhuijsen, *Centre for Research in Environmental Epidemiology (CREAL), Spain*

Background and Aims: To date, many studies addressing long-term effects of ultraviolet radiation (UVR) exposure on human health have relied on a range of surrogates such as the latitude, ambient UVR levels, or time spent outdoors to estimate personal UVR exposure. This study aimed to differentiate the contributions of personal behaviour and ambient UVR levels on personal UVR exposure and to evaluate the impact of using UVR exposure surrogates on detecting exposure-outcome associations.
Methods: Data on time-activity was obtained from Expolis study (www.ktl.fi/expolis/) for adult (aged 25-55 years old) indoor workers in six European cities: Athens (37ºN), Grenoble (45ºN), Milan (45ºN), Prague (50ºN), Oxford (52ºN), and Helsinki (60ºN). Data on daily ambient UVR levels was obtained from Cost Action 726 (www.cost726.org/). Population-based data on holiday destinations of the corresponding countries to these cities were obtained from the Eurostat report on Tourism statistics. Annual UVR facial exposure levels were simulated for 10000 subjects in each city for 1997, using a behavioural UVR exposure model with data on time-activity, ambient UVR, and holiday destinations as inputs (Diffey 2008).
Results: Within-city variations of facial UVR exposure were three times larger than the variation between cities, mainly because of time-activity patterns. Ambient UVR levels, latitude and time spent outdoors alone accounted for less than one fourth of the variation in facial exposure levels. Use of these surrogates to assess long-term exposure to UVR resulted in requiring more than four times more participants to achieve similar statistical power to the study that applied true facial exposure.
Conclusions: Our results emphasise the importance of integrating both personal behaviour (time-activity and holiday behaviour) and ambient UVR levels/latitude in exposure assessment methodologies.

ASSOCIATIONS BETWEEN METEOROLOGICAL FACTORS AND OUTDOOR AIR-POLLUTION IN EACH TRIMESTER WITH ADVERSE BIRTH OUTCOME: 10 YEARS DAILY BIRTHS RECORDS TIME SERIES ANALYSIS

Michael, **Friger** *Ben-Gurion University of the Negev, Israel*
Zinovy Shraga, *Ben-Gurion University of the Negev, Israel*
Relly Hershkovitz, *Soroka University Medical Center, Israel*

Background and Aims: Small for gestational age (SGA) and preterm birth (PTB) are important causes of infant mortality, neonatal, peritoneal, childhood and long-term adult morbidity. There exist epidemiological evidences that environmental factors affect these birth outcomes and their impact in each pregnancy phase is different. However, knowledge about these effects is insufficient and contradictory. This study aimed to assess the association between meteorological and air-pollution factors in each of pregnancy trimester with SGA and PTB.
Methods: The data includes all daily birth records for August 1999 – February 2010 registered at a medical center serving the entire population of Southern Israel. Dependent variables were defined as daily counts of SGA and PTB. Daily total birth count was used as offset variable. Meteorological variables list included daily measurements of temperature, relative humidity, solar radiation and wind velocity. Air-pollution variables list included particular matters PM10, total nitrogen oxides (NOx), sulfur dioxide (SO2), carbon monoxide (CO) and ozone (O3). Natural cycles based on annual and weekly cycles are considered in trigonometric form. GLM Poisson models based on special time series technique with independent variables lagged for each pregnancy trimester were used for assessment of above named associations.
Results: The mean daily temperature and humidity range were associated with SGA and PTB rates. The daily solar radiation negative associated with SGA and PTB rates. Exposure to NOx, CO, O3 were associated with SGA rates, and exposure to SO2, CO, O3 was associated with PTB rates.
Conclusions: Air-pollution and changes in weather are statistically significant associated with adverse birth outcomes in each pregnancy trimester. The possible air-pollution effect is combined and synergistic and influence of environmental exposure on SGA and PTB rates is different in each trimester. Our findings suggest the highest impact of environmental exposure during the third pregnancy trimester on considered births outcomes.

HEATWAVES, POPULATION HEALTH, AND EMERGENCY RESPONSE IN ADELAIDE, AUSTRALIA: LESSONS LEARNT

Peng Bi, *Discipline of Public Health, the University of Adelaide, Australia*
Arthur Saniotis, *Discipline of Public Health, the University of Adelaide, Australia*
Monika Nitschke, South Australian Department of Health
Dino Pisaniell, *Discipline of Public Health, the University of Adelaide, Australia*
Phil Weinstein , University of South Australia, Australia
Kevin Parton, Charles Sturt University, Australia
Gil Soo Han, Monash University, Australia

Background: Heatwaves in the southern regions of Australia have received greater public health attention. An unprecedented heatwave occurred in Adelaide in early 2009, with maximum temperatures over 40 ^{o}C in 5 consecutive days. There was a 14-fold increase in hospital admissions, 2.4% increase in emergency department presentations, and 186 people died over five days. The present article is based on a qualitative study, which examines emergency stakeholder responses to the 2009 heatwave.
Method: A qualitative interview was conducted in 2010. Interviews included the stakeholders from major Adelaide public hospitals, South Australian Ambulance Service, relevant South Australian Government Departments, Non-Government Organisations and other Service Providers. N Vivo has been used in data analysis.
Findings: The results are presented in below sections: (1) the lack of organisation in emergency services responses to the 2009 heatwave was examined; (2) evening temperatures and their impact were explored; (3) coping strategies used by emergency services personnel were inspected; and (4) emergency services and challenges to population health were checked.
The areas in emergency responses which need improvement as cited by key stakeholders were discussed, including (1) A more co-ordinated effort between emergency agencies in relation to their community responses; (2) Better management of triage patients during heatwaves which would prevent bottle-necks; (3) Increasing rest periods of emergency services staff and shorter working shifts in order to prevent fatigue; and (4) Greater clarification of heatwave trigger points in order to diminish misunderstanding by the public.

DDT, MALE REPRODUCTIVE HEALTH AND THYROID HOMEOSTASIS OF NON-OCCUPATIONALLY EXPOSED MEN FROM A MALARIA AREA IN LIMPOPO PROVINCE, SOUTH AFRICA

Christiaan De Jager *University of Pretoria, South Africa*
Natalie Aneck-Hahn, *University of Pretoria, South Africa*
Riana Bornman, *University of Pretoria, South Africa*
Rhena Delport, *University of Pretoria, South Africa*
Paulina Farias, *Instituto Nacional de Salud Publica, Mexico*
Marcello Spano, *ENEA Casaccia Research Center, Italy*

Background and Aims: The Persistent Organic Pollutant (POP), dichloro-diphenyl-trichloroethane (DDT), has been used for malaria vector control in Limpopo Province, South Africa, since 1945. POPs are noted for their toxicity, persistence and bio-accumulative characteristics. The Aim of the study was to investigate the association between DDT, as reflected in plasma concentrations, and seminal parameters, possible adverse effects on human sperm genetic integrity, and thyroid homeostasis, while considering related factors.
Methods: A cross-sectional study, recruiting 546 young males from three communities in an endemic malaria area where DDT is sprayed annually, was conducted. Blood plasma DDT and its metabolite levels were measured. A semen analyses were performed and sperm chromatin structure assay and Aniline Blue test were used to assess sperm DNA/chromatin integrity in 209 participants. Dietary intake, serum retinol-binding protein (RBP), transthyretin (TTR) and albumin concentrations and liver- and thyroid function were compared between cases with evidence of a body burden of DDT in the circulation and controls.
Results: The lipid adjusted DDT mean (+SD) and median concentrations were 109.2 (+106.6) and 83.9 µg/g, respectively; and the lipid adjusted DDE mean (+SD) and median concentrations were 246.2 (+218.5) and 177.8 µg/g, respectively. In additions to effects on seminal parameters, the results point to a weak association between DDT/DDE plasma concentration and the incidence of sperm with chromatin defects. Significantly lower thyroid hormone concentrations were in observed cases ($p \bullet 0.01$). A significant linear trend was observed for S-free T4 and T3 concentrations ($p<0.001$) and relatively low RBP concentrations were associated with significantly higher DDT and DDE isomer concentrations, and a higher DDE/DDT ratio ($p \bullet 0.01$), which signifies long-term exposure.
Conclusions: The results suggest that long-term non-occupational environmental DDT exposure may have a negative impact on seminal parameters, sperm chromatin integrity, and on thyroid function and related parameters of young South African males.

SPATIAL DISPERSION OF ISCHEMIC HEART DISEASE, RESPIRATORY AND NEUROLOGICAL DISEASES AND METEOROLOGICAL , AIR POLLUTION AND SOCIO-ECONOMIC FACTORS IN ISRAEL'S NEGEV DESERT

Background and Aims: The potential effects of ambient air pollution and meteorological factors on health have received much attention over the past decades. Epidemiological studies have shown that even small increases in air pollution are associated with increased morbidity and mortality. The present study aims to identify geographical (meteorological and air pollution) short term and socioeconomic impacts on cardiovascular, respiratory and neurological diseases in Beer-Sheva city, located in the northern part of the Negev desert.

Methods: 1.GIS and spatial statistics to analyze the spatial distribution of diseases of ER and hospitalization cases.
2. Vehicular air pollution dispersion model (AERMOD software) to receive spatial exposure proxy of NO2 and PM2.5.
3. GLM Poisson models based on time series techniques were used to analyze the association of short term meteorological, air pollution and socioeconomic factors with considered diseases rates.
Results: 1. Highest seasonal monthly noninfectious respiratory diseases hospitalization rate is found in the central part of the city. 2. Highest hospitalization rates found during winter. Significantly different hospitalization rate by seasons found for all disease groups studied. 3. Significant association between socioeconomic ranking and monthly hospitalization rates found for non infectiousrespiratory, diseases, heart ischemic and neuroloical diseasesin 2007. Association of meteorological factors (mean daily temperature and relative humidity) for the elderly (65+) and daily hospitalization rate found for non infectious respiratory diseases in 2003-2007. 5. Association was found between Daily traffic related air pollution is significantlyassociated with daily hospitalization respiratory and cardiovasclar diseases rates
Conclusion: The study showed that short-term exposure to meteorological factors and traffic related air pollution in Beer-Sheva were related to an increase in daily hospitalization rate of cardiovascular , respiratory and neurological diseases, especially in winter time and for the elderly (65+). The results should have implications for environmental thresholds and social policies.

USE OF A COMMUNITY-UNIVERSITY ENVIRONMENTAL JUSTICE PARTNERSHIP TO EXAMINE ENVIRONMENTAL HEALTH DISPARITIES IN NORTH CHARLESTON, SOUTH CAROLINA

Sacoby Wilson, *University of South Carolina, USA*
Herb Fraser-Rahim, *Low-Country Alliance for Model Communities, USA*
Erik Svendsen, *University of South Carolina, Columbia, USA*
Hongmei Zhang, *University of South Carolina, Columbia, USA*
Edith Williams, *University of South Carolina, Columbia, USA*
LaShanta Rice, *University of South Carolina, Columbia, USA*
Dayna Campbell, *University of South Carolina, Columbia, USA*

Background and Aims: The Lowcountry Alliance for Model Communities (LAMC), a community-based organization in North Charleston, SC, developed a partnership with the University of South Carolina to study and address local environmental justice and health issues. The objective of this study is to assess spatial disparities in exposure and health for LAMC neighborhoods and other disadvantaged neighborhoods in Metropolitan Charleston.
Methods: Data on the spatial location of EPA regulated facilities and other land uses regulated by the state of South Carolina was obtained. Additional data on air pollution, asthma, diabetes, heart disease, and cancer were obtained from 1998 to 2008 for Metropolitan Charleston. ArcGIS 9.3 was used to map the distribution of facilities, air pollution, and disease rates. Chloropleth maps were created to show the relationship between facility location and demographic composition (percent non-white, percent poverty, percent high school education). The spatial coincidence, spatial approximation, and cumulative distance functions were used to assess spatial disparities in the distribution of environmental hazards and land uses by race/ethnicity and socioeconomic status. SAS 9.2 was used to assess differences in the distribution of pollution-emitting facilities and land uses, pollution levels, and health outcomes at the census tract and census block group levels.
Results: Preliminary analyses have shown that there are spatial disparities in the distribution of environmental hazards and land uses in Metropolitan Charleston based on race and socioeconomic status.
Conclusions: There are racial/ethnic and SES exposure and health disparities in Metropolitan Charleston. Additional work should be performed to explore the linkages between exposure to hazards and pollution and health disparities.

HOUSEKEEPING HEALTH CARE WORKERS HAVE THE HIGHEST RISK FOR TUBERCULIN SKIN TEST CONVERSION

Isabella Karakis, Ministry of Health and Epidemiology department, Faculty of Health Science, Ben-Gurion University, Beer-Sheva, Israel.
Haggai Alexander Sherman, Faculty of Health Science, Ben-Gurion University, Beer-Sheva, Israel.,
Dov Heimer, Division of Pulmonology, Department of Medicine, Ben-Gurion University Soroka University Medical Center, Beer-Sheva, Israel.
Lea Bouhnik, Division of Pulmonology, Department of Medicine, Ben-Gurion University Soroka University Medical Center, Beer-Sheva, Israel.
Moshe Nimrod Maimon, Division of Pulmonology, Department of Medicine, Ben-Gurion University Soroka University Medical Center, Beer-Sheva, Israel.

Background and aims: TB is especially prevalent among health care workers (HCW) as compared to the general population. Not all health care workers are at the same risk for tuberculin skin test (TST) conversion, indicating latent tuberculosis infection. In Israel, reported rates of latent TB infection incidence and prevalence are relatively high. We hypothesized that exposure to hospitalized patients in internal medicine wards will be associated with higher risk of TST conversion. The aim of this study was to identify risk factors for TST conversion among health care workers.
Methods: A retrospective cohort study was conducted at a tertiary university medical center. We included every health care worker who had had a two steps negative TST at work entry and at least one consecutive TST in the five years period of 2005-2009 (mean follow-up period 55 months). Potential risk factors such as age, health care profession, patient exposure profile, workplace division and history of BCG vaccination were entered in the binomic logistic regression model.
Results: There were 450 subjects who met the inclusion criteria and 93 subjects had TST conversion (crude annual conversion rate 4.3%). The highest annual rates of TST conversion occurred in health care workers who worked as housekeeping staff (6.9%).
Older age of staff (above 35), a work environment with high patient turnover and employment in maintenance departments were significant risk factors for TST conversion (adjusted odds ratio of 2.05[1.3-3.3], 5.2[1.3-20] and 8.4[1.7-42], respectively [95% confidence interval]).
Conclusion: Housekeeping staff, older age workers and health care professionals working in the environment of high patient turnover are at increased risk for latent tuberculosis infection. Current measures for latent tuberculosis infection appear to be insufficient. We recommended to increase the awareness of housekeeping staff to occupational hazard of TST conversion and to allocate of more resources to screening system.

USE OF COMMUNITY–DRIVEN RESEARCH TO ASSESS BUILT ENVIRONMENT DISPARITIES AND THE VULNERABILITY OF WATER AND SEWER SERVICES IN UNDERSERVED ENVIRONMENTAL JUSTICE COMMUNITIES

Sacoby Wilson, *University of South Carolina, USA*
Chris Heaney, *University of North Carolina at Chapel Hill, USA*
Omega Wilson, *West End Revitalization Association,* USA

Background and Aims. Some low-income, communities of-color in the United States rely on a complex mixture of unregulated private wells and septic systems and inadequate public drinking water and sewer services. The West End Revitalization Association (WERA) developed and used the community-owned and -managed research (COMR) to assess disparities in the built environment with a focus on the quality of publicly regulated sewer and water infrastructure.
Methods. Community monitor (CM) training workshops and drinking water and surface water tests of fecal pollution were completed at private (target) and regulated public (referent) service households in three low-income African-American communities in Mebane, North Carolina. ArcGIS was used to map sewer and water infrastructure by race/ethnicity to assess disparities in infrastructure. We performed a cross-sectional household drinking water and sewer service survey and measured fecal pollution levels in drinking water and surface water supplies in the communities. Differences in turbidity (NTU) and fecal microbial indicator concentrations at target and referent sites in WERA neighborhoods (MPN/100ml) were evaluated using SAS version 9.
Results. Maps of sewer and water infrastructure showed disparities in access to this infrastructure by race/ethnicity in Mebane, North Carolina. CMs collected survey data showing a mixture of failing private wells and septic systems and regulated public drinking water and sewer infrastructure. Septic system failure ranged from 11-18%. Higher turbidity levels were observed in private wells compared to regulated public drinking water ($p<0.0001$). There was little statistical evidence of differences in surface water fecal pollution at target and referent sites. Drinking water and surface water fecal pollution levels exceeded maximum contaminant levels at several target and referent sites.
Conclusions. Drinking and surface water fecal contamination levels suggest a need for provision of improved water and sewer services to protect health in these underserved and marginalized EJ communities and more enforcement of regulations.

EVALUATION OF THE EFFECTIVENESS OF AN INNOVATIVE ENVIRONMENTAL JUSTICE AND HEALTH COMMUNITY-UNIVERSITY PARTNERSHIP

Sacoby Wilson, University of South Carolina, USA
Omega Wilson, West End Revitalization Association, USA
Leah Williams, University of South Carolina, USA
Roy Charles, University of North Carolina at Chapel Hill, USA
LaShanta Rice, University of South Carolina, USA

Background and Aims: There are gaps in the scientific knowledge on the effectiveness of community-university environmental justice (EJ) and health partnerships.. We will highlight how the West End Revitalization Association's partnership was used to address the lack of basic amenities, EJ issues, and public health issues in underserved black communities in North Carolina.
Methods: Self-administered surveys (N=37) and semi-structured interviews (N=35) were used to evaluate the effectiveness of WERA's partnership and use of the community-owned and managed research (COMR) approach and collaborative problem solving (CPS) model to address EJ and health issues. Interviews were audio-recorded and transcribed. Descriptive statistics and survey results were analyzed using SPSS v. 17.0.
Results: Analysis of interview and survey data has shown that WERA's partnership, particularly COMR, was effective in improving environmental literacy and addressing EJ and health issues in WERA neighborhoods. Survey respondents generally agree that WERA's COMR approach can be used to help build the community's trust in the scientific research process and also can be used to effectively address local environmental justice and health issues. There is more disagreement among survey respondents about the utility of the CPS approach in addressing local EJ and health issues. Analyses of interview data reveal that WERA's community-university partnership has been effective at addressing local EJ and health issues. Interviewees think COMR is a great way for communities to address their local EJ and health issues. Study participants generally agreed that the COMR approach can be adopted by other communities to address local EJ and health issues.
Conclusions: This evaluation provided information on the efficacy of WERA's COMR approach to address EJ and health issues and revealed barriers to participation and some key lessons learned that may be useful for others trying to address environmental health issues using a partnership approach and exposure assessment methods.

URINARY DIALKYL PHOSPHATE LEVELS BEFORE AND AFTER FIRST SEASON CHLORPYRIFOS SPRAY AMONGST FARM WORKERS IN THE WESTERN CAPE, SOUTH AFRICA

Mohamed Aqiel Dalvie, *University of Cape Town, South Africa*
Ina Naik, *National Institute for Occupational Health, South Africa*
Kalavati Channa, *National Institute for Occupational Health, South Africa*
Leslie London, *University of Cape Town, South Africa*

Background and Aims: Chlorpyrifos, an organophosphate (OP) insecticide associated with neurotoxic, reproductive and developmental effects [Perera et.al., 2005] is commonly used worldwide (Barr & Angerer, 2006) including in South Africa. The study investigated urinary levels of dialkyl phosphates (DAP), an OP biomarker, resulting from pesticide exposure amongst 40 farm workers.
Methods: Workers were tested (urinary DAP levels, anthropometry, short exposure questionnaire) before and after the first day of seasonal chlorpyrifos spraying.
Results: The workers (mean age = 42.2, SD: 61.1 years) were mostly male (65%). Median baseline urinary DAP was high amongst both non-applicators (1587.5 µg/g creatinine, n = 8) and applicators (365.6 µg/g creatinine, n = 9). There was not much evidence of an increase in post-spray DAP levels from pre-spray levels amongst both applicators and non-applicators. Hours mixing, spraying, driving a tractor and hours worked by non-applicators were not significantly associated with an increase in post-spray DAP levels adjusting for age, height, weight, gender, use of empty pesticide containers and self-reported kidney problems. Past applicator status was weakly positively associated with pre-spray DAP levels adjusting for age, height, weight, and gender, self-reported kidney problems, smoking and alcohol (• = 1019.5, p = 0.307, R^2 = 0.28.
Conclusions: The relationship between pesticide exposure and OP bio-monitoring require further investigation. The high DAP levels call for an epidemiological investigation into the health effects of OP pesticides.

Peter Fantke, *University of Stuttgart – USTUTT, Germany*
Oleg Travnikov, *Meteorological SYNTHESIZING Centre-East – MSC-E, Russia*
Alistair Hunt, *University of Bath – Ubath, UK*

Background and Aims: A case study has been performed which involved the full chain of assessments from policy drivers to health effect quantification at the population level across the EU-27, including monetary valuation of the estimated health impact. The main policy scenarios cover the period from 2000 to 2020 and include the most important Community policy developments expected to affect the environmental release of lead and the corresponding human exposure patterns. Three distinct scenarios were explored, namely the emission situation based on 2000 data, a business-as-usual scenario (BAU) up to 2010 and 2020, and a scenario incorporating the most likely technological change expected (Best Feasible Technical Reductions, BFTR) as response to current and future legislation (already planned).

Methods: Consecutive model calculations (MSCE-HM, Watson, Xtrafood, IEUBK) were performed by different partners on the project as part of the full chain approach to derive estimates of Pb blood levels in children as a consequence of the consumption of local produce.

Results: The estimated Pb blood levels were translated into an average loss of IQ points/child using an empirical relationship previously established at Vito. The calculated losses in IQ points were subsequently further translated into the average costs/child using a cost estimate of € 10.000 per IQ point based on data from a literature review. The estimated average reduction of costs/child (%) for all countries considered in 2010 under BAU and BFTR are 12.16 and 18.08%, respectively. In 2020 the percentages amount to 20.19 and 23.39%.

Conclusions: The case study provides an example of the full-chain impact pathway approach taking into account all foreseeable pathways both for assessing the environmental fate and the associated human exposure and the mode of toxic action to arrive at quantitative estimates of health impact assessment at the individual and the population risk levels alike at EU scale.

Acknowledgements: This research has been performed within the context of the EU funded Integrated Research Project HEIMTSA

CLIMATE CHANGE AND INCREASED PRECIPITATIONS: THE IMPACT OF HEAVY RAINFALLS ON SURFACE WATER TOTAL ORGANIC CARBON (TOC) AND RESULTING HUMAN EXPOSURE TO TRIHALOMETHANES

Marc-André Verner, *Département des Sciences Biologiques, Université du Québec à Montréal, Montreal, Canada*
Ianis Delpla, *Laboratoire d'Études et de Recherche en Environnement et Santé, École des Hautes Études en Santé Publique, Rennes, France*
Mathieu Valcke, *Institut National de Santé Publique du Québec, Montreal, Canada*
Vincent Bessonneau, *Laboratoire d'Études et de Recherche en Environnement et Santé, École des Hautes Études en Santé Publique, Rennes, France*
Olivier Thomas, *Laboratoire d'Études et de Recherche en Environnement et Santé, École des Hautes Études en Santé Publique, Rennes, France*
Sami Haddad, *Département de Santé Environnementale et Santé au Travail, Université de Montréal, Montreal, Canada*

Background and aims: Several studies suggest that climate change will be accompanied with increased precipitations. Heavy rainfalls can impact surface water total organic carbon (TOC) and, upon treatment, lead to higher trihalomethane levels in drinking water. These meteorological events could therefore exacerbate human exposure to these toxic disinfection by-products. This study aimed at i) assessing the impact of heavy rainfalls on surface water TOC and ii) evaluating subsequent exposure to chloroform and its internal dose metrics in humans.
Methods: Surface water TOC was measured in samples taken from an established sampling point used for drinking water production in a small river in Brittany (France) during dry days and following high precipitations (> 10 mm). Trihalomethane production during water treatment was estimated based on TOC levels, temperature and chlorine dose using an established multivariate model. Finally, drinking water chloroform levels were used to construct different scenarios of exposure (i.e., water consumption, shower/bath and inhalation) in newborns, children, adults and pregnant women using a published physiologically based pharmacokinetic (PBPK) model.
Results: Following high precipitations, surface water TOC increased from a median of 6.2 to 8.9 mg/L. Consequently, median total trihalomethane levels in drinking water were estimated to increase from 29.7 to 33.1 µg/L. Human exposures to chloroform after > 10 mm rainfalls increased hepatic metabolite levels by 11 % when compared to levels reached during dry days. This increase did not vary substantially between exposure routes or physiologic condition.
Conclusions: This study suggests that the occurrence of heavy rainfalls can increase surface water TOC levels. The higher levels of trihalomethanes in drinking water following these precipitations may lead to increased tissue levels in humans. In the context of climate change, risk assessors may need to consider higher exposure to drinking water contaminants.

EFFECT OF EXPOSURE TO P,P' DDE ON MALE HORMONE PROFILE IN MEXICAN FLOWER GROWERS OF STATE OF MEXICO AND MORELOS

Julia Blanco Muñoz, *Instituto Nacional de Salud Pública, Mexico*
Marina Lacasaña, *Escuela Andaluza de Salud Pública, CIBERESP, Spain*
Clemente Aguilar Garduño, *Escuela Andaluza de Salud Pública, CIBERESP, Spain*
Miguel Rodríguez Barranco, *Escuela Andaluza de Salud Pública, Spain*
Susana Bassol, *Universidad Autónoma de Coahuila, Mexico*
Mariano E. Cebrián, *Centro de Investigación y Estudios Avanzados, Mexico*
Inmaculada López Flores, *Escuela Andaluza de Salud Pública, CIBERESP, Spain*

Background and Aims: *p,p'*-dichlorodiphenyldichloroethene (*p,p'*-DDE) acts as an androgen receptor antagonist, (Kelce et al 1995), however the data regarding its hormonal effects in men are limited. The objective of this study was to evaluate the association between serum levels of *p, p'*-DDE and reproductive hormone profile in male flower growers of Mexico.
Methods: A longitudinal study was carried out in a population of men working in the production of flowers and ornamental plants in two Mexican states (Morelos and State of Mexico) during the periods July-October 2004 (rainy season) and December 2004-May 2005 (dry season). A questionnaire including information on their socioeconomic characteristics, tobacco and alcohol use, presence of chronic and acute diseases, occupational history and anthropometry was used and blood and urine samples were obtained. Serum levels of *p, p'*-DDE were analyzed by gas chromatography; FSH, LH, testosterone, estradiol, inhibin B and prolactin levels were measured by enzymatic immunoassay. We also analyzed urinary levels of dialkylphosphates (DAPs) by gas chromatography. Associations between serum levels of *p, p'*-DDE and male reproductive hormones (both transformed to their natural logarithm) were evaluated using multivariate generalized estimating equation (GEE) models.
Results: The median *p,p'*-DDE levels was 678.2 ng/g lipid (range: 9.4-12696.5) during rainy season and 626.7 ng/g lipid (range: 9.4-13668.1) during dry season. After adjusting for potential confounders (age, body mass index, state of residence and DAPs), *p, p'*-DDE levels were negatively associated with prolactin (β=-0.04, CI 95% -0.07, -0.008) and testosterone (β=-0.04, CI 95% -0.08, 0.005) and positively with inhibin B (β=0.11, CI 95% 0.02, 0.21).
Conclusions: These results provide additional support for that *p, p'*-DDE can affect hypothalamo-pituitary-gonadal axis function in humans.

VALIDATING A PHARMACOKINETIC MODEL OF POLYCHLORINATED BIPHENYLS (PCBs) USING BLOOD LEVELS IN CHILDREN FROM BIRTH UP TO 22 MONTHS OF AGE

Marc-André Verner, *Département des Sciences Biologiques, Université du Québec à Montréal, Montreal, Canada*
Kinga Lancz, *Department of Environmental Medicine, Slovak Medical University, Bratislava, Slovakia*
Tomas Trnovec, *Department of Environmental Medicine, Slovak Medical University, Bratislava, Slovakia*
Dean Sonneborn, *Department of Public Health Sciences, University of California-Davis, Davis, CA 95616, United States*
Irva Hertz-Piccioto, *Department of Public Health Sciences, University of California-Davis, Davis, CA 95616, United States*
Michel Charbonneau, *INRS-Institut Armand-Frappier, Laval, Canada*
Sami Haddad, *Département de Santé Environnementale et Santé au Travail, Université de Montréal, Montreal, Canada*

Background and aims: Recent evidence suggests that not only can PCBs disrupt neurodevelopment following prenatal exposure, but also that there are postnatal windows of susceptibility during which exposure may impact additional processes. Estimation of children exposure during different time windows is crucial when assessing such chemically induced ailments. However, the validation of a previously developed pharmacokinetic tool was restricted to the first 6 months of life. We aimed at validating a physiologically based pharmacokinetic (PBPK) model for the postnatal exposure to PCBs using blood levels sampled up to 22 months of age in a birth cohort of children from Slovakia.
Methods: We simulated blood PCB-153 level profiles in 328 children with sufficient information on cord blood levels, weight and height at or close to blood sampling times, duration of breast-feeding, gender and blood levels at two time points (on average at 6 and 16 months, ranging from 5 to 22 months). Predictions were compared to measured levels through Spearman's rank correlations and linear regression.
Results: Estimated levels correlated to measured levels with Spearman correlation coefficients of 0.79 and 0.81 for the 6 month and 16 month sampling times, respectively. Linear regression analyses revealed that estimations explained 62 % and 63 % of the variability in measured levels at 6 and 16 months.
Conclusions: Although correlations in this study were slightly lower than that obtained in our previous study, results suggest that the model is suitable for the estimation of postnatal levels up to 22 months of age. Studies are underway to calibrate the model, extend its validation to children of 5 years of age and to investigate the impact of postnatal exposure to PCBs on a multitude of health outcomes.

MATERNAL OCCUPATION DURING PREGNANCY AND PEDIATRIC ATOPIC DERMATITIS

I-Jen Wang, *Taipei Hospital, Department of Health, Taipei; China Medical University, Taichung, Taiwan*
Shoei-Loong Lin, *Taipei Hospital, Department of Health, Taipei, Taiwan;*
Pau-Chung Chen, *National Taiwan University College of Public Health, Taiwan*

Background and Aims Ž Maternal employment during pregnancy has been considered to be associated with prematurity and low birth weight. However, little is known about the effect of maternal employment on the development of atopic disorders. We want to evaluate associations between maternal employment status and atopic dermatitis (AD).
Methods: We used multistage, stratified systematic sampling to recruit 24,200 mother-newborn pairs from the Taiwan national birth registration in 2005. Maternal occupation categories, working hours, shift work, work stress, and potential confounders during pregnancy were gathered by questionnaires at 6 months of age. Information about development of AD was also collected at 6 months of age. Multiple logistic regression analysis was performed to estimate the association of maternal employment status and AD.
Results: Work stress during pregnancy increased the risk of AD in the offspring (OR=1.5, 95%CI=1.00~2.95). Those who work during pregnancy increased the risk of AD in the offspring compared to those without work (OR=1.44 95%CI=1.00~2.95). Shift work and working hours during pregnancy might increase the risk of AD, but failed to reach statistical significance.
Conclusions: Work stress during pregnancy increased the risk of AD in the offspring. However, there was no evidence that maternal shift work or long working hours had a higher risk of AD. Further follow-up study is warranted for other allergic diseases.

Keywords: atopic dermatitis; pregnancy; occupation

Galina V. Matyukhina, *Federal State Institution of Public Health Center for Hygiene and Epidemiology in the Sverdlovsk Region, Russia*

Background and Aims: Nonferrous metallurgical factories widespread across the Middle Urals, cause substantial environmental pollution with lead, posing a hazard to the health of their employees and to the residents of the cities where they are situated. Earlier we showed that in some of the urban areas lead concentrations in cord blood may exceed 1 µg/dl, or even 10 µg/dl, and that association could be established between these concentrations and adverse impacts on baby's health during the first year of life. Hence follows the challenge of identifying pregnant women with alarming blood lead levels for the purpose of lowering them.
Methods: In 2007-2008, we determined lead concentrations in the venous blood (PbB) by the atomic adsorption method in 1419 residents of 10 industrial cities at 20-24th week of pregnancy. Those with PbB>2 µg/dl were provided with a set of bioprotectors that had been successfully tested in a toxicological experiment. PbB was again measured at 32 to 34th week of pregnancy. For some of these women, lead concentrations were also measure in cord blood (PbB-cord).
Results: A statistically significant positive correlation is shown to be present between PbB at 32- 34th weeks and PbB-cord (Pearson's coefficient = 0.56, Spearman's coefficient = 0.48, P <0.001) with no statistically significant difference between them. Following the course of bio-protectors, the average PbB levels went down to 1.99±0.21 µg/dl from the initial 4.84±0.30 µg/dl (• <0.001). After the course, women also demonstrated a statistically significant reduction in the excretion of ••-ALA and a rise in blood haemoglobin.
Conclusions: Environmentally conditioned lead body-burden of pregnant women creates the risk of a toxic impact on both the woman and the foetus, but this burden may be substantially reduced with the help of a complex of bioprotectors promoting the elimination of lead and enhancing the organism's resistance to its effect.

HEARING LOSS AMONG CH-47D CHINOOKS HELICOPTER CREWS

Yaoh-Shiang Lin, MD, *Tri-Service General Hospital, National Defense Medical Center, Taipei, TAIWAN*

Ai-Ju Hou, *School of Public Health, National Defense Medical Center, Taipei, TAIWAN*

Chia-Hui Wu, RN, *Tri-Service General Hospital Penghu Branch, Penghu County, TAIWAN*

Chih-Hung Ku, ScD, *School of Public Health, National Defense Medical Center, Taipei, TAIWAN*

Background and Aims: The CH-47D Chinook, the most proficient and recognized transport helicopter, is a multi-mission helicopter for the military or rescuer units. According to the manufactures report, it can fly more than 150 mph at full load more than 330 nautical miles with long-range fuel tanks. The sources of rotary-wing aircraft noise include 2,220-shaft- horsepower twin Lycoming, T55-L-5 turbo shaft engines, and two 3-bladed rotors. To investigate the hearing loss among crews, we reviewed a five-year crews' annual physical examination data.

Methods: We conducted a retrospective longitudinal study (2008~2009) focus on the hearing loss among the CH-47D crews. Data were collected from the annual physical examination records, including the hearing loss in left and right ears at frequency 500 Hz, 1000 Hz, 2000 Hz, 4000 Hz and 8000 Hz. A generalized estimating equation (GEE) was used to assess the association of interests, as well with the adjustment with age.

Results: We found that during the pass 5 years: HL was not significantly increased with age (p=0.2753) and different ears (p=0.1380). Compared with the HL in 2005, there were not significant differences since 2006 to 2009. However, only the crews' HL at 4000 Hz had significant 3.94 dB (A) (p=0.0243) higher than the HL at 500 Hz. Moreover, compare with the variation of frequency differences at baseline (2005), there were only two significant difference at 1000 Hz vs. 500 Hz in 2008 (p=0.0112) and at 8000 Hz vs. 500 Hz in 2006 (p=0.0173).

Conclusions: It is evident that occupational NIHL may exist in the crews, especially at 4000 Hz. We suggest that a longitudinal follow-up is needed for the crews.

HEARING LOSS AMONG OH-58D CREWS

Chia-Hui Wu, RN, *Tri-Service General Hospital Penghu Branch, Penghu County, TAIWAN*

Ju-Yun Huang, *School of Public Health, National Defense Medical Center, Taipei, TAIWAN*

Tzu-Yun Chao, *School of Public Health, National Defense Medical Center, Taipei, TAIWAN*

Hsueh-Lu Chang, *Ministry National Defense Medical Affairs Bureau, Taipei, TAIWAN*

Yaoh-Shiang Lin, MD, *Tri-Service General Hospital, National Defense Medical Center, Taipei, TAIWAN*

Chih-Hung Ku, ScD, *School of Public Health, National Defense Medical Center, Taipei, TAIWAN*

Background and Aims: OH-58D Kiowa Warrior reconnaissance/attack helicopter contained 4-blade main rotor and 2-blade anti-torque rotor, which were one of the noise sources. Long-term exposure to the helicopter may result in pilots' hearing loss (HL). We report a 5-year study on the noise-induced hearing loss (NIHL) among the OH-58D helicopter pilots.

Methods: We conducted a retrospective longitudinal study (2005~2009) focus on the hearing loss among the AH-1H helicopter pilots. Data were collected from the pilots' annual physical examination records, including the hearing loss in left and right ears at frequency 500Hz, 1000Hz, 2000Hz, 4000Hz and 8000Hz. A generalized estimating equation (GEE) was used to assess the association of interests, as well with the adjustment with age.

Results: We found that during the pass 5 years: HL was significantly increased with age ($p=0.0255$). Left ear had 1.55 dB (A) higher HL than that of right ear ($p=0.0067$). Compared with the HL in 2005, the HL in 2006 and 2009 had 1.15 dB (A) and 5.21 dB (A) significant difference ($p<0.0001$), respectively. Regarding the HL at difference frequency, 4000 Hz and 8000 Hz had 5.29 dB (A) and 5.77 dB (A) significantly higher ($p<0.0001$ and $p<0.0001$) than the HL at 500 Hz, respectively.

Moreover, compare with the variation of frequency differences at baseline (2005), there were only one significant difference at 1000 Hz vs. 500 Hz in 2007 ($p=0.0100$).

Conclusions: Significant HL at 4000 Hz indicated an occupational hazard. We suggest (1) re-evaluating their hearing protective devices, such as era plug, noise muffs, and helmet, (2) establishing regulation for early warning shift and significant threshold shift, and (3) a longitudinal study for the HL among the crews.

THE APHEKOM PROJECT – A LITERATURE REVIEW OF AIR POLLUTION INTERVENTIONS AND THEIR IMPACT ON PUBLIC HEALTH

Background and Aims: Intervention studies play an important role in supporting and complementing scientific validation of results of epidemiological non-intervention studies linking air pollution and health. In this paper a collection of existing published intervention studies is reviewed with the aim to give a summarized overview spanning a variety of approaches regarding the type of the intervention and findings with the main focus on studies that assessed interventions that improved air quality and the associated positive impact on public health. Air pollution interventions were defined as events aimed at reducing air pollution and also events where air pollution reductions occurred as a side effect.
Methods: Intervention studies published in English from the 1960's up to January 2011 were considered for inclusion in this review. Studies have been selected for inclusion in the review based on the aim to span the diversity of interventions and their assessment of different health outcomes. Where interventions were examined by numerous studies with a variety of publications, only the main, most representative and/or most recent studies were included. The selection was based on a systematic search of Pubmed, Google Scholar, ISI Web of Knowledge^{SM} and Science Direct.
Results: In total, 22 intervention studies have been included in this review. This review shows that air pollution interventions have been successful at reducing air pollution levels. It was shown that there is consistent significant published evidence that most of these interventions have been associated with health benefits, mostly by way of reduced cardiovascular or respiratory mortality and or morbidity. Throughout the majority of reviewed interventions the found decrease in mortality exceeded by far the expected predicted figures based on observations of European multicity studies.
Conclusion: There is consistent and significant evidence that decreased air pollution levels following an intervention resulted in a health benefit for the assessed population.

THE ASSESSMENT OF THE IMPLEMENTATION OF FUEL RELATED LEGISLATIONS AND THEIR IMPACT ON AIR QUALITY AND PUBLIC HEALTH - THE APHEKOM PROJECT

Background and Aims: The main focus of Work Package 6 of the Aphekom project was: to develop innovative methods to analyse the decrease in air pollution levels following implementation of an European regulation to reduce the sulphur content in liquid fuels; to follow the evolution of health risks over time; to track related effect modifiers; and to quantify the monetary costs of health impacts of the implemented regulation.
Methods: Daily SO_2 air pollution and mortality data from 20 participating cities, spread all over Europe, was analysed employing generalized additive models (GAM) using in R statistical software environment. City specific effect estimates were combined using meta-analysis.
Results: A general downwards trend over the study period urban background SO_2 was observed. There was no clear step change in SO_2 concentrations after implementation of the Directives; rather a gradual decline in SO_2 levels was observed.
The health data analysis showed no evidence of change of slope in the dose-response curve after implementation of the legislations and hence observed effects were related to level changes. The analysis showed that an increase of $10\mu gm^{-3}$ in SO_2 levels was associated with an overall (pooled) increase in daily all-cause (0.53%), respiratory (0.49%) and cardiovascular (0.72%) mortality. Intuitively one would expect that a decrease in daily SO_2 levels would result in a decrease in daily deaths.
The meta-analysis of the mortality data suggests that overall 2212 (95% CI: 772; 3663) lives per year were saved associated with decreases in SO_2 for 20 European cities from year 2000 onwards compared to the pre-Directive period. This has been valued at about €192 million relying on preference-derived monetary values.
Conclusion: The findings underscores the health and monetary benefits from drafting and implementing effective EU policies on air pollution and ensuring compliance with them over time.

PROFILING SO_2 AIR POLLUTION PATTERNS IN 9 EU APHEKOM CITIES - THE APHEKOM PROJECT

Background and Aims: A detailed analysis of hourly pollutant concentrations mainly focusing on SO_2 data obtained from 9 centres involved in the Aphekom project was conducted. This involved the generation of individual diurnal SO_2 profiles in order to:

(i) identify city specific patterns including source apportionment and quantification,
(ii) track changes over time,
(iii) analyse the changes in SO_2 concentrations from different emission sources, i.e. traffic, heating, shipping and industrial sources, overtime.

Methods: Individual cities diurnal (24hr) SO_2 profiles were generated using hourly SO_2 measurements from different monitoring sites by season and by weekday for each year. European cities with suitable data included Athens, Bordeaux, Brussels, Dublin, Le Havre, London, Rouen, Strasbourg and Vienna.

Results: For the majority of the examined cities similar diurnal patterns were found with a general decreasing trend for SO_2 levels overtime. Morning and evening traffic rush hours were strongly reflected widely in the diurnal profiles as well as lower weekend SO_2 levels due to missing traffic volume and industry related emissions. Seasonal heating related peaks were observed during evening and night-time hours during the winter months.
City specific SO_2 patterns were identified. For example for Dublin these reflected late-night shopping hours on Thursdays. For London these patterns showed elevated SO_2 levels during midday, suggesting the metropolitan life-style of the city involving constant traffic use.

Conclusion: For the majority of the cities examined road traffic and heating appeared to be the most important sources of SO_2 emissions and hence the driving components widely reflected in the diurnal profiles. Furthermore a decrease in emissions related to those two sources overtime has been observed.
Detailed hourly pollution profiles can prove very useful to policy makers/planners in identifying sources and hence policies to reduce pollution levels.

THE GEOGRAPHY OF VIOLENCE IN A US CITY. ALCOHOL, DRUGS AND NEIGHBORHOOD COHESION.

Robert Lipton, *University of Michigan, United Stated*
Xiaowen Yang, *Beth Israel Deaconess Medical Center, Israel- Harvard Medical School , United States*

Background and Aims: We determine, in the city of Boston in 2008, what geographic/environmental and individual factors are related to the production of violence (including subjective and objective assessments of the environment/neighborhood) as well as assessing dynamic relationships between adjacent geographic areas.
Methods: Data from the Boston Police Department (violence, drug arrests and 911 call data), the census, survey data on neighborhood collective efficacy and Massachusetts state data on alcohol outlet type and location. Spatial modeling, including lags to assess adjacency, is employed (census block groups) and maps of hot spots for violence, alcohol outlets and drug markets are produced.
Results: Census block groups with high levels of violence were associated with high levels of drug trafficking arrests, and high densities of liquor stores and bars, within a given area as well as adjacent to the "target" area, controlling for neighborhood disorganization and collective efficacy. Model based violence hot spot areas were found to be adjacent to areas with high drug arrest rates and high densities of liquor stores. There was no difference found between models including and excluding 911 call data.
Conclusions: Spatial effects were, above and beyond typical socio-demographic measures, found to play a role in the prevalence of violence in Boston in 2008. Further, model based hot spots were identified that were found to be associated with significantly higher values for social-demographic, alcohol outlet and drug arrest measures. This is one of the first analyses in which drug arrest and alcohol outlet data, as well as subjective and objective environmental measures, were included in assessing the prevalence of violence. Further, we include the effects (lags) of adjacent area measures/features on target area violence prevalence. Socio-demographic, environmental and drug arrest information were all found, to some degree, to be significantly related to violence, while controlling for spatial autocorrelation.

OZONE AND PARTICULATE AIR POLLUTION TRIGGER DIFFERENT TYPES OF OUT-OF-HOSPITAL CARDIAC ARREST

Frank S. Rosenthal, *School of Health Sciences Purdue University, United States*
Markku Kuisma, *Helsinki emergency Medical Services, Finland*
Timo Lanki, *National Institute of Health and Welfare, Finland*
Tareq Hussein, *Department of Physics, University of Helsinki, Finland*
James Boyd, *Helsinki Emergency Medical Services, Finland*
Jaana Halonen, *National Institute of Health and Welfare, Finland*
Juha Pekkanen, *National Institute of Health and Welfare, Finland*

Background and Aims: Out-of-hospital cardiac arrest (OHCA) has been previously associated with exposure to air pollution. But it is not clear if it acts by precipitating myocardial infarction or by other mechanisms. We studied the effects of particulate and gaseous air pollution on the risk of OHCA due to myocardial infarction (MI) vs. the risk of OHCA due to other cardiac causes, in Helsinki 1998- 2006.
Methods: Helsinki Emergency Medical Services provided OHCA data. Cardiac cause was identified from prior symptoms, ECGs, hospital and autopsy reports. Pollutant data was obtained from central ambient monitors. A case-crossover analysis determined hazard ratios (HRs) for hourly lagged exposures (Lag 0 - 3) and daily lagged exposures (Lag 0d - 3d).
Results: Among OHCAs due to MI (OHCA_MI), interquartile increases in pollutant exposure were associated with elevated HRs for PM2.5 (Lag 0, 1.16 95% CI:1.04, 1.28, Lag 1, 1.16 CI: 1.04, 1.28, Lag 2, 1.14 CI:1.03, 1.26, Lag 0d 1.21 CI: 1.07, 1.37), PM10 (Lag 0, 1.31 CI 1.02, 1.23, Lag0d, 1.12 CI: 1.05, 1.37), Acc (Lag 2, 1.11 CI: 1.00, 1.22, Lag 0d, 1.18 CI 1.04, 1.34) and NO (Lag 0d, 1.06 CI: 1.01, 1.12). Among OHCAs not identified as due to MI (OHCA_Other), elevated HRs were associated with ozone exposure (Lag 0d, 1.30 CI: 1.03, 1.64; Lag 1d, 1.41 CI: 1.11, 1.79; Lag 2d, 1.37 CI: 1.08, 1.73). HRs for OHCA_MI and ozone were nonsignificantly less than one; HRs for OHCA_Other and PM2.5 were close to one and nonsignificant. HRs for OHCA_MI associated with PM2.5 compared to HRs for OHCA_Other and ozone showed opposite trends with sex and season.
Conclusions: The results suggest that air pollution triggers OHCA via two distinct modes: one associated with particulates and leading to MI and one associated with ozone involving etiologies other than MI, e.g. arrhythmias.

THE INFLUENCE OF IN-UTERO SMOKE EXPOSURE ON ATOPIC DISORDERS VIA EPIGENETIC MECHANISM

I-Jen Wang *Taipei Hospital, Department of Health, Taipei; China Medical University, Taichung, Taiwan;*
Pau-Chung Chen *National Taiwan University College of Public Health, Taipei, Taiwan*

Background and Aims: Evidence has shown that in-utero exposure has important effects on DNA methylation. However, how prenatal tobacco smoke exposure affects DNA methylation leading to atopic disorders remains to be addressed. Since most children suffering from atopic dermatitis (AD) continue to develop asthma later in life, we explored whether prenatal smoke exposure may induce aberrant DNA methylation of specific genes that were related to childhood AD.
Methods: We recruited 261 newborns with cord blood in Taiwan birth panel study. At 2 years of age, information about development of AD and environmental exposures were collected. Cord blood cotinine levels were measured by high performance chromatography-mass spectrometry (HPLC-MS/MS) to stand for prenatal smoke exposure. Methylation differences associated with smoke exposure were screened in cord blood DNA of 14 cohort children by whole genome methylation array. CpG loci that demonstrated a statistically significant difference in methylation were validated by SNaPshot. The functions of the candidate genes were also investigated.
Results: Differential methylation of CpG loci in four genes (TSLP, GSTT1, CYB5R3, and KRT6C) was identified through the screen. Of these, thymic stromal lymphopoietin (TSLP) gene exhibited significant increases in methylation in the exposed than non-exposed children after being validated by SNaPshot (p = 0.001). TSLP gene was therefore selected for further investigation in a larger sample of 54 cohort children. The degree of TSLP 5′CpG islands methylation was inversely related with TSLP protein levels in cord blood.
Conclusions: The effect of prenatal tobacco smoke exposure on the risk for childhood atopic disorders may be mediated through alterations in DNA methylation.

ASSOCIATIONS OF PERSISTENT ORGANIC POLLUTANTS WITH ABDOMINAL OBESITY IN THE ELDERLY: THE PROSPECTIVE INVESTIGATIONS OF THE VASCULATURE IN UPPSALA SENIORS (PIVUS) STUDY.

P Monica Lind, *Occupational and Environmental Medicine, Uppsala University, Uppsala, Sweden*
Lars Lind, *Acute and Internal Medicine, Uppsala University Hospital, Uppsala, Sweden*
David R Jacobs, *Division of Epidemiology, School of Public Health, University of Minnesota, Minneapolis, Minnesota, US*
Samira Salihovic, *MTM Research Center, School of Science and Technology, Örebro University, Örebro, Sweden*
Bert van Bavel, *MTM Research Center, School of Science and Technology, Örebro University, Örebro, Sweden*
Duk-Hee Lee, *Department of Preventative Medicine, School of Medicine, Kyungpook National University, Daegu, Korea*

Background and Aims: Although experimental studies observed that persistent organic pollutants (POPs) could induce visceral obesity, there is little human study on this possibility. This study aimed to evaluate associations between POPs and abdominal obesity using both cross-sectional and prospective data.
Methods: Twenty one POPs (including 16 polychlorinated biphenyl (PCB) congeners, 3 organochlorine (OC) pesticides, 1 brominated diphenyl ether (BDE), and 1 dioxin) were measured in plasma collected at baseline in 969 participants aged 70 years of the Prospective Investigation of the Vasculature in Uppsala Seniors (PIVUS). Prospective analyses were based on 511 participants re-examined after 5 years. Abdominal obesity was defined by an increased waist circumference using the APTIII/NCEP-criteria.
Results: At age 70, 322 subjects were abdominally obese. Plasma concentrations of the less chlorinated PCBs, OC pesticides such as p,p-DDE and dioxin were associated with increased risk of abdominal obesity (adjusted odds ratios of 2 to 3). Many of relations had inverted U-shapes rather than being linear, in particular in women. On the contrary, serum concentrations of highly chlorinated PCBs were strongly inversely associated with abdominal obesity. As plasma concentrations of POPs were highly correlated, when summary measures of the less chlorinated PCBs, highly chlorinated PCBs, and OC pesticides were included in one model, both the positive associations and inverse associations became strengthened. During 5 years follow-up, 100 subjects developed abdominal obesity. Similar associations, however less powerful, were seen between POPs and risk of development of abdominal obesity.
Conclusion: Using both a cross-sectional and a prospective design, low-dose exposure to some POPs, like low-chlorinated PCBs, p,p-DDE, and dioxin, were found to contribute to the development of abdominal obesity, while high-chlorinated PCBs seem to induce the opposite effect in an elderly population.

EXPOSURE TO PERSISTENT ORGANIC POLLUTANTS PREDICTS STROKE IN THE EDERLY.

Lars Lind, *Acute and Internal Medicine, Uppsala University Hospital, Uppsala, Sweden*
P Monica Lind, *Occupational and Environmental Medicine, Uppsala University, Uppsala, Sweden*
David R Jacobs, *Division of Epidemiology, School of Public Health, University of Minnesota, Minneapolis, Minnesota, US*
Bert van Bavel, *MTM Research Center, School of Science and Technology, Örebro University, Örebro, Sweden*
Samira Salihovic, *MTM Research Center, School of Science and Technology, Örebro University, Örebro, Sweden*
Duk-Hee Lee, *Department of Preventative Medicine, School of Medicine, Kyungpook National University, Daegu, Korea*

Background and Aims: The background exposure to persistent organic pollutants (POPs), lipophilic xenobiotics mainly accumulated in adipose tissue, has been recently emerged as a new risk factor of cardiovascular diseases. This prospective study was performed to evaluate if plasma concentrations of selected POPs predict the future risk of stroke among elderly.
Methods: Twenty-one POPs (including 16 polychlorinated biphenyl (PCB) congeners, 3 organochlorine (OC) pesticides, 1 brominated diphenyl ether (BDE), and 1 dioxin) were measured in plasma collected at baseline in 898 participants aged 70 years of the Prospective Investigation of the Vasculature in Uppsala Seniors (PIVUS). Stroke events were identified through hospital records.
Results: During the five year follow-up, 35 subjects developed stroke. During After adjusting for known risk factors of stroke, most PCBs with 4, 5, or 6 chlorine atoms, p,p-DDE, trans-nonachlor, and OCDD significantly predicted the risk of stroke. When we used quartiles of summary measures of PCBs and OC pesticides, the adjusted ORs were 1.0, 0.8, 1.2, and 2.1 for PCBs and 1.0, 1.2, 2.3, and 3.0 (95% confidence interval: 1.0-9.4) for OC pesticides (P for trend =0.11 and 0.03, respectively). The adjusted ORs of summary values among subjects with ≥ 90% were 5.5 (1.7-18.1) for PCBs and 4.0 (1.1-14.6) for OC pesticides. Those among those with ≥ 95% were 7.8 (2.1-29.6) and 9.5 (2.3-38.9), respectively.
Conclusion: The background exposure to POPs may play an important role in the development of stroke in elderly.

MONITORING OF ORGANOCHLORINE PESTICIDES IN WATER BASINS

Anahit Aleksandryan, *Ministry of Nature Protection of the Republic of Armenia, Yerevan, Republic of Armenia*
Artak Khachatryan, *Waste Research Center, Yerevan, Republic of Armenia*

Background and Aims: Organochlorine pesticides as persistent organic pollutants (POPs) possess various degree of stability to photolysis, biological and chemical degradation. These substances are semi-volatile; this latter allows their long- distance transport through air flow to all parts of the globe, even to remote areas thousands of kilometers from the nearest POPs source. The following problem was set: to determine residual amounts of organochlorine pesticides, including in surface water of rivers and Lake Sevan as the largest lake in Armenia and a natural reservoir of drinking water for the entire region.
Methods: Generally accepted gas-chromatography analysis was performed to trace the residues of mentioned pesticides in samples of surface and drinking water.
Results: DDE (metabolite of DDT) was determined in water samples from Sevan Lake at 0.016 mcg/L and Lindane (gamma-HCH) at 0.067 mcg/L. In samples of drinking water from Yerevan DDT made 0.0013 mcg/L, while HCH achieved 0.0028 mcg/L. In samples of drinking water from Vanadzor HCH (summary) made 0.01 mcg/L.
Analyses for Hexachlorobenzene (HCB) in waters of open reservoirs revealed this substance in the range of 0.005-0.056 mcg/L. HCB residue amounts were also determined in samples from water supply network of cities Yerevan and Vanadzor. In 9 out of 12 samples of water collected in Yerevan HCB was revealed within the range of 0.0001-0.0078 mcg/L. In Vanadzor the residues of HCBs averaged 0.005 mcg/L.
Analyses to determine residual amounts of Heptachlor found out that in surface waters it ranged 0.034-0.17 mcg/L (averagely 0.074 mcg/L).
Conclusions: The results signify to continuing circulation of organochlorine pesticides in environmental compartments. From contaminated areas POPs, though at insignificant amounts, penetrate to different environmental media (ground and surface waters, air), plants, agricultural produce, and then by trophic chains POPs residues penetrate into human organism

EXPOSURE OF ENVIRONMENTAL POLLUTANTS IN GANGNEUNG AS A NON-INDUSTRIAL AREA IN KOREA

Dae-Seon Kim, *Environmental health dept. National Institute of Environmental Research, Republic of Korea*
Seung-Do Yu, *Environmental health dept. National Institute of Environmental Research, Republic of Korea*
Seung Chul Ahn, *Environmental health dept. National Institute of Environmental Research, Republic of Korea*
Sang-Hwan Song, *Environmental health dept. National Institute of Environmental Research, Republic of Korea*
Sang-Hoon Nam, *Environmental health dept. National Institute of Environmental Research, Republic of Korea*

Background and Aims: In order to investigate the relation between environmental pollution and the human health effect in large scale industrial complex regions, cohort studies have been launched since 2003.
The main purpose of this Gangneung study is to produce background data of a non-industrial area which can be compared with some large scale industrial complex regions, such as Ulsan, Sihwa.Banwol, Gwangyang.Yeosu, Pohang and Cheongju.Daesan industrial complexes.
Methods: In this Gangneung study, 1,007 local residents were recruited, and the framework of this study designed to evaluate and monitor health effects associated with low-level but long-term exposure to environmental pollutants. This survey has been performed based on identical questionnaires, medical checkup, allergen skin-prick test with 12 common allergens, sampling and chemical analysis basically. And the environmental pollutants including heavy metals(Pb, Cd, Hg, As) in blood and urine sample were analysed.
Results: The diagnosis prevalence and medical treatment prevalence of asthma were lower than industrial complex regions. But allergic rhinitis was higher. The allergen skin test prevalence was 26.0% and the most common allergen was dust mite (D. *pteronyssinus* 18.0% and D. *farinae* 17.3%). The concentration of heavy metals were 1.57 ㎍/dℓ for Pb in whole blood, 0.82 ㎍/g-creatinine for Cd, 0.98 ㎍/g-creatinine for Hg and 15.78 ㎍/g-creatinine for As(3+, 5+, MMA, DMA) in urine. The concentration of Pb-B was lower than, Cd-U and Hg-U were similar with, and As-U in Gangneung was higher than those in large scale industrial complex regions, Korea.
In the analysis of 11 kinds of VOCs, Vinyl Chloride, 1,3-Butadiene, Dichloroethylene were not detected. Anyway, the detection rate in the others was more than 70% except Chloroform(49.7%) and Trichloroethylene(19.0%). In 16 kinds of PAHs, 10 kinds showed more than 80% in detection rate and 0.01-0.21 ㎍/L in concentration, on the otherhand, Acenaphthylene and Acenaphthene were not detected. In 4 kinds of PCBs, it showed 52-78% of detection rate and 0.003-0.005 ㎍/L in concentration. The level of organic compounds was similar with other large scale industrial complex regions, Korea.

WORKPLACE EXPOSURE TO TRAFFIC-DERIVED NANOSCALED PARTICULATES

Mar Viana, *Institute for Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain*
Sergi Díez, *Institute for Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain*
Cristina Reche, *Institute for Environmental Assessment and Water Research (IDAEA-CSIC), Barcelona, Spain*

Background and Aims: Ambient air emissions of sub-micron particles infiltrate into indoor environments and play a major role in occupational exposure (Martuzevicius et al., 2008). Discriminating between particles of indoor vs. outdoor origin is therefore essential when assessing indoor air quality in urban environments. Our study aimed to determine occupational exposure to traffic-derived nanoscaled particulates in a typical Mediterranean environment.
Methods: Sub-micron particles were monitored by means of a multi-angle absorption photometer (MAAP) and a laser spectrometer (GRIMM 1107), providing black carbon (BC) and PM1 concentrations, respectively. The studied laboratory is located on the 5th floor of an 8-storey building in an urban background environment in Barcelona, Spain. The laboratory was not in use during the study period. Windows were kept closed at all times. Indoor BC and PM1 concentrations were compared with ambient BC and PM1 levels from an outdoor monitoring station.
Results: Results evidenced the major impact of outdoor vehicular traffic emissions on indoor particulates: 70% of indoor BC and 73% of indoor PM1 originated from outdoor emissions. This was probably due to due to inadequate insulation of the building. Outdoor/indoor penetration ratios were relatively constant for BC (1.29±0.08) but not for PM1 (1.95±0.38).
Conclusions: In occupational exposure assessment studies, it is advisable to monitor the variability of the penetration factors as a function of time in order to accurately discriminate the contribution to indoor air quality of particulates originating from indoor and outdoor sources. Printing and photocopying contributed with 25-30% (546 ng/m3) of total indoor BC. Dust re-suspension by worker passage was the main source of PM1 (15-20%, 1.1 µg/m3). Workplace exposure to indoor pollutants was determined during day and night work-shifts.

CROSS SECTIONAL AND LONGITUDINAL ASSOCIATIONS BETWEEN PFOS AND PFOA IN THE MID OHIO VALLEY AND CLINICAL MARKERS OF DISEASE

Tony Fletcher, *London School of Hygiene & Tropical Medicine, United Kingdom*
Ben Armstrong, *London School of Hygiene & Tropical Medicine, United Kingdom*
Nicola Fitz-Simon, *London School of Hygiene & Tropical Medicine, United Kingdom*
Giovanni Leonardi, *London School of Hygiene & Tropical Medicine, United Kingdom*
Valentina Gallo, *London School of Hygiene & Tropical Medicine, United Kingdom*
Maria-Jose Lopez-Espinosa, *London School of Hygiene & Tropical Medicine, United Kingdom*
Debapriya Mondal, *London School of Hygiene & Tropical Medicine, United Kingdom*

Background and Aims: Experimental data and epidemiological studies have suggested potential effects of PFCs, in particular PFOA and PFOS, on a number of clinical markers reflective of or predictive of chronic disease, including lipids, hormones and immune markers. While suggestive, results of cross sectional studies pose difficulties in interpretation due to uncertainties regarding causality. The aim of this presentation is to compare estimates derived from a cross sectional with a nested longitudinal study in the same population.
Methods: In the C8 Science Panel Community Study in the Mid Ohio Valley, associations between clinical markers and PFCs have been investigated in 67,000 participants with individual exposure, biomarker and questionnaire data from 2005-6. Within this population a nested sample of 755 participants was recruited for which clinical markers and PFCs were measured in 2010.Exposure to PFOA had largely stopped at or soon after the first survey and PFOS exposure was also largely reduced. By modeling the change in clinical markers versus change in PFCs, we may test more directly the dependence of biomarkers on PFC levels.
Results: PFOA serum levels in 2005-6 (mean 80 ng/ml) and PFOS (mean 25 ng/ml) were raised in comparison to typical US levels due to contaminated drinking water. Cross sectional analyses indicate significant associations with a number of clinical markers, including serum lipids, which increase with increasing PFOA or PFOS, and serum C Reactive Protein and Immunogobulin A, which fall with increasing PFOA or PFOS. Between the two surveys, the mean fall in PFOA was 54% and in PFOS was 56% (adjusted for age and time). We will also report longitudinal changes in biomarkers.
Conclusions: The collection of longitudinal data is expensive and therefore the nested study was smaller than the cross sectional study, leading to wider confidence intervals. Longitudinal studies address evidence of causality more directly.

SOIL CONTAMINATION BY ORGANOCHLORINE PESTICIDES AND HEALTH AFTER-EFFECTS

Anahit Aleksandryan, *Ministry of Nature Protection of the Republic of Armenia, Yerevan, Republic of Armenia*
Governmental Building 3, Republic Square, Yerevan 0010, Republic of Armenia
Vahagn Khachatryan, *National Institute of Oncology, Yerevan, Republic of Armenia*

Background and Aims: The problem of contaminated areas and stocks of inappropriate-for-use pesticides, including obsolete organochlorine pesticides is of top-priority for the Republic of Armenia. The problem is aggravated by obsolete organochlorine pesticides burial located in the vicinity of Yerevan, the capital of Armenia, in the zone of active landslide processes. The damage and a possible "breakthrough" of the contents ("innage") of the burial and the subsequent penetration of residues of buried obsolete pesticides into the environment might result in environmental pollution.
Another problem is pollution from sites of former pesticides shops and storehouses.
Methods: Generally accepted gas-chromatography method of analysis was applied to determine residues of organochlorine pesticides in samples of soil taken from evidently polluted sites in different regions of Armenia. Soil samples were analyzed for DDT and its metabolites, Hexachlorocyclohexane, Lindane, Hexachlorobenzene, Heptachlor.
Results: In soil samples taken near former pesticide storehouses Heptachlor content varied from 1.889 to 3.677mcg/kg, DDT ranged 0.266-40.310mcg/kg. The highest amounts of DDT were determined in samples from Armavir (40.10mcg/kg) and Etchmiadzin (8.32mcg/kg). DDE content in analyzed samples made 0.067-10.039 mcg/kg, DDD: 0.0022-1.039mcg/kg, Hexachlorocyclohexane residues were at 0.002-12.682mcg/kg, Lindane – 0.076-7.086mcg/kg, Hexachlorobenzene –0.063-13.992mcg/kg.
In samples from the territory of former pesticide shops Heptachlor was in the range of 1.611-2.758mcg/kg, DDT- 0.694-55.496mcg/kg, DDE- 0.038mcg/kg, DDD-1.067 mcg/kg, Hexachlorocyclohexane – 0.006-3.502mcg/kg, Lindane – 0.64-1.512mcg/kg, Hexachlorobenzene – 0.46-1.842mcg/kg.

Soil from the territory of the shops was less polluted than the soil near the storehouses.

Conclusions: Solution of the problem relevant to remediation of contaminated areas is of prime significance and urgency for Armenia, taking into account the important role of soil in the entire chain "environment – human health" as the main vehicle and probable carrier of pollutants The problem is more than serious due to the fact that its solution requires a continuous period of time.

ORGANOCHLORINE COMPOUNDS: TROPHIC CHAIN TRANSFER

Anahit Aleksandryan, *Ministry of Nature Protection of the Republic of Armenia, Yerevan, Republic of Armenia*
Vahagn Khachatryan, *National Institute of Oncology, Yerevan, Republic of Armenia*

Background and Aims: Persistent Organic Pollutants (POPs) are capable to migrate for long distance, persist in the environment for long years, cumulate in environmental media, food-stuffs, and adipose tissues of animals and humans.
Methods: Generally accepted gas-chromatography method of analysis was performed to determine residues of Heptachlor, HCH, DDT, HCB in samples of food from different regions of Armenia.
Results: Despite the prohibitive actions, the residual amounts of DDT continue to be revealed in foodstuffs, environmental media (soil, surface water) and even human organism.
DDT content in eggs made 0.07-635.0 mcg/kg, in meat: 0.67-4.45 mcg/kg, in milk: 0.16-1.45 mcg/L, in cheese: 0.19-7.11 mcg/kg.
HCH in eggs made 0.07-1.72 mcg/kg, Lindane – 0.35-0.73 mcg/kg. In meat residues leveled 0.09-1.61 mcg/kg, while Lindane amounted 0.23-0.7 mcg/kg. In samples of milk HCH made 0.02-1.23 mcg/L; residues of Lindane 0.06-2.25 mcg/L. In cheese residues of HCH and Lindane were at 0.20-3.18 and 0.03-5.17 mcg, appropriately.
Monitoring on Hexachlorobenzene (HCB) in foodstuffs from different regions of Armenia signifies to presence of this pesticide in eggs within the range of 0.008-4.54mcg/kg. In samples of meat HCB ranged 0.028-9.16mcg/kg; residues in samples of milk leveled to 0.009-0.74 mcg/L, while in samples of cheese the compound made 0.1-15.65 mcg/kg.
Residues of Heptachlor in eggs made 0.023-0.12 mcg/kg, in meat 0.024-4.23 mcg/kg, in samples of milk 0.023-0.12 mcg/L. In samples of cheese Heptachlor was not revealed, except 1 sample (0.153 mcg/kg).
Conclusions: As residues of all investigated pesticides were revealed in eggs and meat, the findings testify to fresh application of POPs (DDT and HCH).
Contamination of agricultural lands and food-stuffs by pesticide residues poses threat for the environment and human health. Therefore, issues of pesticides management should not be considered as problems of exceptionally ecological significance.

HEAT VS. HEAT WAVE RELATED MORTALITY – ARE THE SUSCEPTIBLE GROUPS COHERENT?

Joacim Rocklöv, *Umeå University, Sweden*
Kristie Ebi, *Carnegie Institution of Science, U.S.*
Bertil Forsberg, *Umeå University, Sweden*

Background and Aims: Several recent studies explored the separate mortality effects of heat and the duration of heat waves. Some of them show large differences in the associated effects. However, few studies have investigated whether the effects related to heat and heat waves are homogeneous or heterogeneous in subgroups of a study population. We aim to study the effects of heat and a heat wave´s duration according to age, cause of death, social factors and medical history.
Methods: We studied the population of Stockholm, Sweden. We used Poisson models adjusting for over-dispersion, regressing daily ambient weather condition on daily deaths by strata of the population. We additionally adjusted for calendar effects, seasonality, influenza and long-term time trends using smooth functions and factor variables. We assessed the sensitivity of confounding by air pollution. To evaluate effect-modification of individual social and medical factors, we employed the case-only design.
Results: For natural causes of death, the effect of heat wave duration was estimated as a RR of 1.024 (1.010 to 1.038) per day in sequence, while the effect of elevated heat was estimated as a RR of 1.006 (1.001 to 1.010) per degree C. The effects varied by age and cause of death. Heat wave duration was significantly related to higher deaths in ages from 65 years and with cardiovascular and non-cardiorespiratory causes, while heat was found associated only with deaths in ages 80+ and with non-cardiorespiratory causes.
Men appeared to have lower RR to heat, while higher RR to heat wave duration compared to women. A recent hospitalization appeared to reduce the RR for both stressors. We found a strong effect-modification of the RR related to heat wave duration for the group having pre-existing mental disorders. A pre-existing cardiovascular hospitalization appeared to reduce the effect of both stressors.
Conclusions: The effect of heat and a heat wave´s duration differs among subgroups of the population in Stockholm, Sweden. A differentiation of heat exposure and heat wave duration can yield a better understanding of when a susceptible group is particularly vulnerable, and, thus, help targeting adaptive and preventive efforts with benefits for the public health.

PRENATAL EXPOSURE TO DDT AND BIRTH OUTCOMES IN WOMEN RESIDING IN A MALARIA ENDEMIC AND NON MALARIA COASTAL REGIONS OF SOUTH AFRICA

Halina B. Röllin, *Medical Research Council and University of Pretoria, South Africa*

Kalavati Channa, *National Institute for Occupational Health, South Africa*

Jon Ø. Odland, *University of Tromsø, Norway*

Torkjel M. Sandanger, *Norwegian Institute for Air Research, Norway*

Background and Aims: DDTs are highly persistent and accumulate in the environment, food chain and humans. Use of DDT for indoor residual spraying (IRS) to control malaria vector is a subject of ongoing debate as DDT and its metabolites are considered to be endocrine disruptive chemicals. Potential risks to the developing foetus and young child are of concern. The objective of this study was to assess the extent of exposure to DDT and its metabolites in pregnant women residing in the malaria control and non malaria coastal regions of South Africa.
Methods: The study included totally 270 women admitted for delivery at the maternity sections of provincial hospitals who donated blood for chemical analyses and signed an informed consent form. They answered a socio-economic questionnaire by interview and allowed access to their post delivery records. Blood plasma samples were analysed for DDT and metabolites using the GCMS techniques. Birth outcomes and confounding factors were also evaluated.
Results: As expected, the highest levels of DDT and metabolites were found in delivering women residing in IRS area, but elevated levels were also observed in some women residing in non malaria region.
Conclusion: It is understood that exposures to contaminants may pose greater health risks to the populations in the southern hemisphere that is highly compromised by poverty and poor health status, compared to the northern hemisphere. This effect may be further potentiated by climate change. Findings of this investigation will inform policy makers both locally and internationally including the work within Stockholm Convention on POPs and Roll Back Malaria initiative. In conclusion, future monitoring and careful follow up of health in the area is needed. The distinct exposure patterns in study sites, makes this area very suitable for the implementation of birth registries.

CYTOGENETIC EFFECT MARKERS IN MOTHERS AND FETUSES EXPOSED TO ENVIRONMENTAL CHEMICAL MUTAGENS

Nina Zaitseva, *Federal Scientific Center for Medical and Preventive Health Risk Management Technologies, Russia*
Marina Zemlyanova, *Federal Scientific Center for Medical and Preventive Health Risk Management Technologies,Russia*

Background and Aims: Maternal exposure to environmental chemical mutagens (heavy metals, formaldehyde) may enhance risk for congenital malformations and chromosome aberrations in fetuses (newborns). We aimed to determine cytogenetic effect markers in mothers and fetuses exposed to environmental chemical mutagens using epidemiological study data.
Methods: A cytogenetic examination of 95 mother-newborn pairs exposed to environmental chemical mutagens including manganese, nickel, lead, formaldehyde (a study group), and 70 non-exposed dyads (a control group) was carried out analyzing metaphase chromosomes from mother and newborn's blood lymphocytes by the standard method. Blood chemical mutagen concentrations were determined applying atomic absorption spectrophotometry, liquid chromatography. The relationship between the frequency of chromosome aberrations, and the exposure to the chemical mutagens was assessed using epidemiological study data and calculating odds ratio (OR).
Results: The blood samples from the pregnant and parturient women were found to contain elevated formaldehyde, manganese, nickel, lead concentrations (1.5-12 fold increase compared to the reference levels) (p=0.001). Polymorphic chromosome changes were detected in 30% of the study group women that exceeded the control group indices by 5-fold. The probability (OR) of chromosome aberrations in newborns from the exposed women with chromosome polymorphism was higher (OR=6.7) compared to the control group. We determined the probability of chromosome aberrations in newborns whose mothers demonstrated high frequency of chromosome polymorphism associated with the exposure to formaldehyde and nickel (OR=10.5, p=0.001). The probability of numerous congenital malformations and chromosome aberrations was higher in newborns of women exposed to manganese, lead and nickel having an increased frequency of chromosome polymorphism (OR=2.7, p=0.001).
Conclusions: Exposure markers are elevated concentrations of manganese, formaldehyde, nickel, lead in the mothers and newborns' blood. Cytogenetic effect markers are high frequency of chromosome polymorphism in the mothers and associated chromosome aberrations in the newborns.

A NESTED CASE-CONTROL STUDY OF INTRAUTERINE EXPOSURE TO PERSISTENT ORGANOCHLORINE POLLUTANTS IN RELATION TO RISK OF HYPOSPADIA

Anna Rignell-Hydbom, *Lund University, Sweden*
Christian H Lindh, *Lund University, Sweden*
Joakim Dillner, *Lund University, Sweden*
Bo AG Jönsson, *Lund University, Sweden*
Lars Rylander, *Lund University, Sweden*

Background and aims: In western countries the prevalence of hypospadias varies from two to eight cases per 1,000 live births. Knowledge about risk factors for hypospadias is still scarce. However, environmental exposures to so called endocrine disrupting chemicals (EDCs) have been suggested as a risk factor. An important group of EDCs is persistent organochlorine pollutants (POPs). Due to the unique personal identification number present in the biobank databases and the national health registries in Sweden we have the possibility to investigate the association between POPs and hypospadias in relatively large studies.

Methods: The Malmö Microbiology Biobank (MMB) contains about 200 000 deep-frozen serum samples, stored after population-based serological screening for virus infections and rubella immunity during pregnancy week 14. Linkages between the Medical Birth Register, the Malformation Register and the In-patient Register resulted in 390 boys with hypospadia. For 237 (61 %) of them, sufficient amount of serum samples were found in the biobank. For each case a control boy was randomly selected from the MMB.

2,2',4,4',5,5'-hexachlorobiphenyl (PCB-153), the major DDT metabolite 1,1-dichloro-2,2-bis (*p*-chlorophenyl)-ethylene (*p,p´*-DDE) and hexachlorbenzene (HCB) were used as biomarkers of POP exposure.

Results: A 65 percent statistically significantly increased risk in the highest maternal exposure quartile of HCB as compared to the three lowest HCB exposure categories was observed. The pattern was, although not statistically significant, similar for maternal exposure for *p,p'*-DDE.

Conclusion: The present study indicates that *in utero* exposure to HCB and perhaps exposure to *p,p'*-DDE is a risk factor for hypospadia. The fact that HCB and *p,p'*-DDE may affect the androgen-signalling pathway should reinforce the concept that ECDs, though present at low doses, may affect human health negatively.

A META-ANALYSIS OF CORD SERUM CONCENTRATIONS OF PCB AND BIRTH WEIGHT

Eva Govarts, *Flemish Institute for Technological Research (VITO), Environmental Risk and Health, Boeretang, Belgium*
Jens Peter Bonde, *Department of Occupational and Environmental Medicine, Bispebjerg Hospital, University of Copenhagen, Denmark*
on behalf of the ENRIECO/OBELIX consortia*

Background and Aims Exposure to high concentrations of persistent organochlorines may cause fetal toxicity, but evidence regarding reproductive effects at lower concentrations is limited. Within the framework of the EC ENRIECO and OBELIX projects, we examined the hypothesis that polychlorinated biphenyls (PCBs) impair fetal growth.

Methods We used maternal and cord blood and breast milk samples in 7.990 women enrolled in twelve European birth cohorts from 1990-2008, and re-expressed all measurements as cord serum estimates of PCB 153. Using identical variable definitions, we performed linear regression analyses of birth weight on cord serum estimates of PCB 153 for each cohort. Analyses were adjusted for gestational age and a priori selected covariates. Summary estimates were obtained by meta-analysis.

Results The median concentration of cord serum PCB 153 was 134 ng/L (range of medians 20–485). In all cohorts except the two smallest, birth weight decreased with increasing cord serum concentration of PCB 153 after adjustment for potential confounders. The meta-analysis across all cohorts indicated a birth weight decline of 150 g (95% CI 50-250 g) per one µg/L increase of PCB 153, which is close to the range of exposure levels across the cohorts. The results did not change substantially in any of the sensitivity analyses in all or subsets of the cohorts. These included control for weight gain during pregnancy, restriction to full term babies, control for lipid concentration in serum and models based upon quadratic and loglinear transformations of exposure measures. Finally, we found no indication of effect modification of gender, tobacco smoking or concentration of the DDT metabolite p,p´-DDE.

Conclusions The findings suggest that low-level exposure to PCB or correlated exposures in Europe impairs human fetal growth.

PHARMACEUTICAL COMPOUNDS IN SOILS IRRIGATED WITH RECLAIMED WASTEWATER: FATE IN THE AGRO-ENVIRONMENT

Benny Chefetz, *Department of Soil and Water Sciences, The Hebrew University of Jerusalem, Israel*
Oshri Burgman, *Department of Soil and Water Sciences, The Hebrew University of Jerusalem, Israel*
Ran Yakir, *Department of Soil and Water Sciences, The Hebrew University of Jerusalem, Israel*
Haniella Harush, *Department of Soil and Water Sciences, The Hebrew University of Jerusalem, Israel*
Moshe Shenker, *Department of Soil and Water Sciences, The Hebrew University of Jerusalem, Israel*

Background and Aims: Irrigation with reclaimed wastewater accounts for more than 50% of total irrigation water in Israel. This unique situation of intensive irrigation with reclaimed wastewater and sludge application containing residues and active pharmaceutical compounds (PCs) provides an excellent opportunity to study the long-term exposure effects of these compounds in soils. The long-term introduction of PCs to arable land may affect the agro-ecosystem in various aspects which are not known to date. In this study we aimed to elucidate the behavior (transport, sorption-desorption and plant uptake) of pharmaceutical compounds in the agro-ecosystem and to evaluate the potential transport of the compounds to groundwater and more importantly to enter the food-chain via crops.
Methods: All the studied compounds were detected in reclaimed wastewater used for crop irrigation. Transport and sorption experiments were performed with soil layers sampled from a plots that have been irrigated with reclaimed wastewater for long period. Uptake by plants was studied in hydroponic greenhouse experiments using different soil types irrigated with fresh water or reclaimed wastewater
Results: Carbamazepine and diclofenac were significantly retarded in the 0-5 cm soil sample rich in soil organic matter. Carbamazepine was not affected by the water quality (freshwater vs. reclaimed wastewater), whereas diclofenac exhibited a higher retardation factor (RF) in the freshwater system. Naproxen exhibited significantly lower RFs than diclofenac but with a similar trend—higher retardation in the freshwater versus reclaimed wastewater system. In the 5-15 cm soil sample containing low soil organic matter, naproxen was highly mobile while carbamazepine and diclofenac were still retarded. In the 15-25 cm sample, all compounds exhibited their lowest RFs. The antibiotics sulfamethoxazole and sulfapyridine exhibited high mobility under both fresh and wastewater application and were not affected by sludge application.
Carbamazepine concentration in cucumber fruits and leaves was negatively correlated with the level of organic matter in the growing medium. The concentrations of carbamazepine in the roots and stems of cucumber plants were relatively low; most of it (76-84% of total uptake) was detected in the leaves. A greenhouse experiment using fresh water and reclaimed wastewater spiked, or not, with carbamazepine at 1 $\mu g\ L^{-1}$ (typical concentration in effluents) revealed that it can be taken up and bio-accumulated from its indigenous concentration in reclaimed wastewater. Our experimental data in hydroponic culture suggest that the uptake of carbamazepine can be considered passive and unrestricted and the translocation is governed by water mass flow; therefore, in the greenhouse experiments, the bioaccumulation factor for the fruits was significantly lower than the value calculated for the leaves.
Conclusions: Our data suggest that carbamazepine and diclofenac can be classified as slow-mobile compounds in soil organic matter-rich soil layers. When these compounds pass this layer and/or introduced into soil organic matter-poor soils, their mobility increases significantly (Chefetz et al., 2008). Other compounds based on their physico-chemical properties can be considered as highly mobile in soils. This study emphasizes the potential uptake of active pharmaceutical compounds by crops in organic-matter-poor soils irrigated with reclaimed wastewater and highlights the potential risks associated with this agricultural practice (Shenker et al., 2011).

DEVELOPMENT OF INDICATORS FOR MONITORING THE IMPLEMENTATION OF INTERNATIONAL COMMITMENTS TO REDUCE HEALTH IMPACTS OF ENVIRONMENTAL FACTORS IN THE WHO EUROPEAN REGION

Andrey Egorov, *WHO European Centre for Environment and Health, Bonn, Germany*
Dafina Dalbokova, *WHO European Centre for Environment and Health, Bonn, Germany*
Christian Gapp, *WHO European Centre for Environment and Health, Bonn, Germany*
Michal Krzyzanowski *WHO European Centre for Environment and Health, Bonn, Germany*

Background and Aims: The WHO European Centre for Environment and Health develops and maintains the Environment and Health Information System (ENHIS) which entails indicators of exposure to and population health effects of priority environmental factors and related policy actions. ENHIS is being expanded in order to monitor the implementation of the commitments of the Fifth Ministerial Conference on Environment and Health in Europe (Parma, Italy, 2010) focusing on the protection of children's health.
Methods: Initial indicator proposals were developed by international experts focusing on the time-bound Parma Conference commitments. A minimum set of indicators to enable monitoring of these commitments was selected at a WHO technical meeting using a structured indicator evaluation approach. Current efforts concentrate on refining indicator methodologies and implementing pilot projects in selected countries.
Results: Indicators characterizing the school environment include access to properly maintained sanitation facilities, hygienic practices, mode of transportation to school, smoking in schools and on school grounds, exposures to dampness and moulds, ventilation rate in classrooms, and exposure to indoor chemical air pollutants, such as formaldehyde and nitrogen dioxide. These indicators require a periodic survey of schools across the European Region. The survey will employ a randomized clustered sampling design and be based, to the extent possible, on the existing national and international monitoring efforts to minimize the costs. New biomarker-based indicators are designed to characterize temporal trends in early life exposure to selected chemical pollutants. Policy indicators relying on national-level surveys will provide insights into actions and regulations aimed at reducing exposure to harmful environmental factors and promoting healthy behaviours.
Conclusions:ENHIS will rely on standardized application of surveillance and epidemiological methods across Europe, and serve as a main source of information on the effects of Parma commitments implementation. A baseline assessment report will be released in 2013.

GEOGRAPHIC AND GENDER DIFFERENCES IN AUTISM SPECTRUM DISORDERS AMONG CHILDREN: ANALYSIS OF THE DATA FROM THE NATIONAL REGISTRY IN TAIWAN

Yen-Cheng Tseng, *Chang Jung Christian University, Taiwan*

De-Chung Lai, *Chiayi Christian Hospital, Taiwan*

Yuh-Ming Hou, *Chiayi Christian Hospital, Taiwan*

How-Ran Guo, *National Cheng Kung University, Taiwan*

Background and Aims: The prevalence of autism spectrum disorders (ASD) in the world has increased dramatically in the recent decades. However, data at the national level are limited, and geographic differences are seldom evaluated. We conducted a study to estimate the prevalence of ASD in Taiwanese children and to assess the geographic and gender differences.

Methods: According to the law, each city and county in Taiwan is mandated to certify the disabled residents and provide various services, and the Department of Interior maintains a registry of certified cases. The registry started to enroll cases of ASD since 1990 and publish summary data annually, which provide a unique opportunity to study epidemiology of ASD at the national level. We analyzed the data from 2000 to 2009.

Results: From 2000 to 2009, the registered cases increased from 2,062 to 9,160 annually, and the prevalence increased every year in all age groups. In each year there were more male cases than female cases, and the male-to-female ratio ranged from 5.99 to 6.80, with an increasing trend over time ($p < 0.01$). A higher prevalence was observed in the urban areas over the years, and the prevalence rate ratio ranged from 2.49 to 2.99, with a decreasing trend over time ($p < 0.01$).

Conclusions: The prevalence of ASD has been increasing in Taiwanese children. The risks were higher in rural areas than in urban areas and higher in boys than in girls. Further analyses of data on individual cases are desirable.

RETROSPECTIVE EXPOSURE ESTIMATION AND PREDICTED VERSUS OBSERVED SERUM PERFLUOROOCTANOIC ACID CONCENTRATIONS FOR PARTICIPANTS IN THE C8 HEALTH PROJECT

Hyeong-Moo Shin *School of Social Ecology, University of California, Irvine, California, USA*
Verónica M. Vieira, *Department of Environmental Health, Boston University, Boston, Massachusetts, USA*
P. Barry Ryan, *Department of Environmental Health, Emory University, Atlanta, Georgia, USA*
Kyle Steenland *Department of Environmental Health, Emory University, Atlanta, Georgia, USA and C8 Science Panel*
Scott M. Bartell *Program in Public Health, University of California, Irvine, California, USA*

Background and Aims: People living or working in eastern Ohio and western West Virginia have been exposed to perfluorooctanoic acid (PFOA) released by the DuPont Washington Works facilities. The specific aim of this work is to estimate historical PFOA exposures and serum concentrations experienced by each of 45,276 non-occupationally exposed participants in the C8 Health Project who consented to share their residential histories.
Methods: Annual PFOA exposure rates were estimated for each individual based on predicted calibrated water concentrations and predicted air concentrations from a previously published environmental fate and transport model, individual residential histories, and default assumptions from the EPA Exposure Factors Handbook. Individual exposure estimates were coupled with a one-compartment pharmacokinetic model to estimate time-dependent serum concentrations.
Results: For all participants (n = 45,276), predicted and observed median serum concentrations in 2005-2006 are 21.6 and 24.3 ppb, respectively (Spearman's rho = 0.67). For participants who provided daily public well water consumption rate and who had the same residence and workplace in one of six municipal water districts for 5 years before the serum sample (n = 785), predicted and observed median serum concentrations in 2005-2006 are 30.3 and 39.3 ppb, respectively (Spearman's rho = 0.83).
Conclusions: Serum PFOA concentrations predicted by linked exposure and pharmacokinetic models are well correlated with observed 2005-2006 human serum concentrations for C8 Health Project participants. These individualized retrospective exposure and serum estimates may be useful for a variety of epidemiologic studies being conducted in this region.

RESIDENTIAL DISTANCE TO ROAD AND THE RISK OF INCIDENT CORONARY HEART DISEASE AND ALL CAUSE MORTALITY

Jaime E Hart, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Department of Epidemiology, Harvard School of Public Health, Boston, MA, USA*
Eric B Rimm, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Departments of Epidemiology and Nutrition, Harvard School of Public Health, Boston, MA, USA*
Kathryn M Rexrode, *Division of Preventive Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA*
Francine Laden, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Departments of Epidemiology and Environmental Health, Harvard School of Public Health, Boston, MA, USA*

Background and Aims: Long-term exposures to ambient air pollution, especially from traffic sources, have been associated with increased cardiovascular morbidity and mortality. Few studies, however, have been able to also examine the effects of changes in pollution exposure on changes in risk. The current study explored the association of residential distance to road with incident CHD and all cause mortality risk during 20 years of follow-up in the prospective Nurses' Health Study cohort of US women.
Methods: Cases of incident coronary heart disease (CHD), defined as first nonfatal myocardial infarction or fatal CHD, and all-cause mortality were identified from 1988-2006. We calculated distance to road for each address 1986-2004 as a proxy for traffic pollution exposure. To examine the effect of changes in exposure to traffic, each consecutive pair of addresses was categorized as: (1) consistently exposed, (2) consistently unexposed, (3) move from exposed to unexposed, and (4) move from unexposed to exposed.
Results: Among the 79,134 women available for analysis, a total of 2,575 incident CHD cases and 9,074 deaths were identified over 1,141,417 person-years. In fully adjusted time-varying Cox proportional hazards models, women with a current address exposed to traffic were at an 8% (95%CI: -5%, 23%) higher risk of an incident CHD event and a 6% (95%CI: -1%, 14%) higher risk of all cause mortality, These risks were similar in women who were in the consistently exposed category. Although the numbers were small, there was a suggestion that the highest risks were seen among women who moved from unexposed addresses to exposed addresses.
Conclusions: Our results suggest an association between residential proximity to roadways and incident CHD and all-cause mortality. The risk was most notable in women who moved from an unexposed to an exposed address.

TRAFFIC-RELATED AIR POLLUTION, CHILDHOOD ASTHMA AND THE INFLUENCE OF CANDIDATE GENES INVOLVED IN OXIDATIVE STRESS

for the TAG Study Team

Background and Aims: We combined previously collected data from two Canadian and four European birth cohorts to examine whether exposure to traffic-related air pollution interacts with a child's genetic profile to impact their risk of developing asthma.
Methods: Logistic regression was used to evaluate the association between traffic-related NO_2 (land use regression or dispersion model) and physician-diagnosed asthma or parent reported 'ever wheeze' at school age, stratified by *glutathione S-transferase P1* (*GSTP1*) and *tumor necrosis factor* (*TNF*) genotypes. Interaction terms were included to test for interaction between genotype and NO_2 in models for asthma and wheeze. Analyses were adjusted for gender, cohort, city, maternal age, parental atopic disease, and environmental tobacco smoke exposure (and intervention status for relevant studies).
Results: The combined dataset contained information for 4,902 children (380 asthma cases; 2,182 wheeze cases) and included three single-nucleotide polymorphisms (SNPs): rs1799811 (*GSTP1*; $C>T^{114}$), rs947894 (*GSTP1*; $A>G^{105}$) and rs1800629 (*TNF*; $G>A^{308}$). Pooled estimates for asthma by rs1799811 were elevated for carriers of the minor (CT,TT) alleles [OR per 10 $\mu g/m^3$ of NO_2: 2.12(95%CI: 1.12-4.00)] but not for major (CC) allele carriers [1.12(0.80-1.56)]. Accordingly, the interaction between rs1799811 and NO_2 was statistically significant (p-value=0.012) for asthma. The estimates for asthma for the remaining two SNPs were not statistically significant and interactions for both were also non-significant (p-value=0.152 for rs947894 and 0.051 for 1800629). Pooled estimates for wheeze, stratified by allele, were not statistically significant for any of the SNPs considered. Interactions for the *GSTP1* SNPs were not statistically significant in models for wheeze (p-value=0.889 for rs1799811 and 0.819 for rs947894), but the interaction for rs1800629 was significant (p-value=0.008).
Conclusions: In the largest study of its kind to date, we find that children with the rs1799811 minor alleles are at increased risk for developing asthma when exposed to traffic-related air pollution.

A FLEXIBLE SPATIO-TEMPORAL MODEL FOR AIR POLLUTION WITH SPATIO-TEMPORAL COVARIATES

Johan Lindström, *Lund University, Sweden*
Adam Szpiro, *University of Washington, United States*
Paul D Sampson, *University of Washington, United States*
Lianne Sheppard, *University of Washington, United States*
Assaf P. Oron, *University of Washington, United States*
Mark Richards, *University of Washington, United States*
Timothy V Larson, *University of Washington, United States*

Background and Aims: We developed a spatio-temporal model for predicting ambient air pollution that combines unbalanced monitoring data with deterministic air quality model output. This work is part of the Multi-Ethnic Study of Atherosclerosis and Air Pollution (MESA Air) study, a prospective cohort study funded by the US EPA to investigate the relationship between chronic exposure to air pollution and cardiovascular disease.

Methods: The monitoring data includes three spatial "snapshots" at 174 locations; rotating monitors giving 2-3 measurements at 84 subject homes; and 25 time series of two-week averages at fixed and regulatory monitoring (AQS) sites. The data are unbalanced because at any given time measurements are available at only a subset of measurement sites. We also have geographic covariates and a spatio-temporal covariate based on the output from a source dispersion model for traffic-related air pollution (Caline3QHC; Wilton et al 2010).

We extended our unified hierarchical spatio-temporal model (Szpiro et al, 2010) to accommodate spatio-temporal covariates. We improved the estimation approach and developed several cross-validation strategies to make the fullest use of the available data. We assessed predicted NOx concentrations in Los Angeles.

Results: The model predicted well with cross-validated spatial R^2 of approximately 0.7 at subject homes. We successfully incorporated the source dispersion model output into the prediction model, but our implementation of Caline3QHC did not improve predictions in a model with road covariates. However, we found some evidence that Caline3QHC could replace the road covariates.

Conclusions: This spatio-temporal model for air pollution concentrations provides a flexible approach to combining irregularly sampled pollution monitoring data with geographic covariates and the output from deterministic air quality models. We successfully predicted long-term average NOx concentrations while taking full advantage of the unbalanced monitoring data available to the MESA Air study. This model has been implemented in an R-package, `SpatioTemporal`.

Research and Analysis on the Current Situation of the Noise Pollution in Xi'an City's Acoustic Environmental Domains

Junhan Liu, *Peking University, China*
Lun Yan, *Peking University, China*
Xiaochuan Pan, *Peking University, China*

Background and Aims: To find out the noise pollution situation in the acoustic environmental domains in Xi'an city
Methods: Measure the noise level in Xi'an city's domains day and night during the period of January to June, from year of 2007 to year of 2009 and report the monitor result in the seasonal average equivalent sound level.
Results: The monitor result of the noise pollution in Xi'an city's five kinds of acoustic environmental domains is listed as follows: Special residential area's daytime noise in the first season is within the national standard, which exceeds the national standard in the second season from year of 2008, the night noise is all beyond it; the relevant indexes of Residential culture and education area are all exceed the national standard; The mixed area's daytime noise is within the limit in the recent years; while its nighttime noise is only within the national standards in 2010; The industrial area's daytime and nighttime is all beyond the limit; The area around the main transportation routes has qualified daytime noise for all four season, yet the night noise is beyond the limit.
Conclusions: The situation of noise exceeding the national limit exists in all domains in the city, and the night noise situation is more serious. Besides, the noise levels in the night time of the third season in the industrial area and the daytime of the second season of the mixed area have an obvious increase compared with other seasons, which might affect the Xi'an city residents' normal quality of life, and should be controlled.

CHRONIC EXPOSURE TO TRAFFIC POLLUTION IS ASSOCIATED WITH REDUCED GLOMERULAR FILTRATION RATE

Shih-Ho Lue, *Seton Hall University School of Health and Medical Science, Elizabeth, USA*
Gregory A. Wellenius, *Brown University, Providence ,USA*
Elissa H. Wilker, *Harvard School of Public Health, Boston, USA*
Murray A. Mittleman, *Harvard School of Public Health, Boston, USA*

Background and Aims: Chronic exposure to air pollution from traffic, as measured using residential distance to major roadway, has been associated with increased incidence of cardiovascular diseases endpoints. Considering that chronic kidney disease and cardiovascular disease share certain common risk factors, we hypothesized that chronic exposure to traffic pollution would be associated with a lower estimated glomerular filtration rate (eGFR).
Methods: Serum creatinine was drawn at the time of hospital presentation among 1120 consecutive patients hospitalized for stroke. We calculated eGFR using the Chronic Kidney Disease Epidemiology Collaboration equation. We calculated residential distance to the nearest major roadway as a measure of exposure to traffic pollution. We abstracted from medical records information on patient demographics, past medical history, and admission medications, and obtained data from the 2000 US Census on income and educational attainment as a measure of census track socioeconomic status. We used linear regression to estimate the association between residential distance to major roadway and eGFR, controlling for age, sex, race, smoking, diabetes, hypertension, heart failure, coronary artery disease, treatment with angiotensin converting enzyme inhibitors, and socioeconomic status. We considered distance to major roadway as both a categorical variable (0-50, 50-100, 100-200, 200-400, and >400 m) and a log-transformed continuous variable.
Results: Living closer to a major roadway was associated with a statistically significantly lower eGFR versus living farther away (p-trend=0.03). When considering distance to roadway as a log-transformed continuous variable, we found that living <=100 m versus >500 m from the nearest major roadway was significantly (p=0.007) associated with a 2.08 mL/min/1.73 m2 (95CI: 0.56-3.60) lower eGFR.
Conclusions: Chronic exposure to traffic pollution, as measured using residential distance to major roadway, was associated with lower eGFR in a population hospitalized for stroke, and the estimated effects were comparable to those of other predictors of eGFR.

Effect modification of the association between nitrates and rectal cancer by drinking water hardness: evidence from an ecological study

Chun-Yuh Yang, *Faculty of Public Health, Kaohsiung Medical University, Kaohsiung, Taiwan*
Shang-Shyue Tsai, *Department of Healthcare Administration, I-Shou University, Kaohsiung, Taiwan.*
Chih-Ching Chang, *Department of Environmental and Occupational Health, National Cheng Kung University, Tainan, Taiwan.*

Background and Aims: The objectives of this study were to (1) examine the relationship between nitrate levels in public water supplies and increased risk of death from rectal cancer and (2) determine whether calcium (Ca) and magnesium (Mg) levels in drinking water might modify the effects of nitrate on development of rectal cancer.
Methods: A matched case-control study was used to investigate the relationship between the risk of death from rectal cancer and exposure to nitrate in drinking water in Taiwan. All rectal cancer deaths of Taiwan residents from 2003 through 2007 were obtained from the Bureau of Vital Statistics of the Taiwan Provincial Department of Health. Controls were deaths from other causes and were pair-matched to the cases by gender, year of birth, and year of death. Information on the levels of nitrate-nitrogen (NO_3-N), Ca, and Mg in drinking water was collected from Taiwan Water Supply Corporation (TWSC). The municipality of residence for cancer cases and controls was presumed to be the source of the subject's NO_3-N, Ca, and Mg exposure via drinking water.
Results: Relative to individuals whose NO_3-N exposure level was <0.38 ppm, the adjusted odds ratio (OR) (95% CI) for rectal cancer occurrence was 1.15 (1.01-1.32) for individuals who resided in municipalities served by drinking water with a NO_3-N exposure > or =0.38 ppm. There was no apparent evidence of an interaction between drinking water NO_3-N levels with low Mg intake via drinking water. However, evidence of a significant interaction was noted between drinking-water NO_3-N concentrations and Ca intake via drinking water.
Conclusions: Our findings showed that the correlation between NO_3-N exposure and risk of rectal cancer development was influenced by Ca in drinking water. This is the first study to report effect modification by Ca intake from drinking water on the association between NO_3-N exposure and risk of rectal cancer occurrence. Increased knowledge of the mechanistic interaction between Ca and NO_3-N in reducing rectal cancer risk will aid in public policymaking and setting threshold standards.

THE DEVELOPMENT OF A MULTIPOLLUTANT SCIENCE ASSESSMENT TO SUPPORT THE REVIEWS OF THE U.S. ENVIRONMENTAL PROTECTION AGENCY'S NATIONAL AMBIENT AIR QUALITY STANDARDS

Doug Johns, *U.S. Environmental Protection Agency, U.S.A.*
Lindsay Stanek, *U.S. Environmental Protection Agency, U.S.A.*
Tom Luben, *U.S. Environmental Protection Agency, U.S.A.*
Ellen Kirrane, *U.S. Environmental Protection Agency, U.S.A.*
John Vandenberg, *U.S. Environmental Protection Agency, U.S.A.*
Mary Ross, *U.S. Environmental Protection Agency, U.S.A.*

Background and Aims: Standard setting, science assessments, and research related to evaluating and reducing the human health effects of exposure to air pollutants have largely focused on single-pollutant approaches. Nonetheless, it has long been recognized that human populations are exposed to a complex mixture of air pollutants that varies in time and space. This work describes efforts of the U.S. Environmental Protection Agency (EPA) to move toward multipollutant approaches to evaluating the human health effects of exposure to air pollution.
Methods: Scientists with EPA's National Center for Environmental Assessment (NCEA) are evaluating the feasibility of assessing the health effects of exposure to air pollutant mixtures as a part of ongoing reviews of the U.S. National Ambient Air Quality Standards (NAAQS). Overcoming the scientific and logistical challenges associated with conducting such an assessment will involve extensive collaboration with partners and stakeholders in government, industry, academia, and the broader research community.
Results: EPA has developed plans to conduct a multipollutant science assessment whereby the health effects of exposures to mixtures of air pollutants may be systematically evaluated. While legally mandated schedules for completing reviews of the NAAQS somewhat complicates the simultaneous assessment of all air pollutants for which NAAQS have been established, there is a clear need to more explicitly address multipollutant issues in the NAAQS review process. Initial plans, scope and approaches related to the development of the proposed multipollutant science assessment will be presented and discussed.
Conclusions: Although there are considerable scientific and regulatory challenges associated with adopting multipollutant approaches for the evaluation of air pollution-induced health effects, significant progress can be made in the near future through parallel advancements in multipollutant policy, health assessments and research. (Disclaimer: The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.)

MORTALITY AMONG PFOA-EXPOSED WORKERS

Kyle Steenland, *Rollins School Public Health, Emory U, Atlanta, Georgia, USA*
Susan Woskie, *U Mass Lowell, Lowell, Mass, USA*

Background and Aims: PFOA is ubiquitous at low levels in the serum of residents of industrial countries, and is biopersistent. It is a suspected human carcinogen based on animal data, and some human evidence suggest it causes increased cholesterol. Few human data exist on health effects. Our aim is to determine if PFOA workers with high exposures show excess mortality from any cause. Among 1025 current workers in 2004 at the plant we have studied, those working in PFOA area had a median PFOA serum level of 494 ng/ml, while those who had never worked in a PFOA area had a median level of 114 ng/ml (Sakr et al. 2007) By comparison the US median serum level in the general population is 4 ng/ml). Previously mortality findings in this cohort have shown an excess of diabetes and kidney cancer compared to other Dupont workers, and some positive trends for heart disease mortality (Leonard et al. 2008, Sakr et al. 2009).
Methods: We have studied mortality through 2008 of 6027 workers occupationally exposed to high levels of PFOA during the period 1950-2004, in a chemical plant producing fluoropolymers. We have used a newly developed job-exposure matrix (JEM) which estimates serum levels over time based on the workers' job history. Observed PFOA serum levels over the period of 1979-2004 were available for 2125 workers directly and indirectly exposed (median 580 ng/ml , vs 5 ng/ml in the general population), as were data on plant usage of PFOA. Mortality was analyzed for 92 causes of death using the NIOSH life table and Poisson regression, using cumulative serum (ppm-days) as exposure.
Results: Results are not yet available but will be presented at the symposium.
Conclusions: To be presented at the symposium.

ENVIRONMENTAL HEALTH RISKS AND BENEFITS CAUSED BY CLIMATE PROTECTION POLICIES IN EUROPE

Rainer Friedrich, *University of Stuttgart, Germany*

Background and Aims: Policies and measures for mitigation of climate change are nearly always chosen with considering only a few criteria like the reduction of CO_2-equivalent emissions, costs and acceptability. However, there are relevant side benefits or side detriments that are also important for the assessment, especially secondary environmental health impacts. 'Secondary' here means that they are not caused directly by climate change, but by changes in environmental pressures caused by mitigation policies. These secondary impacts should be taken into account when designing climate policies; it is thus the aim of the work described here to estimate these health impacts for important climate protection policies.

Methods: The health risks are determined using the 'integrated environmental health impact assessment' methodology developed in the EC projects INTARESE and HEIMTSA. For two scenarios, one with and one without the policies assessed, the changes in pressures to the environment (e.g. PM2.5 emissions) are determined. These are then transformed into concentrations in air or food using atmospheric and multimedia models. The last step is the estimation of health risks with the help of exposure-response- or intake-response-relationships derived from epidemiological studies.

Results: Results show that the health impacts of a number of climate change mitigation policies and adaptation measures are as important as the avoided climate change effects. Policies like e.g. promotion of wind energy or better efficiency of electronic equipment cause a significant reduction of health risks, while others, especially the use of wood stoves and the better insulation of buildings, might under certain conditions cause large negative health risks.

Conclusions: Thus using results of epidemiological studies within an integrated health impact assessment provides an important contribution to support decision making. A number of policies will improve their cost-benefit ratio, others would only be recommended, if accompanying measures like filters for wood stoves or mechanical ventilation systems in insulated buildings are foreseen.

HEALTH IMPACT ASSESSMENT OF MEASURES THAT REDUCE PM10 AND PM2.5 CONCENTRATIONS IN GERMANY

Rainer Friedrich: *University of Stuttgart, Germany*
Wolf Müller: *University of Stuttgart, Germany*
Joachim Roos: *University of Stuttgart, Germany*
Jochen Theloke: *University of Stuttgart, Germany*

Background and Aims: The most important environmental health risks in Europe are caused by exposure to fine particles. Current PM10 and PM2.5 concentrations result in an average reduction of life expectation of the European population of a few (ca 3 to 5) months. Furthermore the PM10 thresholds are frequently exceeded. Thus a further reduction of the fine particle concentration is necessary. However this should be done with efficient measures, i.e. measures with the lowest costs per unit of health risk reduced (e.g. expressed in DALYs – disability adjusted life years). The aim of this paper is to identify and assess measures applied in Germany to reduce health risks.

Methods: The 'impact pathway approach' is used to estimate health effects of the measures. First the change in emissions of primary PM10/PM2.5 and of PM precursors (NOx, SO2, NH3, VOC) caused by the measures is determined. Then using an atmospheric model the concentration of PM10 and PM2.5 is calculated for Europe. The increase in concentration in cities is taken into account by estimating an urban increment. The resulting concentration is then used to estimate different health impacts (e.g. years of life lost, cases of chronic bronchitis, respiratory hospital admissions and many others). These health endpoints are then aggregated to DALYs. For each measure the costs per DALY saved are calculated.

Results: Around 40 measures are ranked according to their efficiency and effectiveness. Important measures are identified in the agricultural sector, e.g. improved application and amount of fertilizer and manure, filter in hog houses or less animal protein (meat) consumption; and in the industrial sector , e.g. improved dust filters and DENOX plants.

Conclusions: Results show the usefulness of health impact assessments for supporting environmental policy decisions. However the results depend on assumptions about the relative toxicity of the different species contained in PM, thus further research is needed.

THE DEBATS STUDY: HEALTH EFFECTS OF AIRCRAFT NOISE NEAR THREE FRENCH AIRPORTS

Anne-Sophie Evrard, *Epidemiological Research & Surveillance Unit in Transport, Occupation and Environment (UMRESTTE), Joint Research Unit of IFSTTAR (French institute of science and technology for transport, development and networks), and Claude Bernard University of Lyon, France*
Laure Barthélémy, *Transport and Environment Laboratory (LTE) of IFSTTAR, France*
Patricia Champelovier, *LTE of IFSTTAR, France*
Mireille Chiron, *UMRESTTE of IFSTTAR, France*
Heikki Jähi, *UMRESTTE of IFSTTAR, France*
Jacques Lambert, *LTE of IFSTTAR, France*
Bernard Laumon, *UMRESTTE of IFSTTAR, France*

Background and Aims: A national survey carried out in 2005 shows that 6.6% of the French population are annoyed by aircraft noise (Lambert *et al*, 2009). While many surveys carried out both in France and abroad address aircraft noise annoyance or report adverse effects on sleep quality, much fewer consider at the same time the physiological effects of this noise exposure. DEBATS aims to characterize the relations between aircraft noise exposure and health status of the French population living in the vicinity of airports, both physically and mentally but also in terms of annoyance.
Methods: DEBATS is an on-going research program (2011-2016) involving residents around three French airports: Paris-Charles de Gaulle, Toulouse-Blagnac, and Lyon Saint-Exupéry. It includes an ecological study based on drug prescriptions, and on nonprescription drug sales, as well as a longitudinal field study following-up approximately 1,200 of these residents for four years. This study addresses the existence of a link between aircraft noise exposure (measured or calculated) and the measurements of different parameters related to health. In particular, annoyance and health status (current and past) are assessed by questionnaires, and physiological variables like blood-pressure or salivary cortisol are also considered within the frame of the study.
Results and Conclusions: While contributing to a wider and deeper knowledge of the French sanitary situation resulting from aircraft noise exposure, DEBATS will make it possible to assess the expected health benefits of the implementation of aircraft noise abatement policies around airports.

A FURTHER EXAMINATION OF VULNERABLE SUBGROUPS OF TEMPERATURE AND MORTALITY IN CALIFORNIA: IS THERE A HARVESTING EFFECT?

Rupa Basu, PhD, MPH, *California Office of Environmental Health Hazard Assessment, USA*
Brian Malig, MPH, *California Office of Environmental Health Hazard Assessment, USA*

Background and Aims: Investigators have consistently demonstrated associations between elevated temperatures and mortality worldwide. Few have recently focused on identifying vulnerable subgroups, and far fewer have determined whether at least some of the observed effect may be a manifestation of mortality displacement. We examined mean daily apparent temperature and mortality in 13 counties in California during the warm season from 1999 to 2006 to identify vulnerable subgroups and to evaluate the potential effect of mortality displacement.
Methods: The time-series method using Poisson regression was applied for data analysis for single lags of zero to 20 days, and for cumulative average lags of five and ten days. The California Irrigation and Management Information System, the U.S. Environmental Protection Agency Air Quality System, and the National Climatic Data Center all provided weather data, while the California Department of Health Services, Health Data and Statistics Branch provided mortality data.
Results: Significant associations were observed for the same-day (excess risk = 4.3%, 95% confidence interval: 3.4, 5.2) continuing up to a maximum of four days following apparent temperature exposure for non-accidental mortality, cardiovascular mortality, respiratory mortality, and mortality among the elderly and children. Since no significantly negative effects were observed in the following single or cumulative days, evidence of mortality displacement was not found.
Conclusions: The effect of temperature on mortality appears to be an acute event with a potentially broad impact on the population with significant public health implications.

ASSOCIATION BETWEEN PLACE OF BIRTH AND ASTHMA PREVALENCE ACROSS MULTIPLE RACE/ETHNICITIES IN THE UNITED STATES

Shahed Iqbal, *Air Pollution and Respiratory Health Branch, Centers for Disease Control and Prevention, USA*
Emeka Oraka, *ORISE Fellow, Air Pollution and Respiratory Health Branch, Centers for Disease Control and Prevention, USA*
W. Dana Flanders, *Division of Environmental Hazards and Health Effects, Centers for Disease Control and Prevention, USA AND Emory University, GA, USA*

Background and Aims: Asthma is a complex disease involving multiple genetic and environmental factors. The United States (US) has one of the highest prevalences of current asthma (8.2%) in the world; the US also has a large immigrant population representing diverse racial and ethnic groups. Migration studies can shed light on the role of environmental factors for asthma development and exacerbation. The objective of this study was to examine the association of birth-place with self-reported current asthma prevalence across multiple racial/ethnic subgroups in the US.
Methods: We analyzed nationally representative data from the 2001–2009 National Health Interview Survey on adults (• 18 years) with self-reported current asthma. Using SUDAAN, model-adjusted marginal estimates from multivariate logistic regression were used to compare the current asthma prevalence among US-born and foreign-born respondents.
Results: During 2001–2009, 7.1% (unweighted N=18,363) of adults had current asthma of whom 7.8% were foreign-born. After adjusting for confounders (e.g., age, sex, poverty level, health insurance, having a regular place of care) and averaging over the interactions, US-born adults had higher ($p<0.05$) current asthma prevalence (7.6%) as compared to foreign-born adults (4.7%). This difference was consistent across all race/ethnicities including Puerto Rican, Asian Indian, Filipino, Other Asian but was significant ($p<0.05$) among: whites (7.7% vs. 4.7 %), blacks (7.5% vs. 4.8%), Other Hispanics (6.7% vs. 3.2%), Chinese (8.1% vs. 3.0%), and Other/Multiple Race (17.1% vs.8.3%). Also, among foreign-born adults, current asthma prevalence was higher ($p<0.001$) among those who resided in the US for • 10 years (4.0%) compared to those residing for <10years (2.7%).
Conclusions: Greater exposure to environmental factors, acculturation, differences in healthcare access and diagnostic practices might contribute to the higher asthma prevalence among US-born adults and foreign-born adults who have resided in the US • 10 years. Continued identification and understanding of these factors can help design effective public health interventions among immigrant populations.

THE RELATIONSHIP BETWEEN POLLUTANT PROPERTIES AND HOSPITAL ADMISSIONS IN ATLANTA, GA

Suh Helen H, *NORC at the University of Chicago, USA*
Antonella Zanobetti, *Harvard School of Public Health, USA*
Joel Schwartz, *Harvard School of Public Health, USA*
Brent Coull, *Harvard School of Public Health, USA*

Background and Aims: Methods that are based on the chemical properties or structures of pollutants offer an alternative approach to assessing health impacts from multiple pollutants. We performed a study to examine whether the odds of daily hospital admission differs by pollutant chemical properties. .
Methods: We categorized pollutants by chemical properties and examined their impacts on the odds of daily hospital admissions in two-stages. In the first stage we applied a case-crossover analysis of 65 pollutants using hospital admissions data from Atlanta counties (1998-2006), controlling for temperature and ozone. We regressed pollutant specific slopes from stage one on pollutant properties in stage two. We calculated uncertainty estimates using a bootstrap procedure. For comparison, we analyzed the association between hospital admissions and $PM_{2.5}$, ozone, elemental carbon, and organic carbon in case-crossover models. We also repeated the two-stage analyses, but running the first stage separately by pollutant while controlling for the same covariates including ozone. We based primary analyses on day of admission exposures.
Results: Ambient $PM_{2.5}$, ozone, EC, and OC were not associated with hospital admissions. 24-h transition metals and alkanes were associated with increased odds (0.26% and 0.37% per IQR, respectively) of hospital admissions for cardiovascular disease (CVD). Transition pollutants were positively associated with hospital admissions for ischemic heart disease, congestive heart failure, and atrial fibrillation. Respiratory-related hospital admissions were positively associated with alkanes. Aromatics and microcrystalline oxides were negatively associated with CVD- and respiratory-related hospital admissions. Results were comparable for alternative pollutant groupings and first stage models.
Conclusions: Transition metals were associated with increased odds of CVD-related hospital admissions. Alkanes were associated with increased odds of hospital admissions for CVD and respiratory disease, whereas aromatics were associated with decreased odds of these outcomes.

SEASONAL VARIATION IN MORTALITY FROM STROKE IN ENGLAND AND WALES, 1997 – 2005

Babatunde Odugbemi, *Lagos State University Teaching Hospital, Lagos, Nigeria*
Osakpolor Ogbebor, *formerly of University of Sheffield, Sheffield, UK*
Ravi Maheswaran, *University of Sheffield, Sheffield, UK*

Background and aims: Seasonal variation in disease events has been widely reported and it has been described as being worse in Britain. Few studies have been done to examine seasonal variation in specific diseases. The aim of this study was to determine if there was a seasonal variation in mortality from stroke in England and Wales.
Methods: This study used mortality data for stroke from 1997 to 2005. The dataset consisted of all deaths in England and Wales whose underlying cause was due to stroke during the time period. Excess winter deaths for each year were determined by comparing the mortality count in the winter (December - March) and the non-winter months (preceding August – November and successive April - July). A comparison of the winter mortality ratio between the age-bands was also done.
Results: There was a pattern of increased mortality in the winter season for each of the years reviewed, which is in keeping with the pattern existing literature had described for mortality from all causes combined. This study also found that each year, there were around 3,100 excess winter deaths due to stroke and this is 20% more than expected during the winter season. An association was also found between winter mortality ratio and advancing age.
Conclusion: The results suggest that excess winter mortality due to stroke in England and Wales is substantial. In addition to general measures used to reduce excess winter mortality, interventions aimed at reducing excess winter mortality due specifically to stroke may be worthwhile.

SeungYeon Cho, *Yonsei University, South Korea*

Background and Aims: Radon is inert gas which causes lung cancer, and it is important to mitigate indoor radon gas as people stay indoors over 80% of their daily life. There are several radon mitigation systems such as Active Soil Depressurization(ASD) and Passive Soil Depressurization(PSD) which have been applied to buildings in America. However, buildings in Korea are different from ones in America due to the different geological structure. For this reason, it was necessary to develop other radon mitigation systems which can be applied to Korean-type of building structure.
Methods: According to radon level measured by Natural Radiation Environmental Health Center, Gangwon and Chungbuk area showed higher level than other areas, thus one elementary schools(initial radon level: 10 pCi/L) and one village office(initial radon level: 5.8 pCi/L) were selected considering radon level and positiveness of the leaders. ASD was applied to the elementary school, and Active Soil Pressurization(ASP) was applied to the office.
Results: It is not seriously difficult to install soil depressurization system in America, but geological structure in Korea generally shows clay bed, hence it is hard to install pipes and suck radon gas through them. In elementary school case, because radon suction was not successful(radon level after ASD installation: 31.2 pCi/L), instead of depressurizing the underground, ASP that is, positive-pressure was slightly blown into indoors so that underground radon cannot penetrate through the building, was used. Radon level after the installation in the elementary school and the office stayed under 2.0 pCi/L(1.5 and 1.9 pCi/L, respectively).
Conclusions: Even though the problem with energy cost can be an issue, it cannot be a problem if indoor radon level can be monitored continuously and connected to the system. Therefore, delicate diagnose and assessment are essential before installing radon mitigation system. Moreover, to perform diagnose and assessment prior to building construction is preferred.

EFFECTS OF THE METAL COMPONENTS OF AIR PARTICLES ON PEAK EXPIRATORY FLOW RATE OF THE SCHOOLCHILDREN

Lina Madaniyazi, *Department of Occupational & Environmental Health Sciences, School of Public Health, Peking University, P.R. China*

Dae-Seon Kim, *National Institute of Environmental Research, South Korea*

Jiajia Wang, *Department of Occupational & Environmental Health Sciences, School of Public Health, Peking University, P.R. China*

Xiaochuan Pan, *Department of Occupational & Environmental Health Sciences, School of Public Health, Peking University, P.R. China*

Background and Aims: The acute effect of the metal components of air particles on schoolchildren's pulmonary function has not been adequately evaluated. This study was conducted to explore the relationship between the metal elements in ambient particulate matter and the peak expiratory flow rate (PEFR) of the exposed schoolchildren in China.

Methods: Panel study design. 225 primary schoolchildren in Baotou city were recruited for the studies in 2005 and in 2006, respectively. In the study the PEFR values of the subjects were measured with a mini-wright peak flow meter, three times a day and recorded by themselves for 40 days continuously with a standard procedure. The basic information such as gender, age, height, weight, asthma attack and family history of chronic respiratory disease, etc. were collected by the questionnaire from the children and their parents. The daily mass concentration of PM10 and PM2.5 was monitored every day. The contents of K, Ca, Na, Mg in the PMs were determined with X ray emission spectrometry, while Pb, Cr and Cd were determined with Atomic Absorption Spectroscopy. The SPSS 13.0 was used for statistical analysis of the data.

Results: A negative correlation was observed between the average PEFR values of the subjects and the concentration of Ca, Na, Mg both in PM10 and PM2.5 ($P<0.01$).The PEFR level was negatively associated with one lag-day level of Pb both in PM10 and PM2.5 ($P<0.01$).The level of Cr in PM2.5 had a negative effect on the average PEFR values ($P<0.01$), while the effect was shown more significantly 1 day after exposure to Cr ($P<0.01$).

Conclusions: It suggested that the concentrations of metal elements in PM such as Na, Mg, Ca, Pb and Cr are negatively associated with PEFR values of the exposed schoolchildren.

COMMUNITY HEALTH BUILDING: ENVIRONMENTAL APPROACH

Tzu-I Chiu, *Central Taiwan university of Science and Technology, Taiwan*

Fu-Hui Lee*, Central Taiwan university of Science and Technology, Taiwan*

Li-Feng Lin, *Central Taiwan university of Science and Technology, Taiwan*

Background and Aim: The concept of environment focuses on that dimension of traditional concern to urban planning, and recently of increasing concern to the public--the quality of the physical environment natural and man-made. The aim of this project was to identify community environmental problem and to develop appropriate solutions to maintain and enhance the quality of life for the community citizens.

Methods: Action-Research Method was used for this project. The project was started with the organization of a committee with 15 community volunteers composed of city officials, environmental planning professions, and private citizens. The committee initiated its activities by discussing the steps to the process. These general guiding steps are proposed to facilitate the community health assessment process. The collection of environmental health issues from the community by using Community-as-Partner Model, with some modifications to meet local needs. The data collection methods include person-on-the street interviews, community randomized telephone surveys, and the use of key community professionals as informants.

Results: Two major environment problems defined for the community. (1) The lack of landscaping on the perimeter of roadways. (2) Visual clutter on the barrenness of the land. Implementations include utilize natural elements as points of street landscaping, transform barrenness land into community center. Suggestion: Community citizens should be committed to protecting the environment for future generations and implementing a full programme of measures to deliver on its ambitions for an eco-friendly economy.

Conclusions: This project is helping to create environmental awareness in the community; to built strong coalitions among the participants; and it is also helping to target the main environmental needs of the community. In addition, the strong positive community involvement indicates that the identified issues will be followed-up and the desired outcomes will be attained.

THE ERA-ENVHEALTH NETWORK

Adrienne Pittman, *ANSES Agence nationale de sécurité sanitaire de l'alimentation, de l'environnement et du travail, France*
Mohssine El Kahloun, *FPS Health, Food Chain Safety and Environment, Belgium*
On behalf of the ERA-ENVHEALTH partners*: Agency of the Environment and Energy Control (ADEME), France; Ministry of Ecology, Sustainable Development, Transport and Housing(MEDDTL), France; Belgian federal Science Policy Office (BelSPO), Belgium; Federal Public Service Health, Food Chain Safety and Environment (FPS), Belgium; Environmental Protection Agency (EPA), Ireland; Superior Institute for Environmental Protection and Research (ISPRA), Italy; Swedish Environmental Protection Agency (Swedish EPA), Sweden; Ministry of Infrastructure and the Environment (IenM), The Netherlands; The National Institute for Public Health and the Environment (RIVM), The Netherlands; Public Health Authority of the Slovak Republic (UVZ), Slovak Republic; Environment Agency England and Wales (EA), The UK; Natural Environment Research Council (NERC), The UK; Ministry of Health (MOH), Israel; Federal Environment Agency (UBA), Germany; National Research Council (CNR), Italy.*

Background and Aims: Reducing uncertainties about the links between environment and health (E&H) and taking action through protection and prevention measures is necessary. For these measures to be effective, cooperation between all concerned actors must be improved and research driven by a common set of priorities. ERA-ENVHEALTH enhances European coordination of E&H research programming.
Methods: The network of 16 E&H research programmers from 10 countries started in September 2008 and has received funding from the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement n° 219 337. To establish sustainable collaboration, an integrated step-by-step approach is implemented to evaluate methods, define priorities and respond to these through joint activities. The originality of ERA-ENVHEALTH is that it launched a first call early on to experiment joint funding and assess its implementation.
Results: Collaboration between ERA-ENVHEALTH partners has enabled the development of a shared vision and improved exchange of knowledge and expertise through access to information at the European level via its website and databases for experts and research programmes. To experiment joint funding and have a better use of resources, two projects are now running, funded by three partners under the first common call, on: "Health vulnerability resulting from future climate change impacts on soil-water ecosystems, land use and water resources at regional scale". The consortium has analysed the collected data on research programmes and is identifying common priorities for collaborative research and activities, including a second common call.
Conclusions: ERA-ENVHEALTH brings dynamism to E&H research in the EU by promoting collaboration and fostering innovative ideas, and by increasing its visibility as a key area for research. With the development of new programmes and changes to existing ones, an increase is expected in the diversity of disciplines involved in research and in multinational projects on E&H issues.

SECONDHAND TOBACCO SMOKE: A SOURCE OF LEAD EXPOSURE IN US CHILDREN AND ADOLESCENTS

Esther García-Esquinas *Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore,USA*
Andria Apostolou *Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, USA*
Jeffrey J Fadrowski *Department of Pediatrics, Johns Hopkins School of Medicine, Baltimore,USA*
Patricia McClain *School of Nursing, University of Maryland. Baltimore, USA*
Virginia Weaver *Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore,USA,U*
Ana Navas-Acien *Department of Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, BaltimoreSA*

Background and Aims: Secondhand tobacco smoke (SHS) remains a major source of indoor pollution worldwide. Lead is a tobacco constituent measured in mainstream and sidestream smoke. Our goal was to evaluate the relationship between SHS exposure (number of smokers at home and serum cotinine) and blood lead levels in US children and adolescents who participated in the National Health and Nutrition Examination Survey, 1999-2004. We also evaluated lead dust concentrations as a potential mediator between SHS and blood lead levels.
Methods: We analyzed data from 6,830 participants 3 to 19 years of age who were not active smokers and had SHS exposure information and blood lead measurements. We performed linear regression models on log-transformed blood lead levels by serum cotinine quartiles or number of smokers at home adjusted for socio-demographic and household characteristics. Stratified analysis by participant characteristics was used to evaluate the consistency of the findings across categories.
Results: Median (interquartile range) blood lead levels were 1.1 (0.8-1.7) µg/dL. After multivariable adjustment, participants in the highest quartile of serum cotinine (≥0.44µg/L) had 28% (95% CI 21, 36%) higher blood lead levels compared to those in the lowest quartile (<0.03 µg/L). Similarly, blood lead levels in children who lived with 1 and ≥2 smokers were 14% and 24% higher, respectively, compared to those living with no smokers. In participants with lead dust information available (3 to 5 years of age), the association between SHS and blood lead levels remained similar before and after adjustment for lead dust concentrations.
Conclusions: SHS may contribute to increased blood lead levels in US children. Lead dust does not appear to mediate this association, suggesting inhalation as a major pathway of exposure. Eliminating SHS exposure could reduce lead exposure in children. These findings have important public health implications for lead and SHS prevention programs.

ACCESS TO SERENE NATURE CONTRIBUTES TO IMPROVED MENTAL HEALTH AMONG WOMEN - RESULTS FROM A LONGITUDINAL COHORT STUDY IN SOUTHERN SWEDEN

Matilda Annerstedt, *Swedish University of Agricultural Sciences, Faculty of Landscape Planning, Alnarp, Sweden*
Per-Olof Astergren , *Lund University, Faculty of Medicine, Lund, Sweden*
Patrik Grahn, *Swedish University of Agricultural Sciences, Faculty of Landscape Planning, Alnarp, Sweden*
Jonas Bjak, *Lund University, Faculty of Medicine, Lund, Sweden*
Erik Skaback, Swedish University of Agricultural Sciences, Faculty of Landscape Planning, Alnarp, Sweden
Peter Wahrborg, *University of Agricultural Sciences, Faculty of Landscape Planning, Alnarp, Sweden*

Background/aims: Despite the fact that average life length is increasing internationally, escalating problems with mental disturbances are reported, especially among women. One way of approaching this issue is by promoting public health through the means of restorative environments. The aim of this observational study was to explore whether number of recreational values and/or any certain characters of the nature could determine change in mental health in a population and whether any difference could be found due to gender.
Methods: We used data from a large health survey distributed to a stratified sample of a southern Swedish population at two occasions (1999/2000 and 2005), facilitating a longitudinal analysis. People from rural, suburban, or smaller town areas were studied (n=9230). Geographical residence codes for every individual were linked to preformed evaluations of restorative landscape characters. Any change in number of recreational characters within 300 meters distance, or change in any single character between baseline and follow-up, was correlated to change in mental health by logistic regression models. Mental health was measured by the General Health Questionnaire (GHQ-12).
Results: On average (in varied subsets of the data) access to a large number of recreational characters was rare, and we found no impact on mental health development from change in number of recreational characters between the two occasions. The specific nature character *Serene* turned out to be a significant factor for women: the odds of improved mental health was 4,5 :1 if access to Serene was gained at follow-up. For men no significant explanation model was found.
Conclusions: The study showed that the character *Serene* in nature might be a specific mental health factor for women which could render a positive development in public health. This may influence landscape and urban planning as well as health policies and potentially create a higher life quality.

AIR QUALITY EFFECTS OF THE AMSTERDAM ENVIRONMENTAL TRAFFIC ZONE

Marieke B.A. Dijkema, *Department of Environmental Health, Public Health Service Amsterdam and IRAS, Utrecht University, the Netherlands*
Pavlos Panteliadis, *Department of Air Quality, Public Health Service Amsterdam, the Netherlands*
Rob T. van Strien, *Department of Environmental Health, Public Health Service Amsterdam, the Netherlands*
Jaap H. Visser, *Department of Air Quality, Public Health Service Amsterdam, the Netherlands*
Saskia C. van der Zee, *Department of Environmental Health, Public Health Service Amsterdam, the Netherlands*

Background and Aims: An environmental traffic zone, constraining access into the city for older and more polluting trucks, was implemented in Amsterdam. The objective of this study was to assess if implementation of this environmental traffic zone reduced traffic related air pollution along one of the major connecting routes into the city.
Methods:A monitoring station of the Amsterdam Air Quality Monitoring Network is situated adjacent to a major street connecting the city centre and the ring highway. The main food wholesale distribution center is located along this road, resulting in a relatively high volume of truck traffic. Daily mean concentrations (NO_2, PM10, and Elemental Carbon) in the first year since the intervention were compared with concentrations in the prior year.
Results: Concentrations at roadside were high, the annual mean NO_2 concentration was well above the EU Limit Value. Preliminary results show that, since the intervention and taking changes in background concentration into account, the traffic contribution to NO_2 has decreased by 5.0 $\mu g/m^3$ (95%-CI: -6.9 – -3.1), for PM10 the difference was -0.3 • g/m^3 (-1.1 – 0.5) and for EC -0.2 • g/m^3 (-0.5 – 0.0). The time span of the study will be prolonged and future analyses will furthermore incorporate correction for long term time trend and meteorological conditions.
Conclusions: In conclusion, these preliminary analyses demonstrate decreased concentrations of traffic related air pollution as a result of the implementation of an environmental traffic zone in Amsterdam.

IDIOPATHIC ENVIRONMENTAL INTOLERANCE ATTRIBUTED TO ELECTROMAGNETIC FIELDS (IEI-EMF): A SYSTEMATIC REVIEW OF IDENTIFYING CRITERIA.

Christos Baliatsas, *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands.*
Irene Van Kamp, *National Institute for Public Health and the Environment (RIVM), Bilthoven,The Netherlands*
Erik Lebret, *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands.*
G. James Rubin, *King's College London, Department of Psychological Medicine, Institute of Psychiatry, London, UK.*

Background and Aims: The lack of validated criteria for defining and assessing IEI-EMF affects the quality of the research into the disorder and increases methodological heterogeneity. Therefore, it is difficult to compare or integrate the findings of different studies. The main aim of this review was to define and summarize the criteria that previous studies have employed to identify IEI-EMF subjects.
Methods: A literature search was performed in April 2010 using a combination of keywords related to 'electrosensitivity,' exposure and health outcome. Databases included were EMBASE, Medline, Psychinfo, Scopus and Web of Science. Additionally, citation analyses were performed for key papers, reference sections of relevant papers were searched, conference proceedings were examined and a literature database held by the Mobile Phones Research Unit of King's College London was reviewed.
Results: Eighty studies were included. The criteria predominantly used in the studies to identify IEI-EMF samples were: 1. Self-report of being (hyper)sensitive to EMF. 2. Attribution of symptoms to at least one specific EMF source. 3. Absence of any medical disorder capable of accounting for these symptoms 4. (Hyper)sensitivity to EMF could be either generalized (attribution to various EMF sources) or mobile-phone specific, visual display unit-specific or even domestic appliance-specific. 5. Symptoms occur soon after the individual enters the "exposed area" or uses an EMF source. 5. Report of a negative impact in daily life functioning 6. Avoidance behaviour towards EMF source(s).7. Increased symptom report. Symptom assessment was mainly based on non-standardized scales which are incomparable between studies. Experimental studies used a larger number of criteria compared to the observational ones.
Conclusions: Remarkable heterogeneity has been found regarding the criteria being used by the reviewed studies due to explicit differences in their conceptual framework. Further work is required to produce consensus criteria for research purposes. This could be reflected by the development of an international protocol.

OCCUPATIONAL NOISE EXPOSURE AND HEARING LOSS AMONG FIREFIGHTERS IN THE UNITED STATES

OiSaeng Hong, *University of California, San Francisco, CA, USA*
Dal Lae Chin, *University of California, San Francisco, CA, USA*
Jamie Feld, *NorthShore University Health Systems, CA, USA*
Stephen Vogel, *NorthShore University Health Systems, Glenview, IL, USA*

Purpose: To assess noise exposure level, prevalence of hearing loss, and use of hearing protective devices (HPDs) among firefighters.
Methods: Focus group discussions were conducted to identify common noise sources of firefighting service. Sound pressure levels were measured and task-based exposure assessment modeling (T-BEAM) was used to estimate noise exposure potentials among firefighters. Exposure durations were based on firefighters' average response times. Demographic and work related survey and hearing tests were completed by a total of 237 firefighters in multiple states in the US.
Results: Ventilation, extraction, and fire suppression were the primary fire fighting job assignments identified. Tools required for these job assignments include chainsaws, circular saws and pneumatic chisels, sirens, axes, generators, fire truck engines, and water hoses. T-BEAM showed that firefighters have a risk potential of 85 dBA time-weighted average (TWA) on any given day. The survey and hearing test participants were predominantly middle aged (mean age=44years), Caucasian (88%), and males (94%) with an average of 17 years of work experience in fire services. About 37% showed hearing loss in the noise sensitive frequencies, 4 and 6 kHz. Firefighters with hearing loss reported significantly longer years of working in fire services ($t=5.83$, $p< 0.001$). The poorest hearing was shown in the left ear at frequencies of 2-6kH ($p<0.05$). The participants reported using HPDs 38% of the time that was needed, despite the importance of using it during all loud noise.
Conclusion: This study demonstrated a considerable noise exposure, high prevalence of hearing loss, and low use of HPDs in firefighters. More comprehensive hearing conservation programs should be implemented to reduce hearing loss, which is a costly, dangerous, and potentially career-ending disability for firefighters.

BISPHENOL-A AND T REGULATORY CELL COUNTS IN AN INNER-CITY BIRTH COHORT

Kathleen Donohue, *Columbia University, USA*
George Vlad, *Columbia University, USA*
Rachel L. Miller, *Columbia University, USA*
Matthew S. Perzanowski, *Columbia University, USA*
Allan C. Just, *Columbia University, USA*
Lori A. Hoepner, *Columbia University, USA*
Srikesh Arunajadai, *Columbia University, USA*
Frederica P. Perera, *Columbia University, USA*
Raphael Clynes, *Columbia University, USA*
Antonia Calafat, *Centers for Disease Control, USA*
Robin M. Whyatt, *Columbia University, USA*

Background and Aims: Bisphenol-A (BPA), an endocrine disruptor widely used in food containers, has been associated with altered T regulatory and Th2 cytokine pathways. As these are critical for asthma pathogenesis, we hypothesized that BPA exposure would be associated with reduced numbers of T regulatory cells and increased risk of wheeze and asthma.
Methods: We recruited 400 mother-child pairs and measured BPA in spot urine collected from the mother prenatally and child at ages three, five and seven. Wheeze in the past twelve months was assessed via standardized questionnaires and current asthma was diagnosed by allergist based on standardized exams and pulmonary function tests. Specific IgE to aeroallergens was measured via ImmunoCAP. Child T regulatory cell counts are being assayed via flow cytometry for CD4+CD25+CD62LFOXP3 expression. Relative risk regression analyses controlled for maternal asthma, exposure to environmental tobacco smoke, gender, and ethnicity.
Results: BPA was detectable in >93% of urine samples at all four time points. BPA concentrations in maternal prenatal urine were inversely associated with wheeze and risk of asthma at age 5 (n=316, RR 0.74, CI (0.59, 0.93), p = 0.01; n=295, RR 0.75, CI (0.57, 0.97), p = 0.03, respectively). There was no association between BPA and atopy. By contrast, urinary BPA concentrations at ages three and five years were associated with increased risk of asthma ($p \leq 0.01$), and BPA concentrations at age five years were associated with increased risk of wheeze at age seven years (p=0.03) (1). Results on T regulatory cell counts will be reported.
Conclusions: Childhood wheeze and asthma are inversely associated with BPA in prenatal urine and positively associated with BPA in child postnatal urine.

ENERGY, LIMITS TO GROWTH AND PUBLIC HEALTH: WHAT IS THE ROLE OF ENVIRONMENTAL EPIDEMIOLOGY?

Colin D Butler, *National Centre for Epidemiology and Population Health, Australian National University, Australia*

Background and Aims: The literature concerning impending energy insecurity, food prices and climate change is growing rapidly. These problems reflect manifestations of "limits to growth", including climate change, though what is "limited" in this case is not carbon emissions, but the capacity of Earth to absorb waste gases without great harm to the climate, ecology and, ultimately, civilisation (hence health). Limits to growth interact. For example rising energy prices lift fertiliser costs and divert agricultural capacity from food to fuel. Climate change impairs crop yields and harms nutrition synergistically in other ways such as by reducing water quality. Collectively, the diverse phenomena of "limits to growth" will place increasing and eventually immense strain on the capacity of global public health services to maintain global life expectancy, especially given the background of rising population size.
Methods: A limited literature search was conducted in health journals (using PubMed, Google Scholar and specific journals) searching for the following terms: "peak oil", "energy scarcity", "limits to growth", "ecological footprint", "global environmental change", "peak health", "peak phosphorus" and "civilisation collapse". The term "climate change" was excluded because the research question studied here is broader.
Results: Within the broader medical and public health literature there is a limited awareness of peak oil, however papers are mainly restricted to or in response to one research group. In the epidemiological literature, including environmental epidemiology, these topics are scarcely mentioned, apart from several articles in the mid 1990s.
Conclusions: Rising energy prices and other manifestations of limits to growth are important environmental determinants of health. Environmental epidemiologists need to urgently consider these dimensions, and to embrace interdisciplinary approaches to consider how to prevent what Homer-Dixon calls "synchronous failure".

Background and Aims: The pathophysiological pathways linking particulate air pollution to cardiovascular disease are still not fully understood. We examined the association between ambient air pollutants and blood markers of inflammation and coagulation in three potentially susceptible populations.
Methods: Three panels of non-smoking individuals were examined: 1) with type 2 diabetes mellitus (n=83), 2) with impaired glucose tolerance (n=104), and 3) with a potential genetic predisposition on the detoxifying pathway (n=87) defined by the null polymorphism for *glutathione S-transferase M1* (*GSTM1*) in combination with a certain single nucleotide polymorphism on the *C-reactive protein (CRP)* or the *Fibrinogen* gene. Study participants had blood withdrawn up to seven times, scheduled every 4-6 weeks between 3/2007 and 12/2008. In total, 1765 blood samples were investigated for CRP, interleukin 6 (IL-6), soluble CD40 ligand (sCD40L), fibrinogen, myeloperoxidase (MPO), and plasminogen activator inhibitor-1 (PAI-1). Hourly means of $PM_{10,}$ $PM_{2.5}$ (particle diameter<10µm and <2.5µm, respectively), particle number concentrations and nitrogen dioxide were collected at a fixed monitoring site and individual 24 hour averages calculated. Associations between air pollutants and blood markers were analysed using additive mixed models adjusting for long-term time trend and meteorology.
Results: For the panel with potential genetic susceptibility sCD40L and PAI-1 showed negative associations with all air pollutants within 24 hours before blood samples were taken (lag 0). Clear positive associations were seen for CRP and MPO especially with lags of 1 to 3 days (% change of geometric mean and 95% confidence interval for lag 1: 14.5 [5.3;24.6] and 4.9 [0.7;9.3] per interquartile range of $PM_{2.5}$, respectively). Results for IL-6, fibrinogen and the two other panels were less conclusive.
Conclusions: Patients with potential genetic susceptibility showed a clear association with ambient air pollutants. Our results support the idea that systemic inflammation may aggravate atherosclerotic disease, especially in susceptible populations.

Background and Aims: Growing evidence suggests that prenatal exposure to organochlorine compounds (OCs), mainly polychlorinated biphenyls (PCBs) and dichlorodiphenyl dichloroethylene (DDE), may increase the risk of respiratory infections in children through suspected immunotoxic mechanisms. Our aim is to examine, in the largest study so far, whether prenatal exposure to DDE increases the risk of LRTI in infants, and to isolate these effects from those of other OCs.
Methods: The study is based on a cohort of 2150 mother-child pairs in Spain. Maternal serum concentrations of DDE and other OCs were measured during pregnancy. Parental reports of physician-confirmed diagnosis of LRTIs were obtained when children were 12-14 months old. Analyses were carried out separately for children from Spanish (N=1342) and Latin-American (N=79) mothers because of their different exposure profiles.
Results: 35.4% of the children born to Spanish mothers developed at least one LRTI episode during their first 12-14 months of life. DDE exposure (median=116.3 ng/gr lipid) was associated with a higher risk of LRTIs (relative risk (95%CI) for 3rd quartile DDE exposure= 1.32 (1.08, 1.62)), which persisted after adjustment for other OCs (RR (95%CI) for 3rd quartile DDE = 1.38 (1.12, 1.71)). No association was found for other OCs. Stratified analyses showed that findings were homogeneous by study region, maternal smoking, maternal history of asthma and atopy, duration of predominant breastfeeding and maternal diet. Children born to Latin-American mothers, with much higher exposure to DDE (385.0 ng/gr lipid), showed a similar, but not statistically significant, increase in risk of LRTI with DDE exposure.
Conclusions: Prenatal exposure to DDE is associated with higher risk of LRTIs in infants. Since LRTIs cause substantial morbidity in infancy and are a possible risk factor for subsequent childhood asthma, especial attention should be paid in countries where dichlorodiphenyltrichloroethane (DDT) is nowadays used for malaria control.

Bo Strandberg, *Occupational and Environmental Medicine, University of Gothenburg and Sahlgrenska University Hospital, Sweden*
Lars Barregard, *Occupational and Environmental Medicine, University of Gothenburg and Sahlgrenska University Hospital, Sweden*

Background: Air pollution increases cardiovascular morbidity and mortality. One hypothesis is that local airway inflammation is a pathway to systemic inflammation, and in the long term atherosclerosis and cardiovascular events. Wood smoke contributes significantly to indoor and outdoor air pollution. The composition is complex, depending on e.g. combustion technique. We examined health effects of two kinds of wood smoke in a controlled chamber study of human subjects.
Methods: Thirteen subjects were exposed to filtered air and two sessions of wood-smoke, one week apart, with smoke from the start-up or the burn-out phase of the wood-burning cycle. The particle mass concentrations were 295 µg/m^3 and 146 µg/m^3; number concentrations 140 000/cm^3 (68% ultrafine) and 100 000/cm^3 (40% ultrafine) respectively. Blood, urine and breath condensate were collected before and on several occasions after exposure, and analyzed for biomarkers of inflammation, coagulation and oxidative stress. Exhaled nitric oxide (FENO) was measured. Net effects of wood smoke compared to filtered air were evaluated.
Results: Clara Cell protein 16 (CC16) increased in serum four hours after exposure to smoke from the start-up phase, and in urine the next morning. There was a net increase of FENO270 after wood smoke in both sessions, but mainly due to a decrease after filtered air. Other markers of airway inflammation were not affected by exposure. No consistent increase was seen for markers of systemic inflammation and coagulation. Urinary isoprostane and plasma-fibrinogen unexpectedly decreased after exposure.
Conclusions: The results indicate that airway effects appear at relatively low levels of exposure to wood smoke, while signs of systemic inflammation, previously shown at higher exposures, do not. Effects could only be shown after smoke from the start-up phase. CC16 is a sensitive marker in both serum and urine for effects of air pollution, but its function and significance need to be clarified.

INFLUENCE OF LOCAL FACTORS IN THE RELATIONSHIP BETWEEN DAILY MORTALITY AND TEMPERATURE DURING HEAT WAVES PERIODS IN CASTILE- LA MANCHA (1975-2003)

Juan Carlos Montero, *Health Sciences Institute, Castile-La Mancha Regional Health & Social Welfare Authority, Talavera de la Reina (Toledo), Spain.*
Isidro Juan Mirón, *Torrijos Health District, Castile-La Mancha Regional Health & Social Welfare Authority, Torrijos, Spain*
JuanJosé Criado-Álvarez , *Castile-La Mancha Health Service (Servicio de Salud de Castilla-La Mancha - SESCAM), Talavera de la Reina (Toledo), Spain.*
Cristina Linares, *Cancer and Environmental Epidemiology Unit, National Centre for Epidemiology, Carlos III Institute of Health, Madrid, Spain*
Julio Díaz, *National School of Public Health, Carlos III Institute of Health, Madrid, Spain.*

Background and Aims: Climate model projections foresee that the principal changes -particularly insofar as temperature extremes are concerned- will occur in the interior of mainland Spain, where Castile-La Mancha is situated. The characteristics that modulate and determine the relationship between high temperatures and health must therefore be ascertained in the greatest possible detail, so that really effective prevention plans can be designed to address temperature extremes. This study sought to characterise and quantify the impact of heat waves on mortality in Castile-La Mancha.
Methods: We examined the effect of heat waves on daily non-accidental-cause mortality across all age groups in the Castile-La Mancha region (Spain) from 1975 to 2003. Quantitative analyses were performed using autoregressive integrated moving average (ARIMA) models, with other covariates, such as pressure trends, relative humidity, and duration and chronological number of heat waves.
Results: For each degree centigrade that temperatures exceeded the designated provincial thresholds in Castile-La Mancha, the percentage increase in mortality amounted approximately 12% over the daily mean, albeit with provincial variations. The longest heat waves were associated with daily mortality, with those at the end of summer causing the lowest mortality. Meteorological situations most closely associated with increases in mortality were cyclonic conditions accompanied by low humidity.
Conclusions: The reported health benefits of implementing heat wave prevention plans are undeniable; it is also evident that these must be optimised through in-depth knowledge of the relationship between temperature and health. The influence of variables, such as heat-wave duration or time of appearance, is important in the total increase in mortality during temperature extremes. Since parameters, such as humidity or pressure trends, can play very different roles in different geographical settings, they should be analysed separately from temperature.

NITROGEN DIOXIDE SPATIAL DISTRIBUTION IN ELCHE, A CITY ON THE SPANISH MEDITERRANEAN COAST

Raquel Esclapez, *Department of Applied Physics, Miguel Hernández University, Spain*
Sandra Caballero, *Department of Applied Physics, Miguel Hernández University, Spain*
Javier Crespo, *Department of Applied Physics, Miguel Hernández University, Spain*
Carlos Pastor, , *Department of Applied Physics, Miguel Hernández University, Spain*
Enrique Mantilla, , *Fundación Centro de Estudios Ambientales del Mediterráneo (CEAM), Spain*

Background and Aims: Because of the unique characteristics of urban areas, important gradients in atmospheric pollutant concentrations can exist. As such, a complete characterization of different zones in a city requires an elevated number of sampling points. The use of diffusive sampling techniques (Ferm & Svanberg, 1998) is an attractive and potentially effective complement to conventional air quality monitoring networks around urban conurbations. This allows adequate spatial resolution to reflect the peculiarities of such a complex environment (Stevenson *et al.*, 2001).
Methods: Eighty-two sampling sites were distributed within the city of Elche (Valencian Community) at locations with different characteristics (vehicular emissions, ventilation, etc.). Systematic samplings of NO_2 concentration measurements (each exposure period was five days) were carried out during winter 2009. To gain an understanding of the meteorological conditions in the city, various meteorological parameters were measured, including wind direction and wind speed, temperature, and solar radiation.
Results: A comparison of the measurements performed under different environmental conditions shows a similar relative behaviour between NO_2 dosimeters, indicating that the relative level of each point is characteristic of the site where it is placed (highly polluted areas, etc.), and therefore characteristic of the specific urban structure.
Conclusions: The behaviour of the measured contaminants shows that the changes in concentration depend mainly on the prevailing environmental conditions (the meteorological conditions dilute and disperse emitted compounds).

THE INTRODUCTION OF LONDON'S CONGESTION CHARGE ZONE AND CHANGES IN ROAD CASUALTIES

Rebecca Steinbach, *London School of Hygiene and Tropical Medicine, UK*
Paul Wilkinson, *London School of Hygiene and Tropical Medicine, UK*
Chris Grundy, *London School of Hygiene and Tropical Medicine, UK*
Phil Edwards, *London School of Hygiene and Tropical Medicine, UK*

Background and Aims: In 2003, a Congestion Charging Zone (CCZ) was introduced in central London, UK, with the aim of tackling worsening traffic congestion. Although the CCZ was not introduced as a measure to benefit public health, there has been much interest in its impact on health, particularly in terms of air pollution and road traffic casualties. This paper quantifies the changes in road traffic casualties following the introduction of the CCZ in London.
Methods: Observational study based on analysis of geographically-coded road casualty data, 1993-2006. Analyses were made of longitudinal changes in counts of road casualties within each of 119,029 road segments with non-zero casualty counts, using conditional fixed-effects Poisson models. Estimates of the effect of introducing the CCZ on casualties were adjusted for changes in counts of casualties outside the zone, and for the effect of the introduction of 20 mph speed zones.
Results: The introduction of the CCZ was associated with an appreciable fall in the number of casualties in the zone relative to other areas within charging hours: a fall of around 16% (95% confidence interval: 11-21%) in all casualties within charging hours, not observed outside charging hours (4% increase, 95% CI: -1-9%). There were relatively large reductions in the number of car occupant and powered two-wheeler rider casualties. We found an appreciable increase in the number of cyclists injured inside the CCZ (30% increase, 95% CI: 9-52%) that appears broadly to parallel an increase in the numbers of people cycling in London.
Conclusions: The introduction of the CCZ in London has been accompanied by a small but important decline in road casualties overall, partly offset by an increase in cyclist casualties that broadly reflects increasing cyclist numbers. These changes would appear to represent part of an appreciable net benefit to population health of the CCZ.

ALLOSTATIC LOAD MODIFIES THE EFFECT OF BLOOD LEAD LEVELS ON HYPERTENSION AMONG MIDDLE-AGED ADULTS IN THE U.S.

Ami R. Zota, *University of California, San Francisco, United States*
Edmond Shenassa, *University of Maryland, College Park, United States*
Rachel Morello-Frosch, *University of California, Berkeley, United States*

Background and Aims: Lead and chronic stress exposures can independently affect hypertension risks but synergistic effects may also be possible.
Methods: We examined whether chronic stress, operationalized as allostatic load (AL), modifies the effect of lead exposure on hypertension outcomes in a nationally representative sample of 6,511 middle-aged U.S. adults (aged 40-65 years) participating in the National Health and Nutritional Examination Survey (NHANES) 1999-2006. AL was defined as the aggregate score of 7 components, reflecting physiologic dysregulation of the cardiovascular, inflammatory, and endocrine systems.
Results: The median (interquartile range) blood lead concentration was 1.70 µg/dL (1.19 - 2.50). Multivariate logistic regression models demonstrated that higher blood lead levels were associated with significantly higher risk of diastolic hypertension, but not systolic or general hypertension. In models stratified by AL, positive associations between lead and hypertension were observed in high AL but not low AL participants. Among the high AL group, adults in the highest quintile of lead exposure had elevated odds of systolic (Odds ratio (OR) = 1.62, 95% confidence interval (CI): 1.11, 2.38) and diastolic (OR = 2.59; 95% CI: 1.57, 4.25) hypertension compared to adults in the lowest lead quintile.
Conclusions: Our results suggest that the effect of lead on hypertension is stronger among those who are chronically stressed. Future research should assess the implications of cumulative exposures to environmental and social stressors for regulatory decision-making in order to better protect the health of vulnerable populations who often face disproportionate and elevated exposures to multiple chemical and non-chemical hazards.

EFFECT OF PFOA ON REPRODUCTIVE HEALTH OUTCOMES

David Savitz, *Brown University, USA*
Cheryl Stein, *Mount Sinai School of Medicine, USA*

Background and Aims: Research on the potential effect of perfluorinated chemical (PFC) exposure and reproductive health endpoints, particularly fetal growth, has proliferated in the past 5 years. Results on pregnancy outcomes have been notably inconsistent. Less extensive information on other health endpoints is available. We examined several reproductive health measures in a sizable number of pregnancies exposed to elevated levels of PFOA..
Methods: Two sources of data were used to examine the association between PFOA and pregnancy outcomes: (1) A survey of residents conducted in 2005-2006 included a complete reproductive history from women, combined with residential history information and estimated historical exposure to assign PFOA blood levels to the mother at the time of pregnancy. (2) Birth records from residents of the area were obtained from health departments for the periods and places when geographic identifiers (Zip Code or street address) were computerized, then linked by space and time to estimate blood PFOA level at the time of pregnancy.
Results: Estimated PFOA levels were around background through the 1970s then rose to markedly elevated levels in the subsequent 30 years, with a mean and median of 49.2 and 13.3 ng/ml, respectively, after 2000. The survey of residents identified 41,456 pregnancies, with 9.2% ending in miscarriage and 1.3% in stillbirth. Among live births, 3.8% reported preeclampsia, 12.7% preterm birth, 2.0% term low birth weight, and 3.8% birth defects. Expected associations were found for advanced maternal age and smoking, providing some confirmation of data quality. We will report results on the association between PFOA exposure and these pregnancy outcomes.
Conclusions: Given the large study size, elevated exposure levels, and combination of self-reported and record-based assessment, we will have the most extensive information generated thus far regarding PFOA and pregnancy. Limitations include the quality of self-reported outcome information and uncertainty in exposure assignment.

VULNERABILITY TO TEMPERATURE-RELATED MORTALITY IN SEOUL, KOREA

Son, Ji-Young, *Yale University, School of Forestry and Environmental Studies, USA*

Lee, Jong-Tae, *Korea University, College of Health Science, Dept. of Environmental Health, Korea*

Anderson, G. Brooke, *Yale University, School of Forestry and Environmental Studies, USA*

Bell, Michelle L., *Yale University, School of Forestry and Environmental Studies, USA**

* Corresponding author

Background and Aims: Temperature's effect on mortality and vulnerability to these risks may vary by population and region. This study examines the relationship between temperature and cause-specific mortality for Korea. We investigated whether some subgroups are particularly vulnerable with respect to sex, age, education, and place of death for Seoul, Korea for the period 2000-2007.

Methods: We applied time-series models allowing nonlinear relationships for heat- and cold-related mortality, and generated exposure-response curves. We also present results comparing mortality risk at mean daily temperatures of 25 ^{o}C to 15 ^{o}C (90th to 50th percentile of temperatures in Seoul) and 29^{o}C to 25^{o}C (99th to 90th percentile) for heat effect. For the cold effect, we present results comparing mortality risk at -1 ^{o}C to 15 ^{o}C (10th to 50th percentile) and -4^{o}C to -1^{o}C (1st to 10th percentile). We considered exposure timeframe, co-pollutants, cause of death, and susceptibilities.

Results: Both high and low ambient temperatures were associated with daily mortality in Seoul, Korea. Mortality risk was 10.2% (95% confidence interval 7.43, 13.0%) higher at the 90th percentile of temperature compared to the 50th percentile. Mortality risk was 12.2% (3.69, 21.3%) comparing the 10th and 50th percentiles of temperature. Cardiovascular deaths showed a higher risk to cold, whereas respiratory deaths showed a higher risk to heat effect. We identified susceptible populations such as female, the elderly, those with no education, and deaths occurring outside of a hospital for heat- and cold-related total mortality.

Conclusions: Our findings provide supportive evidence of a temperature-mortality relationship and vulnerability to temperature effects in Korea.

EXPLORING CHILD PASSENGER SAFETY PRACTICE IN CHINA UNDER RAPID MOTORIZATION

Wei Du, *Institute of Population Research, Peking University, China*
Shuming Pan, *Faculty of Medicine, Shanghai Jiaotong University, China*
Fan Jiang, *Faculty of Medicine, Shanghai Jiaotong University, China*
Lynne Bilston, *Neuroscience Research Australia, University of New South Wales, Australia*
Julie Brown, *Neuroscience Research Australia, University of New South Wales, Australia*
Xiaoming Shen, *Shanghai Key Laboratory of Children's Environmental Health, China*

Background and Aims: China is undergoing rapid motorization and becomes the largest market where most new cars in the world are sold. Many child passengers lose their lives when traveling in motor vehicles in China, e.g., 2,000 fatalities in 2004. Since little was known for child passenger safety practice in China, this study aims to describe where child passengers are seated and whether restraints are used; and investigate the influence of children and/or parental attributes on seating position and restraint use.

Methods: Toll gate observation for child passengers aged ≤12 years was conducted in Shanghai during 2009. Another parent survey for kindergarten enrolled children aged 2-7 years was conducted during 2008-09. The adjusted relative risks (RR) comparing rear with front seating position among child passengers were evaluated using multivariate binomial regression with robust variance estimation. The adjusted RR comparing any restraint use with no restraint use was also evaluated.

Results: Both observation and survey studies revealed common front seating practice and low restraint use among child car passengers. Younger age (≤4 years), single child in a car, and parental license status were associated with decreased likelihood of rear seating position; whereas tertiary education for mothers was associated with increased likelihood of rear seating selection for child passengers. Children traveling with drivers using no restraints were less likely to be restrained; whereas parents having drivers license were more likely to use restraints for their child passengers.

Conclusion: This study demonstrates common front seating and low restraint use as ignored safety concerns, and identified risk factors influencing restraint use and seating position for child passengers. These findings call for urgent attention and appropriate intervention targets to improve child passenger safety in China under rapid motorization.

SAFETY MEASURES AND HEALTH HAZARDS AMONG COAL MINERS

Dr Adnan Khan *Hamdard Unversity Hospital khi,pakistan.*

Background and Aims: Coal is a naturally occurring mineral and a large source of fossil fuel throughout the world. Its importance in Pakistan increases as other fuels, like petroleum are scares and expensive coal is abundant and cheap. Coal dust comprise of carbon, hydrogen, oxygen,nitrogen, sulphur, quartz and some traces of iron, lead and copper. These particles are not degradable and deposit in lung throughout the life of coal mine worker. These particles resulting in fibrosis of lung, initially starting as chronic bronchitis and asthma and finally end up as coal mine worker pneumoconiosis. Almost no significant work is done at major levels either from the government or from private sector, regarding studying the health hazards and their effects among mine workers of Pakistan.The objectives of our study was to find out safety measures practices by coal miners and the occupational health hazards which are suffering from coal mine extraction.

Methods: A cross-sectional descriptive type of study has been carried out. Population targeted during this case study was the coal miners of Lakhra Coal field, Sindh. Random sampling was done and Sample size was 100 coal mine workers. The questionnaire we devised for this study which was then presented to individuals with different educational status, field of work and family background. SPSS software is used for data analysis.

Results: Out of 100 participants, 77% are illiterate. Half (50%) of the workers think that they have risk to their health in this job. Majority of workers (>90%) are not using proper safety measures. 53%of the workers think that safety measures are necessary and required during their work. Nearly 60%of the workers have the back pain and pain in their hands. 39%of the workers have heart burn. Less than 60% of the workers have the symptoms of lung disease like cough and trouble in breathing. Majority 83%of the workers are addicted out of them 76%are addicted to naswar. 84%of the workers have not got any training before joining to job.

Conclusions: Majority of the diseases found in coal mine workers are due to the improper use of safety measures. Proper supply of protective measures, regular medical check up, and different health based educational programs help to improve the quality of the life of coal mine workers.

DNA DAMAGE AND DECREASE OF SPERM QUALITY IN MEN OCUPATIONALLY EXPOSED TO POLYCYCLIC AROMATIC HYDROCARBONS (PAH's)

Edgar Héctor Olivas Calderón, University of Durango, México
Rogelio Recio Vega, University of Coahuila, México
Rebeca Isabel Martínez Salinas, University of San Luis Potosí, México
Guadalupe García Arenas, University of Durango, México
Jorge Antonio Espinosa Fematt, University of Durango, México
Martha Patricia Gallegos Arreola, BiomedicalResearch Center, México
Guadalupe Ocampo Gómez, University of Coahuila, México

Background and aims: Over the last decade, concerns have been mounting over declining levels of semen quality (1). Polycyclic aromatic hydrocarbons (PAHs) constitute a group of genotoxic, lipophilic, and endocrine-disrupting chemicals that are distributed in the environment. **T**he aim was to evaluate the association between the urinary levels of 1-hydroxypyrene with the DNA damage, with sperm quality and with the frequency of CYP1A1, GSST1 and GSTM1 pdymorphisms.

Methods: A cross-sectional study was designed to evaluate the adverse effects of PHAs. A total of 71 subjects, 36 occupationally exposed and 35 unexposed men were included in our study. Semen, blood and urine samples were taken to volunteers to evaluate: sperm quality, 1-hydroxypyrene urinary levels (Biomarker of exposure PAH's), DNA damage and the frequency of polymorphism CYP1A1, GSTT1 y GSTM1.

Results: DNA damage was significantly higher in occupationally exposed subjects ($p < 0.05$). The frequency of genotypes of the enzymes tested was not statistically different between both groups. The sperm quality was significantly lower in the exposed group ($p < 0.05$). 1-hydroxypyrene urinary levels were higher in the exposed group ($p=0.01$). Sperm/ml, total count of sperm and CYP1A1 (m4) polymorphism were negatively associated with 1-hydroxypyrene.

Conclusion: PAH exposure decreases sperm quality and induce DNA damage.

HEALTH EFFECTS OF EXPOSURE TO WATER-DAMAGED HOMES AFTER FLOODING IN JAPAN

Kenichi Azuma , *Kinki University Faculty of Medicine, Japan*
Koichi Ikeda, *Nihon University, Japan*
Naoki Kagi, *National Institute of Public Health, Japan*
U Yanagi, *Kogakuin University, Japan*
Kenichi Hasegawa, *Akita Prefectural University,Japan*
Haruki Osawa, *National Institute of Public Health, Japan*

Background: Torrential downpours and intense typhoons have been on the rise in recent years in Japan, possibly because of climate change due to global warming. Localized torrential downpours can cause serious flooding along rivers and other waterways. Flooding in the aftermath of torrential downpours or typhoon creates poor conditions ideal for indoor air quality such as dampness or mold growth in the water-damaged home, resulting in public health concerns about the possible adverse health effects associated with the poor indoor air quality. Furthermore, the water-damaged home also would cause insomnia, stress-related disorders due to the psychological suffering. We conducted a questionnaire survey on the physical and psychological conditions associated with exposure to water-damaged homes in Japan.
Methods: We randomly selected 593 households in six sites flooded within past 5 years and then distributed a questionnaire to 1 adult per household. Those households include two flooded level homes of flooded below floor level and flooded above floor level, and no water-damaged home as control. The survey was carried out from October 2010 through February 2011.
Results: Total 379 responses were obtained (response rate=63.9%). Indoor dampness, mold, strong odor, poor health conditions and insomnia were significantly increased in water-damaged home compared to the non-damaged home located in the same sites. Those effects were gradually decreased over six months; however the significant differences of those effects were remained. Strength of dampness and poor health conditions were increased in association with higher flooded levels in after a week of flooding.
Conclusions: Poor indoor air quality and health conditions were associated with exposure to water-damaged homes. Those effects were remained over six months after flooding and increased in water-damaged home with higher flooded levels. This study suggests that the rapid actions on public health and environmental hygiene for water-damaged home should be taken after flooding.

HEALTH RISK ASSESSMENT OF ARSENIC INTAKE OF BEIJING RESIDENTS THROUGH DRINKING WATER

Jinhui Zhao, *Beijing Municipal Center for Disease Control and Prevention, Beijing, China*

Yumin Liu, *Beijing Municipal Center for Disease Control and Prevention, Beijing, China*

Fei Liu , *Beijing Municipal Center for Disease Control and Prevention, Beijing, China*

Yan Ye, *Beijing Municipal Center for Disease Control and Prevention, Beijing, China*

Tiantian LI, *Institute for Environmental Health and Related Product Safety, Chinese Center for Disease Control and Prevention, Beijing,China*

Background and Aims: Multiple studies have showed an association between long-term exposure to arsenic by drinking water and development of cancer and Non-cancer adverse effects. However, few studies were conducted to assess on arsenic intake of the general population from drinking water in China. To understand the effects for arsenic in Beijing residents, a pilot survey was conducted to assess the health risk in which the ingestion rate and exposure duration of the individuals should be require computing Average daily dose (ADD).
Methods: We conducted a multi-stage sampling survey to interview 270 Beijing residents in winter (November to December) in 2009 and in summer (June to August) in 2010. Subjects were required to answer questions about water intake and tap water samples were collected to analyze at current residence. Hazard Quotient (HQ) and Oral reference dose (RFD) was computed according to a health risk assessment model.
Results: The concentration of arsenic ranged from <0.1ug/L to 26.20 ug /L, 5(1.9%) of all samples were higher than 10 ug/L. The arsenic concentration of arsenic in summer was slightly higher than of in winter. A positive correlation between ADD and concentration, exposure duration, ingestion rate were observed .However, a negative but non-significant correlation between ADD and body weight was also observed. For non-cancer effects, Only 1 (0.4%) of ADD exceeded the oral reference Dose (3×10-4 mg /Kg. d). For cancer risks, there was 6 (1.4%) residents who had chance risk when compared to the highest safe standard (1 in 10,000), additionally, there was 175 • 65% • residents when using the lowest safe standard for cancer risk (1 in 1000, 000).
Conclusions: Part of Beijing residents faced the health risk for arsenic through drinking water, among them who lived in the northeast of Beijing for long years may be at the greatest risk.

Background and Aims: Hand, foot, and mouth disease(HFMD) is a common viral illness of infants and children. HFMD outbreaks occur regularly in the spring and summer in China. On March 9, we found 4 HFMD cases during 3 days in a class of one kindergarten from surveillance network in Beijing, China. To develop control measures, we began an investigation to identify the cause of the outbreak

Methods: We searched cases by following-up the children's health through Telephone from February 28 to March 12. We interviewed with health doctor and class teacher to know living activities of children. We search attendance records of the children. A retrospective cohort study was used to identify exposure factors.

Results: From February 28 to March 12, 73 %(16) of 22 children developed a case in the kindergarten. The incidence rate of boys is 2.5 times of the girls(95%CI: 1.17-5.34) • The incidence rate of block A is 2.2 times of the non-block A (95%CI: 1.15-4.20) .The stool of cases were still contained coxsackievirus A16 virus when cases were ill after 3-5 weeks, 85 %(11) Of 13 case specimen was positive. The risk of children who need to be reminded washing their hands was 2.29 times the children who do not have to remind ((1.05-4.98).

Conclusions: Coxsackievirus A16 virus caused the outbreak in a kindergarten through close contact between Children. Parents of infants and young children should prepared plastic bags to prevent the environment contamination caused by fecal when they go out.

FINE PARTICULATE MATTER CONSTITUENTS AND CARDIOPULMONARY MORTALITY IN A HEAVILY-POLLUTED CITY

Junji Cao, *Institute of Earth Environment, Chinese Academy of Sciences*
Haidong Kan, *Fudan University, China*

Background and Aims: Although ambient $PM_{2.5}$ has been linked to adverse human health effects, the chemical constituents that cause harm are unknown. No previous studies exist in developing country to investigate the health impact of $PM_{2.5}$ constituents. This study aimed to examine the short-term association between $PM_{2.5}$ constituents and daily mortality in Xi'an, a heavily-polluted Chinese city.
Methods: We obtained daily mortality data and daily concentrations of $PM_{2.5}$, organic carbon (OC) and elemental carbon (EC) between January 1, 2004 and December 31, 2008. We also measured concentrations of fifteen elements between January 1, 2006 and December 31, 2008, and ten water-soluble ions between March 22, 2006 and March 23, 2007. We analyzed the data with over-dispersed generalized linear Poisson models.
Results: During our study period, the mean daily average concentration of $PM_{2.5}$, OC and EC in Xi'an were 182.2 $\mu g/m^3$, 28.3 $\mu g/m^3$, and 12.0 $\mu g/m^3$. We found consistent associations of mortality with $PM_{2.5}$ mass, OC, EC, S, Cl, Ni, Na^+, K^+, Mg^{2+}, Cl^-, and NO_3^-. Many of the constituents demonstrated higher excess risks than $PM_{2.5}$ mass. For transition metals, mortality risk associated with Ni was particularly elevated. Even below the levels of proposed $PM_{2.5}$ standard in China (24-hour average: 75 • g/m^3), we were still able to observe apparent health effects of $PM_{2.5}$.
Conclusions: This first study in developing countries adds to the growing body of evidence linking $PM_{2.5}$ constituents with mortality and indicates that excess risks may vary with the specific $PM_{2.5}$ constituents.

COMMUNITY WELLBEING AND THE TRIP TO WORK: INTEGRATING EPIDEMIOLOGY, POLICY AND COMMUNITY KNOWLEDGE USING PARTICIPATORY SYSTEM DYNAMICS MODELLING

Alexandra Macmillan, *School of Population Health, University of Auckland, Auckland, New Zealand*
Jennie Connor, *Department of Preventive and Social Medicine, University of Otago, Dunedin, New Zealand*
Karen Witten, *Social and Health Outcomes Research and Evaluation, Massey University, Auckland, New Zealand*
Robin Kearns, *School of Environment, University of Auckland, Auckland, New Zealand*
David Rees, *Synergia Ltd, Auckland, New Zealand*
Alistair Woodward, *School of Population Health, University of Auckland, Auckland, New Zealand*

Background and Aims: Achieving healthy and sustainable urban planning requires integration of epidemiological knowledge with other kinds of information in ways that are useful for decision-makers. Informed participation in decisions by a range of stakeholders is also needed for effective policy implementation. Few methods have been described to meet these requirements. The *Community Wellbeing and the Trip to Work* project tested one such method to influence transport policy. We aimed to improve understanding of policy levers required to align health and sustainability outcomes in urban commuting, using a collaborative learning approach with decision-makers and wider stakeholders.
Methods: We used participatory system dynamics (PSD) modelling to explore commuting and wellbeing in Auckland, New Zealand's largest metropolis. This is a sprawling city of 1.4M people, where commuting is mostly by car; public transit ridership and walking are less common; and bicycling is rare. We considered commuting as a complex system comprising feedback, time lags and unexpected consequences. We developed a qualitative and a simulation model of the commuting system demonstrating the likely impacts of policies to change bicycle commuting on a range of outcomes.
Results: Both models provided policy insights. Quantitative simulations compared "business-as-usual" with two bicycling investment scenarios. Investment costs were integrated with health and environmental outcomes. Economic estimates of costs and benefits were compared. A range of stakeholders could explore the structural reasons for success or failure of policies.
Conclusions: PSD allowed the integration of epidemiologic and other knowledge to simulate transport policy outcomes. Learning about the dynamics of commuting and wellbeing improved understanding of factors leading to policy resistance or success. However, the more technical simulation process left some community stakeholders feeling disengaged. Further work will explore how accessibility of the simulation model can be improved through interfacing and web-based tools. PSD is a potentially useful tool to improve evidence-based integrated assessment in urban planning policy.

IMPACT OF EXTREME TEMPERATURE ON HOSPITAL ADMISSION IN SHANGHAI, CHINA

Wenjuan Ma, *Fudan University, China*
Haidong Kan, *Fudan University, China*

Background and Aims: No previous study exists in China examining the impact of extreme temperature on morbidity outcomes. This study aimed at investigating the impact of heat wave and cold spell on hospital admission in Shanghai, China.
Methods: Daily hospital admission data between January 1, 2005 and December 31, 2008 were collected from the Shanghai Health Insurance Bureau. Heat wave was defined as a period of at least 7 consecutive days with daily maximum temperature above 35.0 °C and daily average temperatures above the 97 percentile during the study period. Cold spell was defined as a period of at least 7 consecutive days with daily maximum temperature and daily average temperatures below the 3 percentile during the study period. We calculated excess cases of hospitalization and rate ratios (RRs) to estimate the impacts of heat wave and cold spell on hospital admission.
Results: We identified one heat wave period (from 24 July to 2 August, 2007) and one cold spell period (from 28 January to 3 February, 2008) between 2005 and 2008. Heat wave was associated with 2% (95% CI: 1% - 4%), 8% (95%CI: 5% - 11%), and 6% (95%CI: 0% - 11%) increase of total, cardiovascular and respiratory hospital admission. Cold spell was associated with 38% (95%CI: 35%, 40%), 33% (95%CI: 28%, 37%) and 32% (95%CI: 24%, 40%) increase of total, cardiovascular and respiratory hospital admission. The differences between heat wave and cold spell-related hospital admission were statistically significant for all causes and cardiovascular causes, but not for respiratory causes.
Conclusions: Both heat wave and cold spell were associated with increased risk of hospital admissions in Shanghai. Cold spell seemed to have a larger impact on hospital admission than heat wave. Public health programs should be tailored to prevent extreme temperature-related health problems in the city.

ESTROGEN RECEPTOR ALPHA (ER-α) AND CYTOCHROME P450 17 (CYP17) GENOTYPES, AND PLASTICIZER EXPOSURE ON THE OCCURRENCE OF LEIOMYOMA

Chien-Wen Sun, *Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Miaoli, Taiwan*

Shu-Li Wanh, *Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Miaoli, Taiwan - Institute of Environmental Medicine, College of Public Health, China Medical University and Hospital, Taichung, Taiwan; Republic of China.*

Background and Aims: Evidence has shown that polymorphisms of various genes known to be involved in estrogen biosynthesis and function including CYP17, CYP1A1, estrogen receptor-alpha and -beta, are associated with estrogen dependent diseases. Phthalates are considered estrogenic endocrine disruptors and may act as a risk factor for estrogen dependent diseases (EDDs) in recent studies. We aim to assess the gene-environmental interactions on EDDs.

Methods: We recruited 44 patients with endometriosis or adenomyosis, 36 patients with leiomyoma and 68 healthy controls from a medical center in Taiwan between 2005 and 2007. Urine samples were collected and analyzed for seven phthalate metabolites using liquid chromatography tandem mass spectrometry. Peripheral lymphocytes were used for DNA extraction to determine the genotype of CYP17, CYP 1A1, ER-α and ER-• .

Reasults: Patients with leiomyoma had significantly higher levels of total urinary mono-ethylhexyl phthalate (• MEHP; 52.1 vs. 29.6 • g/g creatinine (• g/g-c)), mono-*n*-butyl phthalate (MnBP; 75.4 vs. 51.3 • g/g-c) and monoethyl phthalate (MEP; 103.7 vs. 59.3 • g/g-c) than the controls, whereas patients with endometriosis or adenomyosis only had an increased level of urinary MnBP. Subjects who carried the ER-α W allele and CYP17 A2 allele showed a significantly increased risk for leiomyoma (OR = 9.98, 95%CI: 1.30-76.52, p=0.027) after adjustment for age, GSTM1, MEHP and cigarette smoking, as compared to those with ER-α and CYP17 wild type. We suggested that both CYP17 and ER-α polymorphism may be a modifier for phthalate exposure in the development of leiomyoma.

Oxidative stress pathway genes, particulate matter, and lung function decline

Background and Aims

Rather than investigating gene-environment interactions with single nucleotide polymorphisms (SNPs), ambient air pollution and smoking effects on lung function decline might be better explained by assessing interactions across entire genes and pathways.

Methods

Decline in forced expiratory volume in one second (FEV1) was regressed on 11-year cumulative exposure to particulate matter <10µm in diameter (PM10) or packyears of smoking, additive SNP effects, and a multiplicative term SNP*exposure in 669 adults from the SAPALDIA cohort. Interaction p-values of 12'679 SNPs from 152 oxidative stress genes and 14 pathways were projected onto gene- and pathway-levels using the adaptive rank truncation product (ARTP) method. Effect estimates for one interquartile range (IQR) contrast in exposure were compared between PM10 and packyears for top-SNPs of significant genes (significance threshold alpha=0.05). Percentage of outcome-variability explained was calculated by including all top-SNPs and interaction terms simultaneously into initial regression models.

Results

Seven genes (*CP, CYP1A2, ERCC1, NDUFA13, PRDX3, PSMB5, RAC1*) significantly interacted with PM10 on FEV1 decline, seven other ones (*AOX1, BCL2, MAP2K1, NOXO1, PSEN1, PTK2B, TPO*) and pathway 'apoptosis' (p=0.001) with packyears. A change of 84.7µg/m^3*years PM10 over 11 years (IQR) yielded beta-estimates of 41.7-97.7ml for the interaction term, 134.4-321.9ml for SNPs, and 20.6-134.6ml for PM10 main effect, with a minimal $p_{interaction}=4.8x10^{-5}$. Corresponding estimates for an IQR of 9.7 packyears were 86.2-206.6ml, 28.0-51.6ml, 23.4-288.6ml, and $p_{interaction}=9.8x10^{-5}$. Full interaction models explained 24.9% outcome variability for PM10, 26.4% for packyears, and 30.7% for both exposures combined compared to 19.6% and 19.1% without interaction terms, and 19.9% without genetic factors.

Conclusions

Including gene environment interaction in a pathway analysis substantially increased the percentage of explained outcome variability. On the population level, PM10 exposure presented a similar impact on FEV1 decline as tobacco smoke regarding effect sizes and percentage variability explained, but susceptibility genes differed between exposures.

ASSESSING THE RISKS OF WATER CONTAMINATION AND HOTSPOTS OF DIARRHEA IN SOUTHERN INDIA USING GIS

Venkata Raghava Mohan, *Christian Medical College, India*
Mark Rohit Francis, *Christian Medical College, India*
Vinohar Balraj, *Christian Medical College, India*
Elena N Naumova, *Tufts University Schools of Engineering and Nutrition, USA, Christian Medical College, India*
Gagandeep Kang, *Christian Medical College, India*

Background and Aims: Recent studies in southern India show that 'treated' drinking water is contaminated with fecal coliforms and storage practices increase contaminations.This study aims to identify potential points of contamination of drinking water supply, assess the water quality, and examine associations with diarrhea in children in rural and urban areas of Vellore District, India.
Methods: The rates of diarrhea were assessed using 6-month surveillance in a cohort of 240 children (<5y.o.) in two rural (32%) and two urban (68%) areas in Vellore (12°55'60N, 79°7'60E). Water supply systems, drainage and sewage networks, households, points of potential water contamination were mapped and identified; physical characteristics of 147 public water taps were determined; 42 water samples from the public distribution system, water from households and overhead storage tanks were collected and analysed. Hotspots of diarrhoea were detected using Cluster/Outlier Analysis (Anselin Local Moran's I).
Results: 377 points of potential contamination (urban: 91%) were detected; 57 drinking water taps (38.8%) were at serious risk of contamination with sewage. All water tap samples had excessive nitrites and no free residual chlorine; 81% of water tap samples and 70% of household water samples had faecal coliforms. The incidence of diarrhea was higher in urban areas compared to rural: 2.07/1000 vs 1.66/1000 person-days, OR=1.26(95%CI:0.76,2.09). Statistically significant hotspots of diarrhea were detected in one rural village and two urban areas, where 87.5% of families used water taps at serious risk of contamination within 85 meters from their homes.
Conclusions: Widespread contamination of 'treated' drinking water exists in both rural and urban areas at source and point of use. Hotspot clustering of diarrhoea is more prevalent in urban households proximal to taps at risk of contamination. Public water distribution systems are difficult to monitor: GIS can be used to predict potential contamination and guide targeted intervention.
References: Brick T, Primrose B, Chandrasekhar R, Roy S, Muliyil J, Kang G (2004). Water contamination in urban south India: household storage practices and their implications for water safety and enteric infections. International Journal of Hygiene and Environmental Health; 207(5):473-480.

VERY HIGH CORRELATIONS BETWEEN FRESH WEIGHT AND LIPID-ADJUSTED PCB-153 SERUM CONCENTRATIONS – IRRESPECTIVE OF FASTING STATUS, AGE, BODY MASS INDEX, GENDER, OR EXPOSURE DISTRIBUTIONS

Lars Rylander, *Lund University, Sweden*
Anna Axmon, *Lund University, Sweden*
Aleksander Giwercman, *Lund University, Sweden*
Bo AG Jönsson, *Lund University, Sweden*
Christian Lindh, *Lund University, Sweden*
Anna Rignell-Hydbom, *Lund University, Sweden*

Background and aims: Persistent organochlorine pollutants (POPs), such as PCBs, DDT and dioxins, are lipophilic pollutants accumulated in the food chain. These compounds have in epidemiological studies been associated with health hazards, not only detected among highly exposed populations, but also among populations with lower exposure levels. The exposure window might be crucial and it is, accordingly, important to analyze exposure concentrations in samples collected at the window of interest. This makes the use of stored blood samples extremely interesting. However, the blood volumes available from stored samples in biobanks are often less than 0.2 ml, which means that the researchers in epidemiological studies have to select a limited number of biomarkers representing the POP exposure and abstain from analyses of lipid concentrations. This raises the question of the necessity of lipid adjustment and the implications for interpretation of health effects. The aim of the present study was to evaluate how well the correlation between fresh weight and lipid adjusted concentrations is?
Methods: We have performed a number of epidemiological studies were we have used the PCB congener 2,2',4,4',5,5'-hexachlorobiphenyl (PCB153) as a biomarker for POP exposure. In all studies fresh weight as well as lipid adjusted PCB-153 concentrations is known. The variety of the cohort members (in total 1628) in the different studies give us the possibility to better understand how well these measures correlate.
Results: When all individuals were included in the analyses a correlation coefficient of 0.95 between fresh weight and lipid adjusted serum concentrations was obtained. Restricting the analyses to specific subgroups (based on gender, fasting status, age and bmi) gave correlation coefficients between 0.90 and 0.97.
Conclusions: This study do strongly support the use of samples from biobanks in epidemiological studies for analyzing PCBs even though it is not possible to lipid adjust the analyses.

IMPACT OF TRAFFIC AIR POLLUTION ON RESPIRATORY SYMPTOMS IN A CHILDREN COHORT IN FLORENCE, ITALY: A BAYESIAN ANALYSIS

Giulia Carreras, *Cancer Prevention and Research Institute ISPO, Florence, Italy*
Marta Blangiardo, *MRC-HPA Centre for Environment and Health, Department of Epidemiology and Biostatistics, Imperial College London, London, UK*
Elisabetta Chellini, *Cancer Prevention and Research Institute ISPO, Florence, Italy*

Background and Aims: The associations between traffic related air pollution and the development of long term respiratory health problems in children is an important issue that has been extensively studied. Recently methods that assess exposure combing spatial air pollution measurements and geographic information system based modeling, i.e. dispersion models, have been favoured.
In this work we study the effect of traffic air pollution on respiratory symptoms in a cohort of children in Florence, Italy.
Methods: Exposure to traffic related pollution for a cohort of children from different schools in Florence, part of the Italian Studies on Respiratory Disorders in Children and the Environment Phase 2, is assessed with a dispersion model in combination with four models to differently weight exposure by distance. A Bayesian hierarchical logistic regression model with school-level heterogeneity is used to study the effect of traffic related air pollution on cough or phlegm and asthma. Risk factors, as second-hand smoking, familiarity of asthma and rhinitis, and socio-economical status, are included in the analysis.
Results: No evidence of increasing risk of asthma with urban air pollution was found, while for cough or phlegm, borderline significant ORs were observed, providing evidence of an association in the cohort.
Conclusions: Familiarity of asthma, exposure to second-hand smoking, and deprivation showed the greatest effect on enhancing the probability of developing respiratory disease symptoms. However, by adjusting for these variables, also a remarkable effect of traffic related air pollution measured by carbon dioxide on cough or phlegm was observed, especially for emissions weighted by the negative exponential function of distance.

OXIDATIVE STRESS PATHWAY GENES, ENVIRONMENTAL TOBACCO EXPOSURE AND ASTHMA

Background and aims. Studies on environment by gene interactions are challenged by multiple comparisons and contrasting findings from analyses conducted at the single nucleotide polymorphism (SNP) level. Until now, joint examination of several genes was performed at the functional level, but not at the pathway analysis level which consider protein interactions.

Methods. A four-step strategy is proposed:
1) Bioinformatic step based on **G**ene **O**ntology (GO) to define a) a list of genes with a given function (here response to oxidative stress) and b) the pathways in which these genes are involved (such as 'Metabolism of Xenobiotics by Cytochrome P450')
2) Selection step to choose candidate pathway(s) based on the biological knowledge of response to environmental hazard
3) Association analyses step performed at 1-the SNPs, 2-the genes and 3-the pathways levels
4) Validation of our findings in other epidemiological studies.

Results of steps 1 to 3 will be presented for 1900 subjects from the EGEA study, using genotypes from genome-wide data (Illumina 610quad, 2M imputed SNPs), and considering asthma, ETS and candidate pathways involved in response to oxidative stress.

Results.

Step 1: 190 genes were defined through GO browser (**GO** term 0006979) and 75 by literature search, corresponding to 285 different pathways according to Ingenuity Pathway Analysis software.

Step 2: 12 pathways (including 106 genes, 10-26 genes/pathway) were retained by taking into consideration biological knowledge regarding both the environment (ETS) and the disease (asthma), such as 'NRF2-mediated Oxidative Stress Response', 'apoptosis', ...

Step 3: Effect estimates for SNP allele dosage, ETS exposure and their interaction on asthma will be presented. Comparisons will be made between methods used for the gene/pathway approach (classical and the adaptive truncated product method to combine p-values).

Conclusions. Beyond collaboration between studies, interdisciplinary approach is needed to develop pathway approach in environmental epidemiology. (Supported by BIO_2NEA, IAGO.)

LOW-LEVEL ENVIRONMENTAL LEAD EXPOSURE IN CHILDHOOD AND ADULT INTELLECTUAL FUNCTION: A FOLLOW-UP STUDY

Maitreyi Mazumdar, *Children's Hospital Boston, Harvard Medical School, Harvard School of Public Health, United States*
David Bellinger, *Children's Hospital Boston, Harvard Medical Schoo, Harvard School of Public Health, United States*
Matthew Gregas, *Children's Hospital Boston, United States*
Kathleen Abanilla, *Children's Hospital Boston, United States*
Janine Bacic, *Children's Hospital Boston, United States*
Herbert Needleman, *University of Pittsburgh School of Medicine, United States*

Background: Early life lead exposure might be a risk factor for neurocognitive impairment in adulthood.
Objectives: We sought to assess the relationship between early life environmental lead exposure and intellectual function in adulthood. We also attempted to identify which time period blood-lead concentrations are most predictive of adult outcome.
Methods: We recruited adults in the Boston area who had participated as newborns and young children in a prospective cohort study that examined the relationship between lead exposure and childhood intellectual function. IQ was measured using the Wechsler Abbreviated Scale of Intelligence (WASI). The association between lead concentrations and IQ scores was examined using linear regression.
Results: Forty-three adults participated in neuropsychological testing. Childhood blood-lead concentration (mean of the blood-lead concentrations at ages 4 and 10 years) had the strongest relationship with Full-Scale IQ (ß = -1.89 ± 0.70, p = 0.01). Full-scale IQ was also significantly related to blood-lead concentration at age 6 months (ß = -1.66 ± 0.75, p = 0.03), 4 years (ß = -0.90 ± 0.41, p = 0.03) and 10 years (ß = -1.95 ± 0.80, p = 0.02). Adjusting for maternal IQ altered the significance of the regression coefficient.
Conclusions: Our study suggests that lead exposure in childhood predicts intellectual functioning in young adulthood. Our results also suggest that school-age lead exposure may represent a period of increased susceptibility. Given the small sample size, however, the potentially confounding effects of maternal IQ cannot be excluded and should be evaluated in a larger study.

SCIENTIFIC COOPERATION FOR A GLOBALIZED AWARENESS ON ENVIRONMENTAL HEALTH RISKS AND POLICIES: DEVELOPING NECOBELAC NETWORK TO PROMOTE SCIENTIFIC COLLABORATIONS IN ENVIRONMENTAL EPIDEMIOLOGY

Daniela Marsili, *Istituto Superiore di Sanità, Italy*
Carlos Agudelo, *Instituto de Salud Publica, Colombia*
Paola De Castro, *Istituto Superiore di Sanità, Italy*
Pietro Comba, *Istituto Superiore di Sanità, Italy*

Background and Aims: An increasing burden of environmental risks is affecting population's health worldwide. Scientific evidence on health effects of hazardous exposures and local knowledge of public health issues do not necessarily meet to address mitigation policies. Economic and cultural barriers limit access to research results globally and the widest diffusion of health information for promoting a shared awareness and empowerment for healthy working and living environments. NECOBELAC is an ongoing collaboration network of European and Latin American-Caribbean (LAC) countries to spread know-how in scientific writing and to provide the best tools for exploiting open access information for public health.
We propose to implement the NECOBELAC network to face specific environmental health issues through a well-established and high-impact training and dissemination methodology.
Methods: NECOBELAC training methodology relies on two training levels: training for trainers and training at local level. To maximize the training impact a core group of European and LAC institutions performed courses for trainers; these trainers replicate training activities at local level utilizing NECOBELAC online contents addressing local needs and priorities.
Results: NECOBELAC mid-term results are corroborated by the effectiveness of the adopted training methodology. Training for trainers were performed in Europe (Italy, Spain) and Latin America (Brazil, Colombia) for a total of 120 participants who are performing numerous training activities at local level in their countries. In this framework, scientific collaborations are developed among institutions of involved countries operating in public health, such as the national health Institutes in Italy and Colombia that collaborate on environmental health issues (asbestos, hazardous waste disposal, polluted sites).
Conclusions: The existence of the NECOBELAC network and the excellent achieved results encourage and motivate this implementation plan. The environmental health issues selected within by this Italian-Colombian cooperation rely on both maturated experiences on public health and currently scientific debates and are of broad impact for society.

PRENATAL ORGANOPHOPHOSPHATE AND CHILD NEURODEVELOPMENT: RESULTS FROM THE MOUNT SINAI CHILDREN'S ENVIRONMENTAL HEALTH AND DISEASE PREVENTION RESEARCH CENTER

Stephanie M. Engel, *Department of Epidemiology, University of North Carolina, Chapel Hill, Chapel Hill, NC USA.*

Background & Aims: Prenatal exposure to organophosphate pesticides has been shown to negatively impact child neurobehavioral development. Paraoxonase 1 (PON1) is a key enzyme in the metabolism of organophosphates. We undertook an investigation of the relationship between biomarkers of organophosphate exposure, PON1, and cognitive development at ages 12 and 24 months, and 6 to 9 years.
Methods: The Mount Sinai Children's Environmental Health Study enrolled a multiethnic prenatal population in New York City between 1998 and 2002 (n= 404). Third trimester maternal urines were collected and analyzed for organophosphate metabolites (n = 360). Prenatal maternal blood was analyzed for PON1 activity and genotype. Children returned for neurodevelopment Bayley Scales of Infant Development assessments at ages 12 (n = 200) and 24 months (n = 276), and for psychometric intelligence tests between 6 and 9 (n = 169) years.
Results: Prenatal total dialkylphosphate metabolite level was associated with a decrement in mental development at 12 months among blacks and Hispanics (log10 • DAP Beta = -3.29, 95% CI -5.88, -0.70). Effects were enhanced among children of mothers who carried the PON1 Q192R QQ genotype which imparts slow catalytic activity for the chlorpyrifos oxon (interaction p-value < 0.01; QQ log10 • DAP Beta = -4.71, 95% CI -7.59, -1.83). In later childhood, increasing prenatal total dialkyl- and dimethylphosphate metabolites were associated with decrements in perceptual reasoning in the maternal PON1 Q192R QQ genotype and followed monotonically decreasing trend with increasing prenatal exposure (interaction p-value = 0.09; QQ log10 • DAP Beta = -7.52, 95% CI -14.53, -0.51).
Conclusion: Prenatal exposure to organophosphates negatively impacts cognitive development, which was apparent at assessments as early as 12 months and continued through early childhood. A critical affected domain is perceptual reasoning. PON1 status is an important mediating factor in identifying populations most susceptible to these deleterious effects.

ATTEMPTS TO DISCRIMINATE AMONG COMBUSTION SOURCES IN ASSESSING THE HEALTH EFFECTS OF AIR POLLUTION

Rebecca Klemm, PhD, *Klemm Analysis Group, Inc.; Washington, DC USA*
Ron Wyzga, B.Sc; *EPRI; Palo Alto, CA USA*

Background and Aims: When executing epidemiological studies relating pollutants to human health (mortality) researchers confront numerous measures of air pollution to consider. Researchers confront both multiple measuring techniques that create series of data for ostensibly the same pollutant measured at the same or neighboring sites (for example, PM2.5, DFPSS and PM2.5 TEOM) and/or measurements of many different, but potentially related pollutants (for example, EC and OC). We discuss steps we have employed, findings of our methods, and suggestions for other researchers.
Methods: We have grouped pollutants using a process that begins with initial analysis of each of the pollutants individually using the same models: 1) average of lag 0 and lag 1 for each pollutant; and 2) pollutant individually as lag 0 through lag 4 or more). Upon review of the results we have clustered the pollutants by the patterns of the estimated coefficients using UNMIX (Lewis, et al., JAWMA 2003), PMR (Ramadan, et al. Chemometrics 2003), knowledge of the source of the pollutants, plus/minus and strength of the coefficients, and Spearman correlation coefficients of the various pollutant series. We also execute two-three pollution models for pollutants that are highly correlated to observe the impact of the multiple pollutants in the same model.
Results: UNMIX and PMF created different factors with only factors created by PMF illustrating significant results. These results were used to identify pollutants considered in subsequent models. In this study, it appeared the significant factors were driven by the chloride ion.
Conclusion: The use of source factors can help identify specific pollutants for further study. This study illustrates the need for researchers to beware of labels of factors and to investigate using multiple methods.

LUNG CANCER AND ELEMENTAL CARBON EXPOSURE IN US TRUCKING INDUSTRY WORKERS

Eric Garshick, *Pulmonary and Critical Care Medicine Section, Medical Service, VA Boston Healthcare System and Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA*
Jaime E Hart, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Department of Epidemiology, Harvard School of Public Health, Boston, MA, USA*
Mary E Davis, Department *of Urban and Environmental Policy and Planning, Tufts University, Medford, MA and Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA*
Thomas J Smith, *Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA*
Francine Laden, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Departments of Epidemiology and Environmental Health, Harvard School of Public Health, Boston, MA, USA*

Background and Aims: An elevated risk of lung cancer in truck drivers has been attributed to vehicle exhaust exposure. We established a large retrospective cohort of trucking company workers to assess the association of lung cancer mortality and elemental carbon (EC, as a measure of vehicle exhaust exposure).
Methods: Work records were obtained for 31,135 male workers age 40+ employed in the unionized US trucking industry in 1985. Lung cancer mortality was assessed through 2000 using the US National Death Index. An industrial hygiene review and current exposure measurements were used to develop annual historical estimates of EC by work location for all job groups. Cox proportional hazards models adjusted for age, race, calendar year, decade of hire, region of the country, and the healthy worker survivor effect were used to examine the association of EC exposure and risk of lung cancer mortality. Exposures were categorized as the cumulative sum of exposure and the cumulative sum disregarding the 5 years of exposure prior to death, i.e., with a 5- year exposure lag.
Results: 779 lung cancer deaths occurred during 424,668 years of person-time. With a 5-year exposure lag, compared to those in the lowest quartile of EC exposure, the hazard ratios were 1.32 (95%CI: 1.01-1.71), 1.37 (95%CI: 1.02-1.85), and 1.37 (95%CI: 0.99-1.91) for those in the second, third, and fourth quartiles, respectively.
Conclusions: Trucking industry workers with regular exposure to vehicle exhaust from diesel and other types of vehicles on highways, city streets, and loading docks have an elevated risk of lung cancer with greater EC exposures. However, the relationship between cumulative EC exposure and lung cancer risk does not appear to be linear.

Background
Previous studies suggest that exposure to pesticides increases the risk of childhood acute lymphoblastic leukaemia (ALL). The aim of this analysis was to investigate whether professional pest treatments in or around the home before birth or during childhood increased the risk of childhood ALL.

Methods
The Australian Study of Causes of Acute lymphoblastic Leukaemia in Childhood was a national population-based, multicentre case-control study of children younger than 15. Cases were eligible if diagnosed with ALL between July 2003 and December 2006. Controls were recruited by national random digit dialling between 2003 and 2006. Data from 366 cases diagnosed and 841 frequency-matched controls were analyzed using unconditional logistic regression, adjusting for study matching variables and potential confounders, to calculate odds ratios (ORs). A meta-analysis of our findings with the published findings of previous studies was also conducted.

Results
The ORs for professional pest control treatments were 1.24 (95% CI 0.86, 1.78) in the year before pregnancy, 1.37 (95% CI 0.89, 2.10) during pregnancy and 1.23 (95% CI 0.91, 1.65) for those done after the child's birth. The ORs for exposure after birth were highest when it occurred between the ages of two and three years. ORs were elevated for termite treatments before birth. ORs were higher for Pre-B than T cell ALL and for ALL of the ETV6-Runx-1 subtype than other cytogenetic subtypes. The pooled OR from a meta-analysis of this study with three previous studies of professional pest control treatments during pregnancy was 1.42 (95% CI 1.03, 1.95).

Conclusions
Our results, and those of our meta-analysis, provide some evidence of an increased risk of ALL for professional pest control treatments done during the index pregnancy and possibly in the child's early years. The analysis of pooled data from international collaborations may provide more certainty regarding these potentially important associations.

ENVIRONMENTAL DRIVERS OF ROSS RIVER VIRUS IN SOUTH-EAST TASMANIA, AUSTRALIA: TOWARDS STRENGTHENING PUBLIC HEALTH INTERVENTIONS

Angela Werner, *The George Washington University, United States of America*
Sarah Goater, *The University of Queensland, Australia*
Scott Carver, *Colorado State University, United States of America*
Greg Robertson, *Sorell Council, Australia*
Geoff Allen, *University of Tasmania, Australia*
Philip Weinstein, *The University of Queensland, Australia*

Background and aims: Ross River virus (RRV) is the most common and widespread mosquito-borne disease in Australia [1] and is predominantly identified and managed through passive surveillance. Here, the proactive use of environmental datasets to improve community-scale public health interventions in south-eastern Tasmania is explored. The potential for RRV to become an emerging public health issue in Tasmania due to projected climate changes is discussed.
Methods: RRV cases for the south-eastern Tasmania study area were obtained from the Tasmania Department of Health and Human Services (DHHS) for the 1993-2009 study period. Climate data (1993-2009) were obtained from the Australian Bureau of Meteorology (BOM) [2]. Tide data were obtained from the National Tidal Centre and Australian Hydrographic Service. Known environmental drivers (temperature, rainfall, and tide) of the RRV vector *Aedes camptorhynchus* were analyzed against cumulative case records for 5 adjacent Local Government Areas (LGAs) (1993-2009).
Results: Fisher's exact analysis showed years with above average rainfall were significantly correlated with [Tasmania-wide] RRV outbreak years. From Spearman's correlation, correlations between the five LGA RRV cases and three key environmental variables separately varied for 0, 1, 2 and 3 month lag periods. Negative binomial regression analyses showed that, allowing for a 0 to 3 month lag period, temperature was the most significant driver of RRV cases at 1 month lag, contributing to a 23.2% increase in cases above the long-term case average.
Conclusions: This research serves as an initial study of environmental drivers of RRV in SE Tasmania. Using these results for future studies and modeling to develop warning systems for local councils could prove very valuable. Implementing these early warning systems might help to prioritize funding towards interventions such as mosquito spray programs and/or public outreach campaigns. These steps will help to further guide public health policy and public health officials to reduce the overall disease burden.

THE POTENTIAL ROLE OF EPIGENETICS IN MEDIATING AIR POLLUTION EFFECTS

Andrea Baccarelli, *Harvard School of Public Health, Exposure, Epidemiology & Risk Program*

Background and Aims: Epigenetics investigates heritable changes in gene expression that occur without changes in DNA sequence. Several epigenetic mechanisms, including DNA methylation and histone modifications, can change genome function under exogenous influence. Results obtained from animal models indicate that in utero or early-life environmental exposures produce effects that can be inherited transgenerationally and are accompanied by epigenetic alterations. The search for human equivalents of the epigenetic mechanisms identified in animal models is in progress.
Results: Published evidence from human studies of air pollution indicating that epigenetic alterations mediate effects caused by exposure to environmental toxicants will be presented. In these investigations, our own results have shown that air pollution exposure is associated with altered methylation of human repetitive elements or genes. In recent preliminary studies, we have shown alterations of histone modifications in subjects exposed to metal-rich airborne particles. Original data will be presented demonstrating that altered DNA methylation in blood and other tissues is associated with environmentally-induced disease, such as cardiovascular disease and asthma.
Conclusions: On the basis of current evidence, possible models for the interplay between air pollution exposure and the human epigenome will be proposed and discussed.

ACUTE EFFECTS OF AIR POLLUTION ON PEDIATRIC ASTHMA ADMISSIONS IN ATHENS, GREECE

Evangelia Samoli, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School University of Athens, Greece*
Panagiotis Nastos, *Laboratory of Climatology and Atmospheric Environment, Department of Geology and Geoenvironment, University of Athens, Greece*
Athanasios Paliatsios, *General Department of Mathematics, Technological Education Institute of Piraeus, Greece*
Klea Katsouyanni, *Department of Hygiene, Epidemiology and Medical Statistics, Medical School University of Athens, Greece*
Konstantinos Priftis, *Allergy-Pneumonology Department, Penteli Children's Hospital, Athens, Greece*

Background and Aims: Several studies have reported adverse acute effects of air pollution on health, but most of them have focused on particulate pollution. We investigated the short term effects of particulate matter with aerodynamic diameter <10μg/m^3 (PM_{10}), sulfur dioxide (SO_2), nitrogen dioxide (NO_2) and ozone (O_3) on asthma emergency admissions in children aged 0-14 years old in Athens, Greece during 2001-2004. We explored effect modification patterns by season, sex, age and by the presence of desert dust transported mainly from the Sahara area.
Methods: We used daily time series data of pediatric asthma admissions from all the major children's hospitals in Athens and of the air pollutants as provided by the fixed monitoring stations' network. The associations were investigated using Poisson regression models allowing for overdispersion, controlling for seasonality, weather, day of the week, influenza and holiday effects. We applied separate stratified analysis by season, gender and age group.
Results: A 10 μg/m^3 increase in PM_{10} was associated with a 2.54% increase (95% confidence interval (CI): 0.06%, 5.08%) in the number of pediatric asthma admissions (during desert dust days: 4.12% (95% CI: 0.11%, 8.30%); non-desert days: 2.06% (95% CI: -1.01%, 5.21%)), while the same increase in SO_2 was associated with a 5.98% (95% CI: 0.88%, 11.33%) increase. O_3 was associated with a statistically significant increase in asthma admissions among older children in the summer. Our findings provide limited evidence of an association between NO_2 exposure and asthma exacerbation. Statistically significant PM_{10} effects were higher during winter and during desert dust days, while SO_2 effects occurred mainly during spring.
Conclusions: Our study confirms previously reported PM_{10} effects on emergency hospital admissions for pediatric asthma and further provides evidence of stronger effects during desert dust days. We additionally report severe effects of SO_2, which in Athens are at a moderate level.

"UNSPINNING" EPIDEMIOLOGICAL RESULTS FOR POLICY MAKERS

Neutra, Raymond, *Neutra Consultancy, USA*

Background and Aims: Environmental health policy decisions are partially influenced by: 1) the strength of evidence for, and 2) the magnitude of an environmental risk. However, the epidemiological literature is rife with adjectives pertaining to these two features, that play on well-known psychological quirks, in order to either alarm or reassure policy makers and the public. Through a publicly vetted process in California we developed a vocabulary to minimize this kind of "spinning" of results.
Methods: Staff of the California Department of Public Health developed "Risk Evaluation Guidelines" that laid out a proposed vocabulary for characterizing evidence and the magnitude of risk. These guidelines were submitted for public comment as well as review by an external advisory committee of scientists from various disciplines. After revision and acceptance by the committee these terms were used in a risk evaluation of low frequency magnetic fields (EMF).
Results: We avoided the common locution: "there is no evidence that…" Instead, we proposed terms to characterize the volume, the quality, and the consistency of the "evidentiary base" as well as the magnitude and the direction of observed effects. We reported estimated magnitudes of effects in both their psychologically reassuring and alarming formats. We were also careful to report facts relevant to "fairness" such as the existence of unequal exposures or the existence of effect modification in disadvantaged groups.
Conclusions: These detailed specifications for vocabulary can be found in the "Risk Evaluation Guidelines" and their actual use can be found in the "Risk Evaluation." Both of these documents received public review before finalization. They can be found on-line at the reference below. Stakeholders on both sides of the EMF issue considered these documents to have avoided "spinning." This vocabulary deserves wider use.

THYROID FUNCTION, PFOA AND PFOS IN CHILDREN LIVING NEAR A CHEMICAL PLANT

Maria-Jose Lopez-Espinosa, *London School of Hygiene & Tropical Medicine, United Kingdom*
Tony Fletcher, *London School of Hygiene & Tropical Medicine, United Kingdom*
Debapriya Mondal, *London School of Hygiene & Tropical Medicine, United Kingdom*
Michael S Bloom, *University at Albany, State University of New York, USA*
Giovanni Leonardi, *London School of Hygiene & Tropical Medicine, United Kingdom*

Background and Aims: Altered thyroid hormone levels following exposure to perfluorocarbons (PFCs) have been found in some animal studies. Published epidemiological findings are not consistent and most prior studies have focused on adults. We investigated if concentrations of two PFCs, perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS), were associated with thyroid function among 10,725 children (aged 1-18 years) living near a Teflon manufacturing facility in the Mid-Ohio Valley, USA.

Methods: Serum levels of thyroid-stimulating hormone (TSH), total thyroxine (TT4), and T3 uptake were measured and free thyroxine index (FTI) was calculated as biomarkers of thyroid function during 2005-2006, at the same time as serum levels of PFCs were measured. We estimated modeled in utero PFOA concentrations. Child-mother pairing allowed maternal serum concentrations of PFOA estimated at pregnancy to be used as a proxy for in utero exposure to PFOA for 52% of children. We performed multivariate regression analyses between thyroid disease status or thyroid hormone levels and PFOA/PFOS concentrations.

Results: At survey, median serum PFOA and PFOS concentrations were 29.3 and 20 ng/mL, respectively, and modeled in utero PFOA concentration was 17.1 ng/mL. The prevalence of reported thyroid disease was 0.5%, and the prevalence of subclinical hypothyroidism and hyperthyroidism based on thyroid hormone levels was 2.6 and 1.0%, respectively. We found a positive association between serum TT4 or FTI and LnPFOS in children (TT4: β=0.19, 95% CI=0.12, 0.26; FTI: β=0.04, 95% CI=0.02, 0.06). Findings for PFOA will also be presented in the conference but must first be shown to the local community.

Conclusions: Our results demonstrate a possible association between altered thyroid hormone levels and PFOS concentrations. This study comprises by far the largest population to date of children studied with such levels of PFOA, in relation to markers of thyroid function.

TEMPORAL CHANGES IN HOSPITALIZATION RATES DUE TO CARDIO-VASCULAR, RESPIRATORY DISEASES AND DIABETES IN URBAN ADULT POPULATION LIVING NEAR INDUSTRIAL PARK

Isabella Karakis , *1Department of Epidemiology and Health Services Evaluation, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel, and 2Environmental Epidemiology Department, Ministry of Health, Jerusalem, Israel*
Ella Kordysh , *1Department of Epidemiology and Health Services Evaluation, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel,*
Arkady Bolotin, *1Department of Epidemiology and Health Services Evaluation, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel,*
Galin Tzur, *1Department of Epidemiology and Health Services Evaluation, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel,*
Lena Novack, *1Department of Epidemiology and Health Services Evaluation, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel,*
Batia Sarov, *1Department of Epidemiology and Health Services Evaluation, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel.*

Background and Aims: In the Bedouin population – as previous studies presented – an increase in birth defects, mortality (perinatal and general), and respiratory hospitalization associates with residential proximity to a local chemical industrial park (IP). The aim of this study was to analyze whether an association between residential proximity to the IP and cardio-respiratory diseases and diabetes hospitalization rates exists for other populations living Beersheba subdistrict in Southern Israel.
Methods: A semi-ecological study has being conducted during 1995-2004 years, in which residential proximity to the IP was used as a surrogate exposure estimate**.** The dichotomic distance “<20 km from IP” was considered as “proximal” or “exposed”, while its complement part “20 + km from IP” was denoted as “distant” or “unexposed”. Such definition was based on the most far-off yet verified odour complaint related to the IP emissions. Given that after the year 2000 levels of the monitored daily emissions dropped along with the decrease in verified odour complaints from 58.2% to 41.3%, we divided the study period into two times before and after 2000 year. Negative binomial regression was used to assess incidence rate ratios (IRR) adjusted to confounders.
Results: Cardio-vascular gender-specific hospitalization rates were significantly higher for "proximal" localities than for "distant" ones throughout the study period. Independently, gender, age and locality type were associated statistically significant with the cardio-vascular hospitalization rates. All population characteristics predicted significantly respiratory hospitalization rates thru the study period, except for residential proximity to the IP, which was found associated statistically with the respiratory outcome in only 1995-1999 with IRR=1.174 (CI: 1.074-1.283). Diabetes hospitalization rates were associated significantly with locality type, but only during 1995-1999 years.
Conclusions: We found that after year 2000, there was a significantly decrease in the respiratory and cardiovascular diseases hospitalization rates in residents living near the IP.

HEAT AND CAUSE-SPECIFIC MORTALITY IN ADULTS AND INFANTS

Xavier Basagaña, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Claudio Sartini, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Jose Barrera-Gómez, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Payam Dadvand, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Jordi Cunillera, *Servei Meteorològic de Catalunya, Spain*
Bart Ostro, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Jordi Sunyer, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Mercedes Medina-Ramón, *Centre for Research in Environmental Epidemiology (CREAL), Spain*

Background and Aims: Mortality has been shown to increase with extremely hot ambient temperatures. A fine stratification of mortality causes can be useful for improving preventive policies. Infants are often identified as a vulnerable population to extreme heat conditions; however, results on heat and infant mortality are scarce, with no studies reporting on cause-specific mortality.
Methods: The study includes all deaths in the Catalonia region (Spain) during the warm seasons of 1983-2006 (503,389 deaths). The case-crossover design was used to evaluate the association between the occurrence of extremely hot days (days with maximum temperature above the 95th percentile) and mortality. Adult and infant mortality were stratified into 66 and 8 causes of death, respectively
Results: Three consecutive hot days increased total daily mortality by 19%. The percent of all deaths that was attributable to heat was 1.59%. About 40% of those deaths did not occur during heat wave periods. The mortality causes with elevated risk included most cardiovascular and respiratory diseases, mental and nervous system disorders, some infectious and digestive system diseases, diabetes, and some external causes including suicide. In infants, the effect of heat was observed on the same day and was only detected for conditions originating in the perinatal period (Relative Risk: 1.53; 95% confidence interval: 1.16-2.02). Within perinatal causes, cardiovascular, respiratory, digestive system and haemorrhagic and haemotological disorders were the causes with stronger effects.
Conclusions: Heat contributes to an increase in mortality via several causes. In infants, the first week of life is the most critical window of vulnerability.

PATTERNS OF AGE OF PUBERTY IN RELATION TO PFOA AND PFOS AMONG CHILDREN IN THE MID-OHIO VALLEY

Maria-Jose Lopez-Espinosa, *London School of Hygiene & Tropical Medicine, United Kingdom*
Tony Fletcher, *London School of Hygiene & Tropical Medicine, United Kingdom*
Ben Armstrong, *London School of Hygiene & Tropical Medicine, United Kingdom*
Bernd Genser, *London School of Hygiene & Tropical Medicine, United Kingdom*
Debapriya Mondal, *London School of Hygiene & Tropical Medicine, United Kingdom*
Giovanni Leonardi, London School of Hygiene & Tropical Medicine, United Kingdom

Background and Aims: Animal studies have suggested that some perfluorocarbons (PFCs), including perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS), may alter sexual maturation. Relationships of human PFC exposure with puberty are not clear. We conducted a study to investigate whether PFOA and PFOS affect pubertal status based on sex steroid hormone levels and self-reported menarche.
Methods: We analyzed patterns of puberty in a 2005-2006 survey of residents with PFOA water contamination from the Mid-Ohio Valley (3,076 boys and 2,931 girls, aged 8-18 years). Participants were classified as having reached puberty based on either hormone levels (total >50 ng/dL and free >5 pg/mL testosterone in boys, and estradiol >20 pg/mL in girls) or onset of menarche. We estimated the odds of reaching puberty and the fitted median age of reaching puberty in relation to serum PFOA and PFOS levels measured when puberty status was assigned, after controlling for other potential explanatory factors. Further analyses of puberty in relation to in utero levels of PFCs are ongoing and will be presented.
Results: Median PFOA and PFOS levels were 26 and 20 ng/mL in boys, and 20 and 18 ng/mL in girls, respectively. For boys, odds to reach puberty were reduced with increasing PFOS (delay of 190 days between the highest and lowest quartile). For girls, odds of post-menarche were lower with higher exposure to PFOA or PFOS (130 and 138 days of delay, respectively).
Conclusions: This is the first study indicating a possible association between delay of puberty and current serum levels of PFOS in boys and PFOA/S in girls. Exposure was assessed at the same time as puberty was classified and this work is being extended to assess timing of puberty in relation to estimates of PFC levels in utero.

NEW POLLEN INDEX FOR CHARACTERIZING POPULATION EXPOSURE TO AIRBORNE POLLEN LOAD AT DIFFERENT GEOGRAPHICAL LEVELS

Janos Bobvos, *Research group "Adaptation to climate change" of the Hungarian Academy of Science, Hungary*
Gergely Manyoki , *National Institute of Environmental Health Budapest, Hungary*
Anna Paldy, *National Institute of Environmental Health Budapest, Hungary*

Background and Aims: The ongoing spread of *Ambrosia artemisiifolia* in Europe is an increasing problem for human health and as an agricultural and non-agricultural weed. Hungarian Aerobiological Network (HAN) has monitored the airborne pollen of ragweed for 18 years, these data are a sound basis to create indicators to monitor the changes of the ragweed pollen season in time and space and the population exposure.
Methods: HAN has 18 monitoring sites out of which 8 sites were selected being representative for the characteristic macroclimate types of the country. The relevant population was defined as the population living around the monitoring site in a circle of 17.5 km. The start and end of the pollen season (1% resp. 99% of cumulative daily pollen count) was defined, daily pollen concentration were categorised into 7 groups (0-9, 10-29, 30-99, 100-299, 300-499, ≥500 pollen grains/m^3 resp. missing value).
Two sub-indices were defined and computed by year. Rate of time of population exposure to pollen concentration categories (TR) and rate of population (PR) exposed to different categories of daily pollen concentration at selected monitoring sites during the pollen season TR(x) and PR(x) indicate, what percentage of the total population is exposed to a given pollen concentration category (x) in what percentage of days of the total pollen season.
Results: Based on selected pollen data for 2010, 52.2% of the population was exposed to daily pollen concentration over 30 grains/m^3 (evoking allergic symptoms in every patient) during 40.8% of days of the season (32 days). 3.7% of the population was exposed to ≥500 grains/m^3 (extremely high category) for 4.8% of days.
Conclusions: In the future the indices can be used to examine spatial differences and time trends.
This project is supported by the New Hungary Development Plan (Project ID:TÁMOP-4.2.1/B-09/1/KMR-2010-0005).

MODELLING OF THE ASSOCIATION OF HEALTH IMPACTS OF EXPOSURE TO 2007-HEATWAVE AND THE EFFECT MODIFIERS AT SMALL AREA LEVEL IN HUNGARY

Anna Paldy, *National Institute of Environmental Health Budapest, Hungary*
Attila Juhasz, *Public Health Organization of Government Office of the Capital City Budapest, Hungary*
Janos Bobvos, *Research group "Adaptation to climate change" of the Hungarian Academy of Science, Hungary*
Csilla Nagy, *Public Health Organization of Government Office of the Capital City Budapest, Hungary*

Background and Aims: There is few evidence of the association between socio-economic factors and human adaptive capacity to climate change. The authors studied, whether the 2007 heatwave had different health impacts on sub-regional levels.
Methods: Daily total and cardiovascular mortality data were gained from the Central Statistical Office. The daily mean temperature data at 25km grids were derived from the European Climate Assessment & Dataset. Using Kriging, a continuous surface was interpolated from grid data to predict a daily mean temperature surface across the country for every summer day in 2007. Time clusters of mortality were studied by SatScan, excess mortality at small area level by Rapid Inquiry Facility module of ArcGis, the association between mortality, temperature, socioeconomical factors by spatial regression analysis using WinBUGS. Age-specific national death rates were used for standardized mortality rates. Small-area factors were defined by using population-weighted averages of temperature, socio-economical factors.
Results: A time cluster of daily mortality was identified between 18-25th July for the total and ≥50 years population. A 30% of excess mortality was detected during the heat wave period compared to the summer mortality rates excluding the heat wave period. Risk of excess total mortality (SMR 1.78) was the highest on the hottest day. No significant differences were seen in the spatial distribution of excess mortality, spatial fraction was 0.2086. A significant association was detected between excess mortality (for both causes) and socioeconomic status adjusted for density of population, whilst there was no statistically significant association between excess mortality and population density adjusted for deprivation.
Conclusions: During the heatwave high temperature, regardless to spatial differences, caused significant excess mortality, the impact was modified by socio-economical status.
The study was funded by EC DG Sanco EUROHEIS2/No2006126 and by by the New Hungary Development Plan (Project ID: TÁMOP-4.2.1/B-09/1/KMR-2010-0005).

METHODS FOR THE ASSESSMENT OF FOOD AND PHYSICAL ACTIVITY ENVIRONMENTS: BROOKLYN SENIORS AND THE BUILT ENVIRONMENT (BSBE) STUDY

Kimberly B. Morland, Ph.D., M.P.H, *Mount Sinai School of Medicine, Department of Preventive Medicine*
Kelly R. Evenson, Ph.D., M.S.,*University of North Carolina at Chapel Hill, Chapel Hill, USA*
Richard Bordowitz, M.D., *Mount Sinai School of Medicine, New York, USA*
James H. Godbold, Ph.D., *Mount Sinai School of Medicine, New York, USA*
Evelyn C. Granieri, M.D., M.P.H., M.S.Ed*, Columbia University, New York, USA*
Arlene Spark, Ed.D*., City University of New York at Hunter College, New York, USA*
Philip J. Landrigan, M.D., MSc, *Mount Sinai School of Medicine, New York, USA*

Background and Aims: Methods to evaluate the food and physical activity environment within the same study remain sparse. It is hypothesized that the types of local food retailers will affect individuals' dietary intake and both density and types of neighborhood infrastructure will influence walking. Therefore, methods to assess all features of local urban residential environments were developed.
Methods: One-thousand four hundred residents of Brooklyn New York, aged 60 years or older, were recruited during 2009-2011. Using Arc-GIS, participants' residential addresses were geocoded and 600-meter buffer zones were created, representing individuals' immediate residential environments. Using walking audits, information on the presence of the following types of places was collected. The categories of places include: (a) General (schools, places of worship, post office, medical, bank, libraries, service industries, retail industries); (b) Food (bodegas, franchised fast food, small grocery stores, specialty food stores, supermarkets, restaurants, tavern/bars, liquor stores, food vendors, convenience stores); (c) Physical Activity (parks, gyms, other physical activity resources); (d) Land Use (vacant commercial, land, residence and office spaces, residential, parking lots, factory/warehouse); and (e) Public Transportation (bus stops, subway stops).
Results: Using data from the New York City Department of Transportation, 38,122 street segments in Brooklyn were identified. A segment is the road length between two adjacent intersections. Some street segments were excluded such as alleys or paper streets, resulting in a total of 35,122 eligible segments. There is an average of 56 street segments (standard deviation (SD)=16.0) per buffer zone. Within each buffer zone, examples from each category of places include an average of 0.41 banks (SD=0.82); 1.3 supermarkets (SD=1.2); 6.3 green space entrances (SD=6.1); 10.4 vacant commercial spaces (SD=7.2); and 10.7 bus stops (SD=16.0).
Conclusions: Characterizing neighborhood infrastructure will allow for a robust evaluation of neighborhood variations and mechanisms of built environments affecting wellness among older adults.

RETROSPECTIVE EXPOSURE ASSESSMENT OF PERFLUOROOCTANOIC ACID (PFOA) SERUM CONCENTRATIONS AT A FLUOROPOLYMER MANUFACTURING PLANT

Susan R Woskie, *University* of Massachusetts Lowell, USA
Rebecca Gore, *University of Massachusetts Lowell, USA*
N. Kyle Steenland, *Emory University, USA*

Background and Aims: A retrospective exposure assessment was conducted as part of an epidemiologic study of the morbidity and mortality of workers exposed to C8, the ammonium salt of perfluorooctanoic acid (PFOA).
Methods: A serum database of 2125 measurements of serum PFOA from workers in the plant was used to model retrospective exposures. Eight job category/job group combinations were modeled using linear mixed models to account for repeated measures along with several variable combinations including a 4 knot restricted cubic spline (RCS) function to reflect the influence of process changes over calendar time on exposure, cumulative years worked in potentially exposed jobs, and the amount of C8 used or emitted by the plant over time.
Results: The trends in serum PFOA levels over time reflect a complex plant history including changes in production levels and engineering controls instituted to decrease C8 exposures. Nevertheless, the models were successful in fitting the serum data, finding a consistent 2-3% increase in serum PFOA level per cumulative prior years worked in a potentially PFOA exposed job. With one exception, all the models included either the amount of C8 used in the plant or the amount of C8 emitted by the plant in the year the sample was collected as a predictor. Both of these were significant positive variables resulting in a 3% increase in serum PFOA level per increase in 1000 pounds of C8 emitted/year or an increase in serum PFOA level of 1% per 1000 pounds C8 used/year.
Conclusion: The approach described here represents an improvement in the specificity of exposure characterization for this cohort. The retrospective models for serum levels described here allow use of employee work histories to predict annual serum levels for the full unsampled cohort for use in the exposure response modeling.

IMPACT ON CHILDHOOD RESPIRATORY HEALTH BY RESIDENTIAL EXPOSURE TO HIGHWAY TRAFFIC EXHAUST IN AN ALPINE VALLEY IN SWITZERLAND

Regina E Ducret-Stich, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Harish C. Phuleria, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Christian Schindler, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
L.-J. Sally Liu, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland, University of Washington, Seattle, USA*

Background and Aims: Little is known about residential exposure to air pollution from trans-alpine highway traffic and its impact on respiratory health. Our previous questionnaire study showed significant associations between respiratory symptoms and highway exposure in adults and children. The current pediatric asthma panel study is focusing on the short-term relationship between residential air pollution exposures and respiratory heath outcomes.
Methods: From November 2007 to June 2009 13 children (ages 7–13) with asthma participated in monthly health monitoring including measurements of exhaled NO (eNO) and oxidative stress markers in exhaled breath condensate (eBC) as well as outdoor and indoor air pollution monitoring. Asthma symptoms, medication use, allergies, exposure to tobacco smoke, and a time-activity diary of the child for the day before the health monitoring were recorded. Measurements of NO2 at 13 locations in the community and PM10 at two fixed and four mobile locations were used to model the home outdoor exposures. Linear mixed regression models are used to assess the association between levels of eNO and eBC markers and modeled traffic air pollution exposures. In addition different source contributions (e.g. diesel trucks, gasoline cars, biomass burning, etc.) to PM10 are quantified by source apportionment methods enabling assessment of their association with respiratory health.
Results: Associations between eNO and pollutants were analyzed for same day and different lag-day measurements. Preliminary results showed an increase of eNO levels per interquartile range of pollutant of 4% (CI: -1.7, 9.9) for elemental carbon, 2.4% (CI: -3.1, 8.3) for NO2 and 1.7% (CI: -2.8, 6.4) for PM10 at lag1 day. Analysis between the respiratory health markers and source apportioned PM10 results is currently underway.
Conclusions: Our first results demonstrate that air pollution from the trans-Alpine highway traffic is likely a significant risk factor for adverse respiratory effects in school children.

THE EFFECTS OF PARTICULATE MATTER SOURCES ON DAILY MORTALITY IN BARCELONA, SPAIN

Bart Ostro, *Centre for Research in Environmental Epidemiology, Barcelona, Spain*
Aurelio Tobias, *Institute of Environmental Assessment and Water Research, Spanish Research Council (IDAEA-CSIC), Barcelona, Spain*
Xavier Querol, *IDAEA-CSIC*
Andrés Alastuey, *IDAEA-CSIC*
Fulvio Amato, *IDAEA-CSIC*
Jorge Pey, *IDAEA-CSIC*
Noemí Pérez, *IDAEA-CSIC*
Jordi Sunyer, *Centre for Research in Environmental Epidemiology, Barcelona, Spain*

Background and Aims: Dozens of studies link acute exposure to particulate matter (PM) air pollution to premature mortality but questions remain about which species and sources in the PM mixture are responsible. While a few studies exist on the effects of species and sources in U.S. cities, European cities, which have a higher proportion of diesel engines and denser urban populations, are not well characterized. Information on the effects of specific sources could aid in targeting pollution control and in articulating the biological mechanisms of PM. Our study examines the effects of various sources on daily mortality in Barcelona, a densely populated city in the northeast corner of Spain.
Methods: Source apportionment using positive matrix factorization was developed for both PM2.5 and PM10 (PM less than 2.5 and 10 microns in diameter, respectively) from 2003 to 2007 and eight different factors were identified. A ninth factor measuring overall traffic was also formed by adding several of the other factors. Case-crossover regression analysis was used to determine the independent effects of daily exposure to each factor on both all-cause and cardiovascular mortality. We also examined multi-source models.
Results: T he results indicate that several sources of PM2.5 including vehicle exhaust, fuel oil combustion, secondary nitrate/organics, minerals, secondary sulfate and road dust were associated with all-cause and cardiovascular mortality. In the multi-source model, traffic (the sum of vehicle exhaust, road dust and 70% of nitrate), minerals and sulfate were all associated with these outcomes.
Conclusions: These results suggest that mobile sources, re-entrained dust, fossil fuel combustion and urban dust (construction/demolition, unpaved areas etc.) are important contributors of the observed adverse health linked to PM. Also, in some cases. the risks for the respective interquartile range in the concentrations were higher for specific sources than for PM2.5 mass.

SEASONAL VARIATION IN THE DIAGNOSIS OF PRIMARY BILIARY CIRRHOSIS

Richard McNally, *Newcastle University, England, United Kingdom*
Peter James, *Newcastle University, England, United Kingdom*
Samantha Ducker, *Newcastle University, England, United Kingdom*
Oliver James, *Newcastle University, England, United Kingdom*

Background and Aims: The aetiology of the autoimmune liver disease primary biliary cirrhosis (PBC) is unclear. Both genetic and environmental factors are likely to be involved. We have previously reported evidence of space-time clustering suggesting that a transient environmental agent may be involved in aetiology. The study aim was to further examine whether a transient environmental agent may contribute to the aetiology of PBC. We have analysed seasonal variation with respect to month of diagnosis using population-based data from northeast England over a defined temporal period (1987-2003).
Methods: Monthly expected (*E*) numbers of cases were calculated under an assumption of a uniform distribution throughout the year. Observed counts (*O*) were compared with the expected numbers. The chi-squared heterogeneity test was used to test for overall non-uniform variation and also for individual months. Poisson regression analysis was used to fit a sinusoidal (harmonic) model to the data, using month of diagnosis as a covariate in the model.
Results: The study analysed 1030 cases of PBC (931 females, 99 males) who were diagnosed during the period 1987 to 2003. The overall chi-squared heterogeneity test showed marginally statistically significant evidence for departure from the uniform distribution ($P = 0.062$). Detailed analyses of individual months showed that there was a marked and highly statistically significant peak for diagnoses in the month of June ($O = 115$, $E = 84.7$, $O/E = 1.36$, $P = 0.001$). Furthermore, Poisson modelling showed that there was evidence of sinusoidal patterning with a June peak ($P = 0.012$) with goodness of fit ($P = 0.302$) and estimated amplitude of 0.111 (standard error = 0.044).
Conclusions: These highly novel results provide further evidence for the involvement of a transient environmental agent in the aetiology of PBC, at least in some patients. Candidate agents include infections, atmospheric pollution or dietary factors.

INCREASING INCIDENCE OF THYROID CANCER IN GREAT BRITAIN, 1976 – 2005: AGE-PERIOD-COHORT ANALYSIS

Richard McNally, *Newcastle University, England, United Kingdom*
Karen Blakey, *Newcastle University, England, United Kingdom*
Peter James, *Newcastle University, England, United Kingdom*
Basilio Gómez Pozo, *Newcastle University, England, United Kingdom*
Nermine Basta, *Newcastle University, England, United Kingdom*
Juliet Hale, *Newcastle University, England, United Kingdom*

Background and Aims: Reasons for recent increases in the incidence of primary thyroid cancer have not been explained. This study aimed to fully examine temporal trends in the incidence of primary thyroid cancers diagnosed in 0-49 year olds in parts of Great Britain (GB) during the period 1976-2005.
Methods: Case data on thyroid cancer were obtained from four regional cancer registries in GB (Northern and Yorkshire, North West, Wales and Scotland). Age-standardised incidence rates (ASRs) and 95% confidence intervals (CIs) were calculated. Negative binomial regression was used to examine the effects of age, sex, drift (linear trend), non-linear period and non-linear cohort.
Results: The study analysed 4327cases of thyroid cancer aged 0-49 years. For males, the overall ASR was 3.9 per million persons per year (95% CI: 3.6-4.1). For females, the overall ASR was 12.5 (95% CI: 12.0-12.9). The best fitting negative binomial regression model included age (P<0.001), sex (P<0.001) and drift (P<0.001). Non-linear period (P=0.42) and non-linear cohort (P=0.71) were not statistically significant. For males aged 0-14 years, the ASR increased from 0.2 per million persons per year in 1976-1986 to 0.6 in 1996-2005. For males aged 15-29 and 30-49 the ASRs increased from 1.9 to 3.2 and from 7.3 to 12.6 per million persons per year, respectively. For females aged 0-14 years, the ASR increased from 0.3 to 0.5 per million persons per year. For females aged 15-29 and 30-49 the ASRs increased from 7.0 to 12.3 and from 21.2 to 40.0 per million persons per year, respectively.
Conclusions: There has been a linear increase in the incidence of thyroid cancer, which has led to a doubling of the number of cases diagnosed over a twenty year time span. The reasons for this increase are not well understood, but it is consistent with findings from other countries.

TRAFFIC-RELATED AIR POLLUTION AT HOME AND SCHOOL AND LUNG FUNCTION IN CHILDREN WITH ASTHMA: THE CINCINNATI ANTI-IDLING CAMPAIGN STUDY

Patrick H. Ryan, *University of Cincinnati, USA*
Tiina Reponen, *University of Cincinnati, USA*
Eric Borton, *University of Cincinnati, USA*
Chris Schaffer, *University of Cincinnati, USA*
Mark Simmons, *University of Cincinnati, USA*
Bridget Whitehead, *University of Cincinnati, USA*
Michael Yermakov, *University of Cincinnati, USA*
Sergey Grinshpun, *University of Cincinnati, USA*

Background and Aims: Diesel idling is a significant contributor to the concentration of traffic-related air pollution (TRAP) at schools. Previous anti-idling campaigns have been implemented, though the impact on air quality and health has been infrequently assessed. The objective of this analysis was to determine the association between exposure to TRAP at the homes and schools of asthmatic children on lung function prior to a community-based anti-idling campaign.

Methods: Four schools were selected to participate in the anti-idling campaign. Asthmatic children attending these schools and their caregivers were enrolled and completed a questionnaire and spirometry. Ambient air sampling was conducted prior to the anti-idling campaign at each school to measure the concentration of elemental carbon (EC), a marker of TRAP. Exposure to EC at the home address of each child was estimated using a land-use regression model. The association between time-weighted EC exposure and Forced Expiratory Volume in 1 second (FEV_1), Forced Vital Capacity (FVC), and Forced Expiratory Flow (FEF_{25-75}) was examined by linear regression and adjusted for height, weight, asthma medication use, number of school buses, gender, race, age, environmental tobacco smoke, and household income.

Results: A total of 102 children completed spirometry and a caregiver questionnaire. The average concentration of EC sampled at the schools was 0.62 $\mu g/m^3$ and was significantly greater than the estimated EC concentration at the children's homes (0.52 $\mu g/m^3$, $p < 0.01$). One interquartile (0.20 $\mu g/m^3$) increase in time-weighted EC exposure was associated with significant deficits in FEF_{25-75} [-0.26 L/s (95% CI -0.46, -0.05)] and decreased FEV_1 [-0.09 L (95% CI -0.20, 0.01)]. Exposure to EC was not associated with FVC.

Conclusions: Exposure to TRAP at homes and schools is associated with deficits in lung function among asthmatic children. The impact of the anti-idling campaign will be assessed by post intervention air sampling and repeated measurement of lung function.

SERUM DIOXIN CONCENTRATIONS AND CANCER RISK IN THE SEVESO WOMEN'S HEALTH STUDY

Marcella Warner, *University of California, United States*
Paolo Mocarelli, *University of Milano-Biccoca, Italy*
Steven Samuels, *State University of New York, United States*
Larry Needham, *Centers for Disease Control and Prevention, United States*
Donald Patterson, *EnvironSolutions Consulting, Inc, United States*
Paolo Brambilla, *University of Milano-Biccoca, Italy*
Brenda Eskenazi, *University of California, United States*

Background and Aims: 2,3,7,8-Tetrachlorodibenzo-para-dioxin (TCDD), a widespread environmental contaminant, disrupts multiple endocrine pathways. The International Agency for Research on Cancer (IARC) classified TCDD as a known human carcinogen, based upon predominantly male occupational studies of increased mortality from all cancers combined.
On July 10, 1976, as a result of a chemical explosion, residents of Seveso, Italy, experienced the highest levels of TCDD in a human population. In 1996, we initiated the Seveso Women's Health Study (SWHS), a retrospective cohort study of the reproductive health of the women. We previously reported a non-significant increased risk for all cancers combined with individual serum TCDD level, based on 21 cases. Herein we report results for risk of cancer from a subsequent follow-up of the cohort in 2008.
Methods: In 1996, we enrolled 981 women who were 0 to 40 years in 1976, resided in the most contaminated areas, Zones A and B, and had adequate archived sera collected soon after the explosion. For each woman, TCDD concentration was measured in the archived serum by high-resolution mass spectrometry. A total of 833 women (85%) participated in the 2008 follow-up study. All cancer cases were confirmed by medical record. We examined the relation of serum TCDD with cancer incidence using Cox proportional hazards models.
Results: In total, 66 (6.7%) women had been diagnosed with cancer. The average age at diagnosis was 48.8 (±11.3) years and geometric mean serum TCDD level was 95.3 (±4.0) ppt, lipid-adjusted. The adjusted hazard ratio for cancer associated with a ten-fold increase in serum TCDD levels ($\log_{10}$TCDD) was 1.80 (95% C.I. 1.29-2.52).
Conclusions: Individual serum TCDD is significantly positively related with cancer incidence in the SWHS cohort, more than 30 years after exposure. This all-female study adds to the epidemiologic evidence that TCDD is a multi-site carcinogen.

MERCURY EXPOSURE IN REMOTE FISH EATING POPULATIONS AND CARDIOVASCULAR RISK FACTORS

Eric Dewailly, *Laval University, Quebec, Canada*
Beatriz Valera, *Laval University, Quebec, Canada*
Pierre Ayotte, *Laval University, Quebec, Canada*
Paul Poirier ,*Laval University, Quebec, Canada*

Background and aims: More and more data suggest that the cardiovascular system should be considered a potential target for mercury. For example, work conducted in the Faeroe Islands in children and in Greenland suggests associations between mercury exposure and blood pressure and heart beat variability which are known risk factors for cardiac health. Other studies conducted in Europe suggest association between mercury and increase risk of myocardial infarction.
Methods: We have studied three large remote fish eating communities in the Arctic, sub Arctic and South Pacific which are exposed to high doses of mercury (3 adults and 1 child cohorts) Mercury was measured in blood as well as potential confounding nutritional factors and Paraoxanase (PON) 1 activity. Heart Rate Variability (HRV) and blood pressure were also measured.
Results: Mercury concentrations in blood averaged 86, 75, 49 and 81 nmol/L in adults from Nunavik, (Arctic Québec), French Polynesians, James Bay Crees Indians and Inuit newborn respectively.
In most of these studies we found that mercury exposure was associated with decrease HRV and increase blood pressure. For example, in Inuit adults, we found that a 10 percent increase in blood mercury was associated with an increase of 0.2 mm Hg in systolic blood pressure after controlling for other factors. Concerning biomarkers, our results in Inuit adults suggest that in a multiple regression model adjusted for age, HDL-C, omega-3 fatty acids, and *PON1* variants, blood mercury concentrations were negatively associated with PON1 activities [beta = -0.022, standard error (SE) = 0.005, $p < 0.001$), whereas blood selenium concentrations were positively associated with PON1 activities (beta = 0.024, SE = 0.004, $p < 0.001$).
Conclusion: Since heart diseases represent the most important causes of death, even a slight negative impact on the cardiovascular system could be of greater public health relevance than any other health effects related to mercury exposure.

PRENATAL BPA BIOMARKER LEVELS AND NEURODEVELOPMENT IN THE MOUNT SINAI CHILDREN'S ENVIRONMENTAL HEALTH CENTER

Stephanie M. Engel, *Department of Epidemiology, University of North Carolina, Chapel Hill, Chapel Hill, NC USA.*
Mary S. Wolff, *Department of Preventive Medicine, The Mount Sinai School of Medicine, New York NY, USA*

Background & Aims: Some studies have suggested that prenatal exposure to BPA negatively impacts child neurobehavioral development. We undertook an investigation of the relationship between BPA biomarker levels and child cognitive and behavioral development at 12 and 24 months, and 4-9 years.
Methods: The Mount Sinai Children's Environmental Health Study enrolled a multiethnic prenatal population in New York City between 1998 and 2002 (n= 404). Third trimester maternal urines were collected and analyzed for BPA metabolite level. Children returned for Bayley Scales of Infant Development assessments at ages 12 (n = 200) and 24 months (n = 276), and for behavioral assessments and psychometric intelligence tests between 4 and 9 (n = 169) years. Results were additionally analyzed according to creatinine tertile to examine sensitivity to urinary dilution.
Results: There were no associations between BPA metabolite levels and the MDI or PDI at 12 or 24 months overall. Within the most dilute strata of creatinine, a slight and imprecise negative association between BPA and MDI at year 1 was observed. Likewise, there were no overall effects with IQ domains. However in the most dilute and concentrated creatinine concentrations, there were suggestions of effects that went in opposite directions for verbal and perceptual reasoning. There were small and imprecise effects of BPA on the BASC aggression and atypicality domains overall. Stratified by creatinine concentration elevated effects were found in the most dilute and concentrated creatinine strata for a number of behavioral domains. For the four domains in which these elevated effects were found for both dilute and concentrated urines, the effect estimates switched direction in all cases.
Conclusion: We observed heterogeneity in BPA biomarker effect estimates according to urinary dilution on several instruments administered independently over several years. In many cases, the most extreme effects were observed in the most dilute tertile of creatinine. Urinary creatinine can fluctuate substantially within and between women over the course of pregnancy. Future studies should carefully consider urinary dilution when analyzing and interpreting their BPA biomarker data.

Accounting for model uncertainty in estimating the relative risk of mortality associated with heat waves.

Jennifer F. Bobb, *Johns Hopkins Bloomberg School of Public Health, United States*
Francesca Dominici, *Harvard School of Public Health, United States*
Roger D. Peng, *Johns Hopkins Bloomberg School of Public Health, United States*

Background and Aims: Estimating the risks heat waves pose to human health is a critical part of assessing the future impact of climate change. While uncertainty in climate model predictions has been studied thoroughly, model uncertainty in estimating the subsequent health effects has not been well explored. This work assesses the contribution of model uncertainty and develops an approach to systematically incorporate model uncertainty into heat wave risk estimation.
Methods: We propose a flexible class of time series models to estimate the relative risk of mortality associated with heat waves and conduct Bayesian model averaging (BMA) to account for the multiplicity of potential models. Methods are applied to data from 105 U.S. cities for the period 1987-2005. We identify those cities having a high posterior probability of increased mortality risk during heat waves, examine the heterogeneity of the posterior distributions of mortality risk across cities, assess sensitivity of the results to the selection of prior distributions, and compare our BMA results to a model selection approach.
Results: Our results show that no single model best predicts risk across the majority of cities, and that for some cities heat wave risk estimation is sensitive to model choice.
Conclusions: While model averaging leads to posterior distributions with increased variance as compared to statistical inference conditional on a model obtained through model selection, we find that the posterior mean of heat wave mortality risk is robust to accounting for model uncertainty over a broad class of models.

APPLICATION OF SPATIO-TEMORAL REGRESSION MODEL ACCOUNTING FOR ASIAN DUST (DESERT DUST) TO REGULATORY AIR QUALITY DATA IN JAPAN

Saori Kashima, *Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan*
Takashi Yorifuji, *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*
Toshihide Tsuda, *Okayama University Graduate School of Environmental Science, Okayama, Japan*
Akira Eboshida , *Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan*

Background and Aims: A 2-stage spatio-temporal regression model has been developed for predicting pollutants, although its application has been limited to western countries. Moreover, most of the models utilized only meteorological factors as the temporal predictors. In Asian countries, Asian dust originating from the desert of Mongolia or China should be considered as an additional temporal predictor since some polluted events due to Asian dust has been reported. Thus, we created the spatio-temporal model accounting for the temporal variation of Asian dust in Hiroshima, Japan.
Methods: We used the monthly-mean nitrogen dioxide (NO_2), sulfur dioxide (SO_2), photochemical oxidant (O_x), and suspended particulate matter (SPM) concentrations between 2005 to 2010. We also obtained the daily Asian dust concentration by Light Detection And Ranging in Matsue. First, we selected spatio-predictors including road type, traffic intensity, land use, and physical component by using land use regression model. Next, we constructed a 2-stage spatio-temporal model including meteorological predictors to predict the monthly-level each pollutant. Then we added the Asian dust concentration as an additional temporal-variable into the models.
Results: The mean concentrations of NO_2, SO_2, O_x, and SPM were 17.2ppb, 3.7ppb, 27.5ppb, and 28.1μg/m^3, respectively. The mean concentration of Asian dust (120m-150m height from the ground) was 30.1μg/m^3. The correlation between each pollutant and Asian dust were 0.18, 0.24, 0.39, and 0.32, respectively. R^2 for NO_2 was 0.85 in the spatio-temporal regression model and 0.84 in Asian-dust model, respectively. R^2 of other pollutants were also greatly improved after introducing temporal-predictors as well as Asian dust, e.g. R^2 for the SO_2, O_x, and SPM was 0.83, 0.91, and 0.86 in Asian-dust model, respectively.
Conclusions: This result suggests that pollutants could be predicted moderately well by the spatio-temporal model even in Asian countries. Further studies which examine the role of the Asian dust would be required.

ENVIRONMENTAL TOBACCO SMOKE AND PARKINSON'S DISEASE IN THE CALIFORNIA TEACHERS STUDY

Nicole M. Gatto, *Department of Epidemiology, School of Public Health, UCLA, USA*
Dennis Deapen, *Department of Preventive Medicine, USC Keck School of Medicine, USA*
Beate Ritz, *Departments of Epidemiology, Environmental Health Sciences and Neurology, UCLA, USA*

Background and Aims: Epidemiologic studies have consistently demonstrated inverse associations between cigarette smoking and Parkinson's disease (PD) risk, leading to speculations about potential neuroprotective effects of smoking. However, it has been hypothesized that behavioral and genetic factors may influence propensity to initiate and maintain smoking in PD.
Methods: We examined cigarette smoking behavior and environmental tobacco smoke (ETS) exposure using questionnaire data obtained at baseline from 403 self-reported female PD cases at a ten-year follow-up and 4,045 randomly selected age- and race-matched female controls in the California Teachers Study.
Results: The study population was an average 60.1 ± 12 years at baseline, predominantly white (91.5%) and largely non-smoking, with 63.3% reporting having never smoked; 46.4% had been exposed to ETS in their lifetime. Women who smoked did so for an average of 22.1 years, with cases smoking two years less than controls (20.4 ± 13.7 vs. 22.2 ± 14.6 years, respectively). Women who had ever smoked were less likely to report PD at follow-up (OR = 0.87, 95% CI = 0.70, 1.08), an effect which was driven by former smokers (OR = 0.86, 95% CI = 0.69, 1.08). Any ETS exposure was not associated with PD (OR = 1.02, 95% CI = 0.76, 1.37) compared to no personal or environmental smoke exposure. Adulthood ETS exposure was not inversely associated with PD (OR = 1.15, 95% CI = 0.83, 1.60).
Conclusions: These results suggest that cigarette smoke and its components at least as inhaled as ETS may not be protective against PD, per se, although one cannot rule out a survival disadvantage for smokers with PD. Other explanations for the documented inverse associations between smoking and PD should continue to be explored, such as possible dysfunction in reward pathways resulting from disruptions in the dopaminergic system early in the course of PD.

PHTHALATE EXPOSURE AND THYROID FUNCTION IN PRE-PUBERTAL CHILDREN FROM CENTRAL TAIWAN

Po-Chin Huang, *Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Miaoli, Taiwan*

Hsin-I, Huang, *Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Miaoli, Taiwan*

Pen-Hua Su, *Department of Pediatrics, Chung Shan Medical University Hospital, Taichung, Taiwan; School of Medicine, Chung Shan Medical University, Taichung, Taiwan*

Hsiu-Ying Ku, *Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Miaoli, Taiwan*

Chien-Jen Wang, *Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Miaoli, Taiwan*

Shu-Li Wang, *Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Miaoli, Taiwan- Institute of Environmental Medicine, College of Public Health, China Medical University and Hospital, Taichung, Taiwan, Republic of China*

Background and Aims: Thyroid hormone is essential for development of pre-pubertal children. Toxicological evidence shows the probable thyroid-like function of some phthalates *in vitro* and *in vivo*, and some studies report that exposure to phthalates may alter thyroid hormones in women and men. However, little information is available on whether exposure to phthalates is correlated with thyroid function in children during pubertal development.

Methods: We studied 186 children, included 85 boy and 101 girls, born to previously established pregnant women cohort in 2009. We measured seven phthalate metabolites (MMP, MEP, MnBP, MBzP, MEHP, 5OH-MEHP, 5oxo-MEHP) in urine samples of children 8-9 years using LC-MS/MS. Serum sample was analyzed for 3,5,3'-triiodothyronine (T_3), thyroxine (T_4), thyroid-stimulating hormone (TSH) and thyroxine-binding globulin (TBG) using radioimmunoassay.

Results: The urinary levels of MnBP and MEHP in Taiwanese children at 8-9 years old were 3 folds higher than those in American children. In girls, we found that T_4 is significantly and negatively correlated with urinary 5OH-MEHP (β: -0.225, 95%CI: -1.57~-0.27, p=0.006), the metabolites of DEHP, after adjustment for TBG, urinay MBzP using step-wise multiple regression. In boys, we found that T_3 is marginal significantly and positively correlated with urinary MEHP (β: 0.258, 95%CI: 0.011~0.063, p=0.006) after adjustment for TBG and maternal education. It is indicated that phthalate exposure, especially for DEHP, in pre-pubertal children may alter thyroid function in different manner between genders.

PRENATAL EXPOSURE TO MULTIPLE HEAVY METALS AND NEONATAL NEUROBEHAVIORAL DEVELOPMENT IN SHANGHAI, CHINA

Background: Epidemiological studies examining the effects of prenatal heavy metals exposure on neonatal development at the population-based level are limited.
Objective: To explore prenatal exposure levels to heavy metals and examine whether exposure is associated with neonatal development.
Methods: A stratified multi-stage cluster sampling methodology was used to investigate 1652 mother-infant pairs from 2008 through 2009 in Shanghai. Cord blood concentrations of Pb, Hg, Mn, Cd, As ,Tl and NBNA (Neonatal Behavioral Neurological Assessments) were tested. We defined three different exposure levels (low, medium and high) according to the normal range values.
Results: The median blood Pb, Hg, Mn, Cd, As and Tl concentrations were 41• g/L, 1.88• g/L, 4.1• g/L, 0.03• g/L, 0.86• g/L and 0.02• g/L, respectively, which all were in the normal range. Increasing exposure to Cd, Hg, Mn, As and Tl during pregnancy was associated with decreasing NBNA scores. High level-exposure (exceeding the normal range) of Hg, Mn, Cd and Tl had lower NBNA scores compared to medium and low levels (both in the normal range), which implied that the normal range of these heavy metals was safe for the newborns' development. The mean decreasing scores of NBNA was 0.61, 1.24, 1.50 and 0.84 (total score = 40) with high-level exposure of Hg, Mn, Cd and Tl, respectively. The medium-level exposure (in the range of normal) to As had lower NBNA scores compared to low-level exposure, which implied that the normal range of As was not safe to the newborns' development. However, prenatal Pb high-exposure did not affect NBNA scores either by single or multiple factor analysis. In addition, important contribution factors for heavy metals pollutants were diet, lifestyle and housing renovation.
Conclusions: prenatal heavy metals except Pb exposures were associated with NBNA. The adverse effect of medium-level As warrants the need to further investigate the safe range of As.

EFFECTS OF ARSENIC EXPOSURE ON CHILD IMMUNE RESPONSE AND COGNITIVE DEVELOPMENT

Rubana Raqib, International Centre for Diarrhoeal Disease Research, Bangladesh

Background and Aims: Inorganic arsenic, a potent toxicant and carcinogen, is frequently present in drinking water, but little is known about consequences of early-life exposure. Our on-going large mother-child cohort study in rural Bangladesh, where arsenic concentrations in drinking-water and food vary considerably, aims at evaluating health effects of pre- and postnatal arsenic exposure. Initially, prenatal arsenic exposure was found to be associated with low birth weight and increased risk of infant mortality and morbidity. Arsenic-related impaired thymus development indicated immunosuppression, why we follow the children's health and development.
Methods: We measured arsenic metabolites in urine twice in pregnancy (first and third trimesters) and twice during childhood (1.5 and 5 years) in 2000 mother-child pairs. Placenta and cord blood at delivery (sub-sample) were analysed for immune (immunohistochemistry) and inflammatory markers (multiplex cytokine assay). Cord blood T cell receptor excision circles (TRECs) were measured by Real Time-PCR. We assessed child development of about 1700 children at 5 years using Wechsler Preschool and Primary Scale of Intelligence (IQ) and morbidity by 14 days recall.
Results: Immunosuppression of arsenic was indicated by reduced number of T cells and increased expression of inflammatory cytokines in the placenta, and altered TRECs and cytokine levels in cord blood. We also found that arsenic exposure was significantly negatively associated with verbal and full scale IQ (multivariable-adjusted models) in a sex-dependent manner. A urinary arsenic concentration of 100 µg/L was associated with decrements of 1-3 points in VIQ and FSIQ in girls, but not in boys.
Conclusion: Early-life arsenic exposure adversely affects children's immune function and cognitive development. Many children continue to be exposed in Bangladesh, in spite of extensive mitigation efforts, and we plan to follow-up these children at an older age.

PAST ARSENIC EXPOSURE, ARSENICAL SKIN LESIONS AND ABNORMALITY OF LUNG FUNCTION IN SOUTHWESTERN TAIWAN

Ling-I Hsu, *Academia Sinica, Taiwan*

Chien-Jen Chen, *Academia Sinica, Taiwan*

Background and Aims: Several epidemiological studies have shown the association of artesian water consumption with respiratory symptoms and decreased lung function. The purpose of this study was to examine the association of past arsenic exposure from drinking water with lung function after 15-year cessation of contaminated water ingestion.

Methods: The study subjects were recruited from the arseniasis area with arsenic level in deep-well water as high as 0.79-0.93 mg/L in Southwestern Taiwan. A total of 787 subjects participated in community health examinations during 1991-1993. Lung function was measured with a portable spirometer by skilled technicians and skin lesions were clinically diagnosed by experienced physicians.

Results: Among male smokers with either hyperkeratosis or skin cancers (Bowen's disease, squamous cell carcinoma, basal cell carcinoma), the average adjusted forced expiratory volume in 1 second (FEV1) was reduced by 237.6 ml (95%CI, 50.0-425.2, p=0.01) but forced vital capacity (FVC) was not significantly reduced (adjusted mean of reduction: 297.7ml, 95%CI,-101.9-297.4, p=0.34). Male nonsmokers with or without arsenical skin lesions were not associated with decreased lung function. Female nonsmokers with hyperkeratosis and/or skin cancers were associated with reduced FEV1 (adjusted mean of reduction: 134.7ml, 95%CI, 21.2-248.1, p=0.02) but not with FVC. Dose-response relationship of arsenic exposure with decreased FEV1 as well FEV1/FVC was shown in male smokers and female (FEV1 mean of reduction: 36.1 ml and 194.3ml among the groups of cumulative As exposure (CAE) 0.1-19.9 and 20+, respectively in male smokers; 116.7 ml and 146.1 ml among CAE 0.1-19.9 and 20+, respectively in female).

Conclusions: Markedly interaction of cigarette smoking with arsenical skin lesions was observed to significantly decrease FEV1 and FEV1/FVC among male. Among non-smokers, female with hyperkeratoses and/or skin cancers was more susceptible to As-induced pulmonary effects than male. After 15-year cessation of contaminated water ingestion, dose-response relation of arsenic exposure with decreased lung function could still be observed in male smokers and female.

Chun-Ya Kuo, *Department of Psychiatry, National Taiwan University Hospital, Taipei, Taiwan,*

Jin-Huei Hsu, *Institute of Occupational Safety and Health, Taipei, Taiwan,*

Background/Aims: After a traumatic event, a significant proportion of victims develop psychiatric disorders. This study aimed to determine the rates of chronic post-traumatic stress disorder and other psychiatric disorders 12 months after occupational injuries.

Methods: A two-staged survey study was conducted. The first stage of investigation involved a self-reported questionnaire including Brief Symptom Rating Scale (BSRS-50) and Post-traumatic Symptom Checklist (PTSC), which was sent to injured workers at 12 months after injury, for screening of mental conditions. Phone interview by a psychiatrist using Mini-International Neuropsychiatric Interview (MINI) was done among those who: (1) scored BSRS of ≥ 2 standard deviations higher than the norm; (2) reported “severe” level or higher among the three items of PTSC; or (3) reported “moderate” levels to two items of PTSC or more. The prevalence rates of PTSD and other psychiatric disorders were estimated by multiplying the percentage of diagnosed disorder among those completed MINI interview by the percentage fulfilling criteria for such interview.

Results: A total of 1233 workers completed the self-report questionnaire (response rate 27.9%). Among them, 167 (13.5%) fulfilled the criteria for MINI interview and were invited. A total of 106 (63.5%) completed the phone interview. The prevalence rates of chronic PTSD, major depression, comorbid PTSD and major depression, and either PTSD or major depression were 3.2%, 2.0%, 1.9%, and 3.3%, respectively.

Conclusion: This study showed that at 12 months after occupational injuries, a significant proportion of workers suffered from chronic psychiatric disorders.

Keywords: occupational injury, major depression, post-traumatic stress disorder (PTSD)

HYPERURICEMIA RISK IN SUBJECTS WITH MODERATE TO HIGH LEVELS OF PCDD/FS EXPOSURE

Jung-Wei Chang, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan*
Horng-Yih Ou, *Division of Endocrinology and Metabolism, Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan*
Po-Chi Liao, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan*
Ching-Chang Lee, *Department of Environmental and Occupational Health, College of Medicine, National Cheng Kung University, Tainan, Taiwan*

Background and Aim: Hyperuricemia, the predisposing condition for gout, has been associated with hypertriglyceridemia and diabetes mellitus (Berkowitz 1966), and also be a risk factor for the development of coronary artery disease (Abbott et al. 1988). PCDD/Fs have been found to cause renal toxicity in experimental animals and elevate uric acid in epidemiology studies. The potential role of PCDD/Fs exposure as a preventable risk factor has raised attention of public health, especially since it's ubiquitous worldwide. We aimed to investigate and clarify the effect of moderate-to-high exposure to PCDD/Fs on hyperuricemia risk.
Methods: This cross-sectional study recruited 1657 healthy participants near a deserted pentachlorophenol factory (Chang et al. 2010). Renal function related factors were measured to examine associations with serum PCDD/Fs. We also investigated associations between serum PCDD/Fs and hyperuricemia risk. We compared associations of serum PCDD/F levels and estimated glomerular filtration rate (eGFR, renal function index) in both gender under and above 50-years-old.
Results: The eGFR reduces gradually with serum PCDD/F levels in all groups (men < and ≥ 50 50-years-old, women < and ≥ 50-years-old), especially for a sudden falling observed in men over than 50 years old. Serum PCDD/Fs were significantly increased with uric acid in male participants (Men: β= 0.230, p= 0.008; Women: β=0.035, p= 0.753; All: β= 0.148, p= 0.037). In addition, we further found that male participants with higher serum PCDD/F levels had a higher hyperuricemia risk than did the reference group (serum PCDD/F levels <11.4 pg WHO_{98}-TEQ_{DF}/g lipid) after adjusting for confounding factors (25 th to <50 th percentile, adjusted Odds Ratio (AOR) = 1.87 [95% CI = 1.13-3.10]; 50th to <75 th percentile, AOR = 2.44 [1.46-4.09]; ≥75 th percentile, AOR = 3.29 [1.89-5.74]).
Conclusions: We hypothesize that accumulated PCDD/Fs may reduce urate excretion and may heighten the risk of hyperuricemia in the general population.

Background and Aims: Organiophosphate triesters (OPE) are a range of compounds widely used as plasticizers and additive flame retarders. To date, only a limited number of studies have examined OPE levels in house dust and their relation to inhabitants' health. The aim of this study was to measure OPE levels in house dust and to evaluate the relationship between exposure to OPE and recent allergy medication in inhabitants.
Methods: Dust samples were collected from the living room of 182 single family dwellings in 6 cities in Japan. The "floor" samples were collected from floor and shelves lower than 35 cm from the floor, and "multi-surface" samples were collected from anything above 35 cm from the floor, such as shelves, furniture, walls, ceilings, etc. After being extracted by acetone, samples were analyzed by GC/FPD to determine the concentrations of 11 compounds. All inhabitants living in the target dwellings were given self-administered questionnaires to assess their allergic medication within the past 2 years.
Results: Collected dust weight that exceed 25 mg was included into the results. The prevalence of asthma, atopic dermatitis, and rhinitis was 4.8%, 9.9% and 18.2%, respectively. TBEP was detected from all samples; the median value was 580 µg/g in floor and 111 µg/g in multi surface dust, followed by TCiPP; 8.69 µg/g and 25.8µg/g, respectively. Significant associations between the prevalence of atopic dermatitis and TBP, TCiPP, TCEP, TEHP, and TDCPP in floor dust (per $\log_{10}$-unit, odds ratio: 1.93-2.26) was obtained after adjustment, but not with multi-surface dust. The prevalence of asthma and allergic rhinitis was related to TBP.
Conclusions: The results suggested that exposure to OPE may cause dermatitis. The levels of OPE in this study were relatively higher compared to previous studies in Europe and the US, and thus further studies of OPE should be conducted.

Gisela Büchele, *Ulm University, Germany*
Barbara Sozanska, *Wroclaw Medical University, Poland*
Charlotte Braun-Fahrländer, *Swiss Tropical and Public Health Institute, Basel, Switzerland and University of Basel, Switzerland*

Background and Aims: Several epidemiological studies found consumption of farm milk to be inversely associated with the occurrence of hay fever, pollen sensitization. GABRIELA, a large cross-sectional multi-centre study, offered for the first time the opportunity to relate analytically measured milk components to asthma and atopy outcomes in children and possibly explain the previously reported protective farm milk effect.
Methods: In four rural regions of Germany, Austria, and Switzerland, farm and milk exposure of 7606 5–13 year old children was assessed by a detailed questionnaire and they also provided blood samples to determine specific IgE levels. Viable bacterial counts, whey protein levels, and total fat content were analysed in 800 milk samples that were collected at the participant's homes. Associations of milk consumption and asthma, atopy, hay fever, and atopic dermatitis were computed by stratified weighted logistic regression analyses adjusted for potential confounders.
Results: Raw milk consumption, that was reported in questionnaires, was inversely associated with asthma (aOR: 0.59, 95%-CI: 0.46–0.74), atopy (0.74, 0.61–0.90), and hay fever (0.51, 0.37–0.69) independent of other farm exposures. Consumption of exclusively boiled farm did not show a protective effect. The heating status of consumed milk as reported by parents was in very good agreement with objective measurements. Total viable bacterial counts or total fat content of milk were not significantly related to asthma or atopy. Yet, increased levels of the whey proteins were inversely associated with asthma but not with atopy. Significant inverse dose-response relations were observed for lactoferrin (p–value for linear trend = 0.02), TGF-beta2 (0.02), alpha-lactalbumin (0.02), and beta-lactoglobulin (0.04).
Conclusions: The protective effect of raw milk consumption on asthma seems to be associated with the whey protein fraction of unprocessed farm milk. Relevant immunomodulatory compounds of farm milk and underlying mechanisms need to be explored in more detail.

ASSESSMENT IS TO ACT – COLLABORATIVE CREATION OF SOCIAL KNOWLEDGE IN ENVIRONMENTAL HEALTH ASSESSMENT AND POLICY-MAKING

Mikko V. Pohjola, *National Institute for Health and Welfare (THL), University of Eastern Finland, Finland*
Jouni T. Tuomisto, *National Institute for Health and Welfare (THL), Finland*

Background and aims: This presentation describes a recent doctoral thesis. It presents the research underlying the work at the National Institute for Health and Welfare (THL), and several projects, in developing novel methods and tools to support societal decision making. Particularly the aim has been to improve effectiveness of environmental health assessment by means of increased openness.
Methods: The research question was: "how can scientific information and value judgments be organised for improving societal decision making in a situation where open participation is allowed?". This question was considered in the context of environmental health, but also in regard to benefit-risk analysis of food and plant-based food supplements, and also beyond these fields. The search for answers built on epidemiology and toxicology as well as different conventions of assessment and risk research. This knowledge was complemented with insights from other disciplines, particularly epistemiology, cognition science, collaborative information technology, and industrial engineering and management.
Results: The tendencies towards deeper engagement between experts and policy-makers, broader participation, and more pragmatic, yet multidisciplinary, assessment framing indicate the incapability of conventional assessment approaches to address the complexity of environmental health. Policy-making, assessment, and participation are not separate, but intertwined aspects of a societal process of knowledge creation and use, which should be open for everyone. Recent advances in theories of learning and collaborative information systems provide means to facilitate such processes. Evaluation of these processes and their outputs is meaningful only according to their societal outcomes. These insights are implemented in open assessment method and Opasnet web-workspace (http://en.opasnet.org).
Conclusions: Environmental health assessment and policy-making are two perspectives to the same social knowledge process. The former answers questions, the latter explores questions and implements knowledge in practice. Openness in this intertwined process is meaningful and possible. However, the methodological and technical enablers alone are not enough, also a cultural change is required.

ACCURACY OF GPS-TRACKING DEVICES IN EXPOSURE ASSESSMENT STUDIES

Johan Beekhuizen, *Utrecht University, the Netherlands*
Hans Kromhout, *Utrecht University, the Netherlands*
Anke Huss, *Utrecht University, the Netherlands*
Roel Vermeulen, *Utrecht University, the Netherlands*

Background and Aims: Current lightweight Global Positioning System (GPS) receivers can be used to track an individual's location over several days to weeks. These tracking devices are increasingly used in epidemiological studies for time-allocation analyses to assess exposure to air pollution or electromagnetic fields. There is little information about the accuracy of these devices and to which extent e.g. different wearing or transport modes affect the performance of a GPS.
Methods: We tracked 12 individuals on two days during their commute to work. The tracked routes included different transport modes (walking, biking, car, bus, train). Each individual carried three different GPS tracking devices simultaneously on the left shoulder and a second set of identical GPSs in a backpack. We assessed the performance by first digitizing the true paths travelled by the participants with aerial imagery and subsequently computing the distance of the locations logged by the GPS to the true paths.
Results: The median error for walking was 3.7m (IQR 1.6-7.6m), biking 2.9m (IQR 1.3-5.9m), train 4.8m (IQR 2.3-8.9m), bus 4.9m (IQR 2.2-9.5m) and car 3.3m (IQR 1.5-5.9m). A higher accuracy (~1m) was observed for wearing the GPSs on the shoulder versus backpack for the transport modes biking and walking. Although 86% of all logged locations fell within 10m of the true path, about 1% of the errors were larger than 50m. Complete signal loss also occurred, in particular in the train where 28% of the total distance was not tracked.
Conclusions: The average accuracy of the GPSs was high. Thus, tracking devices are useful tools for time- and location-based exposure assessment. However, large GPS errors might affect estimates of exposures in the case of exposures with extreme high spatial variability such as radiofrequency fields from mobile phone base stations.

EXCESS MORTALITY IN EUROPE FOLLOWING A FUTURE LAKI-STYLE ICELANDIC ERUPTION

Anja Schmidt, *University of Leeds, UK*
Bart Ostro, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Kenneth S. Carslaw, *University of Leeds, UK*
Marjorie Wilson, *University of Leeds, UK*
Thorvaldur Thordarson, *University of Edinburgh, UK*
Graham W. Mann, *University of Leeds, UK*

Background and Aims: Historical records show that the 1783–1784 Laki eruption in Iceland significantly increased air pollution and posed a health hazard far beyond the borders of Iceland. Given the reasonable likelihood of a recurrence of such an event, it is important to assess its potential impact on public health. We quantified the potential health effects caused by a future Laki-style eruption similar in magnitude to earlier eruptions.
Methods: We combined estimates of air pollution impacts of a potential eruption using advanced global aerosol models and concentration–response functions from the air pollution epidemiology literature. Since the eruption might impact air quality for up to a year, we estimated the mortality impacts from both short- and long-term exposure to fine particles (PM2.5 or particulate matter less than 2.5 microns in diameter).
Results: Averaged over the first three months of the eruption, European-mean PM2.5 concentrations would more than double from current levels. In addition, mean annual concentrations would increase by more than 50 percent. Based on current epidemiological studies, these changes are associated with an additional 139,000 cardiopulmonary deaths (95% confidence interval = 51,000 - 224,000).
Conclusions: Based on our models, a volcanic air pollution event similar in magnitude to those recorded in earlier times, could be a severe health hazard, increasing excess mortality in Europe on a scale that likely exceeds excess mortality due to seasonal influenza. Moreover, the death toll of such an eruption would be larger than that of all but five of the world's earthquakes since 1900.

ASSESSMENT OF INDOOR RADON CONCENTRATIONS WITH A RADON PREDICTION MODEL

Dimitri Hauri, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland*
Martin Röösli, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland*

Background and Aims: Whether indoor radon exposure is associated with childhood cancer is unclear. Within the framework of a cohort study on residential radon and childhood cancer, we aimed to develop a prediction model to assess indoor radon concentrations in Switzerland.
Methods: Our study is based on 45,437 measurements from the Swiss radon database collected between 1994 and 2004 all over Switzerland. Thereof, 36,053 (80%) randomly selected measurements were used for model development and the remaining 9,015 measurements for an independent model validation. We fitted a multivariable log linear regression model and selected relevant predictors according to knowledge from the literature, on the adjusted R^2 and on the AIC criteria.
We evaluated the prediction model by calculating Spearman rank correlation between measured and predicted values. Additionally, we categorized the predicted values into three categories (50th, 50th-90th and 90th percentile) and compared with measured categories using weighted Kappa statistic.
Results: Most relevant predictors for indoor radon levels were tectonic units, soil texture and construction year of the building, followed by degree of urbanisation, floor of residency and housing type (p-values: <0.001).
Median predicted radon values was 70 Bq/m³ (interquartile range 59 – 79 Bq/m³) in the lowest exposure category, 122 Bq/m³ (104 – 145 Bq/m³) in the medium category, and 209 Bq/m³ (194 - 239 Bq/m³) in the highest category. Spearman correlation was 0.45 (95%-CI: 0.44; 0.45) for the development dataset and 0.44 (95%-CI: 0.42; 0.45) for the validation dataset. Kappa coefficients were 0.30 and 0.29 for the development and the validation dataset, respectively.
Conclusions: There is a substantial variability in residential radon levels. Validation of the prediction model in an independent dataset demonstrated that the model is robust. However, random exposure misclassification is unavoidable and has to be taken into account when interpreting the results from the future cohort study.

THE PRESSURES OF URBAN SPRAWL, ENVIRONMENTAL CONDITIONS AND THE EFFECTS ON HEALTH IN THE MUNICIPALITY OF EL SALTO, JALISCO, MEXICO

Arturo Curiel Ballesteros, *IMACH University of Guadalajara, Mexico*
Guadalupe Garibay, *IMACH University of Guadalajara, Mexico*

Background and Aims: The municipality of El Salto is part of Guadalajara's Metropolitan Area. The city has grown in a disorderly manner and without tending to the welfare of new residents, who are thus exposed to various risks. The objective of this study was to identify such risks.
Methods: The methodology indicated in the environmental land-use planning of the INE-MEX was used, as were the risk and exposure assessment of NRC-USA and the development of environmental health indicators established by Corvalán-WHO.
Results: In El Salto, the factors generating risks are population growth—which has doubled three times in the last 20 years—and the presence of industrial activity.
The strains these forces have brought about are a change in land use in already fragile areas, the alteration of watersheds and pollution of surface waters which have resulted in 29 kilometers of dead rivers with a presence of heavy metals (Al,Zn,Hg,Cd,Cr), to which 56,000 persons are exposed along with cattle herds used for meat and milk, and migratory birds.
Diseases which have shown a rate of increase are tumors (stomach, bronchus and lungs, mammary and cervical) and respiratory diseases (pneumonia, chronic obstructive pulmonary disease) which together account for the death of 47 persons each year, 64% of these being considered premature deaths.
The greatest number of deaths due to tumors was registered from 2007 to 2009, the majority being women 40-64 years of age. With respect to respiratory disease, the greatest number of deaths occurred in 2005 and 2009 with most of those affected being men over 64 years of age (68%), children under 5 years of age (14%).
Conclusions: The accelerated population growth and ensuing urban sprawl along with the presence of hazardous industries, have polluted the water far beyond Nature's self-purifying capacities and this means an environmental risks.

EXPOSURE TO MANGANESE IN HIGH VEHICLE TRAFFIC AREAS WITHIN GUADALAJARA, MEXICO

Arturo Curiel Ballesteros, *IMACH University of Guadalajara, Mexico*

Background and Aims: The main source of PM_{10} in Guadalajara's metropolitan area is its vehicle fleet which has increased at rates even higher than those of population growth. In 2010, research on high-traffic areas began in order to establish the facts concerning the presence of heavy metals due to this source.
Methods: Sampling of particulate matter was undertaken in May, 2010, at roadways with over 50,000 vehicles per day, using a portable sampler for particles under 10 microns MicroVol – 1100 low Flow-rate Air Sampler. Analysis of particulate matter was conducted using an X-ray fluorescence spectrometer, S4 Explorer.
Results: Traffic flow varied from 3,078 to 5,664 vehicles per hour. The analyses conducted on the PM10 were: Al, Cd, Cu, Cr, Fe, Mn, Mo, Ni, Pb and Zn.
Aluminum and Manganese were the metals which showed the highest results, over 10 ppm and 46 ppm respectively. The main source of Aluminum was determined not to be the vehicle fleet but rather cement factories and soil erosion, while the source of manganese did prove to be gasoline burned by motor vehicles. The amounts of aluminum varied significantly depending on the wind and proximity to the sources. This variation is much lower for manganese which registered similar quantities for samples taken at the edge of roadways and those taken 100 meters away.
Conclusions: The main manner in which Mn enters the human body is through inhalation or ingestion. Although it has not been found to have carcinogenic effects, it can affect brain development in children, bringing about changes in behavior and a decrease in the capacity to learn and remember; thus it is important to implement monitoring systems.

TEMPERATURE AND HEALTH IN GUADALAJARA, MEXICO

Arturo Curiel Ballesteros, *IMACH University of Guadalajara, Mexico*
Guadalupe Garibay, *IMACH University of Guadalajara, Mexico*
Ana Karen Osuna Osuna, *Technological Institute of Mazatlan, Mexico*
Arturo Pérez Romero. *Ministry of Health Jalisco, Mexico*

Background and Aims: The city of Guadalajara, like many other cities throughout the world, experiences a heat-island condition which has resulted in increased temperatures; thus, it is highly relevant to identify the temperature associated to higher morbidity rates among its inhabitants.
Methods: The criteria to define excessive temperature levels are based on determining maximum temperature thresholds at a 95 percentile, of the series of maximum daily temperatures. That is, the temperature threshold is established based on merely statistical considerations, without necessarily taking into account at and above what temperature the effects on health begin to emerge.
The study proposed to determine whether this is the temperature at which the highest association to heart and vascular diseases –coronary heart disease, cerebrovascular disease, peripheral artery or atherosclerotic disease, rheumatic heart disease, congenital heart defects, deep vein thrombosis and pulmonary embolisms as registered by the Public Health Department—can be established..
Results: The temperature representing the 95 percentile for the period of study, from 1996-2005, was 35.4° C.
The greatest number of days with temperatures above 35.4 occurred in 1998 and 2002. Upon determining the correlation between the number of days with temperatures between 29.4 and 35.4 °C and percentage of the city of Guadalajara population suffering cardiovascular diseases, the results showed that at 29.4°C there is a 0.76 correlation, with diseases increasing upon exposure to such temperatures for more than 150 days per year; 0.79 at 32.4°C with diseases increasing upon exposure for more than 15 days per year, and 0.53 at 35.4°C with diseases increasing upon exposures of 1 day per year.
Based on the foregoing, it is established that a temperature of 32.4°C results in a higher association to cardiovascular morbidity rates.
Conclusions: The rise in cardiovascular diseases is determined at 62% due to increased exposure regarding the number of days with temperatures above 32.4 °C.

SOURCE APPORTIONMENT OF AMBIENT PM10 NEAR A MAJOR HIGHWAY IN A SWISS ALPINE VALLEY

Regina E. Ducret-Stich, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Harish C. Phuleria, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
L.-J. Sally Liu, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland, University of Washington, Seattle, USA*

Background and Aims: Although trans-Alpine highway traffic exhaust is the major source of air pollution along the Alpine highway valleys, little is known about its contribution to residential exposure and impact on respiratory health. This pediatric asthma panel study aims at (1) developing spatial land-use regression models for residential outdoor exposures, (2) estimating the contribution of different sources of PM_{10} using receptor modelling methods, and (3) examining the relationship between spatially refined exposure estimates and respiratory heath. This paper focuses on source apportionment and the source-specific spatiotemporal distribution of PM_{10} in a Swiss Alpine valley.
Methods: From November 2007 to June 2009 two fixed (background and highway) and four mobile sites were monitored for daily PM_{10}, continuous particle number concentrations and NO_x in an alpine community in Switzerland. At the mobile locations measurements were taken for one month in each of the four seasons. PM filters were analyzed for elemental (EC) and organic carbon (OC) and 48 trace elements. Positive Matrix Factorization (PMF) was used to quantify contributions of different local and regional sources.
Results: In a preliminary PMF analysis with 7, 8 or 9 factors about 29% of PM_{10} were explained by secondary pollutants, 23% by biomass burning, 13% by traffic exhaust, 8% by railway and 2% by road salt. The contribution of these factors stayed about constant over all approaches with different factor numbers. The remaining 25% of PM_{10} were split into soil, road dust, break wear and an unknown factor depending on the predefined number of factors. Further analysis will be done using fractionated EC, OC data and an attempt will be made to split the traffic exhaust factor into diesel and gasoline exhaust factors.
Conclusions: These first results indicate significant contribution of highway traffic and local biomass burning on the PM exposure in the community.

PUBLIC TRANSPORT AS INDICATOR OF NOISE EXPOSURE IN URBAN AREAS

Katarina Paunovic, *Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade*, Serbia
Goran Belojevic, *Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade*, Serbia
Branko Jakovljevic, *Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade*, Serbia

Background and Aims: Public transport has never been used as an indicator of noise exposure in studies on noise and health, contrary to noise levels and traffic density. The aim of this study was to investigate the relationship between public transport, noise levels and traffic density in urban areas.

Methods: A cross-sectional study was performed in an urban municipality in Belgrade, Serbia. Noise levels were measured in the middle of all investigated streets in two daily intervals, in one evening interval, and in two night intervals. Simultaneously, traffic density was registered as the number of light vehicles (motorbikes, motors and cars) and heavy vehicles (vans, trucks, lorries, buses, trams, trolleybuses) in all streets. The presence and the type of public transport (bus, tram and trolleybus) were assessed by matching the streets with official public transport maps for Belgrade.

Results: Public transport was running in 65 (23%) streets of the investigated urban area; 218 (77%) of the investigated streets were free of public transport. In streets where public transport was running, noise levels and traffic density were significantly higher during the daytime (by 12 dBA and by 200 to 400 heavy vehicles per hour) and during the nighttime (by 10-13 dBA and by 30 heavy vehicles per hour), compared to streets where no public transport was present. The highest noise levels were measured in streets where public transport included both buses and trams (68.0±2.9 dBA), followed by streets with buses and trolleybuses (66.8±2.7 dBA), streets with busses only (67.7±2.2 dBA); the lowest noise level at daytime was reported in streets where trams were the only mean of transport (62.0±4.6 dBA).

Conclusions: Public transport is strongly related to noise levels and traffic density in urban areas. We propose public transport to be used as an indicator of noise exposure.

CHALLENGES AFFECTING THE INTERPRETATION OF BIOMONITORING DATA IN EPIDEMIOLOGIC STUDIES

Antonia M Calafat, Kayoko Kato, Manori J Silva, Xiaoyun Ye, *US Centers for Disease Control and Prevention, Atlanta, GA*

Background and Aims: Biomonitoring (i.e., measurement of chemicals or their metabolites at trace levels in biological tissues) is useful for investigating background exposures to environmental chemicals and has gained importance in environmental epidemiology. However, limitations in biomonitoring measures do exist. For example, although adequate sampling and processing methods are critical for evaluating biomonitoring data, these methods, especially for ubiquitous non-persistent organic chemicals, have not received as much attention as the analytical techniques. Also, the relevance of toxicokinetics on the selection of both biomarkers of exposure and biomonitoring matrices may have been undervalued.
Methods: We use several case studies including phthalates and bisphenol A, among other chemicals, to illustrate the importance of collection, processing and storage strategies for understanding biomonitoring results and their application in etiologic research.
Results: We discuss the relevance of the following aspects: selection of biomarkers of exposure based on toxicokinetics data (e.g., distribution among body compartments, metabolism), selection of the biological matrix, choice of analytical method, collection protocol—including location and timing of specimen collection, and type of specimen (e.g., first morning vs 24-h urine void)—, variability of the biomarker measures over time, storage and transport protocols, and use of quality control materials, including field and laboratory blanks.
Conclusions: Analytical chemistry advances permit measuring multiple environmental chemicals (e.g., analytes) concurrently at trace levels with the specificity and sensitivity required for biomonitoring. However, not all analytes are optimal exposure biomarkers. In addition to state-of-the-art analytical methods, highly trained laboratory personnel, and strict quality control/quality assurance laboratory practices, other often underappreciated factors (e.g., sampling, storage) must be considered to guarantee the valid interpretation of biomonitoring data and their use for environmental epidemiology. Nonetheless, despite its limitations, particularly for non-persistent chemicals which display considerable variability over time, biomonitoring data strengthens the exposure assessment in environmental epidemiology.

THE IMPACT OF STRESS ON SEMEN QUALITY

Joanna Jurewicz, *Nofer Institute of Occupational Medicine, Lodz, Poland*
Wojciech Hanke, *Nofer Institute of Occupatinal Medicine, Lodz, Poland*
Wojciech Sobala, *Nofer Institute of Occupatinal Medicine, Lodz, Poland*

Background: Stress is one the most important health and social problems. Psychological stress has long been suspected as having important impact on infertility. Studies on the effects of psychological stress on male fertility, especially semen quality have so far yielded equivocal findings.
Methods: The study population consists of 179 men register to infertility clinic in purpose of diagnosis with normal fertility (semen total concentration 15-300 mln/ml) or with little oligozoospermia (semen total concentration 10 do 15 mln/ml).
The semen samples was analysed in one laboratory according to the WHO manual for basic semen analysis. The main semen parameters were assessed: volume, motility, % atypical, % of progressive spermatozoa.
To asses the occupational stress the General Health Questionnaire 28 (GHQ-28) was used. As a results of this questionnaire we used sum of the points obtain by man taking part in the study and the number of stressful events at work (if the stressful events or situation appeared) announced by studied subjects.
Results: The level of stress measured by General Health Questionnaire 28 (GHQ-28) taking into account the number of stressful events, such situations affect semen volume and % of progressive spermatozoa after controlling factor that can have impact on semen quality like: time of couple infertility, abstinence and diseases in the past that can affect fertility.
Conclusions: The study confirms that the occupational stress can affect male semen quality, but as there is little studies in those directions the results need to be confirmed. This cohort being assembled will form a basis for further longitudinal observations.

PRENATAL AND CHILDHOOD EXPOSURE TO PESTICIDES AND NEUROBEHAVIORAL DEVELOPMENT: REVIEW OF EPIDEMIOLOGICAL STUDIES

J. Jurewicz, *Nofer Institute of Occupational Medicine, Department of Environmental Epidemiology, Lodz, Poland*
W. Hanke, *Nofer Institute of Occupational Medicine, Department of Environmental Epidemiology, Lodz, Poland*

Background: Conventional pesticides comprise a diverse group of substances intended to destroy, repel or control organisms identified as pests. Compared to studies of lead, mercury and PCBs few epidemiological studies have assessed the developmental neurotoxicity of pesticides.
Methods: Epidemiological studies focused on the neurobehavioural development of children exposed to pesticides were identified by a search of the PUBMED, MEDLINE, EBSCO, AGRICOLA and TOXNET literature bases.
Results: The results from the presented studies suggest that children exposure to pesticides may impaired development. Exposure to organophosporus pesticides (OP) in children can caused difficulties with tasks involving short-term memory, incrased reaction time, mental development and pervasive development problems. In neonates increased number of abnormal reflexes and mental and emotional symptoms in adolesecents. The results of the studies investigated the association between exposure to organochlorine pesticides and neurodevelopmental problems display inconsistent results. Whereas some studies found reduction in mental and psychomotor function the other studies did not confirmed that.
Conclusions: Information derived from epidemiological studies so far indicate the need to increase awareness among people and children exposed to pesticides about the association between use of pesticides and neurodevelopmental impairment. We should simply apply the principle of prudence, just in case.

EXPOSURE TO PHENOXYACETIC ACID HERBICIDES AND ITS' PREDICTORS OF EXPOSURE AMONG SPOUSES OF FARMERS

Joanna Jurewicz, *Nofer Institute of Occupational Medicine, Lodz, Poland*
Wojciech Hanke, *Nofer Institute of Occupatinal Medicine, Lodz, Poland*
Wojciech Sobala, *Nofer Institute of Occupatinal Medicine, Lodz, Poland*
Danuta Ligocka*, Nofer Institute of Occupational Medicine, Lodz, Poland*

Background: The application of pesticides often takes place close to private dwellings and may contribute to environmental exposure to pesticides of their inhabitants. The purpose of the study was to measure the environmental exposure to two commonly used pesticides 2-methyl-4-chlorophenoxyacetic acid (MCPA) and 2,4-dichlorophenoxyacetic acid (2,4-D) among spouses of farmers, not directly involved in the process of spraying.
Methods: During the spring, exposure to 63 sprayings in the household of 24 women were assessed. Women were asked to collect three urine samples: in the morning before spraying (sample A), in the evening after spraying (sample B) and on the next day (sample C).
Results: The number of samples were the level of pesticides were above limit of detection increase from samples taken before spraying to samples taken after spraying in case of the level of both active ingredients: MCPA and 2,4-D. In the A samples the level of pesticides > LOD was found in about 30% of samples whereas in B and C samples in about 45% of samples. The average levels of herbicides in examined urine samples increased from sample A collected in the morning before spraying (2.8 ng/g creatinine) to sample B collected after spraying(6.0 ng/g creatinine). Mean value from the sample C (4,0 ng/g creatinine) taken on the next day after spraying were lower than B and higher than A. In similar direction were results when the average was calculated for all measurements' (including those below LOD). Only women's outdoor activity during spraying was statistically significant (p=0,023) predict the level of exposure.
Conclusions: The presented study have confirmed that farmers' spouses are exposed to pesticides after spraying which indicates that there is transfer of pesticides from the field to the home environment. But further research is required to be able to predict those individuals who are exposed.

ASSOCIATION BETWEEN THE INCIDENCE OF LYME DISEASE AND TEMPERATURE IN HUNGARY, 1998-2010

Attila Trajer, *Semmelweis University Doctoral School Budapest, Hungary*
Janos Bobvos, *Research group "Adaptation to climate change" of the Hungarian Academy of Science, Hungary*
Katalin Krisztalovics, *National Centre of Epidemiology Budapest, Hungary*
Anna Paldy, *National Institute of Environmental Health Budapest, Hungary*

Background and Aims: The increase of Lyme disease (LD) can be expected due to climate change, however the association hasn't been studied yet in Hungary. Distribution of the disease depends on the annual activity of ticks and on temperature changes. Our aim was to assess the temperature dependence of the disease.
Methods: The weekly LD data and the site of infection on county level for 1998-2010 were gained from the National Epidemiologic and Surveillance System. The temperature data were retrieved from the National Meteorological Service. Regional differences in the weekly incidence were studied in two north-eastern and 3 south-western counties. Descriptive statistics and linear regression models were applied.
Results: For 100 000 inhabitants the incidence was 11.597 in 1998-2003 resp. 15.268 in 2004-2010. The spring mean temperature showed an increase by a 0,052^{o}C/ year during 1998-2010. LD incidence increased more steadily in spring than in summer. The first day with mean temperature of 10^{o}C followed by days with mean temperature >8^{o}C was chosen as start of spring. Based on this criterium spring started by 1.5-2 weeks earlier during the period. Similar shift of 2-3 weeks was observed in the detection of 10 cases/week from week 16 to 14-13. 80% of the increase of incidence was reported in weeks 18-28 with a maximum in weeks 23-24. The season was longer by 1-2 weeks in warmer years. Heatwaves decreased the incidence during summer months. Regional climatic conditions resulted 2-3 weeks difference in the onset and peak of the incidence.
Conclusions: Based on the climatic dependence of LD we can predict the future changes in the annual distribution and increase of the incidence.
The study was funded by the Research group "Adaptation to climate change" of the Hungarian Academy of Science (2006TKI246).

PARTICULATE AIR POLLUTION AND INFLAMMATORY MARKERS

Duanping Liao, *Penn State University College of Medicine, USA*
Fan He, *Penn State University College of Medicine, USA*
Michele L. Shaffer, *Penn State University College of Medicine, USA*
Sol M. Rodriguez-Colon, *Penn State University College of Medicine, USA*
Jeff D. Yanosky, *Penn State University College of Medicine, USA*
Edwards O. Bixler, *Penn State University College of Medicine, USA*
Willard Freeman, *Penn State University College of Medicine, USA*
Alexandros N. Vgontzas, *Penn State University College of Medicine, USA*

Background and Aims: The inflammatory effect of fine particulate matter ($PM_{2.5}$) is one of the potential mechanisms linking PM pollution and cardiopulmonary outcomes. We examined the association between individual level 24-hour $PM_{2.5}$ concentration and blood inflammatory markers in a community dwelling sample.
Methods: We used a Personal DataRam (pDR) to measure 24-hour individual-level real-time $PM_{2.5}$ exposures in 105 middle-aged nonsmokers. Two blood samples were collected from each participant, one immediately before and one immediately after the 24-hour study period. Concentrations of several inflammation markers were assessed and averaged. Linear regression models were used to assess the association between mean 24-hour $PM_{2.5}$ exposure and the mean inflammation markers. Age, race, gender, relative humidity, temperature, and participant's chronic disease status were adjusted for in the regression models.
Results: The participants (mean [SD] age: 56 [8] years) tended to be female (60%) and white (74%). The 24-hour mean (SD) personal $PM_{2.5}$ concentration was 14.33 (14.60) $\mu g/m^3$. We did not observe significant associations between 24-hour mean $PM_{2.5}$ exposure and mean inflammation markers. The regression coefficients (SE) per 10 $\mu g/m^3$ increases in $PM_{2.5}$ were: -0.02 (0.02) g/dL for albumin, 81 (217) ng/mL for C-reactive protein (CRP), -0.56 (0.13) pg/mL for interleukin-1 α (IL-1 α), -0.28 (0.30) pg/mL for interleukin-1 β (IL-1 β), -19 (56) pg/mL for macrophage migration inhibitory factor (MIF), -1.66 (5.37) pg/mL for tumor necrosis factor-α (TNFα), 100 (73) pg/mL for tumor necrosis factor soluble receptor I (TNFsRI),and 0.02 (0.09) x $10^3/mm^3$ for white blood cell count (WBC), respectively (all p-values > 0.05).
Conclusion: Currently low levels of 24-hour mean $PM_{2.5}$ exposure are not associated with blood inflammation markers. More studies on the chronic exposure and inflammatory responses are needed to elucidate the sub-acute and chronic effects of PM on systemic inflammation as a mechanistic link between PM and cardiopulmonary disease.

PARTICULATE AIR POLLUTION, BLOOD COAGULATION AND FIBRINOLYTIC FACTORS

Duanping Liao, *Penn State University College of Medicine, USA*
Fan He, *Penn State University College of Medicine, USA*
Michele L. Shaffer, *Penn State University College of Medicine, USA*
Jeff D. Yanosky, *Penn State University College of Medicine, USA*
Edwards O. Bixler, *Penn State University College of Medicine, USA*
Aaron R. Folsom, *University of Minnesota, USA*
Eric A. Whitsel, *University of North Carolina at Chapel Hill, USA*
Willard Freeman, *Penn State University College of Medicine, USA*

Background and Aims: Whether fine particulate matter ($PM_{2.5}$) affects clinical thrombosis remains controversial, whereas an association between $PM_{2.5}$ and coronary heart disease (CHD) has been reported more consistently. We therefore investigated the cross-sectional association between individual-level short-term $PM_{2.5}$ exposure and blood hemostatic factors--blood markers of coagulation and thrombosis potential.
Methods: We used a Personal DataRam (pDR) to measure 24-hour individual-level real-time $PM_{2.5}$ exposures in 105 middle-aged nonsmokers. Two blood samples were collected from each participant, one immediately before and one immediately after the 24-hour study period. Concentrations of several hemostatic factors were assessed and averaged. Linear regression models were used to assess the association between mean 24-hour $PM_{2.5}$ exposure and the mean hemostatic factors. Age, race, gender, relative humidity, temperature, and participant's chronic disease status were adjusted for in the regression models.
Results: The participants (mean [SD] age: 56 [8] years) tended to be female (60%) and white (74%). The 24-hour mean (SD) personal $PM_{2.5}$ concentration was 14.33 (14.60) $\mu g/m^3$. We did not observe significant associations between 24-hour mean $PM_{2.5}$ exposure and mean hemostatic factor levels. The regression coefficients (SE) per 10 $\mu g/m^3$ increase in $PM_{2.5}$ were: -0.13 (0.78) % for antithrombin III, 1.95 (2.97) % for factor VIII, -2.79 (3.88) mg/dL for fibrinogen, 0.56 (0.54) IU/mL for plasminogen activator inhibitor, 0.06 (0.19) ng/mL for tissue plasminogen activator, and -0.13 (0.15) µg/mL for D-Dimer (all p-values > 0.05).
Conclusion: Low levels of 24-hour mean levels of $PM_{2.5}$ exposure were not associated with blood hemostatic factors. More studies on chronic PM exposure and hemostatic factors are needed to elucidate their role in the pathophysiologic effects of air pollution on deep vein thrombosis and CHD.

ARSENIC EXPOSURE AND PREVALENT DIABETES IN THE STRONG HEART STUDY

Matthew O Gribble, Johns Hopkins University, USA
Barbara V Howard, MedStar Research Institute, USA
Jason G Umans, MedStar Research Institute, USA
Nawar Shara, MedStar Research Institute, USA
Kevin A Francesconi, Karl-Franzens University, Austria
Walter Goessler, Karl-Franzens University, Austria
Ciprian M Crainiceanu, Johns Hopkins University, USA
Eliseo Guallar, Johns Hopkins University, USA
Ana Navas-Acien, Johns Hopkins University, USA

Background and Aims: High-chronic exposure to inorganic arsenic has been associated with diabetes. At low-moderate levels, however, the epidemiologic evidence is inconsistent. In the Western US States, exposure to inorganic arsenic in drinking water is a concern for many populations who live in small communities. Our objective was to evaluate the association of arsenic exposure, as measured in urine, with diabetes prevalence in American Indians from rural communities in Arizona, Oklahoma and the Dakotas who participated in the Strong Heart Study in 1989-1991.
Methods: We studied 2,356 men and women 45 to 74 years of age with available urine arsenic measures. Total urine arsenic and urine arsenic species were measured using inductively coupled plasma-mass spectometry (ICPMS) and high performance liquid chromatography (HPLC)-ICPMS, respectively. Diabetes was defined as fasting glucose • 126 mg/dL, 2-h glucose • 200 mg/dL, hemoglobin A1c • 6.5% or diabetes treatment. Multi-adjusted prevalence ratios were estimated using robust Poisson models.
Results: The median (interquartile range) urine concentrations were 14.7 (7.9, 25.3) µg/L for total arsenic and 10.8 (6.1, 19.1) µg/L for the sum of inorganic and methylated arsenic species. The prevalence of diabetes was 51.1%. After adjustment for demographics, body mass index, smoking, alcohol, hypertension medication, region and urine creatinine, the prevalence ratios (95% confidence interval) of diabetes for a 2-fold increase in total arsenic and the sum of inorganic and methylated arsenic species were 1.07 (1.03, 1.11) and 1.10 (1.05, 1.15), respectively. Without adjustment for urine creatinine the corresponding prevalence ratios were 1.04 (1.00, 1.07) and 1.05 (1.01, 1.08). The associations were consistent by region, although stronger in the Dakotas.
Conclusions: Exposure to inorganic arsenic, as measured in urine, was associated with the prevalence of diabetes in American Indian communities. Prospective evidence is needed to evaluate the temporality of the association between urine arsenic and diabetes development.

CHALLENGES IN THE IMPLEMENTACION OF THE ECOHEALTH APPROACH FOR THE CONTROL OF A NATIVE VECTOR OF CHAGAS DISEASE IN GUATEMALA.

Carlota Monroy *Universidad de San Carlos de Guatemala (USAC), Guatemala*
Antonieta Rodas *Universidad de San Carlos de Guatemala (USAC,) Guatemala*
Barbará Moguel *Universidad Autónoma de México (UNAM) México*
Dulce María Bustamante *(USAC) Guatemala*
Sandy Pineda University of Queensland, *Australia*
Xochilth Castro (*USAC), Guatemala*
Virgilio Ayala (*USAC), Guatemala*
Ranferi Trampe *Ministerio de Salud Pública, Guatemala*
Dionisio Revolorio *Ministerio de Salud Pública, Guatemala*

Background and Aims: The natural habitats of triatomine bugs, the vectors of Chagas disease, include caves, animal burrows and nests, rock piles, and palm and trees cavities. In Central America, rural mud-bricked houses have similar conditions as caves or mud nests and are colonized by triatomines. The bugs probably arrive in human houses during annual migrations. Control of native vectors is not feasible with traditional insecticide application, new ECOHEALTH approach is experienced
Methods: The risk factors that sustain the presence and reproduction of bugs inside houses were addressed by developing community base interventions. The deterioration of wall plasters was addressed with a new mixture of local materials that could be applied with bare hands by women. Dirt floors were improved by applying a mixture of volcanic ashes heated with lime and compacted. The presence of domestic animals inside the house was reduced with the construction of wire corrals.
Results: Wall improvements reduced the number of bugs collected inside houses. Floor improvements reduced the presence of bug's eggs, and also decrease the prevalence of worm parasites in children. The removal of animals from inside the house improved not only the house sanitary conditions, but also the animals' living conditions leading to healthier poultry and pets. Over time the tendency of triatomine´s blood sources is to reduce human blood consumption and switch to other domestic animal as poultry.
CONCLUTION: ECOHEALTH approach is an alternative for the control of native vector of Chagas disease in Guatemala reducing the risks factors that favor the presence of the vector inside human houses, the approach faced some challenges as: capacity building in rural communities and other stakeholders from health and environment institutions, development of a holistic perception of a disease problem, prevention-action approach rather than disease treatment, inter-institutional coordination, and sustainability of community participation among others.

TEMPERATURE, NITROGEN DIOXIDE, CIRCULATING RESPIRATORY VIRUSES AND ACUTE UPPER RESPIRATORY INFECTIONS AMONG CHILDREN IN TAIPEI, TAIWAN: A POPULATION-BASED STUDY

Yu-Chun Wang, *Department of Bioenvironmental Engineering, College of Engineering Chung Yuan Christian University,Taiwan*
Yu-Kai Lin, *Institute of Environmental Health, College of Public Health National Taiwan University, Taiwan; Environmental and Occupational Medicine and Epidemiology Program, Department of Environmental Health, Harvard School of Public Health, USA*
Chin-Kuo Chang, *Department of Health Service and Population Research, King's College London, UK*

Background and Aims: This study investigated whether outpatient visits of acute upper respiratory infections (AURIs) for children aged less than 15 years are associated with temperature, air pollutants and circulating respiratory viruses in Taipei, Taiwan.
Methods: Outpatient visits records for AURIs (ICD9 CM codes: 460, 462, 463,464, 465.9 and 487) from a randomly selected sample (n= 39,766 children in 2005) was used to estimate the cumulative relative risks (RR) associated with per-standard deviation (SD) increases of virus-specific positive isolation rate lasting for 8 days (lag0-lag7 days), air pollutants (NO_2, O_3 and $PM_{2.5}$) lasting for 5 days (lag0-lag4 days), and average temperature lasting for 8 days (lag0-lag7 days) by distributed lag models, 2003-2007.
Results: After controlling for day of week, holiday effects and long term time, per-SD increase of virus specific isolation rate for influenza type A (SD = 13.2%), type B (SD = 8.76%), and adenoviruses (SD = 5.25%) revealed statistical significance for overall 8-day RRs of 1.03 [95% confidence interval (CI): 1.02, 1.03), 1.10 (95% CI: 1.09, 1.10) and 1.06 (95% CI: 1.04, 1.07), respectively, in cold seasons. Overall 5-day RR = 1.05 (95% CI: 1.03, 1.06) for per SD (SD = 7.78 ppb) increase of NO_2 in warm seasons (May-October) and 1.13 (95% CI: 1.12, 1.15) in cold seasons (November- April) were found. The most elevated risk of average temperature per SD (SD = 5.34°C) decrease was identified with an inverse association to AURIs of an RR = 1.17 (95% CI: 1.15, 1.19) in cold seasons.
Conclusions: Current study suggested a positive association between outpatient visits of AURIs and ambient environment factors, including average temperature, air pollutants, and circulating respiratory viruses.

EFFECTS OF HOT AND COLD SPELLS ON CARDIOVASCULAR MORTALITY IN INDIVIDUAL POPULATION GROUPS

Jan Kysely, *Institute of Atmospheric Physics, Prague, Czech Republic*
Eva Plavcova, *Institute of Atmospheric Physics & Faculty of Mathematics and Physics, Prague, Czech Republic*
Hana Davidkovova, *Institute of Atmospheric Physics & Faculty of Science, Prague, Czech Republic*
Jan Kyncl, *National Institute of Public Health, Prague, Czech Republic*
Bohumir Kriz, *National Institute of Public Health, Prague, Czech Republic*

Background and Aims: The study compares impacts of hot and cold spells on cardiovascular mortality in the population of the Czech Republic (Central Europe) over 1986-2006, and examines differences between individual population groups.
Methods: We use analogous definitions for hot and cold spells that are based on quantiles of anomalies of daily average temperature and do not incorporate location-specific thresholds. Epidemics of influenza/acute respiratory infections have been identified and corresponding periods excluded from the analysis in order not to confound results.
Results: We find that both hot and cold spells are associated with significant excess cardiovascular mortality, but there are considerable differences: the effects of hot spells are more direct (unlagged) and typically concentrated on a few days of a hot spell, while cold spells are associated with indirect (lagged) mortality impacts that persist after the end of a cold spell. Although the mortality peak is less pronounced for cold spells, the cumulative magnitude of the excess mortality is larger for cold than hot spells. Differences between mortality impacts in males and females consist mainly in much larger excess mortality of females than males in hot spells, while more lagged effects in females than males in association with cold spells.
Conclusions: The comparison suggests that the relative importance of warm and cold temperature extremes depends on the population group (age and gender), and cold extremes are relatively more harmful in the middle-aged population while warm extremes in the elderly. For both hot and cold temperature extremes, preventive measures implemented by means of warning systems and biometeorological forecast alerts should take the varied effects in individual population groups into account. In the context of climate change, it is probable that reductions in cold-related mortality will be more important than possible increases in heat-related mortality, at least in developed countries that have capacities for reducing the negative effects of hot weather conditions.

COMPARISON OF PERFLUORINATED COMPOUNDS CONCENTRATIONS IN MATERNAL SERUM AND AMNIOTIC FLUID

Stein, Cheryl R *(Mount Sinai School of Medicine, New York, New York)*
Engel, Stephanie M *(University of North Carolina at Chapel Hill, Chapel Hill, North Carolina)*

Background and Aims: Some perfluorinated compounds (PFCs) are ubiquitous, environmental pollutants used to manufacture non-stick cookware and waterproof fabrics. PFCs are found in maternal and umbilical cord blood and breast milk. The extent to which PFCs are detectable in amniotic fluid is unknown. Using paired samples, we compared the concentration of perfluorooctanoate (PFOA), perfluorononanoate (PFNA), perfluorooctane sulfonate (PFOS), and perfluorohexane sulfonate (PFHxS) measured in maternal serum, the standard medium for assessing human exposure to PFCs, and amniotic fluid.
Methods: The Study of Advanced Reproductive Age and Environmental Health prospectively enrolled a cohort of pregnant women receiving amniocentesis for low-risk screening. We used paired samples from 28 women to examine the relationship between PFOA, PFNA PFOS, and PFHxS concentrations measured in maternal serum and amniotic fluid using the Spearman correlation coefficient and graphical techniques.
Results: These four PFCs were detected in all serum samples. The number of amniotic samples with detectable concentrations differed by PFC (PFOA n=24; PFNA n=10; PFOS n=9; PFHxS n=4). The Spearman correlation coefficient, a measure of rank order, varied considerably by PFC (PFOA ρ=0.64, $p<0.001$; PFNA ρ=0.05, p=0.9; PFOS ρ=0.76, p=0.01; PFHxS ρ=0.80, p=0.2). Using graphical techniques, it appears that PFOA is commonly detected in amniotic fluid once the serum concentration reaches approximately 2 ng/mL, whereas PFOS is not commonly detected in amniotic fluid until the serum concentration reaches approximately 8 ng/mL.
Conclusions: PFCs are detectable in amniotic fluid at maternal serum concentrations below the national average. The ability to pass from maternal serum to amniotic fluid appears to differ by PFCs, independent of serum concentration. This disparate ability may be related to the chemical properties conferred by the charged functional moiety, such as the carboxylate in PFOA and PFNA as compared to the sulfonate in PFOS and PFHxS.

VARIABILITY IN ASSOCIATIONS BETWEEN MATERNAL PRENATAL URINARY PHTHALATE METABOLITE CONCENTRATIONS AND CHILD MENTAL, MOTOR AND BEHAVIORAL DEVELOPMENT BY CHILD SEX

Robin M. Whyatt, Columbia University, United States
Xinhua Liu, Columbia University, United States
Virginia A. Rauh, Columbia University, United States
Antonia M. Calafat, Centers for Disease Control and Prevention, United States
Allan C. Just, Columbia University, United States
Lori Hoepner, Columbia University, United States
Frederica P. Perera, Columbia University, United States
Pam Factor-Litvak, Columbia University, United States

Background and Aims: Epidemiologic evidence suggests that effects of prenatal phthalate exposure on child executive function and behavior are sexually dimorphic. We reported (ISEE 2010) adverse associations between prenatal phthalate concentrations and child age 3 mental, motor and behavioral development. Here we evaluate whether the associations varied by child sex.
Methods: 168 girls and 151 boys from inner-city communities in New York City were followed from pregnancy. Mono-*n*-butyl phthalate (MnBP), mono-benzyl phthalate (MBzP), and mono-isobutyl phthalate (MiBP) concentrations were measured in spot urine collected from the mothers during the 3rd trimester. At child age 3 years, mental and motor development were assessed using the Bayley Scales of Infant Development II and behavior problems was assessed by maternal report on the Child Behavior Checklist (1 ½ - 5).
Results: Controlling for specific gravity and potential confounders, $\log_e$MnBP concentrations were significantly associated with motor development among boys only (adjusted estimated B= -3.1 [95% CI -5.8, -0.3]) and with mental development among girls only (B=-2.6 [95%CI -4.6, -0.6]). The child sex-by-MnBP interaction on risk of mental delay was significant (p=0.04). Among boys only, $\log_e$MnBP concentrations were associated with significant increases in emotionally reactive behavior (p=0.005), somatic complaints (p=0.007), withdrawn behavior (p=0.02) and internalizing behaviors (p=0.006). Child sex-by-MnBP interaction on emotionally reactive behavior was significant (p=0.03) and on somatic complaints was of borderline significance (p=0.059). Among girls only, $\log_e$MBzP concentrations were associated with significant increases in anxious/depressed behavior (p=0.004), somatic complaints (p=0.01), withdrawn behavior (p=0.0003) and internalizing behaviors (p=0.0001). Child sex-by-MBzP interaction on withdrawn behavior was of borderline significance (p=0.054).
C**onclusions:** Associations between prenatal exposure to these phthalates and child mental, motor and behavioral development appear to vary by child sex.

HEALTH IMPACT OF PM_{10} IN PO-VENETIAN PLAIN

Francesco Mitis, *World Health Organization, European Centre for Environment and Health, Rome, Italy*
Marco Martuzzi, *World Health Organization, European Centre for Environment and Health, Rome, Italy*

Background and Aims: Adverse health effects of air pollution from particulate matter are known. Health impact of PM10 has already been studied in the 13 major Italian cities in 2006. A total of 8220 deaths could be avoided if average concentration decreased to 20 micrograms. The aim of the study is to provide an estimate of deaths attributable to PM10 in the Po-venetian valley, where concentrations are known to be high.
Methods: Standard methods were applied for the calculation of attributable deaths. A population over 30 years of 30 cities of the plain and of the whole province of Milan (around 6 million inhabitants) was considered. Long-term mortality for non accidental causes, lung cancer and infarction were studied. Relative risks (Pope et al 2002, and Pope et al, 2004) of, respectively, 1.06, 1.08 and 1.18 per 10$\mu g/m^3$ PM10 and an Italian average mortality rate were applied to the population. A scenario with a yearly average concentration of 50 micrograms was considered and the health impact was calculated for abatement to 20 (WHO guidelines).

Results: All cause mortality: a total of 8695 deaths are attributable to PM10 concentration over the WHO guideline value. Samecalculations done for lung cancer and infarction provide, respectively, 669 and 2644 excess cases.
Conclusions:A substantial number of lives could be saved decreasing the yearly average concentration of particulate matter. Concentrations are high, although slightly decreasing, and integrated and permanent policies are required. These are particularly needed in the Po-Venetian valley, where air stagnation, dense industrial activity and intense traffic still contribute to high level of pollution and therefore to a considerable burden in term of health impact and social costs.

DIETARY PREDICTORS OF *HELICOBACTER PYLORI* SEROPREVALENCE IN MEXICAN ADULT POPULATION

Marcia Galván-Portillo, *National Institute of Public Health, Mexico*
Sandra Delgado-Corrales, *Mount Sinai School of Medicine International Exchange Program, NY, USA*
Guadalupe Ayala, *National Institute of Public Health, Mexico*
Lilia Chiu, *National Institute of Public Health, Mexico*
Lizbeth Lopez-Carrillo, *National Institute of Public Health, Mexico*
Jesús Silva-Sanchez, *National Institute of Public Health, Mexico*

Background and Aims: H. pylori (Hp) infection is the main etiological factor for gastritis and peptic ulcer. Prevalence of infection is one of highest around the world, and it varies in different societies and geographical locations. This variability is attributed to factors such as socioeconomic status, life style, family density and other factors such as eating habits. However, factors influencing the risk of acquisition of Hp infection are not well established. The objective of this study was to identify the dietary predictors of Hp seroprevalence in adult Mexican population.
Methods*:* From January 2002 to December 2004 a cross-sectional study was carried out in Mexico City. A total of 349 ambulatory patients were recruited from 7 tertiary hospitals. From each participant, who had not received any previous anti-Hp treatment, Hp strains were isolated from an antral and corpus biopsy. Food and nutrients intake was estimated by a food frequency questionnaire.
Results: A significant reduction in Hp seroprevalence was observed among those who reported high vs low consumption of milk (OR=0.52, 95%CI:0.31-0.89), Oaxaca cheese (OR=0.44, 95%CI:0.26-0.76), and olive oil (OR=0.49, 95%CI:0.28-0.83), adjusted respectively by age, gender and crowding during childhood. Moreover, we can observed a significant protective effect between high vs low intake of calcium (OR=0.49, 95%CI:0.29-0.85) and fatty acids including butyric acid (OR=0.48, 95%CI:0.25-0.93), caproic acid (OR=0.55, 95%CI:0.32-0.94), capric acid (OR=0.57, 95%CI:0.33-0.98), and lauric acid (OR=0.49, 95%CI:0.29-0.85). Inversely, a significant increase in Hp seroprevalence was observed between high vs low consumption of pork stew (OR=1.72, 95%CI:1.01-2.93), cauliflower (OR=1.83, 95%CI:1.07-2.93), broccoli (OR=1.73, 95%CI:1.01-2.95) and Tomato salsa (OR=1.86, 95%CI:1.09-3.18)
Conclusions*:* This study suggests that consumption of fatty acids and dairy products may have a protective effect against H pylori infection. Additional analytical studies are needed to determine whether consumption of fatty acids and dairy food products can prevent H pylori infection.

PROSPECTIVE ASSOCIATION OF CADMIUM EXPOSURE WITH FATAL AND NON-FATAL CARDIOVASCULAR DISEASE: THE STRONG HEART STUDY

Maria Tellez-Plaza, *Johns Hopkins Bloomberg School of Public Health, US; Centro Nacional de Investigaciones Cardiovasculares, Spain*
Eliseo Guallar, *Johns Hopkins Bloomberg School of Public Health, US; Centro Nacional de Investigaciones Cardiovasculares, Spain*
Barbara V Howard, *MedStar Health Research Institute, US*

Walter Goessler, *Institut für Chemie Bereich Analytische Chemie Universitätsplatz, Austria*
Ana Navas-Acien *Johns Hopkins Bloomberg School of Public Health, US*

Background and Aims: Cadmium, a widespread toxic metal, is related to increased cardiovascular mortality in the US population. Prospective evidence evaluating the association of cadmium exposure with cardiovascular events other than mortality is lacking. Our goal was to evaluate the prospective association of urine cadmium concentrations with cardiovascular disease incidence in cardiovascular disease-free American Indians from Arizona, Oklahoma and the Dakotas who participated in the Strong Heart Study (SHS) in 1989-91 and were followed through December 30th, 2007.
Methods: We included 2,078 adults 45 to 74 years old who had complete information on urine cadmium concentrations, potential confounders and fatal and non-fatal cardiovascular end-points (total cardiovascular disease, coronary heart disease, stroke and heart failure). Urine cadmium was measured using inductively coupled plasma mass spectrometry (ICPMS). Multi-adjusted hazard ratios (HR) were computed using Cox-proportional hazards models.
Results: The geometric means of urine cadmium concentrations were 1.26, 0.97 and 0.96 • g/g creatinine in participants from the Dakotas, Oklahoma and Arizona, respectively. A total of 661 cardiovascular events were identified during the follow-up. After adjustment for cardiovascular disease risk factors including smoking status and pack-years, the hazard ratio for total cardiovascular disease incidence comparing the highest to the lowest quartile of urine cadmium concentrations was 1.41 (95% CI 1.08, 1.82). The corresponding hazard ratios for the incidence of coronary heart disease, stroke and heart failure were 1.11 (95% CI 0.82, 1.52), 2.17 (95% CI 1.19, 3.96) and 1.82 (95% CI 1.08, 3.06), respectively. The corresponding hazard ratio for cardiovascular mortality was 2.03 (95% CI 1.30, 3.18).
Conclusions: Urine cadmium, a biomarker of long-term cadmium exposure, was prospectively associated with increased risk of cardiovascular disease, in particular stroke and heart failure. These findings further suggest that cadmium exposure is a cardiovascular disease risk factor. Efforts to reduce cadmium exposure in the population are needed.

APPLICATION OF DISTRIBUTED LAG MODELS TO INVESTIGATE THE TIME COURSE OF FINE PARTICULATE MATTER ON CARDIAC ELECTROPHYSIOLOGY

Michele Shaffer, *Penn State College of Medicine, USA*
Fan He, *Penn State College of Medicine, USA*
Duanping Liao, *Penn State College of Medicine, USA*

Background and Aims: Environmental variables and health outcomes collected for epidemiological studies may give rise to intensive longitudinal data, where the number of repeated measures exceeds the values typical in clinical studies. Well-established methods exist for the analysis of repeated measures; however, methods typically employed for clinical studies with a small number of time points may be difficult to apply or inadequate, as they frequently assume instantaneous effects. We describe methods for handling intensive longitudinal data using the Air Pollution and Cardiac Risk and its Time Course (APACR) study for illustration. The APACR study collected individual-level, real-time $PM_{2.5}$ data and cardiac electrophysiology outcomes over a 24-hour period, with $PM_{2.5}$ and outcome summaries recorded every 30 minutes, producing 48 repeated measures.
Methods: We constructed polynomial distributed lag models, which include models that assume instantaneous effects and moving average models as special cases. For continuous outcomes (e.g., heart rate-corrected QT intervals) we used a linear mixed-effects models framework. For binary (e.g., any ectopic beat) or count (e.g., PVC count, total ectopy count) data we used a generalized estimating equations (GEE) framework. Model selection included examination of competing covariance structures.
Results: Distributed lag models fit to describe QTI% showed lag 0-1 and lag 6-7 $PM_{2.5}$ effects were significantly associated with QTI%, while the middle lags (2-5) were not. The distributed lag models fit to describe PVC count and total ectopy count found only lag 0-1 $PM_{2.5}$ effects to be significantly associated with the counts. These patterns may have been missed by examining only the cumulative effects of the lags or using moving average models, which implicitly assume equal weighting of lags. **Conclusions:** By allowing examination of individual and cumulative lag effects, and not assuming equal weighting of lags, distributed lag models enable us to identify the time course of air pollution effects.

SECONDHAND TOBACCO SMOKE EXPOSURE IN BARS AND NIGHTCLUBS IMPACTS NON-SMOKING AND SMOKING EMPLOYEES

Patrick N Breysse, *Johns Hopkins Bloomberg School of Public Health, USA*
Ana Navas-Acien, *Johns Hopkins Bloomberg School of Public Health, USA*
FAMRI Bar Study Investigators, *Johns Hopkins Bloomberg School of Public Health, USA*

Background and Aims: In the absence of comprehensive smoking bans in public places, bars and nightclubs have the highest concentrations of secondhand tobacco smoke, posing a serious health risk for workers in these venues. The objective of this study was to assess exposures of bar and nightclub employees to secondhand smoke, including non-smoking and smoking employees.
Methods: Between 2007 and 2009, we recruited around 10 venues per city and up to 5 employees per venue in 24 cities in the Americas, Eastern Europe, Asia and Africa. Air nicotine concentrations were measured for 7 days in 238 venues. To evaluate personal exposure to secondhand smoke, hair nicotine concentrations were measured for 625 non-smoking and 311 smoking employees. The relationship between hair nicotine and air nicotine concentrations was estimated using mixed-effect models with country specific intercepts.
Results: Median (interquartile range) air nicotine concentrations were 3.5 (1.5, 8.5) $\mu g/m^3$ and 0.2 (0.1, 0.7) $\mu g/m^3$ in smoking and smoke-free venues, respectively. Median (interquartile range) hair nicotine concentrations were 1.7 (0.5, 5.5) ng/mg and 6.0 (1.6, 16.0) ng/mg in non-smoking and smoking employees, respectively. After adjustment for age, sex, education, living with a smoker, hair treatment and region, a 2-fold increase in air nicotine concentrations was associated with a 29% (95% confidence interval 22%, 37%) increase in hair nicotine concentrations in non-smoking employees and with a 10% (2%, 19%) increase in smoking employees.
Conclusions: Exposure to secondhand smoke in the workplace, assessed by air nicotine, resulted in elevated concentrations of hair nicotine among both smoking and non-smoking bar and nightclub employees. Legislation measures that ensure complete protection from secondhand smoke exposure in indoor public places are urgently needed.

REGIONAL RURAL DIFFERENCES IN THE EPIDEMIOLOGICAL CHARACTERISTICS OF THE MENSTRUAL CYCLE (MC), ACCORDING TO AGROCHEMICAL (AC) USE, IN A COUNTRY OF LATIN AMERICA.

Luz H Sanin, *Universidad Autónoma de Chihuahua, México. Instituto Nacional de Salud Pública de México*
Donald. C. Cole, *Department of Public Health Sciences, University of Toronto, Toronto, ON; Canada*
Sioban D. Harlow, *Department of Epidemiology, University of Michigan, Ann Arbor, Michigan, USA*
Keith R. Solomon, *Centre for Toxicology and Department of Environmental Biology, University of Guelph, ON, Canada*
Dora V. Chavez-Corral, *Universidad Autónoma de Chihuahua, México*
Gabriel Carrasquilla, *Department of Microbiology, School of Health Sciences, University of Valle, Cali, Colombia*

Background and Aims: To describe for first time, the characteristic of menstrual cycle (MC) in a Colombian group of rural fertile women and evaluate if there are differences according rural geographic regions with different use of agrochemicals.
Methods: An ecological study of menstrual cycle characteristics (menarche, cycle length, bleeding length and variability) according physical and sociodemographic characteristics in 1603 Colombian rural fertile women from five rural regions with different use of agrochemicals, was performed.
Results: Age mean was 22.4 (SD 4.4) years, minimal 15 and maxim 54. Mean of cycle length was 31.3 (SD11.4) with a range between 12 to 180 days, bleeding length had a mean of 4.7 (SD 2.0), range 1-47 days, and menarche installation had a mean of 13.0 (SD1.4), range 8-18 years. Distribution of cycle length in different regions doesn't offer great differences but proportion of women with variability was 11.7% and was highest in the region with most intensive use of agrochemicals products cause of illicit crops (21.6%). Regional differences in the menarche age were founded.
Conclusion: It is the first time that a community population based study is performed in order to know general characteristics of MC in a country with special use of agrochemicals. Regional differences were strong but it is impossible conclude that them have been caused only for use of AC products, but this study sheds light to geographical areas where is necessary to make other kind of complementary studies and present a basic information for subsequent studies related with MC.

COMPARISON OF SELF-REPORT VS. CARPET DUST SAMPLING TO ASSESS EXPOSURE TO PESTICIDES IN THE NORTHERN CALIFORNIA CHILDHOOD LEUKEMIA STUDY

Erin E. Kent, *National Cancer Institute, National Institutes of Health, DHHS, Bethesda, MD*
Catherine Metayer, *School of Public Health, University of California, Berkeley, CA*
Mary H. Ward, *National Cancer Institute, National Institutes of Health, DHHS, Bethesda, MD*
Robert Gunier, *School of Public Health, University of California, Berkeley, CA*
Peggy Reynolds, *Northern California Cancer Center, Berkeley, CA*
Patricia A. Buffler, *School of Public Health, University of California, Berkeley, CA*
Joanne S. Colt, *National Cancer Institute, National Institutes of Health, DHHS, Bethesda, MD*

Background and Aims: Epidemiologic studies of childhood cancer typically rely on parents' reports of pesticide use to assess the child's exposure to home/garden pesticides. This approach is subject to recall bias. The Northern California Childhood Leukemia Study (NCCLS) is one of the few studies of this cancer to collect dust samples from participants' homes. Here, we examine the consistency between these two methods overall and by case/control status.
Methods: Carpet dust samples were collected from the homes of 296 cases and 333 population-based controls, and parents were queried about the use of pesticides to treat each of several types of pests during the previous year. We used Tobit regression to compare self-reported pest treatments with concentrations of 15 pesticide active ingredients in the dust, adjusting for other pest treatments.
Results: Associations between self-reported pest treatment and pesticide levels in the dust did not differ significantly between cases and controls. We found the strongest associations for professionally-applied insecticides. If insecticides were applied outdoors, cyfluthrin levels were six times higher (95% confidence level [CI]: 2.6-13.8), and cypermethrin levels were 2.5 times higher (95% CI: 1.1-5.4), than in homes without such treatment. For professional treatment indoors, cyfluthrin concentrations were 3.3 times higher (95% CI: 1.3, 8.6) than in homes without professional indoor treatment. Significant positive associations were observed for householder-applied pesticides (ants/cockroaches and cypermethrin; flying insects and cypermethrin, permethrin; fleas/ticks in the home and permethrin, piperonyl butoxide (synergist); fleas/ticks on pets and piperonyl butoxide; lawn/garden insects and cyfluthrin, chlorpyrifos; and lawn/garden weeds and dicamba, 2,4-D, MCPP). These associations are consistent with known uses of pesticide products.
Conclusions: Self-reported pesticide use was generally consistent with concentrations of expected pesticide active ingredients in dust samples, lending credibility to both methods. Further, the consistency of the associations among cases and controls provides evidence against reporting bias.

EXPOSURE TO METALWORKING FLUIDS AND RISK OF BLADDER CANCER

Background and Aims: Many studies have observed an excess bladder cancer risk among metalworkers that is thought to be due to metalworking fluid (MWF) exposure. We used data from a large population-based case-control study in New England to examine the association between MWF exposure and bladder cancer risk.
Methods: Lifetime occupational histories were obtained from 1,158 patients (895 men, 263 women) newly diagnosed with bladder cancer in 2001-2004 in Maine, New Hampshire, and Vermont, and from 1,402 population controls (1,031 men, 371 women). Participants who reported jobs titles or tasks suggesting metalworking activities were administered detailed questionnaires. An industrial hygienist blinded to case/control status used this information to assess the probabilities of exposure (certain [probability=1], probable [>0.5-<1.0], possible [>0-<0.5]) to straight, soluble, and synthetic MWFs. Unconditional logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs), adjusted for demographic factors, smoking, and employment in other high-risk occupations.
Results: Compared to men never exposed to MWF, those with certain exposure to MWF (67 cases, 52 controls) had a significantly increased bladder cancer risk (OR=1.7, CI=1.1-2.6). The OR decreased to 1.3 (CI=0.9-2.0) if the exposure was probable (55 cases, 59 controls), and to 1.1 (CI=0.8-1.6) for possible exposure (108 cases, 125 controls). Men with certain exposure to straight MWF had a significant two-fold risk compared to men with no MWF exposure (CI=1.3-3.3); the OR decreased to 1.3 (OR=0.6-2.9) for probable exposure and 1.2 (CI=0.9-1.5) for possible exposure. For soluble MWF, the ORs were 1.5 (CI=0.9-2.4), 1.5 (CI=0.98-2.3), and 1.1 (CI=0.8-1.5) for certain, probable, and possible exposure, respectively.
Conclusions: Use of MWF, particularly straight MWF, was associated with a significantly increased risk of bladder cancer among men. Ongoing assessments of the probability, intensity, frequency, and duration of exposure to straight, soluble, and synthetic MWF will further inform this analysis.

HEAT-SUSCEPTIBILITY IN OLDER PERSONS AND BARRIERS TO ADAPTATION: A QUALITATIVE STUDY

Alana Hansen, *University of Adelaide, Australia*
Peng Bi, *University of Adelaide, Australia*
Monika Nitschke, *South Australian Department of Health, Australia*
Dino Pisaniello, *University of Adelaide, Australia*
Jonathan Newbury, *University of South Australia and University of Adelaide, Australia*
Alison Kitson, *University of Adelaide, Australia*

Background and Aims: Extreme heat is a well documented threat to health, and for reasons which are not fully understood, older persons are known to be most at risk. With heatwaves being a common occurrence during Australian summers, behavioural adaptation is important for heat-health, and factors limiting adaptive capacity in vulnerable subpopulations need to be identified. The aim of this study was to investigate stakeholders' perceptions and experiences of heat-susceptibility in older persons, and to identify risk factors and barriers to adaptation during extreme heat.
Methods: The study was undertaken in Adelaide, South Australia where a record-breaking heatwave occurred in the summer of 2009. Interviews and focus groups were conducted with 41 respondents including older persons (n=6); and key stakeholders involved in health and aged care, community services, government sectors, emergency services and policymaking (n=35). Topics for discussion included experiences of recent heatwaves, links between age and vulnerability to extreme heat, and obstacles to effective adaptation. Proceedings were digitally recorded, transcribed verbatim into text, and analysed using thematic analysis.
Results: The narratives of respondents revealed multiple issues accounting for heat-susceptibility in older persons. Findings showed that adaptive capacity may be influenced by physiological, psychological, socioeconomic and behavioural factors. These included an age-related decline in health with associated comorbidities and the use of certain medications, low fitness, limited fluid intake, diminished awareness, isolation, and financial concerns about power costs. Persons with undiagnosed dementia were noted to be particularly vulnerable. Other issues raised included the design features of some newer cooling devices not being conducive to use by older persons, heat-associated anxieties, and specific issues facing the elderly in rural areas.
Conclusions: Improving heat-health knowledge and addressing the social and economic concerns of older persons may assist in minimising heat-related morbidity and mortality in today's ageing population facing a warming climate.

ARSENICALS, WATER TREATMENT, AND WATER QUALITY: CAN WE LEAVE OUT ONE?

Ming-Yie Liu, *Department of Environmental and Occupational Health, College of medicine - Sustainable Environment Research Center, National Cheng Kung University, Tainan, Taiwan*
Victor Raj Mohan Chandrasekaran, *Department of Environmental and Occupational Health, College of medicine*
Dur-Zong Hsu, *Department of Environmental and Occupational Health, College of medicine*

Background and aims: Metals are considered very important and highly toxic pollutants in the various environmental departments. Arsenic-associated human health complications are reported worldwide. Although inorganic arsenic has long been known to be toxic to humans, little is known about its metabolite, dimethylarsinic acid, and its toxicity. The risk of outbreaks of waterborne diseases increases where standards of water, sanitation and personal hygiene are low. Water may be contaminated with naturally occurring inorganic elements such as arsenic and cause disease. The risk for developing a human disease derived from environmental exposure is not based solely on the environmental exposure, but is modified by mitigating conditions, such as other environmental or genetic factors. Therefore, we investigated the hepatic toxicity of dimethylarsinic acid and its interaction with iron and lipopolysaccharide in drinking water.
Methods: Rats were given drinking water with dimethylarsinic acid with or without iron for 3 weeks. A single dose of lipopolysaccharide was given with dimethylarsinic acid-plus-iron treatment.
Results: Dimethylarsinic acid alone, iron alone, and dimethylarsinic acid-plus-iron treatment did not cause hepatic damage. A single dose of lipopolysaccharide increased hepatic damage in dimethylarsinic acid-plus-iron-treated rats.
Conclusions: Our study indicates an important ecological and environmental related public health issue: the arsenic removal system may cause liver damage via arsenic metabolites as well as poor water quality. We conclude that exposure to lipopolysaccharide increases hepatic damage in dimethylarsinic-acid-plus-iron-treated rats.

BEHAVIOURAL ADAPTATION OF OLDER PERSONS DURING EXTREME HEAT IN TWO AUSTRALIAN STATES

Alana Hansen, *University of Adelaide, Australia*
Peng Bi, *University of Adelaide, Australia*
Monika Nitschke, *South Australian Department of Health, Australia*
Dino Pisaniello, *University of Adelaide, Australia*
Jonathan Newbury, *University of South Australia and University of Adelaide, Australia*
Alison Kitson, *University of Adelaide, Australia*
Eleonora Dal Grande, *University of Adelaide, Australia*
Jodie Avery, *University of Adelaide, Australia*
Graeme Tucker, *South Australian Department of Health, Australia*

Background and Aims: Heatwaves regularly occur during summers in southern Australia, and the health impacts are often more marked in the older population. With established physiological links between age and heat-susceptibility, it is important that barriers to behavioural adaptation be identified so that evidenced-based prevention strategies can be formulated accordingly. The aim of this study was to investigate factors affecting the heat-adaptive behaviours of older persons in two Australian states.
Methods: Computer assisted telephone interviews were conducted late in the 2010-2011 summer with a total of 500 older persons in each of two Australian states, South Australia and Victoria. The study population consisted of persons aged 65 years and over residing in the community, and calls were made to listed residential telephone numbers until a person of the target age was found. The survey instrument was informed by a literature review and a prior qualitative study. Questions covered issues such as air conditioner usage, fluid consumption, resilience, risk perception, behaviour change, and knowledge of heat-health messages. Spatial and quantitative analyses of data were performed using logistic regression in multivariate models.
Results: Whilst an unprecedented heatwave occurred in southern Australia in 2009 claiming hundreds of lives, this study was undertaken during a mild summer in which only one short but intense heatwave occurred, and other natural weather disasters (i.e. floods and cyclones) captured the attention of Australians. Nevertheless, the findings have provided valuable insight into the adaptive behaviours and risk perceptions of older persons during extreme heat in two major Australian cities (Adelaide, SA and Melbourne, Vic) and rural areas in the respective states.
Conclusions: This comprehensive study of the heat-adaptive capacity of older persons may provide an evidence base for interventions and influence the formulation of future age-appropriate health promotion and risk communication strategies for heatwave warnings.

ASSESSING HIGH RISK CLUSTERS OF MALARIA MORTALITY ALONG BORDER AREAS IN SOUTH CHINA

Yan Bi, School *of Public Health, and Institute of Biomedical Innovation, Queensland University of Technology, Kelvin Grove, Queensland,Australai - Yunnan Province Centre for Disease Control and Prevention, Kunming, Yunnan, China*
Wenbiao Hu,*School of Population Health, The University of Queensland, Herston, Queensland, Australia*
Xiao-Nong Zhou,*National Institute of Parasitic Diseases, Chinese Centre for Disease Control and Prevention, Shanghai,China*
Shilu Tong,*School of Public Health, and Institute of Biomedical Innovation, Queensland University of Technology, Kelvin Grove, Queensland, Australia*

Background and Aims: Malaria is a major public health problem along border areas in south China, where there are more malaria deaths than any other regions of China. This study aims to assess spatial and space-time distribution patterns of malaria deaths and identify high risk areas of malaria deaths in Yunnan Province, China.
Methods: The annual malaria deaths at a county level were calculated during 1991 - 2006. Poisson models for purely spatial and space-time analyses were performed to identify high risk clusters in 128 counties over 16 years using SaTScan software. Disease mapping was conducted using ArcGIS software.
Results: The high risk clusters were identified in west and south parts of Yunnan along border areas with the most likely cluster (RR=39.03) and secondary cluster (RR=2.49). The most likely cluster (RR=126.5) occurred during 2003-06 while secondary cluster (RR=7.83) occurred during 2003-05.
Conclusions: The identification of high risk locations and periods in Yunnan may provide useful information for health authorities to target high risk hotspot areas. Further research should be carried out to address the determinants of high risk clusters for malaria transmission in this endemic region.

POPULATION-BASED STUDY ON RISK OF STROKE ASSOCIATED WITH TEMPERATURE CHANGE

Fung-Chang Sung, Ph.D., *China Medical University Department of Public Health, Taichung, Taiwan*

Ling-Ya Huang, MS, *China Medical University Department of Public Health, Taichung, Taiwan*

Yi-Lin Huang, Ph.D., *China Medical University Department of Public Health, Taichung, Taiwan*

Yu-Chun Wang, Ph.D., *Chung Yuan Christian University Department of Bioenvironmental Engineering, Chung Li, Taiwan*

Background and Aims: Most of climate related studies on stroke investigated mortality instead of morbidity. This study used insurance claims data to investigate incidences of stroke associated with the temperature change for population in a subtropical island area, Taiwan.

Methods: We used the sample with claims data of one million insured population obtained from the National Health Insurance program of Taiwan to measure the risk of stroke by temperature variations in 1996-2009. Sex- and age-specific risks were also measured. The meteorological and population data were obtained from the Central Weather Bureau and the Ministry of the Interior, respectively.

Results: With the lowest mean temperature of 16.2 Ž during the 13-year period, the mean monthly incidence rate of stroke was at a peak of 19.7 per 100,000 person-days in January. The mean incidence decreased by month to the 1owest of 17.1 per 100,000 person-days in July, the hottest month, and climbed again in August and the rest of months ranging from 17.8-18.9 per 100,000 person-days. Further analyses showed that the incidence had a strong v-shape association with the minimum daily temperature. The incidence rate decreased from 0.67 per 100,000 person-days at < 10 Ž to 0.56 per 100,000 person-days at 20-24 Ž, then climbed to 0.64 per 100,000 person-days as it was $\geq$ 25 Ž. W e also found the risk of stroke was 2.45-fold greater as the daily temperature range was at 18 Ž than was between 1-3 Ž (1.37 vs 0.56 per 100,000 person-days).

Conclusions: The relative risk of stroke is associated with decreasing and increasing rises starting at the ambient temperature of 20-24 Ž. Severe change in temperature enhances the immediate risk further..

(NSC grant no. 99-2521-M-039-001)

THE GEOGRAPHIC DISTRIBUTION OF DENGUE FEVER AND THE POTENTIAL INFLUENCE OF GLOBAL CLIMATE CHANGE

Esther Van Kleef, *(Former Intern) WHO Geneva, Switzerland*
Hilary Bambrick, *University of Western Sydney, Australia*
Simon Hales, *University of Otago, New Zealand*

Background and Aims: We aimed to describe the geographic distribution of dengue transmission (current and historical) and to estimate possible impacts on transmission from climate change.
Methods: We searched PubMed, digital books and archives for literature describing geographically defined outbreaks of dengue. We also searched PubMed and Scopus for studies modelling the potential effects of climate change on dengue transmission.
Results: One hundred and one articles met the eligibility criteria for the first review; there were some contradictions and ambiguities in the data. Current global distribution of dengue is generally less extensive than historical limits of dengue-like illness. In recent years, several countries have reported local transmission of dengue for the first time, but it is unclear whether this represents true geographic spread, rather than increased awareness and reporting. Six papers met the inclusion criteria for the second review. The findings of theoretical and statistical models of dengue and climate are broadly consistent: the transmission of dengue is highly sensitive to climate. Relatively small increases in temperature (around 1°C) can lead to substantial increases in transmission potential
Conclusions: The geographic distribution of dengue has generally contracted, despite increases in global average temperature in the past century. Theoretically, however, temperature trends have increased the risk of dengue in some areas. The independent effect of climate change on historical patterns of dengue transmission cannot be quantified based on current evidence, as existing models of disease transmission provide limited, incomplete, projections of disease risk. The geographic limits of dengue result from a complex interaction between physical, ecological and social factors which have not been included in current climate change models. Keeping this limitation in mind, models estimating changes to geographic boundaries of transmission suggest an increase in the future population at risk of dengue.

THE STUDY ON THE RELATIONSHIP BETWEEN PERSONAL HYGIENE AND INTESTINAL INFECTIOUS DISEASES OF RURAL RESIDENTS

Yajuan Zhang, *Department of Occupational and Environmental Health, School of Public Health, Peking University, 38 Xue Yuan Road, Beijing 100191, P.R. China*

Yuming Guo, *School of Public Health, Queensland University of Technology, Kelvin Grove, Brisbane, Queensland, Australia*

Hui Tao, *Department of Occupational and Environmental Health, School of Public Health, Peking University, Beijing, China*

Liyang Wang, *Beijing AiWeiHui, Beijing, China*

Xiaochuan Pan, *Department of Occupational and Environmental Health, School of Public Health, Peking University, Beijing, China*

Backgrounds and Aims: Epidemiological studies have demonstrated a link between unhealthy hygienic habits and morbidity of the intestinal infectious diseases of the city dwellers, rather than rural residents. Here, we use case-control design to explore the relationship between the personal hygiene and intestinal infectious diseases in rural residents of China.

Methods: About 20,000 persons were recruited for the survey by stratified random sampling. The subjects were interviewed with the questionnaire designed by our research team to collect the information of personal hygiene, e.g. drinking unboiled water, hand-washing before meals, hand-washing after toileting, tableware-washing timely(within an hour after eating), and tableware-washing with detergent, as well as cases of intestinal infectious diseases including infectious diarrhea, abdominal typhus, dysentery and acute gastritis of the subjects. The case and control group were divided according to case report of themselves. The Multivariate Logistic Regression was used for the data analysis.

Results: There were 692 and 19210 subjects in case group and control group respectively. After adjusting the related confounders, drinking unboiled water increased statistical significantly the possibility of suffering from the infectious diseases (*OR*=1.47, 95%CI=1.18~1.83, *P*<0.01)in the exposed population, the cases of intestinal infectious diseases of subjects were negatively correlated with hand-washing after toileting(*OR*=0.44, 95%CI=0.33~0.58, *P*<0.01), tableware-washing timely(*OR*=0.61, 95%CI=0.49~0.77, *P*<0.01) and tableware-washing with detergent(*OR*=0.72, 95%CI=0.56~0.91, *P*<0.01) respectively. While hand-washing before a meal has not significantly associated with the intestinal infectious diseases.

Conclusion: The better habit if personal hygiene could decreases the possibility of intestinal infectious diseases in rural residents. The approach of health education and promotion about personal hygiene is necessary for reducing the chance of being infected by intestinal infectious diseases.

CLIMATE CHANGE AND HEAT-RELATED MORTALITY IN BUDAPEST - COMPARATIVE METHODS OF IMPACT ESTIMATION OF TEMPERATURE CHANGE

Janos Bobvos, *Research group "Adaptation to climate change" of the Hungarian Academy of Science, Hungary*
Norbert Solymosi, *Research group "Adaptation to climate change" of the Hungarian Academy of Science, Hungary*
Anna Paldy, *National Institute of Environmental Health Budapest, Hungary*

Background and Aims: Regional climate models (RCM) allow to assess health impacts. The authors studied how climate-change modify heat-related mortality by different validation methods.
Methods: We assessed 1961-1990 and 2021-2050 heat-related mortality impacts in Budapest by applying temperature projections from 20 RCMs (ENSEMBLES project) and for validation the Budapest station data of the Hungarian Meteorological Service. Based on a previous study, daily mortality increases by 1.03(1.02-1.05) cases/1^{o}C increase resp. by 1.06(1.04-1.07) in the age groups of <75 resp. ≥75-year old population on days with mean temperature above 95% percentile.
Four computation methods were used: only reference and scenario of climate models; observed data compared to scenarios; assuming that excess mortality occurred on equal number of days, resp. assuming the same number of excess deaths occurrred in the observed and reference datasets.
Results: In three models 95% percentile daily mean temperature of the reference period was higher than the maximum values of observed data; in two models the maximum temperature of predicted future was less than the observed maximum. The number of hot days above threshold temperature (23.9^{o}C - 548 days) in observed data fell between 49-1787 days in the reference data. Increase of excess mortality due to climate change was between 16-780%, 7-680% , 21-314%, 21-320% in the computation models. In the last model the yearly heat-related excess mortality was 87(58-145) resp. 174(116-203) in the younger vs. older age group in 1961-1990. The yearly excess mortality predicted by the models will be between 106-366 resp. 212-733 for the younger resp. older age groups between 2021-2050.
Conclusions: When the effect of heat can be modelled for the real past period, the validation should be based on it to produce more reliable prediction.
This project is supported by the New Hungary Development Plan (Project ID:TÁMOP-4.2.1/B-09/1/KMR-2010-0005).

A STRATEGY TO ADJUST FOR CONFOUNDING USING MULTIFACTOR STATISTICAL MODELS IN EPIDEMIOLOGICAL RESEARCH

Anatole N. Varaksin, *The Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Russia*
Vladimir G. Panov, *The Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Russia*
Julia I. Kazmer, *The Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Russia*

Background and Aims: There are two main methods to adjust for confounding at the stage of data analysis in epidemiology: standardization (stratification) and multifactor statistical modeling. Comparison of results obtained with the help of these methods is, therefore, of interest to us. The mathematical equivalence of these methods to adjust for confounding has not been fully investigated in scientific papers. Besides, it is customary to assume that the results of both methods coincide when they are applied to the same primary dataset.
Methods: We have considered different statistical methods to adjust for confounding, such as simple and logistic regression, and analysis of variance and covariance. Strict mathematical methods have been used to compare the results obtained by standardization and by including a confounding variable into the multifactor statistical model. We have used our datasets for performing calculations. These datasets include 1577 adults and 1350 children living in the Middle Urals (Russia). For each of the individuals, we gathered data concerning health status, environmental pollution and information about individual risk factors.
Results: It is shown that the multifactor variance model represents the standardization procedure in the best way. The covariance model could allow us to make the same adjustment for confounding as a standardization procedure if we took into account some special conditions. Multiple regression models (both simple and logistic) give results which are different from those obtained with the standardization procedure.
Conclusions: Formal application of regression models (both simple and logistic) to adjust for confounding may lead to incorrect results. Admittedly, the only reasonable method to adjust for confounding is variance models, and occasionally, covariate models. It has to be admitted that a reasonable method to adjust for confounding is variance models only, and covariate models on some occasions.

BIPHASIC DECLINE OF SERUM PERFLUOROOCTANOIC ACID (PFOA) CONCENTRATIONS AMONG MID-OHIO VALLEY RESIDENTS

Scott Bartell, *University of California Irvine, USA*
Antonia Calafat, *Centers for Disease Control and Prevention, USA*
Christopher Lyu, *Battelle, USA*
Kyle Steenland, *Emory University, USA*
Barry Ryan, *Emory University, USA*

Background and Aims: Two PFOA-contaminated water systems, Little Hocking Water Association and Lubeck Public Service District, have used granular activated carbon filtration since 2007 in order to remove the contaminant. The study aim is to characterize the subsequent rate of decline of serum PFOA concentrations among exposed residents.
Methods: Up to 7 blood samples were collected from each of 200 study participants from 2007 to 2009; serum samples were analyzed for PFOA content. Rates of decline and apparent half-lives are calculated separately in year 1 and year 2, with adjustment for a presumed background serum concentration of 4 ng/mL.
Results: The mean background-adjusted decline in serum PFOA concentrations was 27% during year 1 and 11% percent during year 2. Background-adjusted individual rates of decline differed significantly between year 1 and year 2 (paired t test; $p < 0.001$). Corresponding half-life estimates are 2.1 years during year 1 and 5.0 years during year 2.
Conclusions: PFOA was eliminated from human serum more slowly during the second year after an exposure intervention than it was during the first year, suggesting complex pharmacokinetics and/or ongoing local exposures.

THE ANALYSIS OF PUBLIC HEALTH USING THE URBAN AUDIT DATA

Jan Bruha, *Kolin Institute of Technology, U Borku 607, 28002 Kolin, Czech Republic*;
Hana Bruhová-Foltýnová, *Kolin Institute of Technology, Kolin, Czech Republic*

Background and aims: The aim of the paper is to analyse selected public health indicators based on the Urban Audit database. The Urban Audit contains statistics for 258 cities across 27 European countries. There are almost 300 statistical indicators on demography, society, the economy, the environment, transport, the information society, public health, and leisure. In this paper, we analyse the following public health indicators: mortality rates under 65 and mortality rates under 65 from heart diseases and respiratory illness for both sexes. We are interested in the effect of the environment (air pollution) and active travel (the shares of walkers and bikers) on the above mentioned health indicators.
Methods: We employ statistical bayesian techniques to analyse the impact of observed cities characteristics and unobserved random effects on the public health indicators. The bayesian techniques prove useful to deal with missing data and outliers, which is a real issue when working with the Urban Audit.
Results and conclusions: The statistical results suggest that the share of active transport is significantly associated with the decrease in all investigated mortality rates. The elasticity is stronger for the share of bikers. There is also a non-linear interactions between environmental and transport indicators. We plan to check these results using a set of more advanced techniques.

PLOTTING ISOBOLE WITH LOGISTIC REGRESSION

Vladimir G. Panov, *Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Russia*
Julia I. Kazmer, *Institute of Industrial Ecology, the Urals Branch of the Russian Academy of Sciences, Russia*

Background and Aims: Studies concerning interactions between different toxicants are of fundamental interest and practical importance in toxicology. However, there is still no consensus of opinion with regard to the assessment of interaction between agents. We, therefore, should be careful about using the terms additivity, synergism and antagonism, especially where nothing is known about the mechanisms underlying the toxic action. The Loewe additivity model and its extension in the form of isobolographic method are mostly used for assessing the type of combined action in co-exposure experiments. Moreover, practical plotting of an isobole is a non-trivial task.
Methods: We propose to plot an isobole using a logistic regression equation for primary data. In many cases, the outcome of interest is binary (i.e. taking 0, 1 values), and toxicants are continuous (e.g. air pollutant concentrations). By standard calculation, we can get a logistic regression equation $w = f(x, y)$, reflecting the impact of toxicants on objects. The co-exposure of toxicants may manifest itself in a variety of ways, e.g. additive effects, synergism or antagonism. Each of these cases produces some kind of isobole. We can design this plot in 2 steps. Firstly, we calculate disease prevalence w_0 from primary data. Secondly, we find the corresponding isobole solving the implicit equation $w_0 = f(x,y)$.
Results: We have tested this method on various real and simulated data sets, and have come to the conclusion that it is easier and more correct than others. This method of isobole construction may help, with a certain degree of approximation, find isoeffective doses of toxicants (points of intersection of this isobole with the axes).
Conclusions: The isobole plotting method proposed in this report may have some advantages compared to other methods. It has significant stability to outlets, and may be applied to various data sets with minimal preparation.

Epidemiologic research during the past 10-20 years has confirmed the adverse effects of air pollution on public health, and subsequent cost-benefit analysis has become critical in policy decision-making. Since air quality models are among the main tools available to evaluate the impacts of changes in emissions, either due to growth or resulting from the implementation of source-control strategies, these approaches play a vital role in air accountability studies. In this study we present an air-quality system, AQM.cat, to quantify the impact of air pollution on public health. This modelling system is based on coupling different Eulerian models: a meteorological model, WRF or MM5; an emission model MNEQA; and the photochemical model CMAQ. In this contribution we consider two ways to characterize health effects using AQM.cat: (i) using it to obtain the statistical parameters needed by the exposure models to estimate the temporal and spatial variability of different pollutants; and (ii) linking AQM.cat to concentration-response functions derived from relationships between ambient concentrations and health effects. In the first case, one year of simulation is considered to evaluate statistical parameters such as the mean, median and 90^{th} percentile for the eight 3-hourly time diurnal time intervals, illustrating the temporal variability of several pollutants: ozone, PM10 and nitrogen dioxide. In the second case, we link AQM.cat with concentration-response functions and with spatially disaggregated population data. Changes in health effects due to changes in the emission of each pollutant have been quantified by comparing the baseline case with different scenarios corresponding to different reductions of emissions. Both methods have been applied to north-eastern Spain (Catalonia), showing the capacity of an integrated air quality modelling and assessment system to evaluate damage caused by pollutants, and emission control strategies.

MATERNAL CADMIUM EXPOSURE IN PREGNANCY AFFECTS SIZE AT BIRTH

Maria Kippler, *Karolinska Institutet, Stockholm, Sweden*
Fahmida Tofail, *Karolinska Institutet, Stockholm, Sweden and International Centre for Diarrhoeal Disease Research, Bangladesh (ICDDR,B), Dhaka, Bangladesh*
Renee Gardner, *Karolinska Institutet, Stockholm, Sweden*
Jena Hamadani, *International Centre for Diarrhoeal Disease Research, Bangladesh (ICDDR,B), Dhaka, Bangladesh*
Anisur Rahman, *International Centre for Diarrhoeal Disease Research, Bangladesh (ICDDR,B), Dhaka, Bangladesh*
Marie Vahter, *Karolinska Institutet, Stockholm, Sweden*

Background and aim: The toxic metal cadmium (Cd), commonly occurring in various foods, is embryotoxic and teratogenic in a variety of animal species, indicating that the prenatal period is a critical window of Cd exposure; however, data in humans is limited. The aim of the present study was to assess the effects of maternal Cd exposure in pregnancy on size at birth.
Methods: This prospective cohort study was nested into a population-based supplementation trial in pregnancy, conducted in rural Bangladesh. We selected all women that were recruited in early pregnancy (Gestational Week (GW) 8) from February 2002-January 2003, and who had singleton births with measurements of birth size (weight, length, head- and chest circumference; n=1616). Urinary Cd (GW 8), a marker of long-term exposure, was measured with ICPMS and adjusted by specific gravity. All women were non-smokers.
Results: Multivariable–adjusted linear regression analyses, controlled for potential confounders including sex, showed that maternal urinary Cd (median: 0.63 µg/L) was negatively associated with birth weight and head circumference. Stratifying by sex showed that the negative association of maternal urinary Cd on size at birth was only apparent amongst girls; birth weight (B=0.45; p=0.020), head- (B=-0.26; p=0.0031), and chest circumference (B=-0.24; p=0.025). We found no significant associations amongst boys. In girls, an increment of 1 µg/L Cd in maternal urine was associated with a decrease in head- and chest circumference by 0.26 and 0.24 cm, respectively and in birth weight by 45g. Multivariable-adjusted quantile regression analyses using the 25th, 50th, and 75th percentiles of size at birth indicated that Cd similarly affected girls of smaller and larger size.
Conclusions: We found a remarkable sex-specific association between maternal Cd exposure and birth size, which was only apparent in girls. Clearly, this has public health relevance and further emphasizes the importance to reduce Cd pollution.

THE RELATIONSHIP OF RESIDENCE DISTANCE FROM PUBLIC GREEN PARKS IN KAUNAS TO PRETERM BIRTH RISK

Regina Grazuleviciene, *Vytautas Magnus University, Donelaicio st. 58, 44248-LT, Kaunas, Lithuania, e-mail: r.grazuleviciene@gmf.vdu.lt*
Audrius Dedele, *Vytautas Magnus University, Kaunas, Lithuania*
Asta Danileviciute, *Vytautas Magnus University, Kaunas, Lithuania*
Gediminas Balcius, *Vytautas Magnus University, Kaunas, Lithuania*
Tomas Grazulevicius, *Vytautas Magnus University, Kaunas, Lithuania*

Background and Aims There is some evidence that access to urban green spaces is associated with an increased physical activity, decreased stress level, and improved people's life quality and reduced health problems. We examined the associations between residence distance from green space (parks) and preterm birth.
Methods: We conducted a prospective pregnant women cohort study in Kaunas (Lithuania) and estimated 3,341 maternal residence distance from green space classified as a Formal park. Women's home locations were mapped using the ArcGIS 9.2 Geographical Information System (GIS) and combined with a comprehensive GIS database of neighbourhood and green space characteristics. Preterm birth was defined as infant's whose gestational age was less than 37 weeks. According to the distance from the residents' homes of each respondent to the nearest park, we determined three women groups: residing within 300 m (referent group), 300-1000 m and more than 1000 m. The associations between distance from parks and singleton preterm birth were analyzed by logistic regression models with and without adjustment for maternal education, family status, renal diseases, diabetes, cardiovascular disease, stress, body mass index, smoking, alcohol consumption, parity, previous preterm birth, infant birth year, and NO_2 exposure.
Results: We found positive associations between women home distance to the nearest park and preterm birth. The adjusted risk ratio of delivering a preterm birth infant among women residing within a 300-1000 m from park was 0.90, 95% CI 0.61-1.31 and among women residing above 1000 m from park it was 1.58, 95% CI 1.00-2.51 to compare to the referent women group. Similar results were found when from the model was excluded NO_2 exposure effect.
Conclusion: The findings suggest that there is an association between home location within 1000 m to green spaces classified as a Formal park in urban areas and preterm birth risk.

ROAD TRAFFIC INJURIES IN SOUTH INDIA

Venkata Raghava Mohan, *Christian Medical College, India*
Rajiv Sarkar, *Christian Medical College, India,*
Vinod Joseph Abraham, *Christian Medical College, India,*
Vinohar Balraj, *Christian Medical College, India*
Elena N. Naumova, *Christian Medical College, India, Tufts University Schools of Engineering and Nutrition, USA*

Background and Aims: Road traffic injuries (RTIs) contribute 18% of total deaths in India and the number of RTI-related fatalities has been increasing by 8% annually. This study provides a detailed profile of RTIs on the National, State Highways (NH, SH) and local roads in Vellore district and identifies hotspots of RTIs using GIS methodology.
Methods: 3262 RTI records were abstracted from the police filed First Information Reports (FIRs) between January, 2005 and May, 2007. Each record contained information on accident's location, time, vehicle and injury characteristics. The NH vehicular density and RTIs were mapped. Highway junctions at risk for fatal RTIs and segments with high RTI rates were identified. Poisson regression analysis was used to compare RTIs across road categories and event time.
Results: The highest proportion of RTIs was observed on NH (52%) with 3.77 injuries/day, compared to SH (30%) and local roads (18%), which had 50% pedestrian involvement, in contrast to NH and SH (34% & 40%). Over the study period, the number of fatal RTIs on NH had increased by 57%. A significant 5 and 7-fold increase respectively were observed in all RTIs and fatal RTIs on the local roads. NH RTI rate (8.8/100,000 vehicles/day) varied from 5.8/100,000 (weekends midnight-to-6am) to 13.2/100,000 (weekdays 6pm-to-midnight). RTIs involving heavy motor vehicles (HMV) were more on weekends compared to weekdays (39.4% vs. 32.6%, $p<0.05$).Majority of RTIs on the NH had occurred at five major junctions, two of which had the highest fatality rates (17%). One NH segment exhibited the highest rate for fatal RTIs (1.2/100,000).
Conclusions: Despite the limited specificity of the police reports, this study has demonstrated the patterns and growing trends of RTIs in India. This study also demonstrates the value of GIS for policy makers in the design, maintenance of highways and in implementing preventive strategies.

Jia-Yuh Chen, MD,PhD , *Division of Genetics, Department of Pediatrics, Chung Shan Medical University Hospital, Taichung, Taiwan ; School of Medicine, Chung Shan Medical University, Taichung, Taiwan*

Background and Aims: Neonates are exposed to high levels of di-(2-ethylhexyl) phthalate (DEHP) through numerous medical procedures in the neonatal intensive care unit (NICU). Our aim is to assess the contribution of specific medical devices to the DEHP exposure.

Methods: We recruited 32 premature neonates, 20 with very low-birth weight (VLBW, <1500 g) and 12 with low-birth weight (LBW, <2500 g), and 31 controls at a neonatal intensive care unit (NICU) from a medical center in central Taiwan. We recorded the medical procedures including endotracheal tube (ETT), orogastralic tube (OGT), nasogastric tube (NGT) of each subject and collected their urine samples for determination of three metabolites of di-(2-ethylhexyl) phthalate (DEHP) using reversed-phase high-performance liquid chromatography-atmospheric pressure chemical ionization-tandem mass spectrometry.

Results and Discussions: The median level of DEHP metabolites in premature neonates treated with ETT and OGT or NGT were significantly 2-fold higher than those treated without ETT, OGT or NGT. The median level of DEHP metabolites in premature neonates treated with intravenous (IV) injection was significantly ≥2 fold higher than healthy controls who received IV injections. Median levels of three DEHP metabolites were similar in VLBW and LBW. These data suggest that PVC-containing devices are the major defining factor in DEHP exposure levels in neonates in the NICU. We urge the use of PVC-free or alternative materials in medical devices, especially for ETT, OGT, NGT and IV tubing in the NICU. The health effects of high DEHP exposure on premature neonates in the NICU is worthy of further investigation.

TRIHALOMETHANES INTERNAL DOSE AND MATERNAL GSTT1 AND GSTM1 GENES POLYMORPHISM CONTRIBUTION TO THE RISK OF PRETERM BIRTH

Asta Danileviciute, *Vytautas Magnus University, Kaunas, Lithuania*
Regina Grazuleviciene, *Vytautas Magnus University, Kaunas, Lithuania*
Jone Vencloviene, *Vytautas Magnus University, Kaunas, Lithuania*

Background and Aims: There is some evidence that prenatal exposure to drinking water trihalomethanes (THM) has a detrimental effect on birth outcome. Both environmental factors and genes involved in metabolic detoxification process may be associated with preterm birth. The relationship between THM exposure and preterm birth in genetically susceptible subjects is not clear. The objective of this study is to investigate whether the polymorphisms of metabolic genes GSTT1 and GSTM1 affect the association of maternal exposure to THM with preterm birth.
Methods: We conducted a nested case-control study of 682 pregnant women in Kaunas (Lithuania) using individual information on water drinking, showering and bathing habits during pregnancy, and uptake factors of THMs in blood, estimated as internal dose of THM. We used logistic regression to evaluate the relationship between internal THM dose, preterm births and individual and the joint (modifying) effects of the metabolic gene polymorphisms controlling for family status, maternal smoking, body mass index, alcohol consumption, education, and infant birth year.
Results: The estimated individual total uptake of THMs ranged between 0.0025 and 2.40 μg/d. The findings suggest that carriers of the GSTM1–0 genotype and exposed to THM, chloroform and bromodichloromethane had an increased risk for preterm birth compared to carriers of the GSTM1–1 genotype: the ORs during the second trimester among woman GSTM1–1 genotype carriers were 1.0–1.11, while among GSTM1–0 genotype carriers ORs were 1.66–2.07. Exposure to dibromochloromethane during the first trimester among carriers of the GSTM1–1 genotype was associated with an OR of 7.35, 95% CI 2.62–20.6, and among carriers of the GSTM1–0 genotype produced an OR of 2.81, 95% CI 1.21–6.52.
Conclusions: These data suggest that THM internal dose may affect preterm birth and that maternal GSTM1 and GSTT1 genotypes modify the THM exposure effects on preterm birth.

CHERNOBYL – 25 YEARS AFTER: IS THERE A SIGNAL IN AUSTRIAN HEALTH DATA?

Hanns Moshammer, *Medical University Vienna, Austria*
Hans-Peter Hutter, *Medical University Vienna, Austria*

Background and Aims: Austria was among the areas outside the former Soviet Union hardest hit by the fall-out following the nuclear accident at Chernobyl in April 1986. In the aftermath of this event several claims were made about measurable health effects in Western European countries. No consistent study has so far been conducted in Austria.
Methods: If the findings in other Western European countries were causally related to the accident also an effect should be visible in Austria provided the data were available with sufficient quality. Although a statistically significant effect on cancer incidence is not likely this endpoint was considered because of its high emotional impact. In addition data on chromosomal aberrations were reviewed and effects of the nuclear accident on the birth weight and the sex ratio at birth were investigated.
Results: No significant effect on cancer incidence was observed, but the spatial distribution of adolescent thyroid cancer in the years 1990-2004 was consistent with a small additional effect of the fall-out in the expected magnitude. An even less clear tendency was seen for leukaemia.
Claims of an increase in trisomy 21 in other European countries do not seem very consistent. Austrian data do not indicate an increase in trisomy 21 but surprisingly an increase in other aneuploidies was observed in 1987. There was no influence on the sex ratio at birth. When the first trimenon coincided with the 4 months after the nuclear accident there was a small but significant reduction in birth weight although there was no clear pattern in the spatial distribution of the effect.
Conclusions: None of the findings is proof for a causal impact of the nuclear accident. On theoretical basis some minor effects are to be expected and findings are on the whole consistent with this expectation.

MYOCARDIAL INFARCTION INCIDENCE AND ROAD TRAFFIC NOISE EXPOSURE,PISA (ITALY),2002-2006

Maria Angela Vigotti, University of Pisa and CNR-IFC,Pisa,Italy
Mara Nolli, Environmental Agency of Tuscany,Italy
Cecilia Corsini, University of Pisa,Italy
Claudia Chiari, Environmental Agency of Tuscany,Italy
Marina Bonfanti, Municipality of Pisa, Italy
Nicola Guerrini, Municipality of Pisa, Italy
Mariangela Protti, CNR-IFC,Pisa,Italy
Gaetano Licitra, Environmental Agency of Tuscany Italy

Background and Aims: Evidence is growing on association between exposure to road traffic noise and health effects, in particular cardiovascular and myocardial infarction (MI). The ongoing study aims to evaluate the association between MI incidence and residential exposure to road traffic noise by a case control (CC) study, on current data.

Methods: Mortality and hospitalization data (1998-2006) have been used to obtain cases of first MI incidence in 2002-2006 through a validated algorithm. Five controls will be matched to each case by gender, age and a deprivation index (DI), based on 2001 census. Residential address, residence length and geographical coordinates come from Municipality archives. Road traffic noise exposure have been estimated at the buildings façades from Pisa noise map built by Environmental Protection Agency of Tuscany Region according to new acoustic indicators and interim methods issued by European Directive 2009/49/CE.

Results: The CC study is ongoing. 823 MI cases (age 35+ years) have been identified in 2002-2006 with the aim to analyze also the last- residence noise exposure length.

Preliminary analyses of MI cases on residents, living in the same building (769 different buildings) on the same year, estimated incidence rates, direcly standardized by age and DI, computed by sex and night noise levels (<50dB; 50-54dB; 55+ dB). The rate ratios vs the lowest noise level were 1.14 at 50-54dB, 1.33 at 55+ dB among men while were respectively 1.12 and 1.06 among women.

Conclusions: Preliminary results confirm, in men, the presence of an association between first MI occurrence and high leves of nocturnal traffic noise exposure at residence place. The ongoing CC study will consider the residence length and will try to evaluate the confoundig effect of air pollution exposure by means of traffic characterization (veichles number, pedestrian area, vicinity to airport,railway etc) in the road of residence.

ASSOCIATION BETWEEN POP EXPOSURE AND TYPE 2 DIABETES IN THE HELSINKI BIRTH COHORT STUDY

Riikka Airaksinen, *National Institute for Health and Welfare, Department of Environmental Health, Finland*
Panu Rantakokko, *National Institute for Health and Welfare, Department of Environmental Health, Finland*
Johan G Eriksson, *National Institute for Health and Welfare, Department of Chronic Disease Prevention, Finland*
Paul Blomstedt, *National Institute for Health and Welfare, Department of Chronic Disease Prevention, Finland*
Eero Kajantie, *National Institute for Health and Welfare, Department of Chronic Disease Prevention, Finland*
Hannu Kiviranta, *National Institute for Health and Welfare, Department of Environmental Health, Finland*

Background and Aims: The prevalence of type 2 diabetes is increasing alarmingly in both developed and developing countries. Lately, exposure to persistent organic pollutants (POPs) has been associated with its increasing incidence. The purpose of this study is to examine the association between type 2 diabetes and POP exposure in the Helsinki Birth Cohort Study. The participants were born between the global POP emission peak, and have mainly been exposed during adulthood. This offers an interesting opportunity to study the association when limited exposure during fetal period has occurred.
Methods: The cohort consists of 8760 people born in Helsinki, Finland, during 1934–44. In 2003, a baseline clinical examination was performed, including blood sampling for laboratory analyses of serum lipids and six POPs. Complete data from the baseline examination was available for 1988 participants. A repeat sampling was performed in 2006, but data from this was not yet available for the present study. The concentrations of each POP were categorized into four groups based on percentile intervals and logistic regression was performed across the POP categories, adjusting for sex, age, waist circumference, and mean arterial pressure, and using the lowest category as the reference group.
Results: Among the participants with the highest exposure to oxychlordane, *trans*-nonachlor, *p,p'*-DDE, and PCB 153, the risk of type 2 diabetes was 1.64–2.24 times higher than among those with the lowest exposure (plin=0.003–0.050). In the BMI-stratified analysis, the associations between type 2 diabetes and oxychlordane and trans-nonachlor remained significant, and were strongest among the overweight participants. Exposure to BDE 47 and BDE 153 was not associated with type 2 diabetes.
Conclusions: Type 2 diabetes was associated with high adult-only exposure to organochlorine pesticides in a general urban population.

INDIVIDUAL EXPOSURES TO DRINKING WATER TRIHALOMETHANES AND THE RISK OF PRETERM BIRTH

Gediminas Balcius, *Vytautas Magnus University, Kaunas, Lithuania*
Regina Grazuleviciene, *Vytautas Magnus University, Kaunas, Lithuania*
Jone Vencloviene, *Vytautas Magnus University, Kaunas, Lithuania*

Background and Aims: Evidence for an association between exposure during pregnancy to trihalomethanes (THMs) in drinking water and preterm birth is still inconsistent and inconclusive, in particular, for various exposure routes. The aim of our study was to examine association between of internal dose of THMs and preterm birth in singleton newborns.
Methods: We conducted a prospective cohort study of pregnant women in Kaunas city, Lithuania. Preterm birth was defined as infant's whose gestational age was less than 37 weeks. In total 4.161 women were interviewed to collect personal data on various characteristics and water consumption habits. We used tap water THMs concentrations, geocoded maternal address at birth, individual information on drinking water ingestion, showering and bathing, and uptake factors of THMs in blood, to estimate an internal dose of individual THM. We examined the relation of THM internal dose to preterm birth with a multiple linear-regression models, adjusting for maternal education, family status, renal diseases, diabetes, cardiovascular disease, stress, body mass index, smoking, alcohol consumption, parity, previous preterm birth, and infant birth year.
Results: The estimated individual total uptake of THMs ranged between 0.0025 and 2.40 μg/d. THMs dose was associated with a slightly increased risk across three pregnancy trimesters. We found dose – response relationships for the entire pregnancy and trimester-specific brominated THMs internal dose and preterm birth. For a second trimester bromodichloromethane adjusted RR for second tertile was 1.79, 95% CI 1.03-3.13 and for third tertile it was 1.84, 95% CI 1.04-3.26. The risk increased by 21% per every 0.01 • g/d increase in bromodichloromethane internal dose (OR 1.21, 95% CI 1.01–1.45).
Conclusions: There is some evidence for an association of THMs internal dose during pregnancy on preterm birth. Increased bromodichloromethane dose may affect preterm birth.

LOW-LEVEL NITROGEN DIOXIDE EXPOSURE AND SMALL FOR GESTATIONAL AGE NEWBORNS IN A KAUNAS COHORT STUDY

Audrius Dedele, *Vytautas Magnus University, Donelaicio st. 58, 44248-LT, Kaunas, Lithuania*
Regina Grazuleviciene, *Vytautas Magnus University, Kaunas, Lithuania*
Tomas Grazulevicius, *Vytautas Magnus University, Kaunas, Lithuania*

Background/Aims: Evidence for an association between exposure during pregnancy to traffic-related air pollution and impaired fetal growth is still inconsistent and inconclusive. We examined the relationship of individual exposures to nitrogen dioxide (NO2) during pregnancy on small for gestational age (SGA) risk in singleton births.
Methods: We conducted a prospective cohort study of 4,161 pregnant women in Kaunas (Lithuania). We gathered individual information on social and demographic characteristics, residence history, health behaviour, pregnancy history, and pregnancy outcomes. Infants were considered SGA if they were in the lowest 10th centile of BW for each gestational week stratified by infant gender and maternal ethnic group. Gender-specific and ethnic group-specific deciles were determined from the 2004 data set of all births in Lithuania. We estimated maternal exposure during pregnancy to NO_2 by AIRVIRO dispersion model for 3,341 singleton births at the geocoded residential address. Associations between NO2 concentrations and SGA were analyzed by logistic regression models with and without adjustment for estimated potential confounding variables, such as maternal age, education, family status, ethnic group, body mass index, smoking, parity, previous preterm birth, and infant gender.
Results: The mean levels of NO_2 to which the women were exposed throughout their pregnancies ranged from 5.3 to 53.2 $\mu g/m^3$. We found positive, statistically non-significant associations between exposure to NO_2 during entire pregnancy and SGA. Adjusted odds ratio for SGA of exposed to second tertile NO_2 was 1.00; 95% CI 0.70-1.40 and exposed to third tertile NO_2 was 1.17; 95% CI 0.83-1.65 to compare to the first tertile exposure.
Conclusion: The present study suggests that there was a tendency towards an increased risk of SGA with increasing air pollution exposure, but statistical power was low.

JOINT EFFECTS OF ENVIRONMENTAL EXPOSURE TO GEOMAGNETIC ACTIVITY AND DRINKING WATER TRIHALOMETHANES ON CONGENITAL HEART ANOMALIES RISK IN A KAUNAS COHORT STUDY

Jone Vencloviene, *Vytautas Magnus University, Donelaicio st. 58, 44248-LT, Kaunas, Lithuania*
Regina Grazuleviciene, *Vytautas Magnus University, Kaunas, Lithuania*
Jurate Buinauskiene, *Kaunas University of medicine, Kaunas, Lithuania*
Violeta Kapustinskiene, *Vytautas Magnus University, Kaunas, Lithuania*

Background and Aims: There is growing evidence for an adverse effect of maternal exposure to environmental factors on pregnancy outcomes. Recent epidemiological studies suggested that trihalomethanes (THM) exposures during pregnancy might impair the fetal growth and that exposure to high geomagnetic activity may increase the risk of congenital anomalies. We investigated whether geomagnetic activity might modify the association between THM exposure and risk of congenital heart anomalies (CHA).
Methods: We conducted a case-control study on CHA (ICD-10 codes Q20 – Q28) in Kaunas (Lithuania), using individual information on social and demographic characteristics, residence history, health behaviour, and pregnancy history. We used tap water THM concentrations, geocoded maternal address at birth, and individual information on drinking water ingestion, showering and bathing, and uptake factors of THMs in blood, to estimate an internal dose of THM. As a measure of the geomagnetic activity level we used the average of daily Ap indexes during first trimester of pregnancy. We classified monthly geomagnetic activity exposure into two groups: above median and below median and examined the associations between THM dose, geomagnetic activity and the risk of CHA by multiple logistic regression. All data were adjusted for maternal age, education, stress, body mass index, multiple birth, preterm birth, and miscarriage in previous pregnancy.
Results: The estimated individual total uptake of THMs ranged between 0.0025 and 2.40 μg/d (median 0.1733μg/d). Geomagnetic activity median was 7.33. The adjusted odds ratio for THM dose above median vs. below median and geomagnetic activity below median was 1.39, 95% CI 0.69-2.81 for CHA, while exposure to geomagnetic activity above median and THM dose above median was associated with OR 2.25, 95% CI 1.19-4.25.
Conclusions: These data suggest that THM internal dose may affect CHA and that increased geomagnetic activity strengthen the THM exposure effects on CHA.

EFFECTS OF TRANSPORTATION NOISE ON MYOCARDIAL INFARCTION

Martin Röösli, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland*

Background and Aims: Both, traffic-related air pollution and noise exposure were found to increase the risk for myocardial infarction (MI). The effect of traffic noise exposure on MI was evaluated in a cohort study that also considered indicators for air pollution exposure.
Methods: In the Swiss National Cohort 4.6 million persons were followed from 2000 to 2005. Exposure to aircraft noise, background PM10 and distance to a major road was calculated (Huss, Epidemiology 2010). Results were compared with a population-based case-control study that was conducted in Stockholm County between 1992 and 1994 considering exposure to road traffic noise and NO2 in 3666 participants (Selander, Epidemiology 2009) as well as the Dutch Cohort Study on Diet and Cancer where road traffic noise, background black smoke and traffic intensity was measured for 121,000 subjects (Beelen, OEM 2009).
Results: In the Swiss study MI mortality was increased by 28% (95% CI: -5 to 73%) in the highest aircraft noise exposure category (>60dB). Close to major roads (<100 m) MI mortality was significantly increased by 10%. In the Swedish study the OR for MI was 1.12 (0.95–1.33) for long-term road traffic noise exposure (• 50 dB). The OR increased to 1.38 (1.11–1.71) in a subsample without hearing loss or exposure to noise from other sources. In the Dutch study ischemic heart disease mortality was increased by 15% (-14 to 53%) in the highest noise exposure category (>65dB). Interestingly no strong effect modification from air pollution was observed in the Swedish and the Swiss study whereas in the Dutch study the risk estimate dropped to unity when concurrently considering air pollution indicators in the model.
Conclusions: Epidemiological studies link traffic noise exposure to increased MI risk; although there is considerable uncertainty about the mutual effects of road traffic generated air pollution and noise exposure.

MATERNAL EXPOSURE TO AIR POLLUTION AND THE RISK OF THE CHILD DEVELOPING TYP1 DIABETES

Background and aims: The aetiology of type 1 diabetes [T1D] is not fully understood but it is widely accepted that genetic and non-genetic factors act together to initiate and accelerate the development of T1D. However, this could not explain the raid increase for T1D. One suggested environmental risk factor contributing to the development of T1D is air pollutants.
The aim of this birth cohort study was to investigate if maternal exposure low-level of air pollution was associated with the risk of the child to develop T1D.
Methods: High quality registry information on 81 110 births with individually modelled exposure data at residence for nitrogen oxides NO_x and proximity to roads with differing traffic density were linked to data for each child born after 1999 who had developed T1D prior to august 2010 and date of diagnosis where obtained from the Diabetes Centre in Malmö. The data were analyzed using logistic regression on the dichotomous variable T1D or not and survival analyses based on time of diagnosis.
Results: No extended risks of developing T1D if the child had been exposed prenatally for elevated levels of air pollutions were shown.
Conclusions: We saw no effect on the risk of the child developing T1D if the mother had lived in areas of higher levels of air pollution during pregnancy. Although in this study area the air pollution levels generally are well below the threshold levels set by World Health Organisation.

OCCUPATIONAL EXPOSURE TO DISINFECTANTS AND ADULT-ONSET ASTHMA IN U.S. NURSES – PRELIMINARY RESULTS

Nicole Le Moual: *Inserm, CESP Centre for research in Epidemiology and Population Health, U1018, Respiratory and environmental epidemiology Team, F-94807, Villejuif, France and Univ Paris Sud 11, UMRS 1018, F-94807, Villejuif, France*

Francine Kauffmann: *Inserm, CESP Centre for research in Epidemiology and Population Health, U1018, Respiratory and environmental epidemiology Team, F-94807, Villejuif, France and Univ Paris Sud 11, UMRS 1018, F-94807, Villejuif, France*
Carlos A. Camargo Jr: *EMNet Coordinating Center, Massachusetts General Hospital and Harvard School of Public Health, Department of Epidemiology, 326 Cambridge St, Suite 410, Boston, MA 02114 USA*

Background and Aims: Recent studies suggest a deleterious role of cleaning and disinfecting products on asthma in healthcare workers. Our aim was to examine the association between current occupational exposure to disinfectants and adult-onset asthma in nurses.
Methods: Out of 57,259 women from the Nurses' Health Study II who responded to the 2009 questionnaire and for whom data were already available (at 01/2011), we investigated the association between current job type and current exposure to disinfectants with adult-onset asthma, in 47,391 nurses without asthma at baseline (in 2007) and without missing values for exposures or job. The current use of disinfectants for instruments or surfaces (never(ref), <1day/week, 1-3days/week, 4-7days/week), and current job type: nursing in hospital units (education or administration(ref), ER or ICU, operating room, other inpatient nurse, outpatient, other hospital nursing), nursing outside hospital, non-nursing employment, retired or homemaker, were recorded in the 2009 questionnaire. Data analyses used multivariable logistic regressions, with adjustment for age, smoking status, and body mass index.
Results: New cases of adult-onset asthma was reported by 756 participants (two-year cumulative incidence, 1.6%), women had an average age of 55years, 63% were never smokers, and 43% had a BMI<25kg/m^2. Approximately 31% of nurses reported weekly exposure to disinfectants (12% reported exposure 4-7days/week), varying from 11% (3%, 4-7days/week) for nursing administrative to 70% (40%, 4-7days/week) for operating room nurses. We found significant positive association between occupational exposure to instrument or surface disinfectants and adult-onset asthma (OR [95%CI] for a use 4-7 days/week vs. never: 1.26 [1.01-1.57]). By contrast, no association was found between current job and adult-onset asthma.
Conclusions: Preliminary results from this large cohort study support the hypothesis that regular exposure to disinfecting tasks among nurses is an important risk factor for adult-onset asthma. Exposure to disinfectants may represent an important health issue among healthcare workers.

RELATIONSHIPS BETWEEN CHILD AND MOTHER PFC SERUM CONCENTRATIONS IN A POPULATION WITH PFOA EXPOSURE FROM DRINKING WATER

Debapriya Mondal, *London School of Hygiene & Tropical Medicine, United Kingdom*
Maria-Jose Lopez-Espinosa, *London School of Hygiene & Tropical Medicine, United Kingdom*
Ben Armstrong, *London School of Hygiene & Tropical Medicine, United Kingdom*
Tony Fletcher, *London School of Hygiene & Tropical Medicine, United Kingdom*

Background and Aims: There are few and small population studies on the level of exposure of newborns and children to perflurocarbons (PFCs), in particular perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS). Unlike adult exposure which is from food and water, important routes of exposure to infants and children are transplacental and breast-feeding. Transfer of PFCs from mothers to newborns has been demonstrated by their detection in maternal, cord, infant blood and breast milk. The aim of the present study was to describe the relationship between PFCs in serum in child-mother pairs in a population with high PFOA exposure from drinking water.

Methods: In the C8 Science Panel Community Health Study population, children aged < 20 years at the survey were matched to their mothers using identifiers such as name, date of birth and address. For the successfully matched pairs the relationship was investigated between child and mother PFC serum concentrations and possible modifiers - age of child, whether or not they still lived in a contaminated area after birth, level of mother's exposure and mother's breast-feeding practice-.

Results: The mothers and children in this study population could be matched up with a high degree of confidence for 5,589 children under 20, i.e.63% of the total sample, rising to 73% for those up to 5 years of age. The PFOA (mean 31.20 ng/mL) and PFOS (mean 19.15 ng/mL) serum concentrations in children were highly correlated (especially PFOA) and higher than the mother's serum concentrations (mean PFOA and PFOS: 26.97 and 13.34 ng/mL; rho=0.81 and 0.27, respectively). The child/mother PFOA ratio was higher from in utero and lactation exposure compared to infant exposure.

Conclusion: The relationship between mother's and children's PFC levels can provide insight into the relative importance of pre- and post-natal exposure for infants via the mother and the child's environment.

DETERMINANTS OF VALIDITY OF SELF-REPORTED BMI IN AUSTRIAN ADULTS

Franziska Großschädl, *Medical University of Graz, Division of Obstetrics and Maternal Fetal Medicine, Graz, Austria.*
Willibald Stronegger, *Medical University of Graz, Institute for Social Medicine and Epidemiology, Graz, Austria.*

Background and aim: Self-reported data on body weight and height are conflicting in adults. Therefore the aim of this study was to evaluate the validity of self-reported weight and height and to examine associated socio-demographic determinants.
Methods: Data of 473 Austrian adults (> 18 years) were collected standardised in a public outpatient in a city in southern Austria. We compared self-reported and anthropometric data on weight and height by different socio-demographic characteristics.
Results: Based on self-reported data on BMI the prevalence of overweight (BMI: 25 – 29.9 kg/m²) was overestimated, while those for obesity (BMI: > 30 kg/m²) was underestimated ($p < 0,001$). Anthropometric measurements revealed an overweight prevalence of 37,2% and an obesity prevalence of 12,5%. A multiple linear regression analysis was performed and demonstrated that age was the only significant predictor that was associated with the difference between measured and reported BMI ($p < 0.001$). The difference in the two oldest age groups increased significantly (age group 46 – 55 years: B = -0.39 kg/m², $p = 0.026$; age group 56 years and older: B = -0.70 kg/m², $p < 0.001$). Bland-Altmann plots also showed that the agreement between reported and measured BMI was lower in older study participants (mean difference: -0.60 kg/m², 95 % CI -2.64 kg/m² - 1.44 kg/m²).
Conclusions: Data on self-reported weight and height are a valid method for BMI estimates of overweight and obesity in epidemiological studies for younger adults. But they are limited for adults aged 46 years and older. Analyses based on self-reported data should therefore be adjusted for the age-dependency of the validity.

URINARY MARKERS OF FETAL EXPOSURES TO PHTHALATES AND PHENOLS AND RISK OF MALE GENITAL ANOMALIES, IN EDEN AND PELAGIE MOTHER-CHILD COHORTS

Background and Aims: Exposure during pregnancy to chemicals suspected to disrupt hormonal signalling may alter male reproductive organogenesis, which is controlled by sex hormones. Our aim was to assess the association between risk of hypospadias and undescended testis at birth and fetal exposure to phthalates and phenols.
Methods: We conducted a case-control study nested in two French mother-child cohorts (EDEN, PELAGIE) that enrolled pregnant women between 2002 and 2006. Cases were all boys members of the cohorts with hypospadias (n=21) or undescended testis (n=50) at birth. Three matched controls per case were selected among male singleton livebirths. Eleven phthalate metabolites and 9 phenols (EDEN cohort only) concentrations were measured in the pregnant mothers' urine collected between the 3rd and the 28th gestational week. Conditional logistic analyses adjusted for maternal age, parity, educational level, gestational duration and urinary creatinine were carried out.
Results: Prevalence ranged from 0.3% to 1.1% for hypospadias and from 0.7% to 5.1% for undescended testis according to residence area. Decreased risk of hypospadias, but not statistically significant, was observed with urinary concentrations of both low- and high-molecular-weight phthalate metabolites (p_trend, 0.13 and 0.10, respectively). No evidence of association (p_trend>0.10) with urinary concentrations of phthalates metabolites was observed for undescended testis risk. Risk of undescended testis increased with urinary concentrations of ethylparaben (OR_1st_tertile=reference; OR_2nd_tertile=1.5, 0.4-5.3; OR_3rd_tertile=2.9, 0.9-9.9; p_trend=0.08). Excluding preterm births led to similar conclusions.
Conclusions: Our study did not support an impact of fetal exposure to phthalates or bisphenol A on male genital tract development. It however pointed out a possible role of ethylparaben on testicular descent which needs to be replicated by further studies since it is not supported by animal data. Our study was limited by a modest sample size but provided prenatal exposure assessment (that covers the gestational window of male reproductive organogenesis).

PUBLIC HEALTH BURDEN OF TRIHALOMETHANES IN SELECTED EUROPEAN CITIES

Päivi Meriläien, *Institute of Health and Welfare, Finland*
Luca Bucchini, *Hylobates Consulting SRL, Italy*

Background and Aims: The selection of water treatment methods may have considerable implications for the microbial and chemical quality and furthermore the safety of tap water consumed by over 500 million people in Europe alone. Disinfection by-products (DBPs), which are formed during disinfection treatment of drinking water, may cause serious adverse health effects when exposed to the them. Therefore there is a public health concern on the DBPs in drinking water.
Methods: Disability adjusted life years (DALYs) were calculated for six European cities: Barcelona (Spain), Modena (Italy), Heraklion (Greece), Bradford (United Kingdom), and Kaunas (Lithuania). To estimate the risks of trihalomethas (THMs) due to tap water consumption via drinking, the risk was calculated for five different exposure scenarios including water filtering and different chlorination doses. Bladder cancer and small for gestational age (SGA) were selected to represent the adverse health outcomes of THMs in drinking water. The exposures from drinking water were calculated with Monte Carlo based modelling software Analytica by using Impact Calculation Tool, which was applied the population structure and growth estimates for each city.
Results: Risk estimates show that highest DALYs of bladder cancer and SGA are in Barcelona and Bradford, where the exposure is also highest. Intermediate exposure with lower DALYs is found in Heraklion and Kaunas, and low exposure with low DALYs in Modena. Filtration of drinking water reduces the exposure and DALY estimates significantly. DALY estimates are strongly dependent on the water treatment type such as chlorine dose during disinfection in water treatment.
Conclusions:
Health risks associated with DBPs in drinking water can be significant public health burden when the exposure levels are high. Even EU's regulatory reference concentration 100 µg/L can result in alarmingly high morbidity and mortality rates, especially when using current THM levels exposure is underestimate of life-time exposures.

THE RELATIONSHIP BETWEEN PAH/AROMATIC DNA ADDUCTS IN CORD BLOOD AND CHILD BEHAVIOR

Background. Airborne polycyclic aromatic hydrocarbons (PAH) are widespread urban pollutants from fossil fuel burning and other combustion sources that can bind to DNA to form PAH-DNA adducts. Prenatal PAH exposure measured by personal monitoring has been linked to cognitive deficits in childhood in a prospective study conducted by the Columbia Center for Children's Environmental Health (CCCEH).
Aims. We measured PAH-DNA and other bulky aromatic adducts in umbilical cord white blood cells using the ^{32}P-postlabeling assay to determine the association between this molecular dosimeter and behavioral/attention problems in childhood.
Methods. Children born to nonsmoking African-American and Dominican women residing in New York City (NYC) were followed from *in utero* to 7-8 years of age. At two time points prior to age 8 (mean ages 4.8 years and 7 years), child behavior was assessed using the Child Behavior Checklist (CBCL). To estimate and test the association between adducts and behavioral outcomes, both CBCL continuous raw scores and dichotomized T-scores were analyzed. Potential confounders were included as covariates in the models.
Results. Higher cord adducts were associated with higher symptom scores of Anxious/Depressed at 4.8 years and Attention Problems at 4.8 and 7 years, and with *Diagnostic and Statistical Manual of Mental Disorders (DSM*) oriented Anxiety Problems at 4.8 years.
Conclusions. These results are generally consistent with those using prenatally monitored levels of airborne PAH and suggest that PAH exposure, measured by DNA adducts, may adversely affect child behavior, potentially affecting school performance.

METHODS TO ASSESS SELENIUM EXPOSURE: EVALUATION OF DIETARY INTAKE AND BIOMARKERS IN MELANOMA PATIENTS AND POPULATION CONTROLS

Simone Storani, *Department of Public Health Sciences, University of Modena and Reggio Emilia, Italy*
Carlotta Malagoli, *Department of Public Health Sciences, University of Modena and Reggio Emilia, Italy*
Ilaria Bottecchi, *Department of Public Health Sciences, University of Modena and Reggio Emilia, Italy*
Angela Ferrari, *Department of Public Health Sciences, University of Modena and Reggio Emilia, Italy*
Marco Vinceti, *Department of Public Health Sciences, University of Modena and Reggio Emilia, Italy*

Background and Aims: Selenium is a metalloid of strong nutritional and toxicological importance, whose relation with risk of chronic diseases, including cancer, is still uncertain and currently under active investigation. Different methods to estimate selenium exposure in the human have been suggested, but their strengths and limitations are still controversial. We assessed selenium status in a group of melanoma and cancer patients, by evaluating their average dietary intake of the metalloid and its concentrations in plasma and toenails.
Methods: We investigated selenium status of 54 patients with newly-diagnosed cutaneous melanoma and 56 controls, originally enrolled in a population-based case-control study of environmental and life-style risk factors of cutaneous melanoma in Modena, northern Italy. We sampled subjects' blood and toenails and we administered a food frequency questionnaire including 248 questions on frequency and quantity of consumption of 188 food items, developed within the EPIC (European Prospective Investigation on Cancer and Nutrition) project in northern Italy. Plasma and toenail selenium concentrations were determined by atomic absorption spectrometry.
Results: In the overall study population, plasma selenium levels correlated with toenail concentrations (Spearman rank correlation coefficient (ρ) = 0.22, p=0.02), but these biomarkers were not associated with dietary intake of the metalloid. In subgroup analysis according to disease status, plasma selenium levels were associated with dietary intake only among cases (ρ=0.25, p=0.07), while plasma and toenail concentrations correlated both in cases and in controls.
Conclusions: Study results may be explained by intake of different selenium species in cases compared with controls, or more likely by differences in absorption and metabolism of selenium compounds between the two study groups. These findings suggest that the validity of methods assessing selenium exposure may vary according to disease status.

EXPOSURE MEASUREMENT ERROR DUE TO RESIDENTIAL MOBILITY DURING PREGNANCY

Susan Hodgson, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom*
Peter Lurz, *Institute for Research on Environment and Sustainability, Newcastle upon Tyne, United Kingdom*
Mark Shirley, *Institute for Research on Environment and Sustainability, Newcastle upon Tyne, United Kingdom*
Judith Rankin, *Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom & Regional Maternity Survey Office, Newcastle upon Tyne, United Kingdom*

Background and Aims: Pregnant women are a highly mobile group, yet recent studies suggest exposure error due to migration in pregnancy is minimal. However, the spatial and temporal variability of the exposure of interest, and the scale at which it is measured, are likely to influence the extent of error introduced. We aimed to investigate the impact of maternal residential moves on measurement error for exposures differing in their spatial and temporal variability.
Methods: Deliveries recorded by the Northern Congenital Abnormality Survey (NorCAS) during 2000-2008 were linked to the UK's National Strategic Tracing Service (NSTS) to provide address at conception. Data on continuous and discontinuous urban fabric were obtained at 100m resolution, and the proportion of each land class within a 500m buffer assigned to each postcode (conception and delivery). Total road length within each buffer was also calculated. We contrasted exposure to these variables based on conception versus delivery address.
Results: NorCAS registered 7428 deliveries during 2000-2008. Of these, 7227 (97.3%) were linked to the NSTS data, and postcode at conception and delivery geocoded for 6970 (93.8%). 1609/6970 women (23%) moved during pregnancy with a median moving distance of 1.7km. Amongst movers, 84% and 38% were 'exposed' to the same proportion (+/- 0-10%) of continuous and discontinuous urban fabric respectively, and 36% were exposed to the same length of road (+/- 0-250m) at conception and delivery.
Conclusions: Exposure does not differ between conception and delivery when assessed overall; increases in exposure in some are offset by decreases in others. Nonetheless, for exposures that show substantial spatial variation, a high proportion of pregnancies would have included measurement error if exposure was assigned at delivery rather than conception. For exposures with both spatial and temporal variability, such as air pollution, the probability of exposure error is likely to be higher.

INCREASED RISK OF CHILDHOOD LEUKEMIA IN COMMUNITIES IMPACTED BY HYDRAULIC FRACTURING IN THE MARCELLUS SHALE

Stephanie Moller Hikel, *Epidemiology International, USA*
Katherine Moon, *Epidemiology International, USA*
April Zambelli-Weiner, *Epidemiology International, USA*

Background and Aims: Hydraulic fracturing (HF) is a process by which water, chemical additives, and proppants are injected into geologic formations to facilitate oil and natural gas production from unconventional reservoirs such as shales and coalbeds. The US EPA recently issued a draft plan to examine the potential impacts of HF on drinking water resources, which includes the identification of areas with a high density of existing wells, evidence of impaired water quality, and human populations located in proximity to contaminated water. While the chemical composition of fracturing fluid is proprietary, and is currently unknown to the scientific community, typical fracturing solutions contain known leukemogens such as benzene. Our aim was to perform an exploratory analysis of potential health impacts in areas affected by HF, with a particular focus on risk of childhood leukemia.
Methods: We performed a standardized incidence ratio (SIR) analysis examining the incidence of childhood leukemia in four Pennsylvania counties overlying the Marcellus Shale and meeting the EPA criteria for HF-impacted areas. Expected rates were calculated based on age- and sex-adjusted data from the Surveillance, Epidemiology, and End Results (SEER) Program.
Results: From 1998-2007, a total of 40 leukemia cases were diagnosed in children aged 19 years or younger, which was more than four times higher than expected compared to national rates (SIR=4.08, 95% CI: 2.91-5.55). Individual county SIRs ranged from 2.64-4.91, with all CIs exclusive of 1.0. Subtype analyses revealed the majority of leukemias to be of lymphocytic origin.
Conclusions: Our analysis demonstrates highly increased risks of childhood leukemia in counties with a high density of HF wells and evidence of water contamination due to HF. These data suggest that EPA's recent concerns regarding HF are well-founded, and that children may be particularly susceptible to the adverse effects of HF on water quality.

CHILD NEURODEVELOPMENT IN A BOLIVIAN MINING CITY

Background and Aims: This study evaluates the neurodevelopment of children living near highly contaminated mining industries during their first year of life.

Methods: Participants from the city of Oruro (Bolivia) were prospectively recruited during pregnancy and followed-up between May 2007 and November 2009. Questionnaires were used to obtain information regarding the pregnant women's socioeconomic status, as well as anamnesis. Neurodevelopment was tested on 246 children using the Bayley Scales of Infant Development (BSID) at 10.5 to 12.5 months of age. Trace elements (Pb, As, Cd, Sb, Cs, Zn, Fe, Cu, Se, Rb, Sr) exposure during prenatal life was evaluated by testing maternal blood concentrations before delivery.

Results: The blood lead concentration of pregnant women was low, considering the contaminated environmental context. The geometric mean was 1.85µg/dL (95% IC: 1.71; 2.00), a level almost comparable with those observed in non contaminated areas. The only element found to be relatively elevated was antimony, with 1.03µg/dL (95% IC: 0.94; 1.13). The Bayley Scales of Infant Development (BSID) did not reveal mental or psychomotor abnormalities associated to blood levels of trace metals during pregnancy. Almost all levels were lower than the control limits.

Conclusion: Our results suggest that women from this mining area were poorly exposed.

MODELING OF CRITICAL EPISODES OF AIR POLLUTION FOR PM10 IN SANTIAGO DE CHILE. COMPARISON OF THE PREDICTIVE EFFICIENCY OF PARAMETRIC AND NON-PARAMETRIC STATISTICAL MODELS

Sergio Alvarado O., *División de Epidemiología, Escuela de Salud Pública, Facultad de Medicina, Universidad de Chile - Grups deRecerca d'America i Africa Llatines, UnitatdeBioestadística, FacultatdeMedicina, Universitat Autònoma de Barcelona,Barcelona,España*

Dante D. Cáceres L., *División de Epidemiología, Escuela de Salud Pública, Facultad de Medicina, Universidad de Chile - Grups deRecerca d'America i Africa Llatines, UnitatdeBioestadística, FacultatdeMedicina, Universitat Autònoma de Barcelona,Barcelona,España*
Claudio Silva Z., *División de Epidemiología, Escuela de Salud Pública, Facultad de Medicina, Universidad de Chile*

Backgrounds and aims: To evaluate the predictive efficiency of two statistical models (one parametric and a non-parametric one) to predict critical episodes of air pollution levels by PM10 the after day above national standard. A suitable prediction of such episodes allows the authority to apply restrictive measures that diminish the gravity of the episode with the objective to protect to the health of the community.
Methods: We used PM10 concentrations registered by Net of Air Quality Monitoring during 2001 to 2004, and meteorological information collected during this period considering 14 variables and 152 observations. We fitted a parametric Gamma using STATA v10 software and a non-parametric MARS models using a demo version of Salford-Systems for the construction of predictive models.
Results: In general, both models presented a high correlation between observed and predicted values. However, Gamma model predict in a better way values < 240 ($\mu g/m^3$) of PM10 better than MARS. The last one was more efficient to predict values above 240 ($\mu g/m^3$) of PM10 during the period studied.
Conclusion: MARS model are more efficient to predict extreme values and therefore it would be considered by the sanitary authority to take a more precise decision in a preventive way to avoid critical episodic conditions of air pollution by PM10 in short time and consequently the probable effects on health status. This would be explained because MARS corrects the changes of the series throughout the time fitting the best to the curve associated with the concentration of PM10.

MEASUREMENTS OF INDOOR MAGNETIC FIELDS IN APARTMENT BUILDINGS WITH IN-BUILT TRANSFORMER ROOMS

Anke Huss, *IRAS, University of Utrecht, The Netherlands*
Kelly Goris, *IRAS, University of Utrecht, The Netherlands*
Roel Vermeulen, *IRAS, University of Utrecht, The Netherlands*
Hans Kromhout, *IRAS, University of Utrecht, The Netherlands*

Background and Aims Transformers in apartment buildings might represent an important source of magnetic field exposure for inhabitants. Previous research has indicated that classification of apartments into those directly on top or further away from the transformer room might provide a simple approach for classification into "high" and "low" exposure categories for use in epidemiological studies, as proposed for the international epidemiologic investigation of childhood leukaemia (TransExpo). However, transformer room and building layouts may differ across regions /countries and these results do not necessarily apply everywhere. We aimed at assessing magnetic flux density in buildings with in-built transformers in The Netherlands.
Methods: We performed measurements in 35 apartments in 14 buildings. We took spot measurements of the magnetic flux density in the apartments; 0.5m above the floor, 1.4m from corners and in the middle of each room.
Results: Spot measurements of magnetic flux density yielded a median of 0.17μT (IQR 0.06-0.45) in the apartments (n=7) located directly on top of transformer rooms, 0.09μT (IQR 0.05-0.15) in apartments on the second floor (n=5) and 0.06μT (IQR 0.04-0.10) in apartments located further away (n=23). Apartments placed adjacent to a transformer room had a median of 0.09μT (IQR 0.06-0.38). Maximum magnetic flux densities were encountered in an apartment on top and in an apartment adjacent to a transformer room with 5.7 and 18.8 μT, respectively.
Conclusions: Placement of an apartment relative to the transformer room provided a maximum two-fold contrast in median exposure. Higher, very localized exposures were observed in apartments on top or adjacent to transformer rooms.
Whether or not magnetic field exposure from a transformer room adds considerable to an individual's exposure would therefore depend highly on where most time is spent in the apartment.

MERCURY, THYROTROPIN, AND THYROID AUTOANTIBODIES IN U.S. WOMEN, USNHANES 2007-2008

Carolyn M. Gallagher, *Stony Brook University, Stony Brook, NY, USA*
Jaymie R. Meliker, *Stony Brook University, Stony Brook, NY, USA*

Background and Aims: Mercury accumulates in the thyroid gland, and mercury exposure has been associated with cellular autoimmunity. Elevated thyrotropin coincident with positive thyroid autoantibodies has strong predictive value for hypothyroidism, a disorder more prevalent among women and most commonly caused by autoimmune thyroiditis. The association between thyrotropin, thyroid autoantibodies, and mercury has not been evaluated in epidemiologic studies.
Methods: Data on mercury, thyrotropin, thyroglobulin autoantibodies (TgAb), thyroid peroxidase autoantibodies (TPOAb), and urine iodine (UI) were obtained from the 2007-2008 US National Health and Nutrition Examination Survey files for adult women (n=31,874). We used multiple logistic regression to evaluate the association between mercury and elevated thyrotropin coincident with thyroid antibody positivity in younger (20-59 years) and older (60+ years) women, adjusted for demographic factors, nutrient intake, UI, and stratified by World Health Organization thresholds for iodine deficiency and excess.
Results: Among younger women, relative to women in the lowest Hg quintile (<0.46 µg/L), women with Hg >2.06 µg/L (upper quintile) showed 2.37 (95% CI=1.28, 4.40) greater odds for elevated thyrotropin (>4.0 • IU/mL) coincident with thyroid antibody positivity. Among women with iodine deficiency, those with Hg >2.06 µg/L showed 4.97 (95% CI=1.23, 20.06) greater odds for thyroid antibody positivity coincident with thyrotropin >4.0 • IU/mL. Unlike thyrotropin or TPOAb, TgAB positivity alone was consistently associated with mercury, with an odds ratio above 2.00 for the upper quintile of mercury in overall sample and all sub-groupings of women.
Conclusions: We report a novel association between mercury and elevated thyrotropin coincident with positive thyroid autoantibodies, a strong predictor for hypothyroidism (positive predictive value=86%). Strongest associations were observed among women aged 20-59 and among women with iodine deficiency, and appeared to be driven by TgAB positivity. Further research into mercury, hypothyroidism and autoimmunity is warranted.

MOVING OUT OF CARS AND ONTO BIKES: IMPACT ON HEALTH, AIR POLLUTION AND GREENHOUSE GAS EMISSIONS IN THE NEW ZEALAND URBAN SETTING

Graeme Lindsay, *University of Auckland, New Zealand*
Alex Macmillan, *University of Auckland, New Zealand*
Alistair Woodward, *University of Auckland, New Zealand*

Background and Aims: To estimate the effects on health, air pollution and greenhouse gas emissions if short trips (• 7 km) by adults in the New Zealand (NZ) urban setting were undertaken by bicycle rather than motor car.

Methods: Existing data sources and a number of modelling tools were used to estimate the effects of shifting varying proportions (1-30%) of vehicle kilometres travelled light motor vehicle to bicycles. Modelling tools included the WHO Health Economic Assessment Tool for Cycling to estimate mortality benefits from increased physical activity and Jacobsen's 'Safety in numbers' factor for effects on injury.

Results : A 5% shift of vehicle kilometres to bicycles would return cycling to the levels seen in NZ in the 1980s, reduce vehicle travel by approximately 223 million kilometres each year, save about 22 million litres of fuel and reduce transport-related greenhouse gas emissions by 0.4%. The health effects would include about 116 deaths avoided annually as a result of increased physical activity, six fewer deaths due to local air pollution from vehicle emissions, and potentially an additional five cyclist fatalities from road crashes. In economic terms, including only fatalities and using the NZ Ministry of Transport Value of a Statistical Life, the health effects of a 5% shift represent net savings of about NZ$200 million per year. In addition, a 5% shift would expend about 19 billion kilojoules of energy over baseline resting metabolic rate.

Conclusions: The health benefits of moving from cars to bikes heavily outweigh the costs of injury. For fatalities, the benefit:cost ratio is 3:1 for 1% substitution and over 40:1 when 30% of vehicle trips are substituted.

USING HEALTH IMPACT ASSESSMENT TO TRANSLATE EPIDEMIOLOGICAL EVIDENCE INTO POLICY RECOMMENDATIONS: HEALTH IMPACTS OF A CAP-AND-TRADE PROGRAM IN CALIFORNIA

Maxwell Richardson, MPH, MCP, *California Department of Public Health, United States*
Dr. Paul English, PhD, MPH, *California Department of Public Health, United States*
Dr. Linda Rudolph, MD, MPH, *California Department of Public Health, United States*

Background and Aims: A cap-and-trade program was initiated in California to reduce greenhouse gas emissions to 1990 levels by the year 2020. Legislation also maximize that public health co-benefits be maximized to ensure that vulnerable communities are not disproportionately impacted. The California Department of Public Health performed a health impact assessment and suggested mitigations to minimize health risks while improving health benefits
Methods: The HIA stakeholder process included the 5 stages of screening, scoping, assessment, recommendations, and reporting. Stakeholder-identified health determinants included changes in employment, changes in energy costs, environmental health impacts from emission offset projects, and benefits from the distribution of program revenue. Air-related health impacts were assessed separately as part of the regulatory process. Economic modelling results were used as the basis for qualitatively assessing potential health impacts from a cap-and-trade program in California.
Results: Overall, the potential health effects from a cap-and-trade program in California are expected to be negligible to minor. Health co-benefits can be improved by limiting the use of emission offsets, maximizing the auction of emission allowances, and directing community investments to vulnerable communities. Environmental health monitoring needs to be enhanced to ensure that no population bears a disproportionate health impact from a cap-and-trade program. Due to data limitations, it is difficult to quantify community-level health impacts from a cap-and-trade program, though local impacts are expected to vary.
Conclusions: The health impacts of a cap-and-trade program are largely neutral, though low-income populations may have the least ability to adapt to changes in air emissions, labor shifts, and rising energy costs to the extent that they occur. Mitigation efforts should focus on risk reduction and health promotion, especially among vulnerable populations. HIA proved a useful tool in translating epidemiological evidence into policy recommendations in a highly political regulatory process.

COLD SPELLS AND HOSPITALIZATIONS DUE TO HYPOTHERMIA: UNRECOGNIZED THREATS FOR ELDERLY WITH DIABETES

Alexander Liss, *Boston Financial Research, USA*
Elena Naumova, *Tufts University, USA*

Background and Aims: Climate variability has the potential to substantially increase the number and intensity of extreme weather events worldwide. Extreme cold spells are causing hypothermia, a relatively common but preventable condition, resulting in significant morbidity. This presents an important socio-economic problem for vulnerable populations. We describe functional relations with meteorological conditions and spatial-temporal patterns of hospitalizations due to hypothermia in the older adults residing in the USA.
Methods: 10,522 hospitalization records due to hypothermia (95%) and frostbites (ICD-9M:991,E9583,E9883,E901) in patients aged 65+y.o. were abstracted from MEDPAR files maintained by the Center of Medical Services for 2005-2006. Each record includes patient's age, sex, race, residence, 10 diagnostic codes, and total hospitalization charges. Daily meteorological parameters were abstracted from 1,979 stations nationwide and windchill indexes were estimated. Age- and zipcode-specific rates of hospitalizations were calculated for 3 age groups (65-74, 75-84, and ≥85y.o.), 5 racial groups, and 7 climatic areas based on the modified Köppen classification system. Relative risks (RR) associated with low temperature and windchill indexes were estimated using non-linear regression models, considering effect modification by age, race, and climatic conditions.
Results: The rate of hypothermia was increasing with age from 4.09 [95%CI: 3.08,5.44] to 8.48 [95%CI: 7.03,10.23] and 24.78 [95%CI: 22.12,27.75] in older adults. Patients with diabetes, Black and Native American males, residents of polar tundra and areas with wet winters have the highest rates. Irrespective of age, RR of hypothermia associated with 5℃ was 1.22 [95%CI:1.26;1.15]. Median cost of a hospitalization event was $13,260 [IQR:$7,240,$25,276].
Conclusions: Patient's age, race, place of residence, and co-morbidity (most notable the diabetes) have substantial impacts on frequency, duration, and costs associated with treating hypothermia. Preventive efforts targeted at vulnerable populations and regions are needed to reduce hypothermia hospitalizations. Allocation of resources to a growing segment of elderly with diabetes is warranted.

SURVEILLANCE OF AGRICULTURAL PESTICIDE USE AND POTENTIAL ENVIRONMENTAL EXPOSURE

Nichole Garzia, *University of British Columbia, Canada*
Karla Poplawski, *University of British Columbia,Canada*
Anne-Marie Nicol, *University of British Columbia, Canada*
Paul Demers, *Occupational Cancer Research Centre, Toronto, Canada*

Background and Aims: Limited information exists on pesticide exposure in Canada, and some of the most prevalently used pesticides are classified as "possible" carcinogens by the International Agency for Research on Cancer (IARC). The objective is to characterize environmental exposure to "possibly" carcinogenic IARC pesticides used for agriculture in Canada.
Methods: Region-specific annual agriculture use (AAU) estimates for selected pesticides are derived by multiplying crop production areas (hectares) obtained from the Interpolated Census of Agriculture (2006) by crop-specific intensity use weights (grams/hectare per year) developed using national and provincial pesticide use information. Total AAU (tonnes) is derived for each pesticide as the sum of active ingredient used on all crop types within a sub-provincial region. Regional estimates are mapped using a Geographic Information System (GIS). Population estimates corresponding to sub-provincial AAU estimates are determined using Census of Population (2006) data. These estimates represent the number of persons at risk of environmental exposure to "possibly" carcinogenic pesticides, by exposure potential (i.e. AAU estimate).
Results: AAU estimates were derived for chlorothalonil in Western provinces: British Columbia (BC), Alberta (AB), Saskatchewan (SK). Regions that use chlorothalonil were classified into four 'usage groups' based on AAU (tonnes) quartile distribution: Low (>0-21), Low-Medium (>21-82), Medium-High (>82-273), High (>273-1597). The percent of the total provincial population living in 'High' chlorothalonil use regions are approximately: 16% (n=595,353) for BC; 24% (n=790,014) for AB; and 62% (n=594,712) for SK. When mapped, the regions in which these populations reside are identified. Regions with no chlorothalonil use were classified as 'no use' (0 tonnes); corresponding populations were considered to not be at risk (62% of BC population; 54% of AB population; 5.6% of SK population).
Conclusions: Surveillance of IARC "possible" carcinogenic pesticides provides knowledge on environmental exposure potential, in terms of geographic variation and extent (population counts) across Canada.

SURVEILLANCE OF POTENTIAL ENVIRONMENTAL EXPOSURE TO GOLF TURF PESTICIDES

Karla Poplawski, *University of British Columbia, Canada*
Nichole Garzia, *University of British Columbia, Canada*
Anne-Marie Nicol, *University of British Columbia, Canada*
Paul Demers, *Occupational Cancer Research Centre, Toronto, Canada*

Background and Aims: In Canada, golf courses are often permitted continued use of pesticides banned for cosmetic purposes, including those classified as "possible" carcinogens by the International Agency for Research on Cancer (IARC). As part of a National Carcinogen Surveillance Project (CAREX Canada), we geographically estimate environmental exposure potential for "possibly" carcinogenic pesticides applied to golf turf in Canadian watersheds.
Methods: Pesticide type, application frequency, and course size were obtained from Canadian Golf Superintendents' Association surveys (2004, 2008). Estimated annual use (kilograms active ingredient) were calculated using product label application rates from the Pest Management Regulatory Agency. A Canadian golf course database was compiled in a geographic information system (GIS) from national landuse, business directories and online sources. GoogleEarth was used to verify locations and rank courses by relative surrounding housing density (n): Low 0-2; Low-Medium 2-10; Medium-High 10-20; High >20. A method to develop an average course perimeter polygon for estimating adjacent populations is being developed.
Results: Data sources of course locations were frequently inadequate. Locations were corrected to more accurately assess adjacent housing density. We identified three IARC "possible" carcinogens being used: 2,4-D, MCPP and chlorothalonil. Average annual use was calculated for a typical course and multiplied by number of courses in each watershed. For example, an average course applies 158 kg chlorothalonil annually. We identify hotspot watersheds, such as that in Western Canada using up to 19,586 kg (lower Fraser Valley). Percentage of courses with highest surrounding housing density varies by province: 11.8% British Columbia, 8.6% Alberta, and 1.4% Saskatchewan. Exposure surveillance information is disseminated in map format for comparison within and across provinces.
Conclusions: We geographically assess golf course pesticide use across Canada at the watershed level to identify areas with greatest potential for environmental exposures. Ongoing research will provide more detailed population estimates that account for residential proximity to golf courses.

ESCAPE LUR DEVELOPMENT AT TWO DIFFERENT SCALES: CATALUNYA AND BARCELONA AREAS

Audrey de Nazelle, *Centre for Research in Environmental Epidemiology, Barcelona, Spain*
Marta Cirach, *Centre for Research in Environmental Epidemiology, Barcelona, Spain*
Rob Beelen, *Institute for Risk Assessment Sciences, Utrecht, The Netherlands*
Gerard Hoek, *Institute for Risk Assessment Sciences, Utrecht, The Netherlands*
Kees De Hoogh, *MRC-HPA Centre for Environment and Health, Imperial College of London, London, UK*
Mark Nieuwenhuijsen, *Centre for Research in Environmental Epidemiology, Barcelona, Spain*

Background/Aims: The objective of the study was to develop land use regression (LUR) models at two different scale levels (Catalunya and Barcelona) within the framework of ESCAPE project for assessment of long-term population exposure to air pollution.
Methods: Following the ESCAPE protocol we selected 80 locations spread over Barcelona (40), Sabadell (16) and Girona area (24) and collected NOx/NO_2 levels using passive samplers (Ogawa). We took 14-days measurements in 3 different seasons during 2009 in order to calculate the annual average. We also sampled NO_2 continuously during the year on a fixed station in each area for time adjustment.
We gathered geographical information and created predictor variables at each site using ArcGis 9.2. Using multiple linear regressions, we constructed models for the Catalunya and Barcelona areas separately.
Results: The Barcelona model (40 sites) explained 72% of the intraurban NO2 variability using four variables: high density residential area within 300 m, inverse distance to the nearest major road, inverse distance to the nearest street plus traffic intensity on that street and total length of road within 1000m. The Catalunya model explained 70% of the NO2 variability using three variables: roadlenght1000, traffic intensity within 25m and natural area within 5000m. Results for NOx were similar.
Conclusion: As part of the Europe wide ESCAPE project we have LUR models for Barcelona and Catalunya that can be linked to epidemiological studies in the study areas. Further work will include the comparison of these models with other LUR and dispersion models in the areas.

IMPACT OF AIR POLLUTION AND TRANSPORTATION NOISE ON BLOOD PRESSURE IN THE SWISS STUDY ON AIR POLLUTION AND LUNG AND HEART DISEASES (SAPALDIA)

Background and Aims: Air pollution has been associated with cardiovascular endpoints previously, however, the impact on blood pressure remains controversial. Positive associations have been found in studies on short-term ambient and personal measures, while studies using long term ambient air pollution largely fail to show an association. We aimed at investigating the association between long-term ambient air pollution and blood pressure and potential confounding or interaction by transportation noise.
Methods: Blood pressure was measured in 6450 SAPALDIA participants, age 29-73. Annual average ambient air pollution exposure (µg/m3) of the year prior to exam was predicted by dispersion (PM10, source specific PM10, PM2.5) and a hybrid land-use regression model (NO2). Multivariable linear regression was run, adjusting for potential confounders and predictors of hypertension. Interaction between transportation noise and air pollution is to be tested.
Results: We found borderline significant negative associations for each of the PM estimates, with exception of railway specific PM10. For SBP the largest negative estimate was found for traffic specific PM10 (β= -0.40, 95%CI -0.85;0.05), then PM2.5 (SBP β= -0.19, 95%CI. -0.39;0.01) and the least by PM10 (SBP β= -0.11, 95%CI -0.25;0.02). Effects estimated for DBP are at -0.02 with varying CI for all exposures variables. Railway specific PM10 was positively associated with blood pressure and highly collinear with railway noise. Railway noise was a significant covariate positively associated with SBP and DBP.
Conclusion: The first preliminary analyses yielded consistent negative associations with blood pressure for all traffic related air pollution indicators. The air pollution effect was not confounded by noise. Further analyses, testing additional potential confounders and a vulnerable population approach are underway trying to explain the observed inverse associations. Different exposure time windows will be tested next to capture the actual long-term effect and potential interaction between PM and transportation noise will be investigated.

ELABORATION AND APPLICATION OF A NEW HIERARCHICAL CLASSIFICATION ALGORITHM IN EPIDEMIOLOGICAL RESEARCH

Ekaterina D. Konstantinova, *Institute of Industrial Ecology, Russia*
Anatole N. Varaksin, *Institute of Industrial Ecology, Russia*

Background and Aims: Most noninfectious diseases are caused by a potential influence of a range of risk factors (RF) (100 factors and more) on health. However, only a few those (3 to 5) have a significant influence. The identification of a main RF set is solved by means of multivariate statistical analysis. These methods work well in case of statistically independent RF and when their joint effect is amenable to a clear interpretation. The condition of RF independence is often violated in observation studies where it is impossible to vary experimental conditions.
Methods: In this report, new algorithm to look for main RF set is presented. The algorithm is based on a hierarchical classification method and allows:

- finding small RF sets that produce maximal influence on population health;
- creating decision rules for describing a "generalized image" of the sick and the healthy that would be clear to physicians;
- finding ways to compensate the negative influence of significant RF.

To carry out calculations, an epidemiological database gathered during 2002-2010 for Ekaterinburg preschool children (1300 children) is used. Basic diseases are determined at medical inspection for every child. Levels of atmospheric pollution are measured; data on 50 family-based RFs of health impairment are obtained using parent's questionnaire.
Results: We have identified sets of 3-4 RFs having a maximal negative influence on the prevalence of respiratory, cardiovascular, and musculoskeletal diseases and behavior disorders in children. These factors are: atmospheric pollution, gas-stove in apartment, parent smoking, low-quality drinking water, child's insufficient physical activity, mother's low educational attainment.
Conclusions: The suggested variant of stepwise hierarchical algorithm allows obtaining effective and evident decision rules for classifying children into low and high pathology prevalence categories using 3-4 RF. The algorithm allows one to find factors reducing the adverse impact of environmental contamination on population health.

THE EFFECT OF RELEVANT GENOTYPES ON HEMOGLOBIN ADDUCTS OF ACRYLAMIDE AND GLYCIDAMIDE IN WORKERS EXPOSDE TO ACRYLAMIDE

Shi-Nian Uang, *Institute of Occupational Safety and Health, Taiwan*

Background and Aims: Acrylamide (AA) is an industrial chemical widely used in industries and also an environmental chemical found in tobacco smoke and food. It is classified as a probable human carcinogen (Group 2A) by the IARC. AA undergoes metabolism to glycidamide (GA). Both AA and GA react with hemoglobin (Hb) to form adducts (AA-Hb and GA-Hb), and these adducts are considered as biomarkers for long-term AA exposures. This study elucidates associations between AA- and GA-Hb adducts as well as their ratio with genetic polymorphisms *CYP2E1*, *mEH* (in exon 3 and exon 4), *GSTT1*, and *GSTM1*, involved in the activation and detoxification of AA-associated adducts.

Methods: Fifty-one AA-exposed workers and 34 controls were recruited and provided a post-shift blood sample for this study. Personal air sampling was performed for the exposed workers. AA- and GA-Hb were determined simultaneously using isotope-dilution liquid chromatography-electronspray ionization/tandem mass spectrometry (LC-ESI-MS/MS). *CYP2E1*, *mEH* (in exon 3 and exon 4), *GSTT1*, and *GSTM1* were analyzed using polymerase chain reaction.

Results: Our results reveal that AA personal exposures ranged from 4.37×10^{-3} to 113.61 μg/m^3 with a mean at 15.36 μg/m^3. The AA- and GA-Hb levels in the exposed group significantly exceed those in controls. The ratio of GA-Hb/AA-Hb, potentially reflecting the proportion of AA metabolized to GA, was calculated with a mean of 0.27 and in the range of 0.13-0.45. Multivariate regression analysis demonstrate that *GSTM1* genotypes significantly modify the formation of GA-Hb and the GA-Hb/AA-Hb ratio, polymorphism of exon 4 of *mEH* were all significantly associated with AA-Hb, GA-Hb levels and the GA-Hb/AA-Hb ratio after adjustment for AA exposures.

Conclusions: These results suggest that *GSTM1* and/or *mEH* associated with the formation of blood AA-Hb and GA-Hb. Further studies may be needed to cast light on the roles of both enzymes in AA metabolism.

PRENATAL EXPOSURE TO PCBS AND RISK OF WHEEZING IN CHILDREN: A RELATIONSHIP MODIFIED BY DIET DURING PREGNANCY?

Background and aims: Prenatal exposure to organochlorine compounds (OCs) has been related to immune function and adverse effects on respiratory health. For polychlorinated biphenyls (PCB), associations with respiratory outcomes have been heterogeneous. Given the hypothesis that effects of PCBs may be influenced by dietary factors, we aimed to assess whether maternal diet in pregnancy may modify associations between PCBs and infant wheezing.

Methods:657 mother-child pairs participated in the INMA (Environment and Childhood) population-based birth cohort study in Sabadell (Spain). Wheezing was defined based on maternal reports at age 6 and 14 months. First trimester diet, assessed by a validated questionnaire, was used to derive diet patterns using factor analysis. A “healthy” pattern was identified which discriminated mothers with higher fruit/vegetable and fresh fish intakes, and lower intakes of pastries; scores were dichotomized at the median. PCB exposure (∑PCBs) in first trimester maternal serum was calculated as the sum of lipid-adjusted congeners 118, 138, 153 and 180 and log-transformed. Poisson regression was used to estimate relative risks (RRs) for associations between wheezing and PCBs, adjusting for confounders including other OCs.

Results: Wheezing was present in 34% of the children. Overall, no association between ∑PCBs and wheezing was observed. Interaction between ∑PCBs and a healthy diet pattern was significant ($p<0.05$). In women with less healthy diets, ∑PCBs were positively associated with wheezing (RR=1.89, 1.13-3.15). However, in women with high healthy diet scores, ∑PCBs were not significantly associated with wheezing (RR=0.83, 0.52-1.32). No such interaction with individual food groups, including fruits, vegetables and fish, was observed.

Conclusions:

Results suggest prenatal PCB exposure may increase risk of infant wheezing among women with less healthy diets. The absence of interaction by food groups suggest that global dietary patterns, rather than specific food groups, plays a role. Replication should be performed to confirm these findings.

OUTDOOR AIR POLLUTION AND ITS EFFECTS ON ALLERGIC DISEASES IN AN INDUSTRIAL CITY OF KOREA

In-Bo Oh, *Environmental Health Center, University of Ulsan, Korea*
Ji Ho Lee, *Department of Occupational and Environmental Medicine, University of Ulsan College of Medicine, Korea*
Chang Sun Sim, *Department of Occupational and Environmental Medicine, University of Ulsan College of Medicine, Korea*
Cheol-In Yoo, *Department of Occupational and Environmental Medicine, University of Ulsan College of Medicine, Korea*
Yangho Kim, *Department of Occupational and Environmental Medicine, University of Ulsan College of Medicine, Korea*

Background and aims: The prevalence of allergic diseases (AD) has significantly increased in recent decades. Outdoor air pollution can be considered as an important environmental risk to the increased prevalence of AD. This study aims to identify the major risk factors for childhood AD by a unique and standard ISAAC questionnaire and investigate relationship between outdoor air pollution and the AD prevalence in an industrial city of Ulsan in Korea.
Methods: Data on the physician-diagnosed prevalence in the past 12 months and potential risk factors of AD (asthma, allergic rhinitis and atopic dermatitis) were collected in 2009 and 2010 from the survey of 4,067 schoolchildren (grades 1-6) living near and far from industrial area. Exposure to outdoor air pollution was estimated by using annual mean concentrations of pollutants (PM_{10}, O_3, NO_2, SO_2 and CO) obtained from monitoring sites near the participant's residence. All data were analyzed with SPSS 18.0 and odds ratio was calculated by logistic regression analysis to estimate the independent effect of each study factor on AD.
Results: Current prevalence of AD was most strongly associated with parental AD history and place of residence. After adjusting for the parental AD history and other significant factors, we observed that the AD prevalence ratio for polluted urban area near the industrial complex as compared with the suburban was 1.39 (95% CI: 1.16–1.67). Statistically significant and robust association between air pollution levels and the prevalence of AD were also found both before and after adjustment by confounders. The adjusted odd ratio for the pollution effects were 1.24 (95% CI: 1.04-1.47) and 1.90 (95% CI: 1.23-2.93) with increase in PM_{10} level of 10 $\mu g/m^3$ and O_3 level of 10 ppb, respectively.
Conclusions: Although there should be other risk factors for AD, these results suggest that living in polluted area and exposure to high levels of air pollutants can contribute to the increased risk of childhood AD.

THE EFFECT OF COARSE PARTICLES, MAINLY ROAD DUST, ON DAILY MORTALITY IN STOCKHOLM

Kadri Meister, *Umeå University, Sweden*
Christer Johansson, *Environment and Health Administration, Stockholm City and Stockholm University, Sweden*
Bertil Forsberg, *Umeå University, Sweden*

Background and Aims: Numerous epidemiological studies have been published on health effects associated with PM_{10} and $PM_{2.5}$. Research on the health effects of coarse particles with aerodynamic diameter between 2.5 and 10 µm ($PM_{2.5-10}$) is limited. Our aim was to study the short-term effects of coarse fraction to daily mortality and morbidity in Greater Stockholm area. The concentrations of coarse particles in this region are relatively high in comparison with other cities in Europe. The particles consist largely of crustal materials and the main source during winter and springtime is the wear of road surfaces caused by studded tires.
Methods: Data on daily mortality in Greater Stockholm area (population approx.1.3 mil.) for 2000 - 2008 were collected from the Cause of Death Register at the National Board of Health and Welfare. On average there are 28.4 deaths per day (min=12, max=52). PM_{10} and $PM_{2.5}$ were measured simultaneously at an urban monitoring site in central Stockholm. $PM_{2.5-10}$ was calculated as the difference between PM_{10} and $PM_{2.5}$ and the average concentration was 7.3 µg/m^3 (min=0, max= 61.9 µg/m^3). We used additive Poisson regression models, controlling for trend and seasonality, meteorological variables and influenza episodes. Lag 01 single and multi-pollutant models (with $PM_{2.5}$, O_3 and CO) were considered.
Results: For winter and spring (Nov-May) we found a 0.91% (95% CI: 0.11% to 1.72%) increase in daily mortality per IQR (5.25 µg/m^3) increase in $PM_{2.5-10}$ (lag01) from the single pollutant model. When adjusted for other pollutants, particularly for $PM_{2.5}$, the effect estimate slightly decreased, but was higher than the estimate for $PM_{2.5}$.
Conclusions: Our analysis shows an increased mortality associated with coarse particles, in Stockholm originating mainly from road dust caused by the use of studded tires. Our estimates indicate around 30 premature deaths per year due to coarse particle exposure in Stockholm.

DETERMINANTS OF DENTINE LEAD LEVELS IN CHILDREN LIVING IN NEWCASTLE UPON TYNE

Charuwan Manmee[1], Susan Hodgson[1], Wendy Dirks[2], Thomas Shepherd[3] and Tanja Pless-Mulloli[1]
[1]Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Oral Biology, School of Dental Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]School of Earth and Environment, University of Leeds, Leeds, United Kingdom

Background and Aims: Lead is a toxic environmental contaminant, associated with irreversible health effects in children who are susceptible due to their developing physiology and behaviour. Research on the association between lead and cognitive impairment in children suggests that there is no safe level of lead exposure. In the UK, studies have found differences in children's tooth lead levels by social class, but little evidence of determinants of exposure. This study aimed to use dentine lead levels (DLLs) to explore determinants of lead exposure in children living in Newcastle upon Tyne, a historically heavily industrialised city in the UK.
Methods: The Tooth Fairy study cohort consists of 69 children aged 5-8 years who donated teeth and whose parents answered a questionnaire. DLLs were measured in primary dentine using Laser Ablation Inductively Coupled Plasma Mass Spectrometry (LA-ICP-MS). To identify determinants of early life exposure, associations between lifestyle characteristics and DLLs were assessed.
Results: DLLs ranged from 0.06-0.77ug/g, (Mean±SD=0.25±0.16). In univariate analysis, significant determinants of DLL were methods of cleaning floors in the house; growing fruits/vegetables in the garden; and tap water consumption. Multivariate analysis showed that children living in houses cleaned less than weekly had higher DLLs than those residing in houses where floors were cleaned at least once weekly (mean 0.34 vs 0.18, p=0.047); children who drink up to 1/2 pint tap water daily had higher DLLs than those who reported drinking more than 1/2 pint daily ((mean 0.34 vs 0.22, p=0.035). Socioeconomic status, measured by education of the main wage earner, household income or Index of Multiple Deprivation was not significantly associated with DLL.
Conclusions: Unlike other studies, we did not find an association between socio-economic status and lead exposure. Frequency of cleaning hard floors in house is a possible predictor of elevated DLLs, however, cautious interpretation is required.

THE RELATIONSHIP BETWEEN WATER DISINFECTION BY-PRODUCTS AND EARLY CHILDHOOD NEUROBEHAVIORAL DEVELOPMENT

Yen-Ju Lin, *Institute of Environmental Health, Collage of National Taiwan University, Taiwan*

Gen-Shuh Wang, *Institute of Environmental Health, Collage of National Taiwan University, Taiwan*

Pau-Chung Chen, *Institute of Occupational Medicine and Industrial Hygiene, Collage of National Taiwan University, Taiwan*

Background and Aims: Trihalomethane (THM), the most common DBPs were widely explored the relationship between by-products of disinfection of drinking water and congenital anomalies. However, the impact of THMs exposure on neurobehavioral development in children still remains unclear. The purpose of our study was to investigate the relationship between the TTHM and early childhood neurobehavioral development.

Methods: We conducted a cohort study of 400 mother-infant pairs in 2004-2007 using information from Taiwan birth cohort study (TBCS) and Waterworks Registry. All subjects finished questionnaires and the childhood neurobehavioral development scales when the children were at the ages of 6 months. The exposure periods was grouped into prenatal and postnatal period. We used the proportional hazard model to assess the relationship between different exposure levels and the milestone and controlled for potential confounders including infant sex, birth weight, parity, maternal age, maternal education, breast feeding duration, environmental tobacco smoking exposure, and care style.

Results: The prenatal exposure duration, in the proportional hazard model the hazard ratio of “Smile at the main caregiver spontaneously” (adjusted odds ratio: 0.59, 95% confidence interval: 0.42, 0.82), “Roll over” (0.68, 95% CI: 0.49, 0.95), “Transfer objects from one hand to the other “ (0.58, 95% CI: 0.41, 0.82), and “Creep on belly” (0.39, 95% CI: 0.26, 0.63) were elevated in the high exposure compared to the reference category. And the risk of “Smile at the main caregiver spontaneously”, “Transfer objects from one hand to the other “, and “Creep on belly” showed an exposure-response pattern (test for trend: $p = 0.001$, 0.005, and 0.0001).

Conclusions: The present study suggests that prenatal exposure to disinfection by-products increases the risk of delay motor at 6th months. Our findings indicated that prenatal exposure may influence the children developments significantly than the postnatal.

AIR POLLUTION EFFECTS ON RISK OF ICD-DETECTED ATRIAL AND VENTRICULAR ARRHYTHMIAS: WHO ARE THE MOST VULNERABLE PATIENTS?

Heike Luttmann-Gibson, *Department of Environmental Health, Harvard School of Public Health, Boston, United States*
Francine Laden, *Department of Environmental Health, Harvard School of Public Health, Boston, United States*
Douglas W. Dockery, *Department of Environmental Health, Harvard School of Public Health, Boston, United States*
Joel Schwartz, *Department of Environmental Health, Harvard School of Public Health, Boston, United States*
Brent Coull, *Department of Biostatistics, Harvard School of Public Health, Boston, United States*
Diane Gold, *Department of Environmental Health, Harvard School of Public Health, Boston, United States*
Mark S Link, *Tufts Medical Center, Tufts University School of Medicine, Boston, United States*

Background and Aims: Implanted cardioverter defibrillators (ICD) monitor and treat arrhythmias and provide electrocardiographic records of the timing of ventricular and atrial arrhythmias. Diabetes, history of myocardial infarction (MI) and other risk factors have been shown to increase vulnerability to cardiac air pollution effects. In this study we explore which patient characteristics modify the associations between fine particulate matter ($PM_{2.5}$) and arrhythmias among a cohort of 200 dual chamber ICD patients prospectively followed at the Tufts Medical Center in Boston.
Methods: Patients were followed November 2006 through June 2010. We analyzed the association between air pollution and the onset of arrhythmias with a case-crossover approach. Cardiac events were matched with control time periods by month and day of the week. $PM_{2.5}$ exposure was included as 24-hour moving averages. Effect modification by patient characteristics was examined by including an interaction term. Risks of arrhythmias associated with air pollution were estimated with conditional logistic regression, adjusted for temperature and relative humidity. Odds ratios (OR) are reported for an interquartile range increase in exposure.
Results: A total of 135 patients with a mean follow-up time of 2.0 years had 3012 episodes (1917 atrial and 1095 ventricular arrhythmias). A 5.0 $\mu g/m^3$ increase in 24-h $PM_{2.5}$ was associated with an increased risk of atrial arrhythmias (OR 1.18, 95% CI 1.05 to 1.34) for diabetic, but not for non-diabetic patients (p-value interaction=0.03) and with an increased risk of ventricular arrhythmias (OR 1.17, 95% CI 1.04 to 1.31) for obese subjects, but not for non-obese (p-value interaction=0.06). We also found associations between $PM_{2.5}$ and increased risk of both atrial and ventricular arrhythmias in subjects with a history of angina or MI.
Conclusions: Diabetic and obese subjects and those with angina or MI may be more vulnerable to particle exposure in this population of patients with ICD devices

ASSOCIATIONS BETWEEN DIFFERENT BIOMARKERS USED FOR CADMIUM EXPOSURE IN THE GENERAL POPULATION

Magnus Akerstrom, *Department of Occupational and Environmental Medicine, Sahlgrenska University Hospital and University of Gothenburg, Sweden*
Thomas Lundh, *Department of Occupational and Environmental Medicine, Lund University Hospital and Lund University, Sweden*
Lars Barregard, *Department of Occupational and Environmental Medicine, Sahlgrenska University Hospital and University of Gothenburg, Sweden*
Gerd Sallsten, *Department of Occupational and Environmental Medicine, Sahlgrenska University Hospital and University of Gothenburg, Sweden*

Background and Aims: Biomarkers are normally used to assess the body burden of cadmium (Cd). Urinary Cd needs to be adjusted for variation in dilution using creatinine concentration (Crea) or specific gravity (SG). The aim of this study was to investigate the associations between Cd measured in urine (24h and overnight), blood and plasma.
Methods: Between 1999 and 2005, 152 healthy kidney donors were recruited to the study. Before transplantation, blood and separate 24h urine (U_{24}) and timed overnight spot urine (U_{ON}) samples were collected. Cadmium in blood (B-Cd), plasma (P-Cd) and urine (U-Cd), together with Crea and SG in urine were analyzed. SG standard 1.015 was used in the SG adjustment calculations. Associations between different biomarkers were assessed using the Pearson correlation coefficient.
Results: The mean levels were; U-Cd/24h: 0.51 µg, U-$Cd_{ON,Crea}$: 0.36 µg/gCrea, U-$Cd_{ON,SG}$: 0.32 µg/L, B-Cd: 0.49 µg/L, and P-Cd: 0.02 µg/l. Adjusted U-Cd and excretion rates (U-Cd/h) in the overnight samples were all associated to the 24h excretion of Cd (r=0.59 for U-$Cd_{ON,Crea}$, r=0.55 for U-$Cd_{ON,SG}$ and r=0.70 for U-Cd/h_{ON}; p<0.001). U-Cd/24h was also associated to B-Cd (r=0.32, p<0.001) but not among never smokers and not to P-Cd. There were stronger associations between B-Cd and U-$Cd_{ON,Crea}$, U-$Cd_{ON,SG}$ and U-Cd/h_{ON} (r=0.48, r=0.42, r=0.45; p<0.001) compared to P-Cd (r=0.22, p=0.007, r=0.27, p=0.001, r=0.15, p=0.09). There was an association between B-Cd and P-Cd (r=0.30, p<0.001).
Conclusions: Adjusted U-Cd and excretion rates in U_{ON} samples were significantly associated to U-Cd/24h, indicating that they are useful as biomarkers for Cd body burden, assuming a close relation between body burden and U-Cd/24h. B-Cd seems to be more closely associated to U-Cd than P-Cd. The latter is, however, more difficult to quantify correctly, due to low levels.

THE ROLE OF NON-ACOUSTICAL FACTORS IN NOISE ANNOYANCE OF URBAN POPULATION

Branko Jakovljevic, *Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade*, Serbia
Goran Belojevic, *Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade*, Serbia
Katarina Paunovic, *Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade*, Serbia

Background and Aims: Noise annoyance is influenced by acoustical factors, such as type of noise, noise levels and frequency, and non-acoustical factors, including physiological, psychological and social factors. The aim of this study was to assess the role of some non-acoustical factors in noise annoyance of urban population.
Methods: A cross-sectional study was performed on 1311 adults (452 men and 679 women), aged 42±16 years, residing in noisy urban areas in Belgrade for more than one year. Non-acoustical factors, such as socio-economic status (family income, education and employment) and dwelling characteristics (apartment size, floor level, orientation of windows) were estimated using a questionnaire. Noise annoyance was estimated using self-reported 5-graded verbal annoyance scale. Based on their annoyance level, participants were divided into two groups: highly annoyed (high level of noise annoyance) and less annoyed (low to moderate level of annoyance).
Results: Highly annoyed participants were more likely to be females, married with children and to have higher family income. Educational level and employment were similarly distributed among highly annoyed and less annoyed subjects. Highly annoyed participants were more likely to be living on lower floor levels (on the ground floor, basement or first floor), for a longer period of time, to spend more time indoors, and to have windows of their bedrooms facing the street. Orientation of windows toward the street was the most important predictor of noise annoyance (B=2.690, 95% Confidence Interval =1.796-4.029), followed by the living on the groundfloor or first floor (B=1,448, 95% CI =1.134-1.851), independently from age, gender and noise exposure.
Conclusions: Our study identified several non-acoustical factors as indicators of noise annoyance, independent from age, gender and noise exposure, primarily some dwelling characteristics and time spent indoors. Socio-economic status was not related with noise annoyance, when all the relevant parameters were taken into account.

EFFECTS OF TRANSPORTATION NOISE ON BLOOD PRESSURE

Wolfgang Babisch, *Federal Environment Agency (UBA), Germany*
Elise van Kempen, *Institute for Public Health and the Environment (RIVM), The Netherlands*

Background and Aims: Laboratory experiments on humans and animals, occupational noise studies with high noise levels and transportation noise studies with lower noise levels support the evidence that environmental noise is associated with high blood pressure. The biological plausibility is determined by the general stress concept, referring to the activation of the autonomic nervous system and the endocrine system. Most transportation noise studies looked at aircraft noise and road traffic noise. A recent meta-analyses investigating the relationship between aircraft noise and hypertension reported an odds ratio of 1.06 (95% CI: 1.00-1.13) per 5 dB(A) increase of the weighted day-night aircraft noise level Ldn (range 47-67 dB(A)). Despite the fact that during the last decade the number of studies investigating the association between road traffic noise and high blood pressure increased substantially, no reliable exposure-response relationship is as yet available. A meta-analysis was carried out to fill the gap.
Methods: Based on review papers and an electronic data-base search, epidemiological studies investigating the relationship between road traffic noise exposure and measured high blood pressure and/or use of antihypertensive treatment were considered for a meta-analysis. The studies were published between 1970 and 2010.
Results: Eventually 27 studies were evaluated. Preliminary results showed that road traffic noise was positively and significantly associated with the prevalence of hypertension: data-aggregation produced an of OR of 1.03 (95% CI: 1.01-1.06) per 5 dB(A) increase of the 16 hour average road traffic noise level (LAeq,16hr) (range 45-75 dB(A)).
Conclusions: Overall evidence shows that road traffic exposure is associated with high blood pressure. Based on a meta-analysis a quantitative relationship is derived that can be used for health impact assessment. The results of this meta-analysis are consistent with a slight increase of cardiovascular disease risk in populations exposed to transportation noise.

INTERRELATIONS BETWEEN BLOOD SERUM LEVELS OF PERSISTENT ORGANIC POLLUTANTS AND THEIR DETERMINANTS IN INUIT, POLISH AND UKRAINIAN MALES (CLEAR PROJECT)

9. Dick Heederik, *Institute for Risk Assessment Sciences, The Netherlands*
10. CLEAR, *http://www.inuendo.dk/clear*

Background and Aims: The overall objective of the multi-center CLEAR project is to investigate the possible impact of climate change on human exposure to environmental contaminants and their impact on fertility and child development. CLEAR is a follow-up of the INUENDO project (Bonde et al 2008), comprising parent-child cohorts from Arctic and two local European populations. Numerous environmental contaminants, notably persistent organic pollutants (POPs), are suspected endocrine modulators. As many POPs have common determinants, we anticipate that future epidemiological analyses could suffer from multi-collinearity and multiple testing issues, and thus explored multivariate data analysis approaches.
Methods: Cross-sectional serum blood concentrations of POPs were measured in 602 male partners of pregnant women recruited in 2002-04; 199 Inuit from Greenland, 197 from Warsaw, Poland, and 206 from Kharkiv, Ukraine. Brominated flame retardants, including the polybrominated diphenyl ethers (PBDEs) BDE-28, 47, 99, 100, 153, 154, and 183 and brominated biphenyl BB-153 were measured in a subset of 300 by GC-HR/MS. Six metabolites of di(2-ethylhexyl)phthalate (DEHP) and seven perfluorinated compounds were measured by LC-MS/MS, in addition to dichlorodiphenyldichloroethane (p,p′-DDE) and polychlorinated biphenyl congener (PCB-153) already characterized in the baseline INUENDO study (Jönsson et al 2005). We used bivariate correlation and exploratory factor analysis to explore the relationship between potential determinants and levels of POPs.
Results: Geometric mean concentrations of all compounds differed significantly between the three populations (ANOVA), and highest concentrations were generally measured in Greenland. All compounds showed right skewed distributions, and a high proportion of PBDEs were below the limit of quantification. Several PBDEs and PCB-153 were highly correlated with PFCs ($r>0.7$).
Conclusions: There is a large contrast in body burdens of POPs in the CLEAR cohorts. Multivariate exploratory factor analysis may yield additional insight into common determinants of exposure to POPs in these three populations.

Background and Aims: Aberrant DNA methylation is a common event in cancer development, lung cancer included. Aim of our study is to determine whether alterations in global and gene-specific DNA methylation in peripheral blood lymphocytes (PBLs) can precede and thus predict lung cancer development.
Methods: The study subjects were selected from a Danish prospective study and were free-of-cancer at the enrollment (1993-1997). Blood samples and information on life-style (smoking habits, diet) were collected. 276 lung cancer cases were diagnosed (1994-2003) and a sub-cohort of 303 controls was selected and frequency matched on sex and age according to the case-cohort design. Methylation state of *LINE*-1 repetitive elements (global methylation) and of gene-specific promoters of *microRNA124a*, tumor suppressor (*p16, RASSF1A, DAPK*), DNA-repair (*MSH2, MGMT, hMLH1*) and cell-proliferation genes (*CDH1, CDH13, RARβ*) was measured in PBLs by PCR-Pyrosequencing.
Hazard Ratios (HR) for lung cancer were estimated with Cox models, adjusted for age, sex, and smoking status. We created gene-specific dichotomous variables (equal to 0 or 1 if methylation lays below or above the 75th percentile of each gene-specific distribution, respectively) and summed them (excluding *LINE*-1) to calculate methylation indexes for overall methylation (MI), tumor suppressor genes (TSGI), DNA-repair genes (DRGI), and cell-proliferation genes (CPGI).
Results: Gene-specific methylation indexes were significantly positively associated with lung cancer risk for MI, TSGI and DRGI [HR=1.25 (95%CI 1.14-1.36; p<0.001), HR=1.19 (95%CI 1.02-1.38; p=0.030) and HR =1.59 (95%CI 1.35-1.87; p<0.001)] but not for CPGI and microRNA124a [HR=1.09 (95%CI 0.92-1.29; p=0.301) and HR=1.10 (95%CI 0.84-1.44; p=0.502)]. LINE-1 index was inversely correlated with lung cancer risk [HR=0.13 (95%CI 0.07-0.22; p<0.001)].
Conclusions: Specific methylation tumorigenic patterns are found in PBLs (in particular DNA-repair and tumor suppressor gene hypermethylation together with LINE-1 hypomethylation) and precede lung cancer development. Such results suggest how DNA methylation changes could be predictive of lung cancer risk.

WHO IS ANNOYED AND/OR WORRIED BY LIVING CLOSE TO PETROCHEMICAL INDUSTRIES?

Lars Barregard, *Occupational and Environmental Medicine, University of Gothenburg, Sweden*
Leo Stockfelt, *Occupational and Environmental Medicine, University of Gothenburg, Sweden*
Eva Andersson, *Occupational and Environmental Medicine, University of Gothenburg, Sweden*
Gerd Sallsten, *Occupational and Environmental Medicine, University of Gothenburg, Sweden*
Anita Gidlöf-Gunnarsson, *Occupational and Environmental Medicine, University of Gothenburg, Sweden*
Gosta Axelsson, *Occupational and Environmental Medicine, University of Gothenburg, Sweden*

Background and Aims: People living close to industry may be annoyed by smell or noise, and worried about possible adverse health effects or industrial accidents. Not all people are annoyed or worried, however, in spite of the same distance to emission sources. The aim of the present study was to assess which individual factors were associated with annoyance or worry.
Methods: In 1992, 1998, and 2006, postal questionnaires were distributed to stratified samples of residents 18-75 years in residential areas close to the petrochemical industry in Stenungsund, Sweden, and a control area further away. The samples included 6-800 people on each occasion, and 200-1000 people in a control area, and the response rate was 69-74%. Questions were focused on annoyance by smell and noise, and worry about health effects from chemical emissions or accidents. Individual factors evaluated were age, sex, type of residence, type of employment, children at home, and annoyance or worry due to traffic exhausts. Predictors were evaluated using multiple logistic regression analyses.
Results: About 20 % of responders in Stenungsund were annoyed by industrial smell or industrial noise (1-4% in the control area), and 40-50% were at least sometimes worried of health effects or chemical accidents (10-20% in the control area).
Young age and annoyance by road traffic exhaust were associated with annoyance by industrial smell or noise. Young age and female sex were associated with worry of health effects or industrial accidents. Having children at home increased the worry. The association between worry of health effects from industrial emissions and accidents was strong.
Conclusions: Individual factors contribute to the risk of being annoyed or worried when living close to petrochemical industry. Gender, having children at home, and annoyance or worry regarding traffic exhausts were important predictors.

EFFECTS OF AIR POLLUTION ON BLOOD PRESSURE AND LEFT VENTRICULAR FUNCTION: A PANEL STUDY OF CORONARY ARTERY DISEASE PATIENTS IN SOUTHWESTERN PART OF TAIWAN

Yuan-Horng Yan, *National Taiwan University, Taiwan*

Rei-Yeuh Chang, *Chia-Yi Christian Hospital, Taiwan*

Chu-Chih Chen, *National Health Research Institutes, Taiwan*

Tsun-Jen Cheng, *National Taiwan University, Taiwan*

Background and Aims: Air pollution (AP) has been associated with elevated blood pressure and heart failure (HF). However, the results were inconsistent. We investigated the effects of AP on blood pressure and left ventricular (LV) function using panel data.

Methods: Resting systolic blood pressure (SBP), diastolic blood pressure (DBP), and echocardiography were repeatedly measured every 3 months for 4 times in 61 patients (aged 61.5±10.4, 78.7% were men) with coronary artery disease (CAD) at one teaching hospital in southwestern part of Taiwan. 2-dimension and M-mode echocardiography were used to measure the deceleration time (DT) of E wave, LV end diastolic volume (LVEDV), and LV end systolic volume (LVESV) by Simpson's rule method. LV ejection fraction (LVEF) was calculated. AP concentrations were obtained from nearby fixed-site monitoring stations. We used mixed models that controlled for individual-specific effects, humidity and temperature to examine relationships between AP and hemodynamics.

Results: Average SBP and DBP were 137.9±20.0 and 77.4±11.3 mmHg. Baseline data of DT, LVEDV, LVESV, and LVEF were 189.6±58.3 msec, 63.3±32.9 ml, 30.1±24.2 ml, and 59.0±13.0%. Average concentrations during study period of SO_2, NO_2 , CO, O_3 , PM_{10} and $PM_{2.5}$ were 4.1±1.7 p.p.b., 16.6±7.6 p.p.b., 0.5±0.2 p.p.m., 29.1±11.3 p.p.b., 79.4±42.5 μg/m^3, and 45.8±24.5 μg/m^3 , repectively. The 1 day moving average of increase in 1 p.p.b. SO_2 , 1 p.p.m CO, and 10-μg/m^3 PM_{10} were associated with increase of 1.4 (95% CI 0.4 to 2.9), 11.4 (95% CI 2.1 to 20.8), and 0.5 mmHg (95% CI 0.03 to 0.9) of DBP. $PM_{2.5}$ and O_3 were associated with DT. $PM_{2.5}$, PM_{10}, SO_2, NO_2, and CO were associated with LVEDV. $PM_{2.5}$, PM_{10}, NO_2, and CO were associated with LVESV. SO_2 was associated with LVEF.

Conclusions: Elevated levels of ambient AP may adversely affect BP and LV function in susceptible population.

EMERGING DISINFECTION BY PRODUCTS (DBPS): CHLORATE IN ITALIAN DRINKING AND SWIMMING POOL WATERS

Elena Righi, *Department of Sciences of Public Health*, *University of Modena and Reggio Emilia, Italy*
Guglielmina Fantuzzi, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Guerrino Predieri, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Pierluigi Giacobazzi, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Petra Bechtold, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Katia Mastroianni, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Gabriella Aggazzotti, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*

Background and Aims: Chlorate is a disinfection by-product (DBP) originating from chlorine dioxide water disinfection, which can be a contaminant of sodium hypochlorite solutions as well. Due to its not yet well investigated genotoxic and carcinogenic potential effects, it is considered, together with other DBPs , an emerging DBP for which further research on occurrence levels and toxicological properties is a prior need.
The aim of this study was to evaluate in some Italian regions the potential exposure to chlorate via drinking water of the general population and of a specific population (swimmers).
Methods: Chlorate levels were investigated in drinking water samples collected form 12 waterworks located in Emilia-Romagna, Friuli Venezia Giulia and Lombardia Regions. To investigate spatial and seasonal variability, different water samples (n.194) were collected at different points along the distribution system and over four seasons. In the same period 20 swimming pools in the Emilia-Romagna Region were investigated for the occurrence of chlorate in water pools. Chlorate analysis was performed by ion chromatography (detection limit: 1 µg/l).
Results: Chlorate occurred in 97% of the drinking water samples, (median:18, range: 2-399µg/l) and resulted always below the provisional WHO guidelines (700µg/l). Nevertheless, significant differences in levels were observed according to disinfection methods, and the highest levels occurred in water disinfected both with chlorine dioxide and ozone (median:163, range:83-399µg/l). No clear spatial or seasonal trends were observed. Swimming pool waters showed much more higher chlorate levels (median:4347, range: 5-19537µg/l) and significant differences according to disinfectant applied were also observed.
Conclusions: In the Italian investigated regions, chlorate appears to be widespread both in drinking and swimming pool waters; in the latter particularly high levels were observed in different settings. Swimmers are therefore a potentially highly exposed population subgroup: to evaluate health implications of this specific exposure pathway, however, further investigation is needed.

CORONARY HEART DISEASE BURDEN AND COSTS OF LOCAL TRAFFIC-RELATED AIR POLLUTION AMONG 10 EUROPEAN CITIES – RESULTS FROM APHEKOM

Laura Perez, Swiss Tropical and Public Health Institute and University of Basel, Switzerland
Olivier Chanel, Université de la Mediterranee (Aix-Marseille II), France
Sylvia Medina, Institut de Veille Sanitaire, France
Christophe Declercq, Institut de Veille Sanitaire, France
Bertil Forsberg, Umeå University, Sweden
Patrick Goodman, Dublin Institute of Technology, Ireland
Daniela Haluza, Institute Environmental Health, Medical University of Vienna, Austria
Nino Künzli, Swiss Tropical and Public Health Institute and University of Basel, Switzerland

Background and aims: Animal studies and a few epidemiological investigations suggest a causal role of local traffic-related air pollution in the development of chronic cardiovascular pathologies such as coronary heart disease (CHD). The number of avoidable CHD cases, should this exposure be reduced, has not been evaluated in traditional air pollution risk assessments, which only consider air pollution as a cause of acute cardiovascular episodes (i.e. hospitalizations). The objective of the study was to estimate the health and cost benefits of avoiding the development of CHD through the reduction of local traffic-related pollution among adults (age >65 yrs) in 10 European cities, assuming a causal role of these pollutants in the development of CHD.
Methods: We obtained population attributable numbers by combining the concentration-response function (CRF) for the association between CHD prevalence and living within 150m of busy roads (OR:1.85 [95%CI:1.21-2.84]; Hoffmann et al, 2006), the proximity distribution of urban populations (i.e. the number of persons living within 150m of roads with more than 10,000 vehicles per day), and the CHD prevalence in these populations. We monetized this burden using direct and indirect medical costs as well as intangible costs.
Results : We estimated that 28% (95%CI: 9%-44%) of CHD cases could be attributable to local traffic-related pollution among the estimated total 132,000 elderly with CHD. Avoiding this burden translated into a total of 249 million Euros saved per year. This monetary estimation is more than 30 times larger than an estimation considering only acute cardiovascular episodes attributable to air pollution levels above the recommended World Health Organization annual guidelines.
Conclusions: If traffic-related pollutants play a causal role in the development of CHD, the reduction or elimination of this exposure could be a very effective primary prevention to reduce a substantial public health burden.

ISCHEMIC STROKE AND FISH CONSUMPTION IN SOUTHERN SWEDEN

Anna Oudin, *Occupational and Environmental Medicine, Umeå University, Sweden*
Maria Wennberg, *Occupational and Environmental Medicine, Umeå University, Sweden*

Background and Aims: Fish intake can have both beneficial effects (via omega-3 fatty acids) and adverse effects (via the environmental pollutants methyl mercury and PCB). Quite a few researchers have reported fish intake to reduce stroke risk, but there have also been inconsistencies in results; high fish consumption have for example been observed to increase stroke risk in men from northern Sweden. We aimed at studying lean and fat fish consumption as a risk factor for ischemic stroke in southern Sweden, separately for men and women.
Methods: Data on fish intake and other variables were obtained from an already available population based case-control study, with incident first-time ischemic stroke patients. Complete data on all relevant variables were obtained for 2718 controls and 2455 cases. The data were analyzed with logistic regression analysis.
Results: Stroke risk decreased with fat fish intake (• 1/week versus <1/month) in both men and women; adjusted Odds Ratio (OR) 0.69, 95% Confidence Interval (CI): 0.54-0.89. However, stroke risk for women increased with intake of lean fish; adjusted OR 1.6 (95% CI: 1.2-2.3), whereas there was no association with men's lean fish intake; adjusted OR 0.97(95% CI: 0.73-1.3).
Conclusions: Our results suggest fat fish intake to decrease ischemic stroke risk and lean fish intake to increase women's stroke risk. However, fish intake the year before the stroke occurred was self-reported retrospectively yielding potential recall bias. The findings regarding lean fish would be explained by recall bias if inclination to report fish consumption depended on both disease status and sex. The fact that the association between fat fish intake and stroke was similar in men and women does not support such a differential in recall. Our results stress the inconsistencies in literature regarding fish intake and stroke risk.

PROJECTING HEAT-RELATED MORTALITY UNDER CLIMATE CHANGE SCENARIOS: A SYSTEMATIC REVIEW

Cunrui Huang, *Queensland University of Technology, Australia*
Adrian Barnett, *Queensland University of Technology, Australia*
Xiaoming Wang, *CSIRO Climate Adaptation Flagship and CSIRO Ecosystem Sciences, Australia*
Pavla Vaneckova, *Queensland University of Technology, Australia*
Gerard FitzGerald, *Queensland University of Technology, Australia*
Shilu Tong, *Queensland University of Technology, Australia*

Background and Aims: Heat-related mortality is a matter of great public health concern, especially in the light of climate change. Although many studies have found associations between high temperatures and mortality, more research is needed to project the future impacts of climate change on heat-related mortality. We conducted a systematic review of research and methods for projecting heat-related mortality under climate change scenarios.
Methods: A literature search was conducted in August 2010, using the electronic databases PubMed, Scopus, ScienceDirect, ProQuest, and Web of Science. The search was limited to peer-reviewed journal articles published in English up to 2010.
Results: Most projections showed that climate change would result in a substantial increase in heat-related mortality. Significant differences in projected mortality were found by different emissions scenarios, suggesting that a greenhouse gases mitigation policy is important to reduce the health risks of climate change. However, because different studies used different scenarios, time periods, temperature exposures and assumptions, it is not possible to conduct a meta-analysis to create a combined estimate of the impacts of climate change on heat-related mortality. Projecting heat-related mortality requires an estimation of the historical temperature-mortality relationship, and consideration of the future changes in climate, population and acclimatisation. Further research is needed to provide a stronger theoretical framework for projections, including a better understanding of socio-economic development, adaptation strategies, land-use patterns, air pollution and mortality displacement.
Conclusions: Climate change is projected to increase heat-related mortality. Although the methods used for projections are still in their early stages and have limitations, the need for evidence-based assessments of future health impacts of climate change is urgent. Such research will significantly contribute to assessing and managing the potential impacts of climate change on heat-related mortality.

ANIMAL CONFINEMENT BUILDINGS AS A SOURCE OF AMBIENT PM10 AND ENDOTOXIN PM10

Lidwien A.M. Smit, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands*
Dick Heederik, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands*

Background & Aims: While most PM10 exposure studies focus on traffic related sources, PM10 emitted by animal buildings has hardly been studied. It has been suggested that PM10 exposure from animal buildings, especially poultry houses, may impose respiratory health risks. In addition, PM10 dust composition i.e. microbial content may vary. We investigated ambient PM10, endotoxin, *Coxiella burnetii* and methicillin-resistant *Staphylococcus aureus* (MRSA) exposure levels in areas with varying animal farm densities.
Methods: Week-averaged PM10 dust was collected simultaneously at five sampling sites with various animal farm densities and at one urban background location. Density of animal buildings around a sampling point was calculated using a Geographic Information System. Endotoxin content was determined by LAL assay. DNA isolation and qPCR were performed to determine *C. burnetii* and MRSA DNA content. Association between exposure and number of surrounding animal farms was determined by regression analysis.
Results: The number of animal farms within a 1000 meter radius of the sampling location ranged from 3 to 23 (provence licence data) or 5 to 37 (animal registry data). Geometric mean concentration of PM10 and endotoxin ranged from 16.1–22.2 $\mu g.m^{-3}$ and 0.16–0.31 $EU.m^{-3}$, respectively. PM10 levels were increased compared to urban background at sampling points with highest animal densities only, whereas endotoxin levels were increased at all sampling points. Endotoxin levels and to a lesser extent PM10 levels increased with animal farm density (endotoxin Beta 0.017 per farm, standard error (0.009), PM10 Beta 0.007(0.005). The association was more clearly observed with pigs and poultry than cattle. Microbial DNA analysis is ongoing.
Conclusion: Levels of PM10 and endotoxin PM10 were positively associated with the number of surrounding animal farms. Since this was less clearly observed for PM10 dust, the microbial diversity might possess additional information Livestock farming should be considered when modeling PM10 exposures.

ARE PESTICIDES RELATED TO PARKINSON'S DISEASE? SOME CLUES TO HETEROGENEITY IN STUDY RESULTS

Marianne van der Mark, *Institute for Risk Assessment Sciences, Utrecht University, Netherlands*
Maartje Brouwer, *Institute for Risk Assessment Sciences, Utrecht University, Netherlands*
Hans Kromhout, *Institute for Risk Assessment Sciences, Utrecht University, Netherlands*
Peter Nijssen, *St. Elisabeth Hospital Tilburg, Netherlands*
Anke Huss, *Institute for Risk Assessment Sciences, Utrecht University, Netherlands*
Roel Vermeulen, *Institute for Risk Assessment Sciences, Utrecht University, Netherlands*

Background and Aims: Previous systematic reviews have indicated that pesticide exposure is possibly associated with Parkinson's disease. However, large heterogeneity has been observed in study results. We aimed at providing an update of the literature published on Parkinson's disease and exposure to pesticides, by performing a systematic review and meta-analysis. In addition, we investigated if methodological differences between studies could explain the heterogeneity in study results.
Methods: Studies were identified through a systematic literature search. Summary risk ratios (sRR) for pesticide exposure and subcategories were calculated using random effects meta-analyses. Potential sources of heterogeneity were investigated by meta-regression and stratified analyses.
Results: Thirty-eight case-control studies, 4 cohort studies and 3 cross-sectional studies were identified. An sRR of 1.65 (1.42-1.92) for pesticide exposure (ever vs. never) was found. This association was also observed for exposure to herbicides and insecticides but not for fungicides. Heterogeneity in individual study results was not related to study design, source of control population, adjustment of results for potential confounders or geographical area of the study. However, heterogeneity was possibly related to differences in the exposure assessment. Pesticide exposure assignment based on job-titles resulted in a higher sRR than studies relying on self-reported exposure with sRR of 2.5 and 1.5, respectively.
Conclusions: This review strengthens the evidence that exposure to herbicides and insecticides can increase the risk of Parkinson's disease. A suggestive effect for method of exposure assessment was found. Future studies should therefore focus on more objective and improved methods of exposure assessment.

HEALTH IMPACT ASSESSMENT: EXPERTS' EXPECTATIONS AND VIEWS IN THE APHEKOM PROJECT

Hanns Moshammer, *Medical University Vienna, Austria*
Manel Nebot, *Agència de Salut Pública Barcelona, Spain*

Background and Aims: At the ISEE 2009 conference in Dublin we launched a questionnaire among participants regarding their views on Health Impact Assessments (HIA) with a special focus on air pollution. Afterwards other epidemiologists and public health experts were also contacted by e-mail and the questionnaire was made available on the internet.
Methods: Respondents were asked about their expectations and needs regarding HIA, what in their opinion were the weakest parts of a HIA, and how HIA could be improved and the results should be communicated to the different stakeholder groups.
In a second questionnaire stakeholders were asked about their perceptions and needs. The responses to both questionnaires will be contrasted.
Results and Conclusions: Twenty-six responses were received from experts. Most of the respondents have already authored a HIA (21 persons) or used it as reviewer or teacher. All are at least acquainted with the principles of HIA because they used HIA in their daily work and have at least read or reviewed examples. Thus, all respondents were scientists with a complete knowledge and understanding of HIA. Most of them have dealt with HIA regarding air pollution.
Answers regarding the weakest part ranged from the underlying model assumptions regarding the exposure-response function and its applicability to the specific setting under discussion, the general lack of appropriately considering lag effects and/or the impact on susceptible subgroups or combined effects and interactions as far as a lack of transparency regarding the assumptions for the economic valuation. Many good proposals were made regarding the presentation of HIA results especially in communicating with the general public.
Among lay stakeholders expectations differ considerably from the experts.

ARE METEOROLOGICAL FACTORS ASSOCIATED WITH SUICIDE?

Xin (Chester) Qi, *School of Public Health, Queensland University of Technology, Brisbane, Australia*
Shilu Tong, *School of Public Health, Queensland University of Technology, Brisbane, Australia*
Wenbiao Hu, *School of Population Health, University of Queensland, Brisbane, Australia*

Background and Aims The Northern Territory (NT) has the highest suicide mortality among all the states and territories in Australia. However, little has been done in determining how meteorological factors influence suicide in this area, compared with studies in other Australian areas and other countries. This study aims to explore the association between meteorological factors and suicide variation in Darwin, the capital of NT and a tropical city.
Methods Monthly suicide (146 suicides, 128 males and 18 females between 1999 and 2003) and meteorological data (including rainfall, maximum and minimum temperature, humidity at 9:00am and 3:00pm and sunshine hours) of the Darwin Statistical Division (metropolitan area) were collected. Time-series analysis was applied to examining the association between these factors and suicide variation using a generalized linear model with Poisson distribution after adjustment for autocorrelations and over-dispersion.
Results Months with increased sunshine hours were accompanied with less suicides among male population (RR = 0.58, 95% CI: 0.38 – 0.88), as well as 25-44 year group (RR = 0.52, 95% CI: 0.29 – 0.92). When humidity at 9:00am increased, there were more suicides among male population of 24-year and below (RR = 1.24, 95% CI: 1.05 – 1.45). However, there was no significant association between temperature, humidity at 3:00pm, rainfall and suicide. Among female population and population aged 45 and over for both genders, the associations were not significant.
Conclusions Humidity and sunshine hours were associated with suicide in Darwin, especially in all males and groups of 44-year and below. This may be attributed to the influence of sunlight on the human mood. The influence of other factors, such as socioeconomic status, life style and personal issues will be explored in future studies.

RISK OF PARKINSON'S DISEASE AND AGRICULTURAL PESTICIDE EXPOSURE.

Background and Aims: Several studies have found an association between agricultural pesticide exposure and Parkinson's disease (PD), but uncertainties remain about the characteristics of exposure that are involved. Our objective was to determine agricultural pesticide exposures associated with PD in a French case-control study.
Methods: The study was conducted in 2007 in five French districts in an agricultural population (≤ 80 years). Cases were identified through antiparkinsonian drug claims; PD diagnosis was verified by clinical examination. Two controls per case were matched for age, sex, and district. A comprehensive questionnaire described tasks associated with pesticide use. The cumulative number of pesticide applications and years of exposure, and the average number of applications per year were computed overall, by type of products (herbicides, fungicides, insecticides), and by target (crops, livestock). The Mini Mental State Examination (MMSE) assessed cognitive performances. Analyses were performed using conditional logistic regression and restricted to men whose main occupation was farming.
Results: The study included 192 cases (72% farmers) and 382 controls (72% farmers). After adjustment for confounders (smoking, coffee, MMSE, pesticide use for gardening), PD was not associated with the cumulative number of applications (p-trend=0.070) or years of exposure (p-trend=0.566), but an association was observed with the average number of applications per year (p-trend=0.011). PD was associated with the average number of applications of fungicides per year (p-trend=0.037) but not with insecticides or herbicides. An association was observed with the number of pesticide applications for crops (p-trend=0.046) but not for livestock.
Conclusions: A detailed description of agricultural pesticide exposure is important in order to better understand the association between PD and pesticides. We found a stronger association with the intensity of applications than with the cumulative number of applications or duration of exposure. In addition, fungicides and applications for crops were more particularly associated with PD.

YEARS OF LIFE LOST DUE TO COLD AND HOT TEMPERATURES IN BRISBANE, AUSTRALIA

Cunrui Huang, *Queensland University of Technology, Australia*
Adrian Barnett, *Queensland University of Technology, Australia*
Xiaoming Wang, *CSIRO Climate Adaptation Flagship and CSIRO Ecosystem Sciences, Australia*
Shilu Tong, *Queensland University of Technology, Australia*

Background and Aims: Temperature is an important determinant of population health. Most previous studies were formulated in terms of temperature-related mortality risk, but it is also useful to consider years of life lost. Information on years of life lost is of great concern for policy makers, as evidenced by the issue of mortality displacement. This study aims to estimate the years of life lost associated with changes in season and temperature in Brisbane, Australia.
Methods: We used daily time series data on climate and mortality collected for Brisbane city between 1996 and 2004. The years of life lost were estimated by matching each death by age and sex to Australian life tables for the years 2002–2004. Regression was used to estimate the association between daily total years of life lost and daily maximum temperature, with adjustment for day of week, trend and season. To examine the non-linear and lagged effects of temperature, we used the distributed lag non-linear model.
Results: There was no effect of season on years of life lost. The association between daily maximum temperature and daily total years of life lost was V-shaped with increased years of life lost for cold and hot temperatures. The lowest years of life lost were at 30 °C for men and 27 °C for women. The greater heat-related years of life lost were most associated with a shorter lag (same day exposure), and the largest cold-related years of life lost were most associated with a multiple days lag.
Conclusions: This study provides evidence of increased years of life lost due to cold and hot temperatures. Extreme temperatures are known to cause increases in the number of deaths, our study demonstrates that temperature extremes also cause significant increases in years of life lost.

THE EFFECTS OF HIGH TEMPERATURES ON ELDERLY MORTALITY DIFFERED BY YEAR, CITY AND REGION IN THE UNITED STATES

Yuming Guo, School of Public Health, Queensland University of Technology, Brisbane, Australia
Adrian Barnett, School of Public Health, Queensland University of Technology, Brisbane, Australia
Shilu Tong, School of Public Health, Queensland University of Technology, Brisbane, Australia

Background and aims: Studies examining the impacts of high temperatures on mortality are useful for quantifying their public health burden and establishing warning systems that aim to reduce their health effects. However, most previous studies have only considered the effects during the whole study period, and have ignored the variability in effects in different years. We aimed to examine the variation in the effects of high temperatures on elderly mortality (age • 75 years) for 83 large US cities for the years 1987–2000. We also explored the overall trend of high temperature-related elderly mortality.
Methods: We defined high temperature days as two or more days with temperatures above the 90th percentile for each city during each warm season (May 1 to September 30). We used a time series Poisson regression model and decomposed the mortality risk for high temperatures into: a "main effect" due to high temperatures using a distributed lag non-linear function, and an "added" effect due to consecutive high temperature days. We pooled yearly effects across regions using a random effects meta-analysis. We used a Bayesian hierarchical model to generate an overall high temperature effect at regional and national levels.
Results: The high temperature effects (both main and added effects) on elderly mortality varied greatly by year, city and region in the United States. Some of the variation in the heat effect is a regular fluctuation of "bad" years being followed by relatively "good" years. The elderly mortality due to high temperatures generally declined over the study time.
Conclusion:
High temperature effects on elderly mortality vary greatly from year to year and by city and region. This variability makes it difficult to predict the future effects of heat, and is likely to cause false positives in heat-warning systems.

USING SATELLITE AEROSOL OPTICAL DEPTH DATA TO INVESTIGATE THE ASSOCIATION BETWEEN MORTALITY AND LONG AND SHORT TERM EXPOSURE TO PM $_{2.5}$ IN MASSACHUSETTS

Itai Kloog, *Department of Environmental Health - Exposure, Epidemiology and Risk Program, Harvard School of Public Health, Landmark Center 401 Park Dr West, Boston, MA, USA*
Bill Ridgway, *Science Systems and Applications, Inc, 10210 Greenbelt Road, Suite 600, Lanham, MD, USA*
Petros Koutrakis, *Department of Environmental Health - Exposure, Epidemiology and Risk Program, Harvard School of Public Health, Landmark Center 401 Park Dr West, Boston, MA, USA*
Brent A Coull, *Department of Environmental Health - Exposure, Epidemiology and Risk Program, Harvard School of Public Health, Landmark Center 401 Park Dr West, Boston, MA, USA*
Joel Schwartz, *Department of Environmental Health - Exposure, Epidemiology and Risk Program, Harvard School of Public Health, Landmark Center 401 Park Dr West, Boston, MA, USA*

Background and Aims: A large number of studies have reported associations between ambient particulate matter (PM) exposures and adverse health effects, yet all these studies have focused on the effects of either short-term (acute) or long-term (chronic) PM exposures. In this paper we aim to use a novel PM $_{2.5}$ exposure model based on satellite aerosol optical depth data to investigate both the long and short term effects of PM $_{2.5}$ exposures on mortality in Massachusetts, USA.
Methods: Using our novel predictions model for exposure, we preformed a time series analysis where daily death counts in each geographic grid cell were regressed against the long and short term $PM_{2.5}$ exposure, temperature, socio-economic data, lung cancer rates and a spline of time to control for season and trends.
Results: Our results indicated that for every10-$\mu g/m^3$ increase in short term PM $_{2.5}$ exposure there is a 1.07 percent increase in mortality (CI=0.52 to 1.61), while concurrently for every10-$\mu g/m^3$ increase in long-term PM $_{2.5}$ exposure there is a 44.2 percent increase in mortality (CI=17.7 to 76.8).
Conclusions: We have developed a novel $PM_{2.5}$ exposure model based on remote sensing data to assess both short- and long-term human exposures. Our approach relies upon gaining spatial resolution in the acute effects and allowing an assessment of long term effects in the entire population, rather than a selective sample from urban locations

ESTIMATION OF EXPOSURE TO URBAN AIR POLLUTION IN TWO CITIES USING A GAUSSIAN DISPERSION MODEL: THE EDEN-AIR PROJECT

Julien Galineau, *AIRLOR, France*
Nathalie Marquis, *AIRLOR, France*
Fabrice Caïni, *ATMO Poitou-Charentes, France*
Agnès Hulin, *ATMO Poitou-Charentes, France*
Johanna Lepeule, *Inserm, Team of Environmental Epidemiology applied to Reproduction and Respiratory Health, U823, Grenoble University, France*
Department of Environmental Health, Harvard School of Public Health, Boston, MA, United States, France
Rémy Slama, *Inserm, Team of Environmental Epidemiology applied to Reproduction and Respiratory Health, U823, Grenoble University, France*

Background and Aims: Air pollution exposure models used in epidemiology are often based on the network of air quality monitoring stations (AQMS). The spatial resolution of these models is limited, which is of concern in urban areas, where atmospheric pollutants exhibit strong spatial fluctuations. Dispersion models are expected to increase the spatial resolution. Our aim was to implement such a model in two cities using a harmonized methodology.
Methods: ADMS Urban dispersion model has been implemented in Nancy and Poitiers (France) to estimate the hourly atmospheric concentrations of nitrogen dioxide (NO_2) and particulate matter (PM_{10}). Domain size for each area is about 30km x 30km. The model relied on a spatialized and temporally-resolved emission inventory including data on traffic, industrial sources and heating, as well as on hourly data on meteorological parameters and background air pollution levels from AQMS. Traffic emissions were described with linear sources, while other sources were aggregated on a 1km-resolution grid. Validation of the model has been done by comparing hourly estimated concentrations with permanent stations measures.
Results: Annual concentrations measured by AQMS were 30 µg/m^3 for NO_2 and 22 µg/m^3 for PM_{10} in Nancy, and 20 µg/m^3 and 18 µg/m^3 in Poitiers. Hourly model predictions and measured concentrations at the AQMS locations exhibited a correlation of 0.6 for NO_2 and 0.5 for PM_{10} in Nancy (0.7, and 0.9, respectively, for Poitiers). In each area, the relative error between annual measured averages and model estimates was always below 30% for NO_2 and below 20% for PM_{10} (based on 7 locations in Nancy and 3 in Poitiers).
Conclusions: NO_2 and PM_{10} levels estimated by a dispersion model showed good correlation with measures, and low error in urban background and traffic locations. Implementing dispersion models in different cities in a standardized way appears feasible.

Background and aims: Different techniques of geocoding can lead to important differences in distance between the true and the geocoded location. To which extent such differences can impact the estimates of air pollution effects on health outcomes has not been studied. The objective is to assess the differences in health estimates of home outdoor air pollution on lung function using 2 geocoding techniques (spatial interpolation versus parcel matching).

Methods: FEV1% predicted was assessed between 2001-2007 for 393 adults living in Grenoble, France, from the follow-up of the Epidemiological study on the Genetics and Environment on Asthma (EGEA) and the European Community Respiratory Health Survey (ECRHS). Home addresses were geocoded automatically using a map developed with spatial interpolation technique and manually using the cadastral map and geocoding the building's center. Annual concentrations of NO_2 (2004) and PM_{10} (2008) lestimated at the home addresses, using a dispersion model with a $10m^2$ grid, were combined to time-specific measures from the permanent air quality monitoring stations to capture temporal variations in exposure. Linear regressions, adjusted for sex, age, BMI, active smoking, ETS, occupational group, atopy and asthma were conducted.

Results: Medians concentrations ($\mu g/m^3$) were 34 (IQR 31-38) for NO_2 and 31 (29-33) for PM_{10} using the automatic geocodes and 33 (31-36) for NO_2 and 30 (29-32) for PM_{10} using the manual geocodes. The median distance in meters between the two techniques was 29 (IQR 14-59). For a $10\mu g/m^3$ increase in NO_2 and PM_{10}, FEV1% predicted decreased by 2.42 (p=0.06) and 8.96 (p=0.05) using the automatic geocodes, and by 2.71 (p=0.09) and 12.32 (p=0.02) respectively using the manual geocodes.

Conclusion: These first results suggest that a more precise geocoding technique has a minimal impact on the assessment of NO_2 and PM_{10} effects in lung function.

THE IMPACTS OF EXTREME COLD AND HOT TEMPERATURES ON MORTALITY IN TIANJIN, CHINA: TOWARDS RESPONSE FOR CLIMATE CHANGE

Yuming Guo, School of Public Health, Queensland University of Technology, Brisbane, Australia
Adrian Barnett, School of Public Health, Queensland University of Technology, Brisbane, Australia
Shilu Tong, School of Public Health, Queensland University of Technology, Brisbane, Australia
Weiwei Yu, School of Public Health, Queensland University of Technology, Brisbane, Australia
Xiaochuan Pan, School of Public Health, Peking University, Beijing, China

Background and aims: There has been increasing interest in assessing the impacts of temperature on mortality as global warming continues. However, little evidence is available on the temperature-mortality relationship in China, or what temperature measure is the best predictor of mortality. Also, no study has used the case–crossover design to examine the non-linear and distributed lag effects of temperature on mortality. In this study, we aim to examine the non-linear and distributed lag effects of temperature on mortality in Tianjin, China; to explore which temperature measure is the best predictor of mortality; to apply the distributed lag non-linear model (DLNM) as a part of case• crossover design.
Methods: The DLNM was applied to a case• crossover design to assess the non-linear and delayed relationship between temperatures (maximum, mean and minimum) and deaths (non-external, cardiovascular and respiratory). The Akaike information criterion was used to determine which temperature measure was the best predictor of mortality.
Results: A U-shaped relationship was found for all temperature measures and mortality categories. The lagged effects of cold temperatures lasted longer than hot temperatures. Mean temperature had a better AIC than maximum and minimum temperatures.
Conclusions: In Tianjin there was a relatively large comfortable temperature zone, but extreme cold and hot temperatures increased the risk of mortality. The effects of cold lasted longer than the effects of heat. Mean temperature had the best predictive ability. It is possible to combine the case• crossover design with DLNM to estimate non-linear and delayed effects of temperature whilst controlling for season.

LONG-TERM EXPOSURE TO TRAFFIC RELATED AIR POLLUTION AND HOSPITAL ADMISSION IN THE NETHERLANDS

Ulrike Gehring, *IRAS, Utrecht University, the Netherlands*

Background and aim: Cardiopulmonary effects of long-term exposure to outdoor air pollution have been observed in several cohort studies, but the association between hospital admission and long-term exposure has not received much attention. This study aims to explore this relation focusing on respiratory and cardiovascular hospital admission in the Netherlands.
Methods: This study was based on hospital registration (2001-2004) and general population data for the West of the Netherlands (population 4.04 million). At postcode area level (n=683) the association between the land use regression modeled annual average outdoor NO_2 concentrations and hospital admission for respiratory and cardiovascular causes was evaluated. Analyses were adjusted for differences in composition of the population of the postcode areas (age, sex, income).
Results: Outdoor NO_2 concentration was associated with increased prevalence of hospital admission for asthma, chronic obstructive pulmonary disease (COPD), all cardiovascular causes, ischemic heart disease (IHD) and stroke. For these causes of admission exposure-response relations for the second to fourth quartile of exposure were found, relative to the first quartile of exposure. Adjusted Prevalence Ratios (and 95%-confidence intervals) were 1.87 (1.46-2.40), 2.34 (1.83-3.01) and 2.81 (2.16-3.65) for asthma, 1.44 (1.19-1.74), 1.50 (1.24-1.82) and 1.60 (1.31-1.96) for COPD and 1.07 (0.99-1.15), 1.08 (1.00-1.17), 1.10 (1.01-1.19) for all cardiovascular causes, 1.08 (0.98-1.20), 1.12 (1.01-1.23) and 1.13 (1.02-1.25) for IHD and 1.11 (0.98-1.25), 1.12 (0.99-1.26) and 1.28 (1.13-1.45) for stroke. All respiratory causes showed significantly elevated prevalence ratios with increased exposure, but no exposure-response relation was observed.
Conclusion: Long-term exposure to traffic related air pollution was associated with increased hospital admission for respiratory and cardiovascular causes.

EPIGENETIC EFFECTS OF IN-UTERO ARSENIC EXPOSURE

Michele Avissar-Whiting, Devin Koestler, E. Andres Houseman, Carmen J. Marsit
Brown University, USA

Margaret R. Karagas
Dartmouth Medical School, USA

ABSTRACT

Background and Aims: There is a growing body of epidemiologic evidence that arsenic exposure in-utero, even at the low levels found in the United States, is associated with adverse reproductive outcomes and may contribute to long-term health effects in exposed individuals. Animal models, in-vitro studies, and human cancer data suggest that arsenic may elicit epigenetic alterations as its mode of toxicity, specifically, by altering the pattern of DNA methylation. This study aims to identify differences in the profiles of DNA methylation in infant cord blood samples associated with low-level chronic arsenic exposure in a U.S. cohort.
Methods: DNA methylation of cord-blood derived DNA from 150 infants involved in a prospective birth cohort in New Hampshire was profiled using the Illumina Infinium Methylation450K array. In-utero arsenic exposure was assessed using urine and toenail samples. Infinium methylation data were analyzed using the semi-supervised recursively partitioned mixture modeling approach.
Results: Ongoing analyses of the DNA methylation array data suggest differences in DNA methylation profiles associated with in-utero arsenic exposure, and the top loci identified in these analyses are being validated for their methylation status using bisulfite pyrosequencing.
Conclusions: This works demonstrates that arsenic may be acting through epigenetic mechanisms to produce its developmental effects. Prospective follow-up of these children will allow for the long-term assessment of the health-related risks associated with these alterations.

PRENATAL PHTHALATE EXPOSURE AND CHILDHOOD WHEEZING IN A MULTIETHNIC COHORT

Jessie Buckley, *University of North Carolina at Chapel Hill, USA*
Stephanie Engel, *University of North Carolina at Chapel Hill, USA*
Mary Wolff, *Mount Sinai School of Medicine, USA*
Susan Teitelbaum, *Mount Sinai School of Medicine, USA*
Antonia Calafat, *Centers for Disease Control and Prevention, USA*

Background and Aims: Experimental studies suggest that phthalates may affect respiratory function by altering immune or inflammatory responses. Associations between asthma and childhood exposure to phthalates detected in building materials or house dust have been reported, but prenatal exposures have not yet been studied. Our objective was to assess the relationship between prenatal phthalate exposure and asthma or wheezing in childhood.
Methods: The Mount Sinai Children's Environmental Health Study enrolled a multiethnic prenatal population in New York City between 1998 and 2002 (n = 404). Third-trimester maternal urines were analyzed for phthalate metabolites and a wheezing questionnaire was administered at the age of 6 or 7 years (n = 165). Adjusted odds ratios (aOR) and 95% confidence intervals (CI) for the association between questionnaire responses and micromolar sums of di(2-ethylhexyl) phthalate (ΣDEHP), low molecular weight (ΣLMW), and high molecular weight (ΣHMW) phthalate metabolites were estimated via logistic regression. Models were adjusted for creatinine, baseline maternal characteristics, race/ethnicity, prenatal smoke exposure, sex, breastfeeding duration, and child's relationship to primary caretaker. Adjustment for childhood overweight status did not alter conclusions.
Results: Prenatal phthalate exposure was positively associated with wheezing or whistling in the chest in the past 12 months; aORs (95% CI) for a unit increase in natural log ΣLMW, ΣHMW, and ΣDEHP metabolites concentrations were 1.19 (0.88, 1.60), 1.29 (0.88, 1.88), and 1.37 (0.94, 1.99), respectively. The aOR for wheezing in the past 12 months comparing the highest to the lowest tertile of ΣDEHP metabolite concentrations was 3.05 (95% CI 1.08, 8.63). Ever wheezing or whistling in the chest and physician-diagnosed asthma were also elevated in the highest ΣDEHP metabolites concentrations tertile, though estimates were imprecise.
Conclusions: These findings support a link between the plasticizer DEHP and development of wheezing in childhood, but confirmatory studies in larger populations are needed..

FOOD FOR THOUGHT: ETHICAL ISSUES IN FOOD AND NUTRIENT RESEARCH

Adetoun Mustapha, *MRC-HPA Centre for Environment and Health, Imperial College London, UK*

Heads of governments at the 1996 World Food Summit reaffirmed "the right of everyone to have access to safe and nutritious food, consistent with the right to adequate food and fundamental right of everyone to be free from hunger". In 1999, the UN Committee on Economic, Social and Cultural Rights, clarified the 'right to adequate food' to mean that every human being should have physical and economic access to food that is culturally and nutritionally acceptable. Increasing world population, conflicts and climate change have created global food shortages. Efforts aimed at solving world hunger through mass production of cheap and readily available food have resulted in agricultural practices that harm the environment, workers and public health, as well as food systems that are changing cultural landscapes and lifestyles.

Epidemiologic data have supported the association between dietary patterns and health effects, such as the high intake of vegetables and fruits and the low risk of chronic disease. The importance of nutrition in building disease resistant body and mental capacity, starting from early life, has also been recognized. However, sustainable food production and processing methods at local levels and achieving healthy dietary patterns in socio-economically disadvantaged groups remains challenging.

This session will be a moderated open forum to discuss the ethical dilemma of addressing food shortages, personal dietary intake and nutritional status in the context of resource availability and food affordability, and the need to comply with ethical principles of the individual's right to self-determination, beneficence and non-maleficence. The focus of the discussion will be on identifying the unaddressed issues and emerging priorities that the research community should consider from the papers presented in this session.

URBAN AIR POLLUTION AND EFFECTS ON BIOMARKERS IN BLOOD

Sandra Johannesson, *Occupational and Environmental Medicine, Gothenburg, Sweden*
Eva M Andersson, *Occupational and Environmental Medicine, Gothenburg, Sweden*
Leo Stockfelt, *Occupational and Environmental Medicine, Gothenburg, Sweden*
Lars Barregard, *Occupational and Environmental Medicine, Gothenburg, Sweden*
Gerd Sallsten, *Occupational and Environmental Medicine, Gothenburg, Sweden*

Background and Aims: Exposure to ambient air pollution is associated with cardiovascular diseases and mortality. The mechanistic pathways are still unknown, however one hypothesis is that particulate air pollution induces airway inflammation, causing systemic inflammation leading to cardiovascular events and atherosclerosis. The aim was to study the effects of short term alterations in ambient air pollution on biomarkers of inflammation and coagulation in a panel consisting of healthy volunteers.
Methods: The study group consisted of 16 individuals (8 men and 8 women), all non-smokers and living in Gothenburg, Sweden. Median age was 35 years (range 26-55 years). The subjects were called for blood sampling the morning after either a day with high levels of air pollutants (PM_{10}>30 µ/m^3 as 24-hour mean) or after a day with low levels of air pollutants (PM_{10}<15 µg/m^3 and NO_2<35 µg/m^3). Blood samples were analyzed for biomarkers of inflammation and coagulation (CRP, serum amyloid A (SAA), intercellular adhesion molecule 1 (ICAM-1), fibrinogen and factor VIII). Associations between each biomarker and exposure to air pollution were examined using linear mixed-effects models (SAS, version 9.1).
Results: All together, 12 sampling sessions were performed (six days of high and six of low levels of air pollutants). No significant increase in any of the biomarkers was found after days with high levels of PM_{10} (median: 49 µg/m^3) compared with days with low levels (median: 10 µg/m^3) in preliminary analyses. Similar results were found when the exposure instead was classified by the urban background NO_x concentrations, as a marker of traffic exhausts (median: 95 µg/m^3 and 42 µg/m^3 for high and low pollution events, respectively).
Conclusions: We found no significant increases in biomarkers of inflammation and coagulation after high ambient air pollution events compared with low pollution events when performing repeated investigations in a group of healthy study subjects.

*presenting author

Background and aims: The development of more and more precise techniques to assess environmental exposures, particularly using geographic information systems (GIS), has raised the necessity to geocode the addresses of participants in cohort studies. Our objective is to assess the distance of the geocodes obtained for the same address using different techniques of geocoding in French urban areas.
Methods: Within the context E3N, a French Cohort, we geocoded 1809 addresses in 4 urban areas, with 3 techniques:
A. automatically by a commercial firm that uses NavTEQ® streets network to geocode by spatial interpolation along street axis. Location of the coordinates corresponds to 15m to the left or the right from the street centre (depending on the street number if even or odd)
B. automatically using a free Internet service developed using Google Maps® Internet mapping application programming interface (API) where the returned location of the coordinates corresponds (in theory) to the entrance of the building/parcel on the street
C. manually using the free on-line French cadastral maps and locating the coordinates in the center of the building, these were considered as the "true" ones.
Results: We only kept the 1656 addresses for which the 3 techniques found the complete address without doubt. The median difference in m between A and C was 21 (IQR 12-41), and between B and C was 23 (14-45). Comparing A and C, the distance was between 50 and 75m for 9% of the addresses and above 75m for 11%, comparing B and C the percentages were 10 and 12 respectively.
Conclusion: We did not observe large differences between the different techniques however around 20% of the addresses were geocoded at more than 50m from the "true" location. It will be interesting to assess if this alters the exposure estimates and the health effects.

SOCIO-ECONOMIC PREDICTORS OF IPM TRAINING PARTICIPATION AND IMPLEMENTATION IN ILLINOIS CHILDCARE CENTERS

Background and Aims

A comprehensive program for childcare providers and supervisors to reduce pesticide use and promote integrated pest management (IPM) in Illinois childcares is analyzed, in order to determine its impact on different populations. Since populations are non-uniform in their perception and response to environmental challenges, researchers are looking for criteria to identify at-risk populations and opportunities for promoting environmental behavior.

Infants and young children are particularly vulnerable to pesticide impacts because of their physiology, metabolism and behavior. Critical neurodevelopment processes are especially at risk from toxins. The majority of childcares report using pesticides, where approximately 53 million US children spend up to ten hours daily.

While regulated school IPM programs have proliferated, childcares are more difficult to influence as they vary in location, size, and government oversight; while socio-economic factors help explain access.

Method

A listing of licensed trained and untrained childcares from the post-survey was analyzed for pest incidences, IPM training participation and implementation and the results compared to census 2000 socio-economic data.

Results

Childcares in underprivileged populations were significantly more likely to participate in training than middle socio-economic populations; and mostly large centers participated. Understanding IPM benefits correlated positively with lower socio-economic and negatively with middle to high status, while IPM actions only coordinated with spending a high percentage of income on rental. Training resulted in selective adoption of IPM practices, especially pest prevention.

Conclusions

The training program raised awareness leading to IPM implementation in large licensed childcare centers in underprivileged, but not higher socio-economic populations; homes or license exempt childcares where children may be at even greater risk. This may reflect the formal organization and resources of government subsidized centers serving weaker populations and the strong motivation of childcare providers to protect children.

SPATIAL METHODS FOR ANALYSIS OF CANCER INCIDENCE AND MORTALITY IN VICINITY OF LARGE INCINERATORS IN ENGLAND 1998-2008

Nicola Reeve *CHICAS, School of Health and Medicine, Lancaster University, Lancaster, LA1 4YD, UK*
Thomas J Keegan *CHICAS, School of Health and Medicine, Lancaster University, Lancaster, LA1 4YD, UK*
Tom R Fanshawe *CHICAS, School of Health and Medicine, Lancaster University, Lancaster, LA1 4YD, UK*
Peter J Diggle *CHICAS, School of Health and Medicine, Lancaster University, Lancaster, LA1 4YD, UK*

Background and aims In response to health concerns by residents in the vicinity of large waste incinerators in England, a study of incidence and mortality from selected cancers has been undertaken in collaboration with the Health Protection Agency (HPA).
A particular aim is to develop and apply spatial and temporal statistical methods of risk estimation using a novel matched control-area design.
Methods The study includes five incinerators in England with a capacity > 150,000 tonnes pa of waste, operational $\leq$ 31/12/1998. A *case area* is a circle of radius 10km centred on an incinerator. A *matched control area* is a 10km circle of similar demographic profile to the case area, obtained using matching criteria based on the National Statistics 2001 Area Classification for Local Authorities. Cancer incidence and mortality rates are compared between paired areas, and spatial variation in risk estimated within areas.
Results Spatial and temporal trends in annual health outcome data within each circle are analysed using a Poisson log-linear model including age-standardised expected count as an offset, matched case-control areas, deprivation and a plume model for distance and directional effects. Statistically significant distance and directional effects in case areas but not in control areas are indicative of elevated risk attributable to the incinerator. Disease rates in case areas compared to both national rates and control areas are presented.
Conclusion This study develops and applies statistical methods for analysing spatially-referenced health outcome data in regions with a suggested exposure relative to matched regions with no such exposure. Disease risk can be estimated using a combination of classical case-control methods at whole-area level and spatio-temporal methods within case and control areas.

A CASE-CROSSOVER STUDY OF AMBIENT AIR POLLUTION AND STROKE: AN EVALUATION OF PATIENT FACTORS THAT MODIFY ASSOCIATIONS

Paul J. Villeneuve, *Health Canada, Ottawa, Ontario, Canada*
Julie Johnson, *Health Canada, Ottawa, Ontario, Canada*
Brian Rowe, *University of Alberta, Edmonton, Alberta, Canada*
J Lowes, *University of Alberta, Edmonton, Alberta, Canada*
Dion Pasichnyk, *University of Alberta, Edmonton, Alberta, Canada*
S Kirkland, *University of Alberta, Edmonton, Alberta, Canada*

Background: Several studies have demonstrated positive associations between short-term increases in ambient air pollution and the risk of stroke. While these studies have compared risks across different seasons, type of stroke, and age, the influence of individual level patient characteristics has remained unstudied.
Methods: This was a time-stratified case-crossover of 5,945 patients who presented to emergency departments (ED) in Edmonton, Canada between 2003 and 2009 with stroke or a transient ischemic attack (TIA). Chart reviews were conducted to extract information on patient's disease history, medication use and smoking status. Daily concentrations of ambient pollution (NO_2, $PM_{2.5}$, O_3, CO, and SO_2) were obtained from fixed-site monitors. Conditional logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI) in relation to an increase in the interquartile range of each pollutant. Stratified analyses were conducted by season, and across variables that captured patient's disease history, medication use and smoking status.
Results: Consistent with a previous ED study conducted during 1992-2002, we observed positive associations between NO_2, and $PM_{2.5}$ between April to September. Specifically, for ischemic stroke the OR for an increase in the interquartile range of the 3-day average of NO_2 was 1.57 (95% CI: 1.16-2.11). No statistically significant associations were observed with NO_2 or $PM_{2.5}$ for TIAs, or hemorrhagic strokes. SO_2 levels were not associated with any of the stroke types examined. Stratified analysis by patient characteristics for ED visits between April and September revealed stronger associations between NO_2 and ischemic stroke for those with a history of stroke (OR=2.43, 95% CI: 1.44-4.08), or heart disease (OR=2.08, 95% CI: 1.25-3.46), and use of insulin or oral hypoglycaemic drugs (OR=2.19, 95% CI: 1.22-3.95).
Conclusions: Our results support the hypothesis that individuals with pre-existing comorbid health conditions are at greater risk of experiencing a stroke due to their exposure air pollution.

HEALTH IMPACT MODELLING OF ALTERNATIVE ACTIVE TRAVEL VISIONS FOR ENGLAND AND WALES USING A TRANSPORT AND HEALTH INTEGRATED MODELLING TOOL (THIM)

James Woodcock *UCL, UK*
Moshe Givoni, *Transport Studies Unit, Oxford, UK*
Phil Edwards, *LSHTM, UK*
Zhiwei Cao*, UCL, UK*

Background and Aims: Achieving health benefits while reducing greenhouse gas emissions from transport offers a potential policy win-win,however, the magnitude of potential benefits is likely to vary by setting. This study presents a new Transport and Health Integrated Modelling tool (THIM) to evaluate the health and environmental impacts of high walking and cycling transport scenarios for English and Welsh urban areas outside London.
Methods: A series of integrated travel time, distance, and trip based scenarios were generated using THIM as part of the Visions 2030 Walking and Cycling project. Environmental modelling was used to estimate changes to CO_2 emissions. Health impact assessment modelling was used to estimate changes in Disability Adjusted Life Years (DALYs) resulting from changes in exposure to PM 2.5, road traffic injury risk, and physical activity.
For each transport scenario THIM generates age and sex specific weekly active travel time distributions, assuming log-normality. THIM uses these log normal distributions to estimate physical activity exposure under each scenario, and from these it calculates the expected changes to DALYs and age/sex specific population body mass index distributions. THIM allows parameter estimates either to be entered for each scenario, or for default values to be used based on existing data.
Results: This paper will present the findings of the new modelling study and discuss them in the light of previous research. The sensitivity of the findings will be considered with reference to parameter uncertainty including, 'safety in numbers', variation in active travel times by age, and the dose-response relationship between physical activity and risk of health outcomes.
Conclusions: Methods to estimate the health impacts from transport related physical activity and injury risk are in their infancy, but this study has demonstrated an innovative integration of transport and health impact modelling approaches. The findings have implication for transport and health policy, and for future empirical and modelling research.

CLUSTER ANALYSIS OF ENVIRONMENTAL AND ELECTROMAGNETIC FIELD HEALTH RISK PERCEPTION IN TAIWAN

Yi-Ping Lin, *Institute of Science, Technology and Society, National Yang Ming University, Taiwan*
Yen-Chun Lin, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University, Taiwan*
Tsun-Jen Cheng, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University, Taiwan*
Chang-Chuan Chan, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University, Taiwan*
Jung-Der Wang, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University, Taiwan*

Background and Aims: We surveyed the health risk perception of the environment and electromagnetic fields (EMF) in Taiwanese adults, and analyzed its response clusters.
Methods: A cross-sectional telephone surveys was conducted by the Center for Survey Research, Academia Sinica in August to September, 2007, with a randomized sample of 1,251 adults aged 18 years and beyond.
Results: There were 77% of Taiwanese adults who considered food safety affected health to a big extent, followed by quality of outdoor air, drinking water, and dumping of waste. There were four clusters in the survey, namely, high risk, low risk, environment, and EMF. Within the high risk group, there were more women, middle-aged, married, and high school educated participants. Further, there were higher percentages of reported hypersensitivity to EMF in the high risk and EMF groups.
Conclusions: Taiwanese adults were highly concerned of the health risks of food. Issues of hypersensitivity to EMF warranted further investigation.

RELATIVE DEPRIVATION BETWEEN NEIGHBOURING WARDS IS PREDICTIVE OF CORONARY HEART DISEASE MORTALITY AFTER ADJUSTMENT FOR ABSOLUTE DEPRIVATION OF WARDS

Thomas Keegan *School of Health and Medicine, Lancaster University, Lancaster, UK*
Steven Allender *WHO Collaborating Centre for Obesity Prevention, Deakin University, Australia*
Peter Scarborough *Division of Public Health and Primary Health Care, University of Oxford, Oxford, UK*
Mike Rayner *Division of Public Health and Primary Health Care, University of Oxford, Oxford, UK*

Backgrounds and aims: An association between income inequality and health has been widely reported, as has an association between levels of income inequality and poor health. Here we are interested in whether, at a small area level, health is affected by the relative deprivation of a ward compared to its neighbours. We aim to assess whether deprivation inequality at small area level in England is associated with coronary heart disease (CHD) mortality rates, and assess whether this provides evidence of an association between area-level and individual-level risk.
Methods Mortality rates for all wards in England were calculated using all CHD deaths 2001 - 2006. Ward-level deprivation was measured using the Carstairs index. Deprivation inequality within local authorities was measured by the interquartile range of deprivation for wards within the local authority. Relative deprivation for wards was measured as the modulus of the difference between deprivation for the ward and average deprivation for all neighbouring wards.
Results Deprivation inequality within local authorities was positively associated with CHD mortality rates after adjustment for absolute deprivation ($p < 0.001$ for all models).
Relative deprivation for wards was positively associated with CHD mortality rates after adjustment for absolute deprivation ($p < 0.001$ for all models).
Sub-group analyses showed that relative deprivation was independently associated with CHD mortality rates in both affluent and deprived wards.
Conclusions Rich wards surrounded by poor areas have higher CHD mortality rates than rich wards surrounded by rich areas. Poor wards surrounded by rich areas have worse CHD mortality rates than poor wards surrounded by poor areas. Local deprivation inequality has a similar adverse impact on both rich and poor areas, supporting the hypothesis that income inequality of an area has an impact on individual-level health outcomes.

EVALUATION OF BREAST CANCER RISK IN RELATION TO NIGHT SHIFT WORK IN A CASE-CONTROL STUDY IN A SPANISH POPULATION

Background and Aims: Recent epidemiologic and animal data indicate that night work may increase the risk for breast cancer. We evaluated breast cancer risk in female night shift workers in a population based case-control study in Spain, the Multi Case-Control study (MCC-Spain).
Methods: Incident breast cancer cases (n=795) and randomly selected population controls (n=849) were enrolled in 7 regions of Spain. Lifetime occupational history including questions on shift work and information on reproductive and lifestyle factors were assessed by face-to-face interviews. We estimated the risk of different shift profiles using unconditional logistic regression models adjusting for a wide range of potential confounders.
Results: Among 1644 female subjects, 14 controls and 16 cases had ever worked in permanent night shift and 49 controls and 52 cases in rotating night shift for ≥1 year. Having ever worked in permanent night work was associated with an increased risk for breast cancer (Odds Ratio (OR) 1.36 (95% Confidence Interval (CI) 0.62-2.97), compared to permanent day workers, after adjusting for confounders. The corresponding OR for rotating night workers was 1.17 (95%CI 0.71-1.92). Women who had worked in night work for more than 10 years during lifetime, had an OR=1.43, (95%CI 0.79-2.57). This risk was higher in postmenopausal women (OR=1.67, 95%CI 0.79-3.53) as compared to premenopausal women (OR=1.09, 95%CI 0.41-2.89).
Conclusions: A moderate increased risk for breast cancer was associated with having ever worked in night shift, but results were not statistically significant. Risk estimates tended to increase among permanent night workers, among workers with long-term exposure to night work and in postmenopausal women. These estimates were based on small numbers due to the low prevalence of night shift in this population. The study is ongoing and, at the conference, results will be presented for a much larger population sample.

Philippe Glorennec, *EHESP-School of Public Health / IRSET-Environmental & Occupational Health Institute / INSERM-French National Institute of Health and Medical Research, U625 (GERHM), Rennes, Frances*

Background and Aims: Reductions of environmental lead concentrations and therefore of Blood Lead Levels (BLLs) have been achieved last decades thanks to public health policies (ban of leaded gasoline and leaded paints …). However, children's lead exposure remains a major public health concern, considering the increasing scientific evidence for adverse effects (including cognitive and neurobehavioral deficit) without apparent threshold. The aim of this study is to propose risk based environmental lead concentrations levels in the residential dust, soil and water for policy making.

Methods: 484 French children were enrolled from the survey of the National Institute of Health surveillance (InVS) in a way to be representative of French children aged from 6 months to 6 years. Lead concentrations in blood and environmental samples (water, soils, home dusts, paints and other unusual sources such as cosmetics and traditional dishes) were measured using an ICP-MS, both for total and bioaccessible lead. Social and individual characteristics were collected in addition to housing data. A predictive multivariate model was built with a priori assumption on the covariates to be introduced. Missing data were replaced using multiple imputation by chained equations; the sampling design and sampling weights were taken into account in the model, and cross-validation based on bootstrapping was used.
Results: The population weighted Geometric mean (GM) for BLLs was 1.4 µg/L. The preliminary analyses yielded to significant positive associations between BLLs and lead concentrations in environmental medias after adjustment on sexe, age, tobacco, child's time activity pattern, hobbies at risk, parents educational attainment and use of cosmetics and traditional dishes. More analyses and adjustments are ongoing in order to validate the model. The final results will display: i) action levels (corresponding to BLL increment) for lead concentrations in water, soils and dusts, ii) the most predictive lead concentration measurement method (total or leachable) of BLLs.
Conclusions: This predictive model intended to be a basis to establish and update regulatory action levels for lead concentrations in the different residential medias of exposure, in the context of Public Health attention paid to lower BLLS of young children.

PRESENCE OF ORGANOCHLORINE PESTICIDES IN BREAST MILK SAMPLES FROM WOMEN OF BOGOTA, COLOMBIA

Ximena Rojas-Squella, *University of Los Andes, Colombia*
Juan Ramos-Bonilla, *University of Los Andes, Colombia*
Wolfram Baumann, *University of Los Andes, Colombia*
Adriana Jaimes, *University of Los Andes, Colombia*
Olga Lucía Sarmiento, *University of Los Andes, Colombia*
Juan Carlos Correa, *Fundación Santa Fé de Bogotá, Colombia*

Background and aims: The presence of organochlorine pesticides (OCPs) in biological and environmental samples has been widely studied in many countries around the world because of their environmental persistence and potential toxicological effects. Determining the presence of OCPs on human fluids, including breast milk, has been used to understand general population exposures and potential health risks derived from these substances, and for surveillance purposes. Exposure to OCPs has not been studied systematically in Colombia. Thus, there is very limited information about the magnitude of the problem (i.e., current and historically), and the potential health implications for the Colombian population.

Methods: Fifteen pregnant and/or breastfeeding mothers who met the sampling criteria of the World Health Organization Persistent Organic Pollutant Surveillance Program were randomly selected to voluntarily participate on the study. Breast milk samples were analyzed for 10 OCPs (alpha-, beta-, gamma-, delta-HCH, Heptachlor, alpha-, gamma-Chlordane, 4,4 DDT, 4,4 DDE, 4,4 DDD). The participants answered a questionnaire regarding diet and socioeconomic status. Milk samples were analyzed using liquid-liquid extraction, followed by sulfuric acid clean-up, and quantified using GC/• ECD. Results were confirmed by GC/MS. OCPs concentrations were normalized by gravimetrically quantified sample's fat content.

Results: The most common OCPs found on breast milk samples were (range ng of OCP/g of fat) alpha-HCH (5,5–8,8 ng/g), and 4,4 DDE (51,8–143,8 ng/g). For all the OCPs reported the analytical method percent recoveries were above 80%.

Conclusions: The OCPs concentrations observed were similar or below the levels found over the last 5 years on other countries, except for alpha-HCH (i.e., our results were higher). Despite the small sample size, the DDE/DDT ratio suggests that the use of DDT has been drastically reduced in Colombia.

INDOOR AIR POLLUTION (CHLORINATED ORGANIC HYDROCARBONS) IN ELEMENTRY SCHOOL IN ISRAEL

Joseph Azuri MD MHA, *Family Medicine Department, Sackler Faculty of Medicine, Tel Aviv University, Israel*

Background: In 1997, heavy contamination was discovered in groundwater in Tel Aviv with heavy metals and volatile organic compounds (VOC)
These VOC's were also found in soil gases in one of the neighborhoods, especially near industrial areas. As a result, the authorities began monitoring VOC's in the neighborhood elementary school.
We report the results of VOC's measurements made at the school expressing exposure of children aged 6-12 years.
Methods: Samples were taken over the years 2001 - 2011 in various methods and included indoor air samples (24-hour canister sampling, passive and active - active charcoal tubes sampling), shallow drills in the school yard, nearby buildings, and "head space" from different materials found in school.
Results: Trichloroethylene was found in all indoor-school measurements (concentrations up to 30.8mcg/m^3). Carbon Tetra-Chloride (up to 49mcg/m^3), Vinyl Chloride (up to 10.4mcg/m^3), cis1,2 Dichloroethene (up to <3.97mcg/m^3), and 1,2 Dichloroethane (up to 14.4mcg/m^3) were found only on ground and underground floors. Chloroform was found in high concentrations (up to 95mcg/m^3) in all 3 school floors. One test even showed a gradient of lower levels in higher floors.
Head-space testing for VOC's from different products found in the school showed low concentrations of chloroform from detergent (3.35mcg/m^3) and Trichloroethylene from a classroom rug (3.61mcg/m^3).
VOC's were not measured in non-ground level distant buildings (above method threshold).
Recurrent measurements were not consistent. However, this may be due to differences in tests performance (classroom ventilation, sampling location, etc.), different test methods (charcoal tubes, canisters, air flow rates, etc.) and laboratory analysis.
Conclusions: The results demonstrate significant exposure of children to carcinogens.
Assisted ventilation of classrooms and continuing measurements were recommended, as well as avoidance from learning in classrooms on the ground and underground floors. Further tests to identify the source of the pollution (indoor or outdoor) were warranted.

GENOTOXIC DAMAGE IN WORKERS OF THE LEATHER SHOE INDUSTRY, EXPOSED TO NOISE

Corina Flores-H, *DCAT,Universidad de Guanajuato, México.*
Verónica Díaz de León-M, *Instituto Mexicano del Seguro Social, México*
María-Raquel Huerta-F, *DCAT,Universidad de Guanajuato, México.*
Daniel Hernández, *Consultores ambientales, México.*
Ismael Morales*, DCAT,Universidad de Guanajuato, México*

Background and Objectives: In functional studies has shown that mice carrying the Ahl gene are more sensitive to noise which makes them more sensitive to noise. Other authors have shown an increased cell migration (comet) in subjects exposed to noise levels above 90 dB.
The purpose of this study was to evaluate hearing loss and genotoxic damage in workers chronically exposed to noise in the leather-footwear industry.
Methods: Through an epidemiological design we evaluated 225 workers and identified 44 workers exposed to chronic noise. Hearing loss was assessed using pure tone audiometry. Genotoxic damage caused by noise was determined by measuring DNA migration (comet assay technique.) The results were controlled for age of workers, the use of tobacco and alcohol, working hours, exposure time, intake of NSAIDs and other drugs.
Results: Of a total of 225 audiological examinations, found that 44 patients showed abnormalities of varying degrees. Hearing curves were below the surface profiles of profound hearing loss, indicating that there are probably following systemic damage: 1) surface to severe losses, 2) moderate loss and moderate to severe. This compared with parameters <20 dB. Blood samples were taken at 44 subjects to determine the existence of comet cells. This study showed that 50% of the worker had DNA migration, which correlated significantly with noise level and exposure time $R = 0.503$, $p < 0.05$
Conclusions: This study showed that there genotoxic damage and hearing damage. The comet assay is an excellent biomarker to assess the level of damage in subjects exposed to chronic environmental factors.

LONGITUDINAL STUDIES OF NOISE AND MENTAL HEALTH

Stephen Stansfeld, ***Barts & the London School of Medicine, London, UK***
Charlotte Clark, ***Barts & the London School of Medicine, London, UK***
Russell Ecob, ***Ecob Consulting, Glasgow, Scotland***

Background and Aims: Most studies of environmental noise exposure and mental health have been cross sectional and may be prone to selection bias. Studies of symptoms, clinical disorders and medication use suggest associations between aircraft and road traffic noise and anxiety disorders. There have been few longitudinal studies. This paper examines the results of current longitudinal studies adding further data from the 1958 Birth Cohort.

Methods: The UK 1958 Birth Cohort has followed a cohort of 18,000 born during one week in 1958. At age 45 they were interviewed with the Clinical Interview Schedule to measure common mental disorders. In these analyses occupational noise exposure during adulthood was examined in relation to depressive and anxiety symptoms at 45 years taking potential confounding factors into account.

Results: In the 1958 Birth Cohort occupational noise exposure was weakly prospectively associated with depressive symptoms in men but much of this may be explained by confounding factors. These findings are compared with previous studies including the Caerphilly Study where road traffic noise exposure was associated with a non-linear increase in anxiety symptoms (Stansfeld et al, 1996).

Conclusions: There is weak evidence for environmental noise influencing mental health in longitudinal studies. There is a need for further studies with good measurement of noise exposure, confounding and moderating factors, such as noise sensitivity and a greater reliance on standardised interview measured psychiatric disorders in order to answer the question of whether noise can be implicated in the causation of common mental disorders.

PREVALENCE OF LIP AND PALATE IN COMMUNITIES BRICK ASSOCIATED POLYCYCLIC AROMATIC GUANAJUATO

Corina flores-hernández, *Departamento de Atención Primaria de la Facultad de Odontología Universidad De La Salle Bajío.*
Luz veronica diaz de leon-m, *Escuela de Educación Universida De La Salle Bajío.*
Marcela vazquez, *Departamento de Atención Primaria de la Facultad de Odontología Universidad De La Salle Bajío.*
Gabriela ceballos, *Departamento de Atención Primaria de la Facultad de Odontología Universidad De La Salle Bajío.*

Background and Aims: Exposure to environmental an occupational and inhalation of hazardous substances (polycyclic aromatic), toxins and pregnant before 25 or after age 35 are factors that increase the risk of some congenital malformation (originating during pregnancy), such as lip and palate, neural tube defects, and Down syndrome or Turner.
The aim was to determine the prevalence of cleft lip and palate in brick business communities by environmental and occupational exposure to polycyclic aromatic compounds.
Methodology: The study was descriptive, using a Medical History and Diagnosis environmental community, families with presence of cleft lip and palate infants born during the January 1, 2009 and Oct 31, 2010. Was studied gender, occupational activity during pregnancy, weight, maternal age, number of deeds, origin, malformation and history of alcoholism and smoking positive
Results: Of the neonates with cleft lip and all were born alive, 6 were female (33.33%) and 12 males (66.66%) with a F / M of 0.20. The average birth weight was 2943 grams. The average age was 25.1 years, the 50%, a history of alcoholism on their partners on weekends. This type of malformation in children, 15 (83.33%) with cleft lip and palate type I, 2 girls (11.11%) cleft lip and 1 child (5.55%) cleft palate. With regard to the number of deeds, could be seen that most infants with cleft lip and palate were the product of multiparous mothers (66.66%). The frequency of congenital cleft lip and palate were from communities of brick producers. León 13.5%, 54% of Salamanca, Silao 12%, 11% of capital and Celaya Guanajuato to 6%.
Conclusions: Data obtained from the review of the families engaged in the activity of the brick mothers worked or cooked by burning furnaces throughout the pregnancy.

TIMING OF AND LOCATION AT STROKE ONSET: IMPLICATIONS FOR CHARACTERIZING SHORT TERM EFFECTS FROM AMBIENT AIR POLLUTION

Julie Johnson, *Health Canada, Ottawa, Ontario, Canada*
Paul J Villeneuve, *Health Canada, Ottawa, Ontario, Canada*
Brian Rowe, *University of Alberta, Edmonton, Alberta, Canada*
J Lowes, *University of Alberta, Edmonton, Alberta, Canada*
Dion Pasichnyk, *University of Alberta, Edmonton, Alberta, Canada*
S Kirkland, *University of Alberta, Edmonton, Alberta, Canada*

Background and aims: Time-series and case-crossover studies have found that short-term increases in ambient air pollution are associated with a higher risk of stroke. These studies have typically used the day of presentation to an emergency department to infer the time of stroke. The objective of this study is to improve our understanding of potential sources of bias that could arise from the use of hospital administrative data to estimate the risk of stroke from exposure to ambient air pollution.

Methods: We collected survey data from 336 stroke patients in Edmonton, Canada on the date, time, location and nature of activities at onset of stroke symptoms. The daily mean concentration of ambient NO2 and PM2.5 on the self-reported day of stroke onset was estimated from continuous fixed site monitoring stations.

Results: Among the 241 patients who were able to recall when their stroke started, 72.6% experienced stroke onset the same day they presented to the emergency department; there was no systematic difference in assigned pollution levels for either NO2 or PM2.5. At the time of stroke onset, 90% were inside at the time of stroke onset. On the day of their stroke, most patients (84.5%) reported that for most of the day they were within a 15 minute drive from home.

Conclusions: Our analysis suggests that day of presentation obtained from hospital administrative records can reasonably capture onset of stroke, and that any associated errors are unlikely to be important source of bias when estimating air pollution risks.

THE ROLE OF GENDER IN INORGANIC ARSENIC INDUCED OXIDATIVE STRESS AMONG BANGLADESHI POPULATION EXPOSED TO HIGH ARSENIC THROUGH DRINKING WATER

Nayar SULTANA, *Department of Human Ecology, Graduate School of Medicine, University of Tokyo, Japan*
Chiho WATANABE, *Department of Human Ecology, Graduate School of Medicine, University of Tokyo, Japan*
Hana FURUSAWA, *Department of Human Ecology, Graduate School of Medicine, University of Tokyo, Japan*
Masahiro UMEZAKI, *Department of Human Ecology, Graduate School of Medicine, University of Tokyo, Japan*
Tsukasa INAOKA. *Department of Environmental Sciences, Faculty of Agriculture, Saga University*

Background: Arsenic acts as a carcinogen may be due to oxidative stress induction through the generation of reactive oxygen species (ROS). Gender disparity has been reported in many arsenic-exposure related diseases like cardiovascular diseases, hypertension, liver diseases, as well as skin lesions or cancers. However, no study had been reported about gender disparity in arsenic induced oxidative stress in Bangladeshi arsenic-exposed population.
Objective: The objectives of the study are to examine the levels of urinary 8-OHdG and F2α –isoprostane, two established oxidative stress biomarkers, in relation to the urinary arsenic within Bangladeshi arsenic-exposed men and women.
Methods: Data were obtained from 219 healthy participants, aged 18-45 years, from two communities of southern-west part of Bangladesh in August 2009. One hundred four participants were participated from high arsenic- contaminated area and other 115 participants from arsenic free area.
Results: Urinary arsenic was positively associated with oxidative biomarkers-namely 8-OHdG and F2α-isoprostane ($r=0.59$, $p<0.001$ and $r=0.43$, $p<0.001$, respectively). The exposed group showed higher urinary arsenic (Geometric mean 166 µg/g Cr 95% CI 102.8-230.9) than the non-exposed group (Geometric mean 54 µg/g Cr, 95% CI 38.8-70.9). Higher 8-OHdG level was found in As-exposed group (Geometric mean 8.4 ng/mg Cr, 95% CI 2.5-14.2 vs Geometric mean 6.5 ng/mg Cr, 95% CI 3.9-9.6) than in non-exposed group, but result was different for F2α-isoprostane (Geometric mean 5.5 ng/mg Cr, 95% CI 4.1-6.9 vs Geometric mean 7.0 ng/mg Cr, 95% CI 2.8-11.2). Among arsenic-exposed subjects urinary arsenic and 8-OHdG levels were significantly lower ($p<0.05$) in women than men. In case of F2α-isoprostane, women have higher values than men within the non-exposed group, but no sex difference was found in As-exposed group.
Conclusions: The results suggest that oxidative DNA damage and lipid peroxidation were associated with arsenic exposure, which were sex-dependent to some extent.

ASSOCIATION BETWEEN URINARY 3, 5, 6-TRICHLORO-2-PYRIDINOL, A METABOLITE OF CHLORPYRIFOS AND CHLORPYRIFOS-METHYL, AND SERUM THYROID HORMONES IN NHANES 1999-2002

Gamola Z Fortenberry, *University of Michigan, USA*
Howard Hu, *University of Michigan, USA*
Mary Turyk, *University of Illinois at Chicago, USA*
Dana Boyd Barr, *Emory University, USA*
John D Meeker, *University of Michigan, USA*

Background and Aims: Thyroid hormones (TH) are vital to a host of human physiological functions in both children and adults. Exposures to chemicals, including chlorpyrifos, have been found to modify thyroid signaling at environmentally relevant levels in animal studies. The aim of this study was to examine circulating TH levels in relation to urinary concentrations of 3, 5, 6-trichloro-2-pyridinol (TCPY), a metabolite of the organophosphorus insecticides chlorpyrifos and chlorpyrifos-methyl, using data from individuals 12 years and older from the U.S. National Health and Nutrition Examination Surveys (NHANES).
Methods: NHANES datasets from 1999-2000 and 2001-2002 were combined, and individuals with thyroid disease were excluded (N=4304). Multivariable linear regression models for relationships between log-transformed urinary TCPY and total serum T_4 or log (TSH) were constructed and adjusted for urinary creatinine, age, BMI, race, serum cotinine, income, and thyroid altering medications. Models were stratified by sex and a categorical age variable (<18, 18-40, 40-60, and >60 years).
Results: In male participants, an interquartile range (IQR) increase in urinary TCPY was associated with statistically significant decreases in serum T_4 of 3.7% (95% CI 0.77%-6.8%) among those <18 years of age, and 3.3% (0.03%-6.8%) in the 18-40 year age group, relative to median T4 levels. An IQR increase in TCPY was also associated with decreases in TSH of 9% (1%-17%) among men 18-40 years old and 21% (12%-29%) among men >60 years old. Conversely, urinary TCPY was positively associated with TSH in females >60 years of age.
Conclusion: These results, from a representative sample of the U.S. population, support the limited human and animal data that have reported a relationship between chlorpyrifos, chlorpyrifos-methyl, or TCPY exposure and altered thyroid hormones. Further research to confirm these findings, elucidate mechanisms of action, and explore the clinical and public health significance of such alterations in thyroid hormones is needed.

Assessment of Personal Exposure to Manganese in Children Living Near a Ferromanganese Refinery

Erin Haynes, *University of Cincinnati, USA*
Tiina Reponen, *University of Cincinnati*
Patrick Ryan, *University of Cincinnati, USA*
Aimin Chen, *University of Cincinnati, USA*

Background and Aims: Airborne exposure to manganese (Mn) can result in neurologic effects. Stationary air sampling is the traditional technique to assess Mn exposure for communities, yet may not accurately reflect children's personal exposure. The study aimed to 1) determine personal air Mn exposure in children residing near a ferromanganese refinery, and 2) identify the relationship between personal air Mn, stationary air Mn, and time-weighted distance from the refinery (TWD).
Methods: A subset of children living in non-smoking households ages 7-9 enrolled in the Marietta Community Actively Researching Exposure Study during March – June 2009 and 2010 were invited to participate. Participants wore a $PM_{2.5}$ sampler (Personal Modular Impactor) for 48 hours. TWD was based on time spent at home and school and the distance of each from the refinery. Stationary outdoor air sampling was conducted 8 km from the refinery using a Harvard-type $PM_{2.5}$ impactor. The relationship between personal Mn exposure and TWD was examined by multiple regression controlling for stationary air Mn concentration, wind speed and direction, and average precipitation.
Results: We collected complete personal air sampling data on 38 children. TWD ranged from 4.7 km to 28.5 km with a mean distance of 11.1 (4.7 st.dev) km. Mn concentration in personal air samples ranged from 1.5 ng/m^3 to 54.5 ng/m^3 (mean, 11.7 ng/m^3; st.dev, 12.5 ng/m^3). TWD was the most significant predictor of personal air Mn concentration with an associated decrease of approximately 8% of the natural log of personal air Mn for each km TWD ($p<0.005$, 95% CI -13% to -2%). Wind speed and stationary Mn levels were also significantly associated with personal exposure.
Conclusions: A child's location (home and school) relative to the refinery is a significant predictor of personal Mn exposure. Future analyses will evaluate ambient air Mn exposure on childhood neurobehavioral development.

A METHOD FOR DETECTION OF RESIDUAL CONFOUNDING IN SPATIAL AND OTHER OBSERVATIONAL STUDIES

W. Dana Flanders, *Emory University, Atlanta, USA*
Mitchel Klein, *Emory University, Atlanta, USA*
Lyndsey Darrow, *Emory University, Atlanta, USA*
Matthew Strickland, *Emory University, Atlanta, USA*
Stefanie Sarnat, *Emory University, Atlanta, USA*
Jeremy Sarnat, *Emory University, Atlanta, USA*
Lance Waller, *Emory University, Atlanta, USA*
Andrea Winquist, *Emory University, Atlanta, USA*
Paige Tolbert, *Emory University, Atlanta, USA*

Background and Aims: Detection of residual confounding is a difficult issue in observational studies. We recently described such a method and justified its use primarily for time-series studies (Flanders et al, 2009; Flanders et al 2011). The method depends on an indicator with two key characteristics: it is conditionally independent (given measured exposures and covariates) of the outcome in the absence of confounding, misspecification and measurement errors; second, it is associated with the exposure and, like the exposure, with unmeasured confounders. We proposed using future exposure levels as the indicator to detect residual confounding. This was a seemingly natural choice for time-series studies because future exposure cannot have caused the event yet could be spuriously related to it. A related question of interest – that addressed here - is whether an analogous indicator exists that can be used to identify residual confounding in a study based on spatial, rather than temporal contrasts.
Methods: Using directed acyclic graphs and specific causal relationships, we show that future air pollution levels may have the characteristics appropriate for an indicator of residual confounding in spatial studies of environmental exposures
Results: In simulations based on a spatial study of ambient air pollution levels and birth weight in Atlanta, with ambient air pollution one year after conception as the indicator, we were able to detect residual confounding. For the study size used, the discriminatory ability approached 100% for some factors intentionally omitted from the model, but was very weak for others.
Conclusions: The simulations illustrate that the indicator based on future exposures can have excellent ability to detect residual confounding in spatial studies, although performance varied by situation and study size.

PRENATAL ENVIRONMENTAL EXPOSURE, SUPPLEMENTATION WITH OMEGA-3 FATTY ACIDS DURING PREGNANCY AND RISK OF ATOPIC DERMATITIS IN MEXICAN INFANTS

Albino Barraza-Villarreal, *Instituto Nacional de Salud Pública, Cuernavaca, Morelos, México*

Isabelle Romieu, *International Agency for Research on Cancer, Lyon France*

Background and aims: The identification of family and environmental risks factors in early stages of life could help early detection of risk of atopy in children and studies suggest that omega-3 polyunsaturated fatty acids could play a role in preventing allergic diseases. We conducted this study to identify the main prenatal environmental risk factors of the atopic dermatitis in childhood whose mothers participated in a randomized clinical trial of supplementation with omega 3 fatty acids during pregnancy.
Methods: We included 785 children whose Mothers were randomly assigned to receive daily supplement of 400 mg of docosahexaenoic acid or placebo from week 18-22 of pregnancy until childbirth. During pregnancy, we obtained information on sociodemographics characteristics, environmental exposures and perceived stress. Clinical information of signs and symptoms of atopic dermatitis in infants was obtained every three months from birth until 18 months of age based on the classification of objective SCORAD at cutoff $\geq$ a 1. Logistic regression models were used to identify the main prenatal risk factors.
Results: We didn't observe significant differences in SCORAD prevalence for treatment group (25% in placebo vs 24.5% in DHA group). We observed that the higher risk of atopic dermatitis were for the infants that has been born in autumn (OR= 1.99; 95%CI 12.4, 3.19) and winter (OR= 1.85; 95%CI 1.18, 2.90) vs. spring and those born by cesarean (OR= 1.38; 95%IC 1.00, 1.92). Having spiders in the home (OR= 1.29; 95% CI 0.93, 1.79) and maternal history of allergic rhinitis (OR= 1.39; 95% CI 0.96, 2.01) were marginally associated.
Conclusions: This study strengthens the evidence that the family history and prenatal environmental exposure increase the risk of atopic dermatitis in early stages of life.

METHODS FOR ESTIMATING HEALTH EFFECTS OF MULTIPOLLUTANT MIXTURES IN COHORT STUDIES

Sverre Vedal, University of Washington, Seattle, USA
Adam Szpiro, University of Washington, Seattle, USA

Background: Given the complexity of the pollutant mix in ambient air, it is reasonable to assume that the focus on a few regulated air pollutants in health effects research provides only a limited picture of air pollution health effects and may hamper the effectiveness of air quality management programs. Data on many features of the complex ambient mix are now becoming more readily available, both from government monitoring networks and research-related monitoring campaigns. Besides the opportunities that such data provide in furthering understanding of pollution effects, there are challenges in specifying exposure estimates based on these complex data for use in health effects analyses. Many options can be considered in attempting to tackle these challenges.
Methods: We are working on an integrated methodology to predict a multivariate exposure for members of a cohort that accounts for correlation in space and between pollutant components and for differential measurement error between pollutants. Prediction will be based on a universal kriging model that incorporates land-use and other geographic data, and a principal component analysis approach to reducing the dimension of the exposure in order to obviate the need for high-dimensional effect modification. Using this methodology, relative disease risks of contrasting pollutant mixtures will be estimated with the aim of better understanding the relative toxicity of different mixtures and more effectively focusing regulatory efforts to lessen air pollution exposure effects.

ASSOCIATIONS BETWEEN GREENSPACE AND MORTALITY IN A POPULATION-BASED COHORT STUDY OF 574, 834 ADULTS IN ONTARIO, CANADA

Paul J. Villeneuve, *Health Canada, Ottawa, Ontario, Canada*
Michael Jerrett, *University of California Berkeley, California, United States*
Jason Su, *University of California Berkeley, California, United States*
Mark S. Goldberg, *McGill University, Montreal, Quebec, Canada*
Hong Chen, *McGill University, Montreal, Quebec, Canada*
Richard T. Burnett, *Health Canada, Ottawa, Ontario, Canada*

Background: Access and exposure to green space is associated with a wide range of potential health benefits. Few studies have examined the direct impact of exposure to greenspaces on mortality. We investigated the association between greenspaces and mortality using a population-based cohort design.
Methods: A cohort of 574,834 adults who were residents in one of 10 urban areas in Ontario, Canada in the early 1980s was assembled using income tax records. Vital status was determined through record linkage to the Canadian Mortality Data Base until the end of 2004. Six-character postal codes, representing a block face or large apartment building, from income tax records were used to identify the geographical coordinates for subjects' place of residence. To these locations we assigned the Normalized Difference Vegetation Index (NDVI) as a measure of greenspaces. The NDVI is derived from Landsat Thematic Mapper (TM) data at 30m x 30m resolution for the years 1989-1997. Rate ratios for mortality were estimated using the Cox model and adjusted for income, marital status, neighbourhood characteristics, ambient PM2.5, and smoking prevalence estimates from the 1990 Ontario Health Survey. Mortality endpoints studied included: all non-accidental causes, cardiopulmonary disease, ischemic heart disease, and stroke.
Results: A total of 181,107 non-accidental deaths occurred in the cohort. An inverse association was observed across increasing quartiles categories of 'greenspace'. For all non-accidental causes of death, the risks in the upper three quartiles relative to the lowest greenness quartile were: 0.95 (95% CI=0.94 – 0.96), 0.95 (95% CI=0.94 – 0.96), and 0.93 (95% CI=0.92 – 0.95). The corresponding risks for cardio-pulmonary mortality were: 0.95 (95% CI= 0.93 – 0.96), 0.94 (95% CI= 0.92 – 0.96), and 0.92 (95% CI=0.90 – 0.94). Inverse associations were also observed with ischemic heart disease, and stroke mortality.
Conclusions: Our study suggests that greenspace in urban environments is associated with lower rates of mortality.

COMMUNITY PARTICIPATION TO LOWER ARSENIC EXPOSURE MORE EFFECTIVELY IN BANGLADESH

Christine Marie, George, *Columbia University, Department of Environmental Health Sciences, New York, New York, USA*

Background/Aims: Millions of villagers in Bangladesh drink groundwater containing elevated levels of arsenic from their own well water even though arsenic safe water is often available within short walking distance. Well water arsenic testing has been shown to reduce arsenic exposure; however there have been no studies looking at the effectiveness of having a local villager conduct the well testing program.

Methods: We conducted a cluster-based randomized controlled trial(RCT) of 1000 households in 20 villages to investigate the impact of having a local person present within a village in comparison to an outside person conducting water arsenic testing and arsenic education in Singair,Bangladesh. Six months after the intervention the rate of well switching and the change in urinary arsenic from baseline was determined. This is the first RCT of arsenic education conducted in Bangladesh using a biological outcome indicator.

Results: The trained arsenic testers were able to convince 58% of study households with unsafe wells to switch to alternative drinking water sources. Although we did not find a statistically significant difference between the local and outside tester villages, this overall rate is more than twice the rate of well switching observed in areas that only received well testing from the nationwide Bangladesh Arsenic Mitigation Water Supply Project(BAMWSP). Furthermore the urinary arsenic levels of all study participants with unsafe wells that switched to safe drinking water sources(<50µg As/L) dropped from an average of 215µg As/g creatinine at baseline to 133µg As/g creatinine at follow-up, a 38% reduction in average urinary arsenic content. Those with unsafe wells that did not switch had an average urinary arsenic of 235µg As/g creatinine at follow-up.

Conclusions: The success of this intervention demonstrates that training upazila level staff to provide arsenic testing and education is an effective means of reducing arsenic exposure in villages in Bangladesh.

Background and Aims: The lung is a surprising target site for health effects of exposure to arsenic in drinking water (Smith et al. 2006; von Ehrenstein et al. 2005). Though we know such exposure causes lung cancer and respiratory effects in adults, we have yet to establish lung health effects after early life exposure. Exposure to arsenic is widespread in Bangladesh, but little is known about the effects on children (Smith et al. 2000). We will investigate lung health endpoints among children aged 7 to 16, after exposure in utero and in early childhood.

Methods: This population-based cohort study assessed the lung function and respiratory symptoms, including chronic cough and shortness of breath, of children 7 to 16 years old after arsenic exposure in utero and in the first five years of life. In utero exposure was assessed based on drinking water arsenic concentrations consumed by the mother during pregnancy. Here we compare children with in utero exposure to more than 500 ug/L of arsenic to children exposed to less than 10ug/L in utero.

Results: The most notable findings to date are that exposed children have considerably higher prevalence of several chronic respiratory symptoms compared to unexposed children. For example, children who had experienced in utero exposure to more than 500ug/L of arsenic were more likely to report shortness of breath when walking fast or climbing (OR=3.19, 95% CI 1.22-8.32, $p<0.01$), and nearly four times more likely to report shortness of breath when walking on level ground (OR=3.86 CI 1.09-13.7, $p=0.02$). However, there was little evidence of effects on lung function.

Conclusions: This is the first comprehensive study of early life exposure to arsenic in drinking water on lung health effects in children. Increased respiratory symptoms were identified, but so far we have found little measurable effect on lung function.

Prenatal Exposure To Butylbenzyl Phthalate And Early Eczema In Seroatopic Versus Nonatopic Children

Allan C. Just, *Columbia University, USA*
Robin M. Whyatt, *Columbia University, USA*
Matthew S. Perzanowski, *Columbia University, USA*
Antonia M. Calafat, *Centers for Disease Control and Prevention, USA*
Frederica P. Perera, *Columbia University, USA*
Inge F. Goldstein, *Columbia University, USA*
Rachel L. Miller, *Columbia University, USA*

Background and Aims: In a cross-sectional study, butylbenzyl phthalate (BBzP) concentrations in house dust were associated with eczema and rhinitis among children ages 3-8 years. Our aim was to test whether concentrations of monobenzyl phthalate (MBzP), a BBzP biomarker, in maternal urine during pregnancy are associated with allergic symptoms in young children and whether that varies by seroatopy.
Methods: MBzP was measured in a spot urine sample collected in 1999-2006 during the 3^{d} trimester of pregnancy from n=385 nonsmoking African American and Dominican women residing in New York City. Mothers completed repeat child symptom questionnaires through child age 60 months. Repeat child blood samples through age 84 months were analyzed for cockroach, dust mite, and mouse specific IgE defining seroatopy as ≥1 result of ≥0.35 IU/ml.
Results: MBzP was detected in >99% of urine samples (geometric mean (IQR), 18.4 (7.9, 41.0) ng/ml). By 24 months, 30% of children reported ever having eczema, with the proportion higher among African-Americans (48%) than Dominicans (20%), p<0.001. In multivariable logistic regression analyses, MBzP urinary concentration was associated positively with the odds of eczema (Odds Ratio 2.02, 95%CI [1.32, 3.09], p<0.001, n=385) for an IQR increase in log MBzP concentration, adjusting for specific gravity, child sex, and ethnicity. Stratified analysis suggests a stronger association for ever-eczema up to 24 months among non-atopics (OR 2.52, 95%CI [1.49, 4.25], p<0.001, n=264) than among atopics (OR 1.28, 95%CI [0.48, 3.41], p<0.62, n=92) for an IQR increase in MBzP. The association between MBzP and child ever-eczema remained significant through child age 60 months.
Conclusions: Prenatal exposure to BBzP may influence the risk of developing eczema in early childhood, especially among nonatopics.

A COHORT STUDY OF TRAFFIC-RELATED AIR POLLUTION AND CARDIOVASCULAR MORTALITY AMONG ADULTS IN THREE CANADIAN CITIES

Hong Chen, *McGill University, Montreal, Canada*
Mark Goldberg, *McGill University, Montreal, Canada*
Richard Burnett, *Health Canada, Ottawa, Canada*
Michael Jerrett, *University of California, Berkeley, California, U.S.A*
Amanda Wheeler, *Health Canada, Ottawa, Canada*
Paul Villeneuve, *Health Canada, Ottawa, Canada*

Background: Several longitudinal studies have demonstrated associations between air pollution and cardiovascular mortality, but few studies have assessed intra-urban variation in traffic-related pollution or evaluated health effects at lower levels of pollution that are typically seen in Canadian cities. The purpose of this study was to determine whether an association exists between traffic-related air pollution and cause-specific cardiovascular mortality among adults living in Ontario, Canada.

Methods: This population-based cohort study used as a sampling frame the Federal income tax database which captures 95% of Canadians. More than 660,000 adults who were 35 years of age and older and lived in 10 cities in Ontario between 1982 and 1986 were randomly selected from income tax database and were followed up through 2004. Mortality from cardiovascular and cerebrovascular disease were ascertained for all subjects over the period of 1982-2004 using the Canadian Mortality Database. We report herein an analysis of a sub-cohort who, at the time of entry, lived in either Toronto, Hamilton, and Windsor, Ontario (n=205,430), for whom we were able to make use of concentrations of NO_2 estimated from land use regression models. Adjusted Cox models included known individual risk factors and ecological covariables, and we conducted sensitivity analyses using indirect methods to adjust for smoking.

Results: For each increase of 5ppb of NO_2, the adjusted rate ratios (RR_{5ppb}) were 1.08 (95%CI: 1.04-1.11) for all cardiovascular mortality and 1.09 (95%CI: 1.04-1.14) for ischemic heart disease. Further indirect adjustment for smoking reduced the effect estimates, but the positive associations remained: all cardiovascular mortality, 1.04 (95%CI: 1.00-1.09) and ischemic heart disease, 1.05 (95%CI: 1.00-1.11). We did not find any effect for cerebrovascular disease (RR_{5ppb}=0.96; 95%CI: 0.89-1.03).

Conclusion: Our findings support the hypothesis that long-term exposure to traffic-related air pollution increases the risk of cardiovascular disease and in particular, from ischemic heart disease.

RESIDENTIAL PROXIMITY TO MAJOR ROADS AND PLACENTAL WEIGHT RELATIVE TO BIRTH WEIGHT

Takashi Yorifuji, *Department of Epidemiology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*
Hiroo Naruse, *Department of Obstetrics, Seirei Hamamatsu General Hospital, Hamamatsu, Shizuoka, Japan*
Saori Kashima, *Department of public health and health policy, Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan*
Toshihide Tsuda, *Department of Environmental Epidemiology, Okayama University Graduate School of Environmental Science, Okayama, Japan*
Hiroyuki Doi, *Department of Epidemiology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan*
Ichiro Kawachi, *Department of Society, Human Development, and Health, Harvard School of Public Health, Boston, MA, USA*

Background and Aims: The ratio between placenta and birth weight could be a useful indicator of placental function and a disproportionately large placenta may show an inefficient placenta with decreased ability to translate its own growth to fetal growth. A recent study suggests that a disproportionately large placenta is associated with increased risk of cardiovascular disease death in later life. We thus evaluated the association between proximity to major roads (as an index for air pollution) and placental weight relative to birth weight.
Methods: Data on parental information and birth outcomes were extracted from the database maintained by the perinatal hospital in Shizuoka, Japan. We restricted the analysis to mothers who delivered liveborn single births from 1997 to 2008 (n = 14,189). Using the geocoded residential information, each birth was classified on its proximity to major roads. We estimated the multivariate-beta coefficients and their 95% confidence intervals (CIs) for the association of proximity to major roads with the placenta-birth-weight-ratio as well as placental weight, using multiple linear regression.
Results: We found a positive association between proximity to major roads and the placenta-birth-weight-ratio. Mean of the placenta-birth-weight-ratio was 20.1 % for mothers living outside 200m from major roads, in contrast the mean was 20.5 % for mothers living within 200 m. After adjusting for potential confounders, living within 200 m increased the ratio by 0.45 % (95% CI = 0.13 – 0.78). Proximity also decreased the placental weight by 13.67 g (95% CI = 5.15 – 22.18); however the association was attenuated after birth weight adjustment.
Conclusions: This study demonstrates that exposure to traffic-related air pollution increases the placenta-birth-weight-ratio.

BREAST CANCER RISK AND TETRACHLOROETHYLENE-CONTAMINATED DRINKING WATER IN CAPE COD, MASSACHUSETTS: A REANALYSIS OF CASE-CONTROL DATA USING GIS, RESIDENTIAL HISTORIES, AND A MODIFIED EXPOSURE ASSESSMENT

Verónica Vieira, *Boston University School of Public Health, USA*
Lisa Gallagher, *Boston University School of Public Health, USA*
David Ozonoff, *Boston University School of Public Health, USA*
Thomas Webster, *Boston University School of Public Health, USA*
Ann Aschengrau, *Boston University School of Public Health, USA*

Background and Aims: A population-based case-control study was undertaken to investigate the association between tetrachloroethylene (PCE) exposure from public drinking water and breast cancer among residents of Cape Cod, Massachusetts. PCE, a volatile organic chemical, leached from the vinyl lining of water distribution pipes into drinking water from the late 1960s through the early 1980s. A retrospective exposure model was needed given the lack of historical environmental data and the long latency of breast cancer.

Methods: Historic PCE exposure estimates were generated by integrating residential histories with a water distribution modeling software (EPANET 2.0) using GIS. We modified the publicly available source code for EPANET to include an algorithm for the PCE-leaching component. The exposure distribution using the modified EPANET model was compared to estimates generated with a simplified location-only exposure method that did not account for water flow patterns and to PCE concentrations measured in water samples. Lastly, we reanalyzed the risk of breast cancer using the modified EPANET exposure model to determine how an improvement in exposure assessment changes the results of an earlier study.

Results: Estimates using the modified exposure model had a higher correlation with PCE concentrations in water samples (Spearman correlation coefficient =0.65, $p<0.0001$) than estimates generated using the location-only exposure method (0.54, $p<0.0001$). However, we found a similar modest increase in the risk of breast cancer for women with high PCE exposure levels for both exposure methods (adjusted ORs 1.3-2.0).

Conclusions: The incorporation of sophisticated flow estimates in the exposure assessment method shifted the PCE exposure distribution downward, but did not meaningfully affect the exposure ranking of subjects or the strength of the association with the risk of breast cancer found in earlier analyses. Thus, these breast cancer associations are relatively robust to refinements in exposure modeling.

A CALIBRATION FUNCTION FOR HANDHELD PM2.5 MONITORS IN DIESEL-POLLUTED ENVIRONMENTS

Gregory J. Howard, *Dickinson College, United States*
Kevin Lane, *Boston University School of Public Health, United States*
Greg Patts, *Boston University School of Public Health, United States*
Madeleine Kangsen Scammell, *Boston University School of Public Health, United States*

Background and Aims: Handheld fine particulate matter ($PM_{2.5}$) monitors are increasingly used for exposure assessment due to the expense and lack of portability of reference methods. These handheld monitors have been shown to provide data that is not directly comparable to reference monitors. Although typically calibrated with dust standards (e.g., Arizona Road Dust), they are often used to measure particles dominated by compositions with different characteristics, such as diesel. Previous authors have attempted to determine a constant factor by which measurements of handheld monitors can be corrected. In urbanized areas where PM predominantly derives from diesel emissions, distribution of particle sizes differs from dust, and a constant calibration factor may not be appropriate. Instead, we derive a linear calibration function which more accurately represents the relationship between handheld and reference readings of diesel-related $PM_{2.5}$.
Methods: We collected data with co-located handheld and reference monitors simultaneously at sites contaminated with diesel PM in Boston, MA and Carlisle, PA. Handheld monitors were Sidepak AM510 (TSI Inc); references were beta attenuation monitors. Pilot data consisted of 80 hours (four monitor-days) of simultaneous measurements. Data collection continues during the summer of 2011.
Results: The Sidepaks read PM2.5 values substantially higher than the BAMs, consistent with previous studies. A linear calibration function was observed, ranging from about 1.0 at low $PM_{2.5}$, to about 3.5 at the highest PM2.5 levels (over 30 $\mu g/m^3$, twice the USEPA annual average standard), resulting in an excellent fit (R^2=0.8). Slopes and intercepts of each monitor-day regression were similar. A simple equation for a calibration function was then derived to correct Sidepak to BAM readings.
Conclusions: The proposed calibration function substantially improves correction of handheld monitor $PM_{2.5}$ data. In areas where transportation-related diesel contributes to PM, this provides more accurate PM measurements for exposure assessment and comparison with national standards.

ATRAZINE EXPOSURE FROM DRINKING WATER AND ADVERSE BIRTH OUTCOMES IN KENTUCKY, U.S.A.

Claudia Hopenhayn,*University of Kentucky, United States*
Jessica Rinsky, *University of North Carolina at Chapel Hill, United States*
Vijay Golla, *Western Kentucky University, United States*
Steve Browning, *University of Kentucky, United States*
Heather Bush,*University of Kentucky, United States*

Background and Objectives: Herbicide useis widespread worldwide, with atrazine being one of the most common in the U.S.A. and other countries. Recent studies suggest a possible association betweenatrazine exposure and adverse birth outcomes. Kentucky, a largely ruralstate with high atrazine use, ranks among the highest in the U.S.A.in rates of prematurity and low birth weight.We examinedthe relationship between atrazine in drinking water andpreterm births, gestational age and birthweight.
Methods: Kentucky birth certificate data were analyzed to assess birth outcomes and other individual-level covariates. Data from 2004-2006 were used for all singleton births toKentucky residents. Atrazine levels in drinkingwater were assessed at the county level using data from the Department of Water andthe Kentucky Geologic Survey.Counties were categorized into tertiles of atrazine exposure (high, moderate, low). Multivariate linear and logistic models were used to assess the potential risk contribution of atrazine to birth weight, gestational age and preterm births (<37 weeks of gestation).
Results: A significant risk was observed for preterm births forwomen residing in the high versus low exposure counties while controlling for relevant individual covariates (OR= 1.26; 95% CI 1.19, 1.33). Similar results were found for gestational age as a continuous variable, with a difference of -0.20 weeks (95% C.I. -0.25, -0.16), and for birth weight, with a decrease of -25.8 grams (95% C.I. -34.9,-16.6).
Conclusions: The results of this study indicated a modest association between atrazine exposure and adverse birth outcomes. The results were consistent with similar recent studies.However, due to the ecologic nature of the exposure assessment and the possibility of exposure misclassification further individual-levelresearch is strongly recommended to assess the relationship between atrazine exposure and adverse birth outcomes.

PARTICULATE AIR POLLUTION AND SURVIVAL: PROPORTIONALITY ASSUMPTION, TIMING OF DOSE, AND DOSE-RESPONSE RELATIONSHIP IN THE HARVARD SIX CITIES STUDY

Johanna Lepeule, *Department of Environmental Health, Harvard School of Public Health, Boston, MA, United States*
Francine Laden, *Department of Environmental Health, Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States*
Channing laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States
Joel Schwartz, *Department of Environmental Health, Department of Epidemiology, Harvard School of Public Health, Boston, MA, United States*

Background and Aims: The association of fine particulate air pollution ($PM_{2.5}$) with mortality is well established, however questions have been raised about the sensitivity of results to model specification, including whether covariates are proportional and whether the dose-response is linear. We addressed these issues using an extended follow-up of the Harvard Six Cities Study through 2006, incorporating more recent lower exposures.
Methods: 8111 white adults were included. Personal characteristics were collected at enrollment (1974). Vital status has been updated using the National Death Index. Annual $PM_{2.5}$ was measured by study or US EPA monitors. We replicated the original results for $PM_{2.5}$ and all-cause mortality using a Cox regression and repeated with a Poisson survival analysis with separate hazard rates for each year of follow-up. To relax the proportionality assumption, we included interactions between year of follow-up and smoking, sex, and education. We examined the shape of the dose response relationship using penalized splines and the fit of models with different lags.
Results: Poisson and Cox models produced similar results, which did not change with time-varying covariate effects. Akaike's information criterion was lower for models using current year's $PM_{2.5}$ than for the models including earlier years. Each 10µg/m^3 increase in $PM_{2.5}$ exposure in the year of death was associated with an adjusted RR=1.13 (95% CI, 1.06-1.20). The penalized spline model chose one degree of freedom, indicating a linear dose-response relationship. The results did not show any rationale for threshold in the association, and the effects of $PM_{2.5}$ did not change by time period.
Conclusions: Including more recent observations with exposures below the US standard (15µg/m^3), we found a strong linear association without any threshold between $PM_{2.5}$ and all-cause mortality. Results showed that current year was the best exposure window and that the toxicity of $PM_{2.5}$ has not changed over time.

ASSOCIATION BETWEEN VEHICULAR DENSITY AND HOSPITALIZATION BY RESPIRATORY DISEASES AMONG CHILDREN IN THE CITY OF SAO PAULO, BRAZIL

Maria Regina Cardoso, *University of São Paulo, Brazil*
Clarice Freitas, *Secretariat of Health of São Paulo, Brazil*
Adelaide Nardocci, *University of São Paulo, Brazil*
Agnes S. Silva, *Panamerican Health Organization, USA*
Helena Ribeiro, *University of São Paulo, Brazil*
Samuel L. Almeida, *University of São Paulo, Brazil*
Marco A. Oliveira Jr, *University of São Paulo, Brazil*
Mirta Rodrigues Silva, *Secretariat of Health of São Paulo, Brazil*

Background and aims: Traffic-related air pollution has been associated with respiratory disease (RD) in children in different developed countries. In Brazil, this is the first study to look at the impact of this exposure on the respiratory health of this population subgroup.

Methods: Hospital admissions by RD (ICD-10: J00-J06; J10-J16; J18; J20-J22 and J45-J46) of children <5 years old, from public and private hospitals of the city of Sao Paulo in the period 2004-2006, were geocoded according to their residence addresses . Vehicular density (VD) was calculated for micro-areas of 500m2 of the city and was used as the indicator of exposure to traffic-related air pollution. The number of resident people, household density (HD) and the Human Development Index (HDI) were available for these micro-areas. Admission rates for children were calculated for the micro-areas and VD, HD and HDI were categorized into quartiles. Multiple logistic regression models with the admission rates as the dichotomous dependent variable (equal or greater than the median) and VD, HD and HDI as independent variables were used.

Results: 76,351 admissions of children were analyzed in 3,755 micro-areas of Sao Paulo. Having the first quartile of VD as baseline and allowing for HD and HDI, the adjusted OR for children admissions were: 1.87(95%CI:1.53-2.93); 2.42(95%CI:1.93-3.02); 2.49(95%CI:1.98-3.12). When VD was treated as continuous, a significant association was observed (OR=1.009; 95%CI:1.004-1.014). Thus, for a vehicle per 500m2 increase there was an increase of 0.9% in the chance of a child being hospitalized by RD. Similar associations were observed when the type of fuel (gasoline or diesel) and disease subgroups (asthma, pneumonia and upper respiratory infections) were considered separately.

Conclusion: These findings indicate that mobile sources of air pollution have great influence on hospitalization by RD among children in the city.

TRANSFER RATE DIFFERENCE ACCORDING TO THE CONGENERS AND ISOMERS SHOULD BE CONSIDERED IN RISK ASSESSMENT OF FETAL EXPOSURE TO PBDEs AND POPs

Yoshiharu Matsuno, *Chiba University, Japan*
Takeyoshi Fujisaki, *Chiba University, Japan*
Emiko Todaka, *Chiba University, Japan*
Michiko Shimoda, *Chiba University, Japan*
Hiroko Nakaoka, *Chiba University, Japan*
Masamichi Hanazato, *Chiba University, Japan*
Noriko Nakamura, *Marshall University, USA*
Chisato Mori, *Chiba University, Japan*

Background and Aims: Polybrominated Diphenyl Ethers (PBDEs) and Persistent Organic Pollutants (POPs) have been reported to have toxicity and endocrine disrupting effects. However, the health effects of PBDEs, PCBs and Dioxins have been reported to be different among the congeners and isomers. The purposes in the current study were; 1) to see the current exposure level of PBDEs and POPs in human adults and fetuses by using maternal blood (MB), cord blood (CB) and umbilical cord tissue (UC), 2) to see the difference of trans placental transfer situation of PBDEs, PCBs and Dioxins, and 3) to see the correlations among the POPs in fetus by using UC.
Methods: Eighty set samples (MB, CB and UC) and 86 UCs were collected at deliveries in Chiba University Hospital and some other obstetrics in Japan. The congeners and isomers of PBDEs, PCBs and Dioxins(PCDDs+PCDFs+Co-PCBs) were measured in 10 set samples, 29 set samples and 41 set samples, respectively. Also, PCBs and POPs (p,p'-DDE, trans-Nonachlor, cis-Nonachlor, Oxychlordane, HCB, Mirex, • -HCH) were measured in 86 UCs. All the measurements were done by GC/MS.
Results: PBDEs, PCBs and Dioxins were found from all the set samples. Also, PCBs and POPs were found from all the UC. Transfer rates of each congener and isomer of PBDEs, PCBs and Dioxins from MB to CB and from MB to UC were different. Also, a negative correlation was found between transfer rates of each congener and isomer and molecular weight (MW). It was found that the congeners and isomers larger than 1000MW didn't transfer from mother to fetus. Also, significant correlation between PCBs and other POPs was found in UC.
Conclusions: In risk assessment of chemicals, it is important to consider the difference of exposure level and the difference of transfer rate among congeners and isomers between adults and fetuses.

SHIFTS IN MORTALITY DURING A HOT WEATHER EVENT IN VANCOUVER, CANADA: RAPID ASSESSMENT USING CASE-ONLY ANALYSIS

Tom Kosatsky, *BC Centre for Disease Control, Canada*
Sarah Henderson, *BC Centre for Disease Control, Canada*
Sue Pollock, *Public Health Agency of Canada*

Background: During the summer of 2009, greater Vancouver (in British Columbia, Canada) experienced several days of unusually hot temperatures. Episodes of extreme heat in other northern cities have been associated with considerable excess mortality, especially among the most elderly, and those living in dense, and/or disadvantaged urban neighbourhoods.
Methods: A case-only analysis was used to compare characteristics of individuals who died during the hottest week of 2009 with those who died (1) during earlier summer weeks in 2009 and (2) during the same calendar weeks in the summers of 2004-2008.
Results: Risk of mortality during the hot weather event was significantly higher in the 65-74 age category than in the 85+ category (OR = 1.50; 95%CI = 1.09–2.06). Deaths at home were increased over deaths in hospitals or institutions (OR = 1.39; 95%CI = 1.06–1.80). Densely populated administrative health areas were more affected.
Conclusions: A significant shift towards deaths at home suggests that home-based protective measures should be part of planning for hot weather in Vancouver. Targeting should be considered for persons in the 65-74 age category. The case-only approach is quick and easy to apply, and it can provide authorities with useful information about patterns of mortality during localized, time-limited events

EFFECTS OF DIURNAL TEMPERATURE CHANGES ON ASTHMATIC CHILDREN: A CASE CONTROL STUDY

Yau-Chang Kuo, *Department of occupational and environmental medicine, National Cheng-Kung University Hospital, Tainan, Taiwan - National Cheng Kung University, Tainan, Taiwan.*

Yu-Shing Lo, *Kaohsiung Municipal United Hospital, Kaohsiung, Taiwan*.

Chao-Yu Chang, *Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*.

How-Ran Guo*, *Department of occupational and environmental medicine, National Cheng-Kung University Hospital, Tainan, Taiwan - National Cheng Kung University, Tainan, Taiwan*.

Background and Aims: The prevalence of childhood asthma has been increasing in Taiwan despite the efforts of air pollution control. This case-control study was performed to evaluate whether diurnal temperature changes may affect the exacerbation of asthma.

Methods: Data on both climate factors and air pollutants were obtained from local governmental agencies. During our year long study period, the case group was defined as the days of admission for asthma and the other days were classified as the control group. The days with admissions included the days when patients under 18 years of age were admitted to hospitals with the chief problem of asthma. We assessed 7,623 patients with asthma (age Ž 18) and compared the characteristics between these two groups of days, including diurnal temperature changes. Multiple linear regressions were used to assess the effects of both temperature changes and air pollution.

Results: The effects of diurnal temperature changes were relatively consistent in a given geographic area during a specific season. During the winter period, there were positive correlations in the regions south of the Tropic of Cancer and negative correlations in the northern regions. In other seasons, we found positive associations in plain regions near the coastline and negative associations in mountain regions away from the coastline.

Conclusions: Diurnal temperature changes may affect the exacerbation of childhood asthma, but the effects vary across different geographic areas and seasons. The relatively consistent trends in a given season within a given geographic zone indicated both the seasons and landforms might affect the associations. The diurnal changes of temperature can be an important index to predict the acute onset of asthma, and it may affect the exacerbation of asthma in children through the mechanism of physical accommodation.

DIARRHOEAL MORBIDITY PREVALENCE IN UNDER-FIVE CHILDREN ASSOCIATED WITH ENVIRONMENTAL FACTORS AND HYGIENE PRACTICES IN DANGILA ZURIA WOREDA, NORTHWEST ETHIOPIA

Wondwossen Birke Eshete, *Jimma University, Ethiopia*
Dessalegn Dadi, *Jimma University, Ethiopia*
Mulgeta Mekonnen, *Dangila Zuria Woreda Health Bureau, Ethiopia*

Background and Aims: Though the relationship between environmental and hygiene risk factors, and the occurrence of diarrhoea in children have been documented elsewhere, there are limited studies in Ethiopia in general and in Dangila Zuria Woreda in particular. The present study aimed to assess under-five diarrheal morbidity prevalence associated with environmental factors and hygiene practices.
Methods: Community-based cross-sectional study was conducted in Dangila Zuria Woreda from March 24-April 21, 2010. 520 mothers of index under-five children living in systematically taken households from 7 randomly selected Kebeles out of 28 in the Woreda constituted the study population. Data were collected using structured and pre-tested questionnaire, entered into a computer, edited and analysed using SPSS version 15.0. Stepwise logistic regression model was used to calculate the Odds ratios and 95% confidence interval for the different risk factors.
Results: Out of 520 sampled mother-child pairs, 498 participated in the study giving a response rate of 95.8%. Prevalence of diarrheal morbidity over a period of two weeks preceding the study was about 24.9%. In the bivariate analysis, a number of risk factors including latrine condition, presence of handwashing facility ($P<0.001$) and latrine availability, all family latrine use, reason to use latrine as excreta dangerous, proper child faeces disposal, mothers' handwashing practice and handwashing with soap after defecation ($P<0.05$) appeared to be significantly associated with under-five childhood diarrheal morbidity. However, all family latrine use, reason to use latrine as excreta dangerous, proper child faeces disposal, mothers' handwashing practice and handwashing with soap after defecation were the only significant variables on multivariate analyses ($P< 0.05$).
Conclusions: As diarrhoea morbidity was major problem among under-five children in the Woreda, continuous, regular and targeted hygiene education programs are very essential in order to bring about behavioral change and reduce the risk of childhood diarrhoeal morbidity.

ASSOCIATIONS BETWEEN OZONE EXPOSURE AND DYSFUNCTOIN OF CARDIAC AUTONOMIC NERVOUS SYSTEM IN HEALTHY ELDERLY SUBJECTS

Xiaofeng Jia, *Peking University School of Public Health, Beijing, China*
Xiaoming Song, *Peking University School of Public Health, Beijing, China*
Masayuki Shima, *Hyogo College of Medicine, Nishinomiya, Japan*
Kenji Tamura, *National Institute for Environmental Studies, Tsukuba, Japan*
Furong Deng, *Peking University School of Public Health, Beijing, China*
Xinbiao Guo, *Peking University School of Public Health, Beijing, China*

Background and Aims: Previous studies have provided strong evidences that elevated levels of ambient ozone (O_3) are associated with the increased cardiovascular mortality and morbidity. The dysfunction of cardiac autonomic nervous system (ANS), indicated by the disturbed heart rate variability (HRV) indices, is the major contributor to the triggering of electro-physiologic diseases. Heterogeneous associations between O_3 exposures within several hours and HRV in subjects with compromised health status are reported in some previous studies. No studies, however, have focused on the effect of several minutes O_3 exposure on healthy elderly subjects.

Methods: Real time ambient O_3 concentration and HRV indices of 20 healthy elderly subjects were measured continuously and concurrently by 5-min segment in winter, Beijing. Mixed linear model was used to evaluate the associations between ambient 5-min average O_3 and concurrent 5-min HRV frequency indices adjusting for the time-variant variables (temperature and relative humidity) and subject characteristics.

Results: Elevated ambient O_3 exposure was associated with decreased High Frequency (HF) (• =-0.00213, *p*=0.024) and increased low-frequency/high-frequency ratio (LFHFR) (• =0.00177, *p*=0.016) in healthy elderly subjects.

Conclusions: We conclude that ambient O_3 exposures within several minutes may exert predominance of cardiac sympathetic nervous activity, which may increase the risk for acute cardiac events.

HEALTH CONCERN AND CHALLENGES OF ADOLESCENTS

Abebe Gbremariam Hailu, *Jimma University, Ethiopia*

Background and Aims: Adolescence is a time where they tend to become involved in high-risk, health compromising behaviors and yet feel invincible to the negative consequences of their actions. The aim of this study is to asses the health concerns and challenges and factors influencing their health care utilization to fill gaps of scarcity of literature in Jimma zone Southwest Ethiopia.
Methods: this is a cross-sectional study conducted among adolescents 10-19 years The source population for the study were all (N= 11, 048) adolescents aged 10-19 years enrolled in 8 Junior and senior high schools in seven Districts. 1768 adolescents were proportional to class size were randomly selected from the school roasters stratified (grades 7&8; 9&10, & 11&12th) according to operational definition of age of the adolescents. Pre-tested, self- administered questionnaires was used to collect the required information. Data was analyzed using SPSS/PC + computer statistical package version 12.0.
Results: 1768 adolescents responded to the questionnaire making a response rate of 100%. Male respondents (53.6%) and female (55.1%) age lies in the age group of 17-19 and 14-16 years respectively. 75.1% reported ill-health conditions that include headache (29.9%), dental problems (20.6%), Sexually Transmitted Infections (20.4%) and abdominal problems (8.7%). 56.8% sought help for their health problem. Gender, grade, occupation of parents and living with both biological parents showed statistically significant association with encountered health problems reported and seeking health care ($p<0.001$).
Conclusions: this study showed important health problems of adolescents, with their influencing factors. The proportion of treatment seeking behaviors is discouraging. Factors contributing to health seeking behavior should be strengthened and sustained to the current trend. Identification and early prevention of adolescents behavioral, social and physical health problems, establishment of special adolescent health service in schools and at the community setting at large is recommended.

URBAN AIR POLLUTION AND EMERGENCY VISITS AND IN-HOSPITAL MORTALITY IN TEHRAN HEART CENTER

Soheil Saadat, *Sina Trauma Research Center (STRC), Tehran University of Medical Sciences, Iran*
Saeed Sadeghian, *Tehran Heart Center hospital, Tehran University of Medical Sciences, Iran*
Mosoumeh Lotfi, *Tehran Heart Center hospital, Tehran University of Medical Sciences, Iran*
Mohammad Ali Najafi, *Air Quality Control Company, Tehran Municipality, Iran*

Background and Aims: Tehran -the capital of Iran- with a population of approximately 7.9 million, only 30% of the days in a year profits healthy air quality. Critical air pollution happened in the June 2009 that resulted in closure of governmental offices in this city. The aim of this study was to evaluate the effect of air pollution on the emergency visit, hospitalization and in-hospital mortality of acute coronary syndrome (ACS) patients referred to a referral heart center (THC) in the capital of Iran.
Methods: Patients admitted to the emergency ward of THC between 22 June and 22 July 2009 were included in this cross sectional study. Meteorological data were obtained from "Air Quality Control Corporation Geophysics station" which is located about 1000 meters away from THC. A principal component analysis was utilized to extract a linear combination of air pollutants which represented eigenvalue > 1. Then, a regression analysis was utilized to determine the air pollution exposure level and the frequency of patients admitted with unstable angina, myocardial infarction and arrhythmia. The principal component linear combination was considered as the exposure level for the regression analysis.
Results: Three thousands and ninety patients were included. The mean daily number of patients referred to THC was 112.5±12.6 during the polluted period and 100.8±17.6 during the other days ($P<0.001$). Hospitalization rate and the in hospital mortality were 20.0±4.9 and 0.9±0.1 during the pollution period compared to 17.0±3.9 and 0.2±0.4 in other days ($P<0.001$).
The proportion of patients aged 85 and more referred to THC, was directly associated with the concentration of PM-10 during the study period. The principal component score was higher in admission date of patients expired during hospitalization compared to that of patients discharged alive from the hospital ($P<0.05$).
After adjustment for the effect of age, sex, smoking, hypertension, hyperlipidaemia and diabetes, a statistically significant relationship between principal component score at the admission date of patients and the frequency unstable angina ($P<0.05$) and arrhythmia ($P<0.05$) was detected.
Conclusions: Air pollution is associated with increased emergency visit and hospitalization of patients, especially elderly, referred with unstable angina and arrhythmia. It is also associated with increased in-hospital mortality of patients admitted with ACS.

Xinbiao Guo, *Department of Occupational and Environmental Health Sciences, Peking University School of Public Health, Beijing, China*

Background and Aims: Epidemiological studies have linked particulate matter (PM) and carbon monoxide (CO) exposures with alterations in cardiac autonomic function as measured by heart rate variability (HRV) in populations. Recently we reported association of several HRV indices with marked changes in particulate air pollution around the Beijing 2008 Olympic Games in a panel of healthy taxi drivers (Wu et al., 2010). We further investigated the cardiac effects of traffic-related air pollutants over wide exposure ranges with expanded data set in this panel of healthy adults.

Methods: We obtained real-time data on nine taxi drivers' in-car exposures to particulate matter ≤2.5 μm in aerodynamic diameter ($PM_{2.5}$) and CO, and on multiple HRV indices during a separate daily work shift in four study periods with dramatically-changing air pollution levels around the Beijing 2008 Olympic Games. Mixed-effects models and a loess smoother method were used to investigate the associations of exposures with HRV indices.

Results: Results showed overall negative associations of traffic-related air pollutants with HRV indices across periods, as well as differences in period-specific and individual associations. After stratifying the individuals into two different response groups (positive group/negative group), cardiac effects of air pollutants became stronger within each group. For example, a 7.5% (95% CI, 2.8%, 12.5%) increase and a 3.6% (95% CI, -5.4%, -1.8%) decline in standard deviations of normal-to-normal (SDNN) intervals per interquartile range (IQR: 75.1 $\mu g/m^3$) increase at 30-min $PM_{2.5}$ moving average were found for the positive group and negative group, respectively. Exposure-response modeling identified changed curvilinear relationships between air pollution exposures and HRV indices with threshold effects.

Conclusions: Our results support the association of exposure to traffic-related air pollution with altered cardiac autonomic function in healthy adults free of cardiovascular compromises. These results suggest a complicated mechanism that traffic-related air pollutants influence the cardiovascular system of healthy adults.

HEALTH BENEFITS OF POLICIES TO CLEAN UP POLLUTED SITES OF GELA AND PRIOLO, ITALY.

Carla Guerriero,, *London School of Hygiene and Tropical Medicine, London, UK*
Fabrizio Bianchi *NRC Institute of Clinical Physiology, Unit of Environmental Epidemiology, Pisa*
John Cairns *London School of Hygiene and Tropical Medicine, London, UK*
Liliana Cori *Institute of Clinical Physiology, Unit of Environmental Epidemiology Rome*

Background and Aims: In 1998, law 426/98 established Priolo and Gela among the first 15 Italian sites included in the National Reclaim Program. Since then little has been done to reclaim the two petrochemical industrial sites. To date the agreed funds allocated for cleanup are €774.5 million for Priolo and € 127.4 million in Gela. However, these estimates cover only a part of the cost for the interventions required. This study aims to quantify in monetary terms the health benefits resulting from cleanup interventions in the toxic hot spots of Gela and Priolo and to evaluate if further needed investments would be cost beneficial (benefits outweigh cost).
Methods: A damage function approach was used to estimate the number of health outcomes attributable to industrial pollution exposure. Extensive one-way analyses and probabilistic analyses were conducted to investigate the sensitivity of results to different model assumptions.
Results: It has been estimated that, on average, 47 cases of premature death, 281 cases of non-fatal cancer and 2,702 hospital admissions could be avoided each year by removing environmental exposure in these two areas. Assuming a 20 years cessation lag and a 4% discount rate we calculate that the potential monetary benefit of removing industrial pollution is €3,592 million in Priolo and €6,639 million in Gela.
Conclusions: Given the annual number of health outcomes attributable to pollution exposure and the limited amount of funds up to now established, the effective cleanup of Gela and Priolo should be prioritised. This study suggests that cleanup policies costing up to €6,639 million in Gela and €3,592 million in Priolo would be cost beneficial. These two amounts are notably higher than the funds allocated thus far to clean up the two sites, implying that further economic investments – even considerable ones - could still prove cost beneficial.

EPIDEMIOLOGY OF TRAFFIC INJURIES AND MOTOR VEHICLES UTILIZATION IN TEHRAN: A POPULATION BASED STUDY

Soheil Saadat, *Sina Trauma Research Center (STRC), Tehran University of Medical Sciences, Iran*
Hamid Soori, *Safety Promotion and Injury Prevention Research Center, Shahid Beheshti University of Medical Sciences, Iran*

Background and Aims: Road traffic injuries are considered to be the second highest cause of mortality in Iran (1). Iran has one of the greatest fatality rates from RTIs. There is not a reliable national injury surveillance system available in Iran and there is uncertainty on measures of RTIs.
We studied the annual incidence of RTIs, the incidence of RTIs per 1000 vehicles and utilization of vehicles in Tehran, the capital of Iran.
Methods: In this population based study, 2488 households were randomly selected to be interviewed using the registry of residential addresses. They were asked to report any RTIs in their household during the past year.
Results: Nine thousand and one hundred inhabitants were included. There were 119 RTI (38.7% pedestrians, 46.2% motor cyclist and 15.1% car occupants) and 3 deaths in the survey sample. The annual incidence of all RTIs for 100000 population was 1310 (CI: 1080-1560) and that of fatal traffic injuries was 32.97 (CI: 6.8-96.3). Motorcycles were involved in 41.3% of RTIs that occurred for pedestrians. 19.7% of the households had motorcycle; 2.4% belonged to women. Women mostly rode as passengers rather than driving a motorcycle. The annual incidence of collision RTI for 1000 motorcycle was 95. Moreover, 32.5% of the Motorcycle riders had experienced non-collision transport accident (i.e. fall). 58.5% of the households owned a car; 12.3% belonged to women. The annual incidence of car occupant RTI per 1000 car was 10.
Conclusions: This population-based study showed that the morbidity rate of RTIs is about ten times higher than the national figures reported by other available sources. This is an important alarm to countries like Iran to put the issue as a priority in their public health activities. Although the number of motorcycles was one thirds of cars, they are involved in a considerable proportion of RTIs. The attributable risk of RTI for motorcycles is estimated as 46.3%. There is need for effective safety regulations to control this pattern.

STUDY DESIGNS THAT MAY LEAD TO UNETHICAL RESEARCH OR THE INAPPROPRIATE INTERPRETATION OF FINDINGS; ADDRESSING WHISTLE BLOWING

Dr. Wael K Al-Delaimy
University of California, San Diego, United States

Several stakeholders are involved in the discipline of Environmental Epidemiology and conflicting interests are regularly encountered by researchers and professionals working in this field. Guidelines are therefore needed to provide an ethical framework for environmental epidemiologists to help minimize ethical challenges when conducting research and when applying their knowledge in practice. In this symposium, presenters highlight these guidelines which are now revised to address more recent ethical challenges. In this presentation, two topics related to these guidelines will be addressed citing examples involving fellow epidemiologists. The first is study design as the responsibility of the epidemiologist. The design must enable researchers to test the hypothesis and association in question. An environmental epidemiologist has to decide on the most appropriate design, given all other factors of cost, feasibility, study power, and the ability to measure the exposure and outcomes. Study design will influence the quality of results, interpretation, and the impact the study may have on public health practice, education and policy. It therefore becomes unethical to conduct a study with an inappropriate study design that could lead to biased and invalid findings. This becomes further ethically unacceptable when these biases and weaknesses are not clearly described in the limitations of the study and its conclusion. Another important topic in environmental epidemiology is the persecution, discrimination, harassment and threats that fellow epidemiologist face when they become whistle blowers and report inappropriate institutional conduct or release important study findings that are being obstructed by their institutions. ISEE has clear guidelines on dealing with whistleblowers which has helped in support of such cases in the past. This presentation will engage the audience and provide the opportunity for discussion during the session by addressing the above points in light of the revised ethics guidelines and explicated through case studies.

BIOMARKERS IN ENVIRONMENTAL EPIDEMIOLOGY: ETHICAL CHALLENGES

Wael K Al-Delaimy MD, PhD, *University of California, San Diego, USA*

Environmental epidemiology is a multidisciplinary science and covers a range of methodological and design approaches. Exposure assessment is a critical component of the discipline and there are continued efforts to improve it in order to determine smaller scale, but widespread, environmental risks. Biomarkers are promising tools to overcome measurement error from subjective, less sensitive, and nonspecific questionnaires. However, this involves collection of bodily fluids or tissue, which is an invasive and potentially more ethically challenging approach than self-reports or other forms of exposure assessment. If such biospecimens are collected from study participants, the benefits, risks, and discomfort associated with collection should be explained during the consent of participants. This can lead to lower response rates and more scrutiny by Institutional Review Boards. The study aims that biospecimens will be needed to address, must be disclosed beforehand to study participants. Furthermore, the final disposition of any remaining samples after the study is completed must be explained. If future studies require the use of these samples for different questions there must be prior approval and consent by participants to that. If less invasive or more accurate methods of exposure assessment are available, it may be unethical to utilize biomarkers that do not offer better quality measurement data. There are more biobanks established through out the world than in previous years, but there is no corresponding increase in literature on ethical use of these biomarkers in environmental epidemiology. The presentation will discuss some of these questions in light of the relevant oral sessions in the symposiums that involve biomarkers.

ASSOCIATION BETWEEN VEHICULAR DENSITY AND HOSPITALIZATION BY RESPIRATORY DISEASES AMONG THE ELDERLY IN THE CITY OF SAO PAULO, BRAZIL

Adelaide Nardocci, *University of São Paulo, Brazil*
Maria Regina Cardoso, *University of São Paulo, Brazil*
Clarice Freitas, *Secretariat of Health of São Paulo, Brazil*
Agnes S. Silva, *Panamerican Health Organization, USA*
Helena Ribeiro, *University of São Paulo, Brazil*
Samuel L. Almeida, *University of São Paulo, Brazil*
Marco A. Oliveira Jr, *University of São Paulo, Brazil*
Mirta Rodrigues Silva, *Secretariat of Health of São Paulo, Brazil*

Background and aims: Traffic-related air pollution has been associated with respiratory disease (RD) in the elderly in different developed countries. In Brazil, this is the first study to look at the impact of this exposure on the respiratory health of this population subgroup.
Methods: Hospital admissions by RD (ICD-10: J00-J06; J10-J16; J18; J20-J22, J30-J39 and J40-J47) of people aged 65 and over, from public and private hospitals of the city of Sao Paulo in the period 2004-2006, were geocoded according to their residence addresses . Vehicular density (VD) was calculated for micro-areas of 500m2 of the city and was used as the indicator of exposure to traffic-related air pollution. The number of resident people, household density (HD) and the Human Development Index (HDI) were available for these micro-areas. Admission rates for the elderly were calculated for the micro-areas and VD, HD and HDI were categorized into quartiles. Multiple logistic regression models with the admission rates as the dichotomous dependent variable (equal or greater than the lower quartile Q1) and VD, HD and HDI as independent variables were used.
Results: 132,976 admissions of elderly people were analyzed in 3,367 micro-areas of Sao Paulo. Having the first quartile of VD as baseline and allowing for HD and HDI, the adjusted OR for elderly admissions were: 2.16(95%CI:1.70-2.75); 2.28(95%CI:1.77-2.93); 1.43(95%CI:1.1-1.82). Similar associations were observed when the type of fuel (gasoline or diesel) was considered separately. Hospitalization by RD decreased with increasing HDI ($p<0.001$).
Conclusion: These findings indicate that mobile sources of air pollution have great influence on hospitalization by RD among the elderly people in the city.

Background and Aims. Associations between damp/mouldy homes and depression among adults were described for the first time in the European LARES Study. As they were found in a cross-sectional epidemiological study, causal relationship could not be established though clear dose-response relationships were observed between size of the mouldy areas and the prevalence of depression. It was not clear either whether people suffering from depression neglected their home which became damp and mouldy or damp/mouldy homes had some kind of direct or indirect (e.g. through asthma) impact on the mental health of the inhabitants. These associations were further explored using the database of our country-wide survey among 9-10 year old children.

Methods. Out of the 62,711 questionnaires completed by the parents 57,362 contained data on the children's behaviour. Fatigue, sleeping disorders and reservedness were the three symptoms considered to be characteristic for depression. Associations between the number of symptoms and the size of the mouldy areas (no; some cm^2; some dm^2; $>1m^2$) were analysed by logistic regression adjusted for age, gender, smoking during pregnancy, the parents' respiratory or allergic diseases, the mother's education and busy traffic nearby.

Results. At least one of the three depression symptoms was found in 20.35%, and all the three ones were present in 1.29% of the children. Significant dose-response relationships were found (independently of the presence of asthmatic symptoms) between the prevalence of depression symptoms and the presence of damp/mouldy areas in the homes (adjusted OR=1.47; 95% C.I.: 1.39-1.56) for at least one symptom and aOR=1.83; 95% C.I.: 1.49-2.26) for all three symptoms present, respectively.

Conclusion: The possible significant association between damp/mouldy homes and depression was confirmed in our study involving large number of children, though the biological mechanism is still not clear.

A RAPID, DATA-DRIVEN APPROACH TO SETTING TEMPERATURE THRESHOLDS FOR HEAT HEALTH EMERGENCIES

Sarah B. Henderson, *BC Centre for Disease Control (BCCDC), Canada*
Tom Kosatsky, *BC Centre for Disease Control (BCCDC), Canada*

Background and Aims: During the summer of 2009 a hot weather event in Vancouver, Canada resulted in considerable excess mortality (Kosatsky et al. *Submitted.*). As a direct result local authorities decided to develop a Heat Health Emergency (HHE) action plan. In late spring 2010 the BCCDC was asked to provide a rapid, evidence-based recommendation for the temperature at which an HHE should be called.
Methods: Data on all-cause mortality for the summers of 2004-2009 were obtained from the BC Vital Statistics Agency. Measured and forecasted temperatures at the Vancouver (coastal) and Abbotsford (inland) airports were obtained from Environment Canada for the same period. Candidate thresholds were identified and tested by combining forecasted and measured temperatures in four early warning scenarios with different lead times, which has been identified as a priority for such work (Hajat et al. 2010). Early warning estimates were compared with measured temperatures using their sensitivity and positive predictive values (PPV).
Results: In Vancouver the relationship between early warning estimates and measured temperatures deviated considerably from the 1:1 line, which resulted in multiple false positive HHE identifications for a 2-day average of maximum temperatures • 30ºC. All three true positive events were succesfully identified at the 18- and 6-hour lead times (sensitivity = 1, PPV = 0.43). In Abbotsford the relationship was more linear for a 2-day average of maximum temperatures • 36ºC, but the three true positives were not all identified until the 6-hour lead time (sensitivity = 1, PPV = 0.6).
Conclusions: The BCCDC recommended that the HHE early warning system be based on data from Abbotsford, where the relationship between predicted and measured temperatures was most stable. We also suggested that a long-term educational campaign should be concurrently developed, especially if the HHE system is based on 2-day averages (i.e. one hot day must pass to trigger it).

ASSOCIATION BETWEEN CLIMATIC VARIABLES AND DENGUE IN THE REGION OLMECA, MEXICO

Grea Litai Moreno-Banda, *Instituto Nacional de Salud Pública, Cuernavaca, México*
Magali Hurtado-Díaz, *Instituto Nacional de Salud Pública, Cuernavaca, México*
Stephen Rothenberg, *Instituto Nacional de Salud Pública, Cuernavaca, México*
Horacio Riojas-Rodríguez, *Instituto Nacional de Salud Pública, Cuernavaca, México*

Background and Aims: Dengue is the most serious and prevalent arboviral disease in the world today. Roughly three billion people are at risk of contracting dengue virus. From 1995 to 2005, Veracruz remained one of the states with a high number of reported cases of dengue fever. For 2005 the national rate in Mexico of classic dengue morbidity was 16.3 per 100,000, however in the state of Veracruz this was 53.5 per 100,000 inhabitants. The main aim of this study was to assess linkages between the climatological variables and longer-term ENSO related weather forcing on the week-to -week changes in dengue incidence in 10 municipalities of the region Olmeca, over a recent decade of dengue observations.
Methods: A study ecological time series analysis was made using the weekly dengue cases registered in the municipalities of the Region Olmeca of Veracruz during the period 1995-2005 and daily weather data from the same period. Information on the index of social backwardness for 2005 was obtained from the National Council of Evaluation of Social Development Policy .We used a negative binomial model to assess the relation between climatic variables and dengue and including sine and cosine functions for seasonal adjustment. We evaluated the goodness of fit.
Results: In Mecayapan there is a statistically significant relationship between minimum temperature and incidence rates given at one week time lag. In Acayucan there is a statistically significant relationship between SST and incidence rates given at 5 months time lag. The results indicate that it takes aprox. 5 months for environmental conditions, as measured by SST and adjusted by precipitation and minimum temperature, to affect dengue incidence.
Conclusions: We need to incorporate to the model: social, demographic, geographical and physical factors, which determine the vulnerability into the each municipality.

MATERNAL LEAD LEVELS AT ONE-MONTH POSTPARTUM IN RELATION TO DIETARY FOOD GROUP INTAKE

Alejandra Cantoral, *Center for Evaluation Research and Surveys, National Institute of Public Health, Cuernavaca, Morelos, Mexico*
Adrienne S. Ettinger, *Yale School of Public Health, New Haven, CT USA*
Karen E. Peterson, *University of Michigan, Ann Arbor, MI USA*
Chitra Amarasiriwardena, *Harvard School of Public Health, Boston, MA USA*
Mauricio Hernández-Avila, *Ministry of Health, Mexico City, Mexico*
Martha María Téllez-Rojo, *Center for Evaluation Research andSurveys, National Institute of Public Health, Cuernavaca, Morelos, Mexico*
Howard Hu, *University of Michigan, Ann Arbor, MI USA*

Background and Aims: Increasing evidence suggests that dietary intake of fiber and micronutrients such as calcium, iron and vitamin C may interact with lead absorption, deposition, and excretion; however, there is limited information on the association with specific food groups so we assessed relationships between their intake over the course of pregnancy and lead levels in blood, bone, and breast milk at one-month postpartum in a cohort of 613 lactating women in Mexico City.

Methods: Maternal dietary intake was assessed using a semi-quantitative food frequency questionnaire of 120 foods that were grouped into 8 groups: dairy products, legumes, fruits and vegetables, whole grain cereals, refined cereals, all-meats, fats and oils and typical Mexican foods. Blood and breast milk were analyzed for lead by ICP-MS and maternal bone lead was estimated by K-x-ray fluorescence (KXRF).

Results: In a multivariate linear regression model using log-transformed blood and breast milk lead, women in the highest (v. lowest) tertile of intake of whole grain cereals had 0.10□g/dL lower blood lead levels (95% CI: -0.19, -0.01). Women in the highest (v. lowest) tertile intake of fruit and vegetables had lower lead levels in breast milk and tibia bone: -0.21 □g/L (95% CI: -0.42, 0.007) and -1.05□g/g (95% CI: -1.97, -0.12), respectively. Results were adjusted for parity, exclusive or partial breastfeeding, current use of lead-glazed ceramics, hemoglobin, body mass index, dietary energy intake, years of living in Mexico City, education and number of previous pregnancies. We found no association with patella lead levels.

Conclusions: Dietary fiber in whole grain cereals may inhibit lead absorption. The lower lead levels associated with higher intake of fruits and vegetables may be related to decreased absorption and/or the impact of Vitamin C, which has been previously reported to increase excretion of lead by acting as a natural chelating agent.

Background. Bakery and hairdressing rank high among occupations at risk of asthma. We explored the early incidence of occupational asthma (OA) along the first years of activity among young workers.
Methods. Subjects who graduated between 2001 and 2006 underwent telephone interviews on the occurrence of respiratory symptoms. Workers in occupations not exposed to known airways irritants or allergens were also included. Subjects who had asthma when starting apprenticeship were excluded. Those who declared work-related respiratory or ENT symptoms and a sample of asymptomatic subjects were proposed a medical visit (spirometry tests, exhaled NO measurements, daily surveillance of peak flow values, blood sample for assessment of common allergens and work-specific IgE). Diagnosis of OA was established by expert judgment and the sensitivity and specificity of symptoms declared during the telephone interviews were assessed.
Results. 866 subjects were interviewed (mean age: 25.3 years), among which 282 underwent a medical visit. The cumulative incidence of 'probable' OA among bakers was high in the first quartile of exposure duration (median value=3.0 years; risk = 15.8 % [95%CI=9.9–21.7]); several had to quit this activity because of this condition. It was reduced to 13.1 % [7.2–19.0] in the second exposure duration quartile (5.3 years) and increased regularly across the third (7.4) and fourth (9.5) quartiles, with 14.7 % [7.8–21.7]) and 17.2 % [8.7–25.6]), respectively. The corresponding figures among hairdressers are 8.3 % [0.6–16.0]), 6.1 % [0.7–11.5], 4.3 % [0.1–8.6] and 6.4 % [1.5–11.3]. Atopy is highly associated with incidence of OA among bakers (RR= 7.4), and, to a lesser extent, among hairdresser (RR= 3.6). No new case of OA occurred in the reference group.
Conclusion. Incidence of OA starts soon after engaging in bakery and hairdressing, activities that entail exposure to low or high molecular weight agents.

Temperature, Myocardial Infarction, and Mortality: Effect Modification by Individual and Area-Level Characteristics

Jaime Madrigano, *Harvard School of Public Health, USA*
Murray Mittleman, *Beth Israel Deaconess Medical Center, USA*
Andrea Baccarelli, *Harvard School of Public Health, USA*
Robert Goldberg, *University of Massachusetts Medical School, USA*
Steven Melly, *Harvard School of Public Health, USA*
Stephanie Von Klot, *Helmholtz Zentrum Munchen-German Research Center for Environmental Health, Germany*
Joel Schwartz, *Harvard School of Public Health, USA*

Background and Aims: Many studies have reported associations between temperature and cardiovascular disease (CVD) mortality, but fewer have investigated the relation between temperature and CVD incidence rates and at risk groups. We examined the association between temperature and incidence of myocardial infarction (MI) and subsequent mortality in a population-based study of residents of central Massachusetts. We also examined patient vulnerability by individual and area-level characteristics.

Methods: Data for this study were obtained from the Worcester Heart Attack Study, a community-wide investigation of confirmed episodes of MI occurring during the 5 biennial study years of 1995, 1997, 1999, 2001, and 2003. Temperature measurements were obtained from a nearby airport. We used a case-crossover approach to examine the association between temperature and MI incidence, and subsequent all-cause mortality, while adjusting for $PM_{2.5}$ and humidity. We examined effect modification by individual and area-level socio-demographic characteristics, medical history, clinical complications, and surrounding physical environment.

Results: A total of 4,765 incident MIs were included in our analysis. A decrease in an interquartile range (IQR) in temperature on the same day was associated with an increased risk of MI [RR=1.15 (95% CI: 1.01, 1.32)]. Extreme cold during the 2 days prior was associated with an increased risk of MI [RR=1.36 (95% CI: 1.07, 1.74)]. Extreme heat during the two days prior was associated with an increased risk of mortality [RR=1.43 (95% CI: 1.05, 1.95)]. The effect of cold on MI incidence was stronger in individuals living in census tracts with the lowest median income and individuals with a previous MI. Individuals living within 400 m of a large water body were protected from the effect of cold on MI incidence.

Conclusions: Exposure to cold increased the risk of MI and exposure to heat increased the risk of mortality. Individual and area-level characteristics modified this association.

HEALTH HAZARD FROM ENDOGENOUS GAS EMISSIONS AT CAVA DEI SELCI (ROME, ITALY)

Maria Luisa Carapezza, Nicola Pagliuca, Tullio Ricci *Istituto Nazionale di Geofisica e Vulcanologia, Roma, Italy*
Gabriele De Simone, Francesco Iacobelli, Carlo Lucchetti, Massimo Ranaldi, Luca Tarchini *University of Roma Tre, Italy*

Background and Aims: Hazardous emissions of endogenous gas (mostly CO_2 and H_2S) occur in many volcanic or geothermal areas. Cava dei Selci (Roma) is a densely inhabited zone on the flank of Colli Albani quiescent volcano where many lethal accidents to animals and also to one person occurred in recent years. In 2010, three houses had to be evacuated because the indoor gas concentration (CO_2 and H_2S) reached hazardous values. A systematic investigation of gas air concentration in houses, near the main gas emission site, has been carried out in 2010-2011 with the aim of assessing the gas hazard.
Methods: In more than 300 houses the CO_2 and H_2S air concentration was measured, by Draeger devises (Xam-7000, IR for CO_2 and electrochemical cell for H_2S). In each house gas analyses were made in bedroom, diningroom bathroom and cellars for a total of 1300 investigated rooms. For a few days, continuous gas monitoring was carried out in houses exposed to high risk. Outdoor gas release from the soil was also estimated by flux measurements (accumulation chamber method).
Results: The investigation has given very worrying results. In the three evacuated houses lethal levels of both gas were found (CO_2 28vol% and H_2S ≥500ppm). An additional 30% of inhabited houses show a potentially hazardous gas concentration that might become very dangerous should the endogenous gas release increase (as in case of local earthquakes). Preliminary indoor Rn concentration measurements (max 23,500 Bq/m^3) indicate that it often exceeds the recommended thresholds and the inhabitants are potentially exposed to a severe risk of lung cancer.
Conclusions: Dangerous indoor air concentrations of H_2S (>250 ppm) and CO_2 (>8 vol%) occur in many houses at Cava dei Selci due to endogenous gas emissions creating a delicate health and socio-economic problem.

TRANSPORTATION, AIR POLLUTION, AND PHYSICAL ACTIVITY (TAPAS), A SIX-CITY INTEGRATED HEALTH RISK ASSESSMENT PROGRAM OF ACTIVE TRAVEL POLICIES: COPENHAGEN CASE STUDY

Zorana Jovanovic Andresen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*
Ole Raaschou-Nielsen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*
Audrey de Nazelle, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*

Background and Aims: Within the TAPAS research program, quantitative assessments are developed for six case study cities in Europe, linking determinants of active travel to potential co-benefits and co-risks of modal shifts from motorized to non-motorized modes of travel. We describe here the Copenhagen case study.
Methods: We identified local sources of information from government agencies and municipalities describing active travel and environmental conditions. We selected policies of local and international interest, with quantifiable or demonstrated effectiveness. We reviewed local municipality and national governmental publically available data and documents on respective websites and met individually with elected officials and other stakeholders. We are also conducting epidemiological study generating new data to help fill research gaps in current framework.
Results: Copenhagen, capital of Denmark, has 620.000 inhabitants. With 37% of Copenhagen inhabitants commuting by bike (28% by bus or train, 31% by car, 5% on foot) and 383km of bike lanes, Copenhagen is proud to be one of the most biking-friendly cities in TAPAS, and in Europe. Copenhagen is still working hard to improve its biking statistics, by improving biking infrastructure, establishing green biking lanes (40km currently, goal 110km) and improving safety. In 2008, 121 cyclists were seriously injured and 5 died, which is a half of the numbers from 1996. Copenhagen air pollution levels have been decreasing in a last decade, with 21 $\mu g/m^3 PM_{10}$, 13 $\mu g/m^3 PM_{2.5}$, and 20$\mu g/m^3$ NO_2 average annual concentrations in 2008, but street levels for NO_2 still exceed the limit values. About 38% of Copenhagen inhabitants are active less than recommended 30 minutes per day, and 37% are overweight. Relevant policies we are considering for assessment include 1) Congestion charging and 2) Regulation of Parking Fees.
Conclusion: Copenhagen with its high and increasing biking rates, but also increasing number of cars, is an interesting case for assessing potentials to increase physical activity while addressing challenging environmental conditions to mitigate risks.

DIABETES INCIDENCE AND LONG-TERM EXPOSURE TO AIR POLLUTION: A COHORT STUDY

Zorana J. Andersen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*
Ole Raaschou-Nielsen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*
Bendix Carstensen, *Steno Diabetes Center, Gentofte, Denmark*
Martin Hvidberg, *National Environmental Research Institute, Aarhus University, Roskilde, Denmark*
Steen S. Jensen, *National Environmental Research Institute, Aarhus University, Roskilde, Denmark*
Matthias Ketzel, *National Environmental Research Institute, Aarhus University, Roskilde, Denmark*
Steffen Loft, *Section of Environmental Health, Department of Public Health, University of Copenhagen, Copenhagen, Denmark*

Kim Overvad, *School of Public Health, Aarhus University, Aarhus, Denmark; [6]Centre for Cardiovascular Research, Aalborg Hospital, Aarhus University Hospital, Aalborg, Denmark*
Mette Sørensen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*

Background and Aims: Emerging data from cross-sectional epidemiological and animal studies suggest air pollution as a risk factor for diabetes, whereas prospective data are sparse and conflicting, precluding conclusions about causality. We examined the association between exposure to traffic-related air pollution over 35 years and incident diabetes in a prospective cohort study.

Methods: We followed 57 053 participants of the Danish Diet, Cancer and Health cohort in the Danish National Diabetes Register between baseline (1993-1997) and 2006 and used two definitions of incident diabetes: original from Diabetes Register and more strict, by excluding those with unconfirmed diabetes diagnoses. We estimated the annual mean levels of nitrogen dioxide (NO_2) at residential addresses of the cohort participants since 1971 and modeled association between mean NO_2 levels and incident diabetes by Cox regression analyses. We tested for modification of the effect of air pollution by gender, body mass index, waist-to-hip ratio, smoking status, physical activity, educational level, and cardiovascular diseases.

Results: Over a mean follow-up of 9·7 years of 51 818 eligible subjects, there were 4 040 (7.8%) and 2 877 (5.5%) diabetes cases with all original and confirmed only diabetes cases, respectively. We found no association between mean levels of NO_2 since 1971 and diabetes according to the original definition (hazard ratio1.00; 95% confidence interval 0.97-1.04, per IQR of 4.9 $\mu g/m^3$), whereas borderline significant association was detected when using the modified definition of diabetes, (1.04; 1.00-1.08). Identical associations were observed with mean NO_2 levels since 1991 and 1-year mean at the follow-up (mean exposure during the year prior to stroke), and attenuated with 1-year mean at baseline (1.02; 0.98-1.05). Non-smokers, physically active, and those generally more healthy, seemed to be most susceptible to the effects of air pollution.

Conclusions: Long-term exposure to traffic related air pollution may contribute to the development of diabetes.

URINARY CONCENTRATIONS OF BISPHENOL-A IN AN URBAN MINORITY BIRTH COHORT IN NEW YORK CITY, PRENATAL THROUGH AGE 7 YEARS

Lori A. Hoepner, *Columbia University, New York City, USA*

Andrew Rundle, *Columbia University, New York City, USA*

Background and Aims: There is growing epidemiologic evidence that prenatal and early childhood exposures to ubiquitous endocrine disruptors, such as bisphenol A (BPA) can result in adverse disease outcomes. Insufficient information is available on the effects of BPA on minority populations in the US. Our aim is to describe BPA concentrations and correlated factors in a birth cohort through age seven years.
Methods: As part of the Columbia Center for Children's Environmental Health (CCCEH) birth cohort of African American and Dominican children living in the South Bronx and Upper Manhattan, 568 mother-child dyads were analyzed for total BPA in spot urines. Mothers were selected if they had a sample analyzed prenatally and their children were selected if they had at least one sample analyzed at age three, five or seven years. All analyses used log-transformed BPA and adjusted for specific gravity.
Results: BPA was analyzed in 377 prenatal samples (94% above limit of detection (LOD)), 419 age three year samples (98% above LOD), 401 age five year samples (98% above LOD), and 318 age seven year samples (96% above LOD). BPA concentration geometric means were higher among African Americans compared to Dominicans in prenatal ($p=0.007$), five year ($p=0.001$) and seven year ($p=0.001$) samples. Geometric means for the five and seven year samples were higher ($p=0.002$, $p=0.015$ respectively) for children of mothers never married at baseline compared to mothers ever married at baseline. BPA concentrations were significantly correlated with eight phthalate metabolite concentrations prenatally and at three and five years (r values from 0.12 to 0.35, all p-values <0.05). Calendar season predicted BPA concentrations in children ages three, five and seven years (summer=reference, Beta estimates -.26 to -.12 ng/ml, all p-values <0.05).
Conclusions: The CCCEH is uniquely poised to evaluate early life exposures to BPA in urban minority children.

INVESTIGATION OF THE RISK FACTORS FOR PULMONARY TUBERCULOSIS: CASE CONTROL STUDY IN THE ABSHERON RAYON OF AZERBAIJAN REPUBLIC

Samaya Ismayilova, *Public Health and Reforms Center, MoH Azerbaijan*

Alexander Pasechnikov, *Abt Associates Inc., Azerbaijan*

Background. With the re-emergence of TB, affecting mainly developing countries, investigation of the risk factors is important for identification of high risk groups in a community to adjust and adapt TB control policies. The study was carried out to assess the contribution of host related, socio-economic and environmental factors in the development transmission of TB in Azerbaijan.
Objective. The objective of the study is to provide information that will help to identify high-risk groups and will be useful for the improvement of TB control program in Azerbaijan.
Methods. A population-based case-control study was conducted in the Absheron rayon of Azerbaijan republic from May 2010 till October 2010. Cases were all TB patients >15 newly registered at the Absheron rayon policlinic between 1 January, 2008 and December 31, 2009 and recruited to a WHO DOTS program. Three controls were recruited for each case.
Results. The univariate analysis by logistic regression of host related factors based on the comparison of 178 cases/household controls and 222 cases/community controls showed that male sex is a significant risk factor for TB. Male sex also remained as a significant risk factor in multivariable analysis of the host-related factors in these comparison groups. The univariate analysis of environmental risk factors among cases and community controls/polyclinic controls showed that those not having a house and living in a single room, have no or less number of the selected domestic items and low household monthly income were significantly more likely to have TB. Multivariable models were then constructed, including variables that showed an effect in the prediction of TB in the univariable analysis at the $p<0.05$ level of significance.
Conclusion. In the Absheron rayon male sex (OR=8.69), none/basic education (OR=4.69), secondary education (OR=2.41), not having a house (OR=16.1), and low household monthly income (OR=13.88) are the standout risk factors for TB disease.

Acute coronary syndrome and long-term exposure to air pollution: a cohort study

Ole Raaschou-Nielsen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*

Background and Aim: Air pollution is one of the most important triggers of myocardial infarction.[1] Long-term exposure was also linked to coronary heart disease including myocardial infarction, but data show consistent associations only with fatal events.[2] We studied the association between exposure to traffic-related air pollution over 35 years and incidence of acute coronary syndrome (ACS) in a prospective cohort study.

Methods: We followed 57 053 participants of the Danish Diet, Cancer and Health cohort since baseline (1993-1997) until 2006 in the Danish National Patient Register for incident (first-ever admission) cases of ACS, and included only confirmed cases through review of hospital records. ACS diagnoses include myocardial infarction, angina pectoris, and cardiac arrest. We estimated the annual mean levels of nitrogen dioxide (NO_2) at residential addresses of the cohort participants since 1971, and linked mean levels of NO_2 to incident ACS by Cox regression analyses. We tested for modification of the effect of air pollution by gender, body mass index, waist-to-hip ratio, smoking status, physical activity, and educational level.

Results: Over a mean follow-up of 9·7 years of 50 141 eligible subjects, there were 1 535 (3.1%) incident ACS cases. We detected significant association between incident ACS and mean levels of NO_2 since 1971 (hazard ratio 1.09; 95% confidence interval 1.02-1.16, per IQR), as well as with proxies of major road within 50m (1.24; 1.06-1.46) and 100m (1.17; 1.03-1.32) at baseline.

Conclusions: Long-term exposure to traffic related air pollution may increases the risk of coronary heart disease.

MAPPING VULNERABILITY AND ENVIRONMENTAL CONTEXTS OF HEALTH PROMOTION IN RURAL VALLEY JAGUARIBE, CEARÁ, BRASIL, 2011.

Fernando Ferreira Carneiro – *University of Brasília, Brasil*
Lara Queiroz Viana Braga – *University of Ceará, Brasil*
Vanira Matos Pessoa - *University of Ceará, Brasil*
Raquel Maria Rigotto - *University of Ceará, Brasil*
Vicente Eduardo Soares de Almeida – *EMBRAPA, Brasil*

Background and Aims: Brazil has long adopted an agro-export model, intensifying agricultural expansion in all regions. The impacts are felt differently in each region, since those cover quite diverse biomes. At the national level, the northeast region is one of the poorest in the country yet has recently attracted investments for the purpose of promoting economic development. Such investments are focused on fruit production for export resulting in critical social and environmental impacts.
Methods: The present project that looks into the epidemiological impact of pesticide contamination, held a workshop with communities focusing on the mapping of socio-environmental vulnerability and approaches to environmental health promotion. Through the use of a matrix, each community reported on aspects in their environment that they considered as promoting and, or threatening their lives and their territories. As such, they were able to record their perceptions and observations concerning changes taking place in their territories pointing out a variety of related factors. To facilitate the presentation of these perceptions the community drew a map depicting the dynamics of community life, featuring the main factors present in the matrix.
Results: The results showed a perception of communities about the changes that are happening in the territory. Hence, the process of agricultural modernization leads a re-structuring of the social space contributing to the deterioration of various social, economic, cultural and environmental factors which impact the health of residents and workers.An increase in domestic and urban violence, alcoholism, drug use and prostitution are other conditions that ensued. Other situations that were cited were work-related accidents, cases of poisoning, acute and chronic exposure to pesticides by the workers.
Conclusions: Strengthening production models that include an agro-ecological perspective was presented as a possible route to social and environmental sustainability and to the promotion of human and environmental health in the region.

BROUSSONETIA PAPYRIFERA, THE MOST DOMINANT POLLEN ASSOCIATED WITH ALLERGIC RHINITIS AND ASTHMA ATTACK IN TROPICAL TAIWAN

Pei-Chih Wu, Chang Jung Christian University, Taiwan, R.O.C.
Chen Mo-Jen, National Cheng Kung University, Taiwan, R.O.C.
Wei-Ping Lin, National Cheng Kung University, Taiwan, R.O.C.
Huey-Jen Su, National Cheng Kung University, Taiwan, R.O.C.

Background and Aims: Pollen is one of the most common aeroallergens that contributing to the development and occurrence of seasonal allergic respiratory illness in European and North American countries. The sensitive pollens are different geographically because of the variants of climate, nature, and vegetation. Comparing to the abundant literatures of pollen allergy in many parts of the world, very few studies have been conducted in tropical regions. Because of lacking of pollen monitoring database in Taiwan, the prevalence of pollen allergy were usually misleading the information for using the pollen taxa usually in European and North American countries. Our study establish an aeroallergen monitoring station in southern Taiwan to collect and quantify the daily pollen concentration in atmosphere for studying the contribution of major pollen allergen in allergic respiratory illness in Taiwan.
Methods: A Burkard 7-day volumetric sampler was set up to collect atmospheric pollen at a flow rate of 10 l min-1 in Tainan City and operated routinely all year round. Counts and taxa of pollen during Jan. 2005 to Dec. 2006 were identified and daily concentrations in atmosphere were estimated. Daily clinic visits of various allergic diseases were collected from Medical Center where the station was located. The meteorological and air pollutants data were also obtained from Central Weather Bureau and Environmental Protection Administration. Generalized Additive Mixed Model (GAMM) was used to assess the multiple-lag effects of pollen concentrations and air pollution components on allergic diseases. The multiple-lag effects were examined from 0 to 4 days.
Results: *Broussonetia papyrifera*, paper-mulberry, is the most dominant pollen comprised around 30.38% and 39.51% of total pollen in 2005 and 2006. The temporal trend of *B. papyrifera* pollen level was consistent with total pollen with highest concentrations in Mar. and consistent to Nov. Elevated daily *B. papyrifera* pollen was significantly associated with increasing relative risks of allergic rhinitis visits (RR=1.023, 95% C.I.=1.003, 1.043) at lag 2 and 3 when adjusting daily average temperature and other air pollutants. Increasing relative risks of asthma visits was also shown at lag 3 when increase equal in magnitude to its mean (RR=1.023, 95% C.I.=1.009, 1.036). The effects of *B. papyrifera* also shown to be an independent role on increasing risk when adjusting different weather and air pollutants in the model. One study had shown that allergy of *B. papyrifera* might only triggered by fresh pollen materials and that might be the rationale of allergic sensitization to *B. papyrifera* may regard in many places of the world.
Conclusions: Our study is the first study showing pollen calendar and trying to establish the relationships between dominant pollen taxa and the occurrence of allergic diseases in tropical Taiwan. This preliminary analysis addresses the need of aeroallergen monitoring station and using the regional pollen taxa for diagnosis and prevalence investigation in our region.

PROSPECTIVE STUDY ON MINOR ACCIDENT AND INJURY RISKS PER TRAVELLED DISTANCE FOR CYCLISTS

Luc Int Panis, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium - Transportation Research Institute, Hasselt University, Belgium*
Grégory Vandenbulcke, *C.O.R.E. and Department of Geography, Université catholique de Louvain, Belgium*
Bas de Geus, *VUB, Vrije Universiteit Brussel, Belgium*
Joris Aertsens, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*
Bart Degraeuwe, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*

Background and aims: Utilitarian cycling reduces risks for adverse health outcomes such as obesity and cardiovascular diseases. Active transport also contributes to better environmental conditions and hence better health for other inhabitants. Unfortunately there are also health risks which are poorly understood. Cycling accidents are the most important health risk to cyclists yet available statistics are very poor. Only a small fraction of accidents is officially registered and reliable data on minor injuries and the distance cycled are not available. This lack of data hampers policy decisions on cycling.
Methods: The SHAPES-project executed a full year prospective cohort study using electronic surveys. 1,187 participants reported their bicycle use for a total of 20,107 weeks (1,474,978 kilometres; 214,644 trips). A Poisson regression was performed to analyse contributing factors. Injured cyclists were also asked to fill out a questionnaire to determine injuries and other indirect costs.
Results: 219 minor accidents were reported (148 per million kilometres). Most accidents occurred on roads (69%), and fewer on bicycle lanes (21%) or bicycle paths (10%). Slipping (36%) and collisions with cars (19%) were the most frequent causes of injuries (mostly abrasions (42%) or bruises (27%) to arms and legs. Fractures and head injuries are rare. The average cost per accident is 841€ (95% CI: 579-1205€) or 0.125€/km cycled. Women (-3.3 km/h) and urban cyclists (-3.1 km/h) cycle slower and shorter distances. Age and gender are significantly related to the accident risk but there is no gender difference for the injury risk. Cycling paths are associated with longer trip distances to work (+38%) and higher speed (+1.5 km/h)
Conclusions : A prospective cohort study including accidents and distance cycled can be used to calculate accident and injury risks. Risks and costs have been accurately quantified and can now be objectively compared to the health benefits of cycling.

EFFECT OF SPEED AND PHYSICAL CONDITION ON EXPOSURE OF CYLISTS TO PM AND UFP IN TRAFFIC

Luc Int Panis, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium - Transportation Research Institute, Hasselt University, Wetenschapspark 5 bus 6, 3590 Diepenbeek, Belgium*
Hanny Willems, *Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*
Grégory Vandenbulcke,*C.O.R.E. and Department of Geography, Université catholique de Louvain, Belgium*
Bas de Geus, *Dept. Human Physiology & Sports Medicine, Fac. LK, Vrije Universiteit Brussel, Belgium*
Bart Degraeuwe*, Flemish Institute for Technological Research, Unit Environmental Risk and Health, Belgium*

Background and aims: Cyclists are more exposed to air pollution compared to motorists, due to increased ventilation which the SHAPES project estimated is 4.3 times higher for cyclists. We examine whether this higher exposure is linked to cycling speed. We define the optimal speed that minimizes inhalation of pollution and compare this to field trips to determine the scope for reducing exposure.
Methods: Maximal Exercise Test data (with heart rate and minute ventilation measured simultaneously at increasing intensities) are used to convert power into cycling speed. We check the results with heart rate and speed recorded during real life cycling. We group persons according to gender and VO2max to check if differences depend on the physical condition of the test persons.
Results: There is an optimal cycling power range that minimizes exposure associated with a minute ventilation below the first ventilatory point. When power is converted into speed the optimal interval is 18.6-21.8 km/h for men and 15.3-19.2 km/h for women. Higher speeds increase exposure to air pollution. When comparing the optimal cycling speed with the self-selected speed during the field trips, we conclude that cyclists tend to cycle at a speed that is slightly too high. Cyclists could have cycled 2.5 km/h slower than their self-selected speed, resulting in 10.7 % less pollution exposure and 14.0 L/km less air intake. There are no differences in ventilation (L/km) between well trained and less trained cyclists around the optimal speed interval.
Conclusions : Reduced ventilation associated with cycling at the optimum speed will not offset the large exposure difference between cyclists and car passengers. Well trained cyclists can cycle at higher speeds without increasing their exposure per kilometre. Their interval of optimal speed tends to get wider when physical condition improves, but it is important not to train in highly polluted areas.

SYNERGISTIC ECOTOXICOLOGICAL IMPACT OF CHRONIC EXPOSURE TO PERSISTENT ENDOCRINE DISRUPTING CHEMICALS (EDCs) MIXTURES IN WASTEWATER EFFLUENTS

Uri Zoller, *Haifa University-Oranim, Israel*

Background and Aims: The occurrence and persistence of anthropogenic pollutants in the environment showing estrogenic-endocrine modulating effects in aquatic organisms is a “hot” issue of major health- and environment-related concern worldwide. The population growth and the increasing scarcity of water in many regions of the world have led to a comprehensive reuse of treated wastewater that, ultimately, may cause a long-term concentration build-up of toxic persistent organic pollutants (POPs) in both the cycles of the reused wastewater and the aquatic environment at large. Given the well established presence in *mixtures* of endocrine disrupting pharmaceuticals/hormones, non-ionic alkylphenol ethoxylates (APEOs) and carcinogenic polycyclic aromatic hydrocarbons (PAHs) in wastewater effluents, worldwide, the overriding aims of our study were: Determining (1) the concentrations/isomeric-homologic profiles of the actual EDCs-PAHs mixtures in waste water treatment plants (WWTP) (to be) reused effluents; (2) the ecotoxicological impact of *chronic* exposure to each of the individual EDCs in these mixtures; and (3) the ultimate synergistic (or antagonistic) ecotoxicological impact of *chronic* exposure to *real* 2-4 component EDCs mixtures in conventional (activated sludge-based) WWTP effluents in Israel.
Methods: EDCs concentrations were determined via HPLC- and GC/MS-based chemical analysis and the *chronic* ecotoxicological impact by the zebrafish egg production test (ZFEPT).
Results: The most important: A meaningful *synergistic* ecotoxicological impact of chronic exposure of zebrafish to persistent EDCs mixtures in WWTP effluents was observed and quantitatively determined**.**
Conclusions: The magnitudes of these impacts (their implications to be critically discussed) suggest, that (a) even an extremely low concentration of certain EDCs, not exerting any ecotoxicological impact while ‘standing alone’, the synergistic impact of EDCs mixtures is very meaningful ecotoxicologically; and therefore, (b) there is a potential long range *health risk* in being chronically exposed to low concentrations (ng-• g) of EDCs-PAHs mixtures in reused effluents and receiving aquatic environments (Zoller & Hushan, 2010).

Natalya Bilenko, *Epidemiology and Health Services Evaluation Department, Faculty for Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel - [2]Ministry of Health, Medical Office of Southern District, Beer-Sheba, Israel - [3]The S. Daniel Abraham International Center for Health and Nutrition, Ben-Gurion University of the Negev, Beer-Sheva, Israel*

Background. A growing number of environmental exposures in the peri-conception period have shown to cause adverse pregnancy outcome (APO): low birthweight, small for gestational age, preterm birth and cardiac birth defects. Validity of exposure information collected retrospectively in case-control studies has been questioned. We aimed to assess repeatability and possible recall bias of self-reported environmental exposures collected after birth. .
Methods. Women registered for prenatal care in Maternal and Child Health clinics (MCHC) by week 25 of gestation comprised the study population (n=411). Information about place of residence and exposures to various risk factors during the 3 months prior to conception and first 3 months of pregnancy was obtained by personal interviews, using a structured questionnaire. Women with APO (gestational age at birth/miscarriage/induced abortion, low birth-weight, perinatal morbidity, fetal death, and in-hospital neonatal death), and a sample of control women without adverse outcome, matched by MCH clinic, were re-interviewed, after end of pregnancy (n=241). Kappa statistics was used to assess reliability of retrospectively reported exposures.
Results. Low agreement (kappa <0.4) between 1st and 2nd interview was observed regarding exposures to flu, fever, medications and vitamins consumption, cellphone use, home and work repairing, disinfestations, passive smoking. Better agreement (kappa >0.4) was observed regarding water filtering, maternal occupational exposures, living in proximity to antennas, contraceptive methods, urinary tract infections, smoking before/during pregnancy ,fertility treatment, and physical exertion at work. There were no differences in agreement estimates for cases and controls.
Conclusions. While no recall bias was found, the validity of most retrospectively reported exposures was rather low, suggesting that OR estimated from case-control studies may be underestimated it is therefore advisable that, whenever possible, cohort studies should be performed to detect effects of perinatal exposures on pregnancy outcomes.

Aino Nevalainen, *National Institute for Health and Welfare, Department Environmental Health, Kuopio, Finland*
Dick Heederik, *Institute for Risk Assessment Sciences, Department of Environmental Epidemiology, Utrecht University, Utrecht, the Netherlands*
and the HITEA study group.

Background and aims: Indoor air quality is essential for human's health. The HITEA-project evaluates health effects of biological and chemical exposures in primary schools. The aim of this study was to characterise exposure to PM2.5, absorbance (soot), NO2 and CO2 in schools in Spain, The Netherlands and Finland.

Methods: Schools with (index) and without (reference) dampness problems were selected based on building questionnaires and on-site inspections. Indoor PM2.5, soot, NO2 and CO2 was measured during 5 consecutive school days. PM2.5, soot and NO2 were measured in the school's central hallway, CO2 was measured in a classroom, and NO2 was additionally sampled in 2-3 classrooms. Measurements were performed twice: during winter/spring 2009 and winter/spring2010.

Results: 7 Spanish, 10 Dutch and 6 Finnish schools were included. Average soot and NO2 concentrations were highest in Spain (median: soot=2.27$m^{-1}10^{-5}$, NO2=30µg/m3), intermediate in the Netherlands (soot=1.20$m^{-1}10^{-5}$, NO2=20µg/m3) and lowest in Finland (soot=0.60$m^{-1}10^{-5}$, NO2=10µg/m3). PM2.5 was comparable in Spain and the Netherlands (17.51 vs 17.16µg/m3) and lowest in Finland (5.65µg/m3). PM2.5, soot and NO2 stayed constant over the two assessments, only NO2 in Finland concentrations were higher during the second measurement. CO2 (during school hours) reached highest levels in Spain (median:1165ppm) vs the Netherlands (median:844ppm) and Finland (median:701ppm). CO2 levels were not related with PM2.5, soot and NO2. PM2.5 and soot did not depend on a school's damage status. NO2 was higher in Finnish index schools, while in Spain NO2 was lower in index schools. In Dutch index schools CO2 was higher, while in Spain levels were higher in reference schools.

Conclusions: PM2.5, soot, NO2 and CO2 levels in schools differed considerably between countries, probably because of differences in outdoor air pollution levels, climate and building construction. These agents may, in addition to biological pollutions, play a role in occurrence of potential health effects of occupants.

ADAPTIVE RESPONSE TO HIGH EXPOSURE OF CARCINOGENIC POLYCYCLIC AROMATIC HYDROCARBONS

Radim J. Sram, Institute of Experimental Medicine AS CR, Czech Republic

Jan Topinka, Institute of Experimental Medicine AS CR, Czech Republic
Katerina Uhlirova, Institute of Experimental Medicine AS CR, Czech Republic

Background and Aims:. Ostrava Region in the Northern Moravia (Silesia) is the most polluted region in the Czech Republic by carcinogenic polycyclic aromatic hydrocarbons (c-PAHs) as benzo[a]pyrene (B[a]P). The aim of the study is to gain new knowledge on the mechanisms of the effects of complex mixtures bound on dust particles (c-PAHs) in the ambient air on biomarkers of exposure and effect during the period of inversion.
Methods: In the Ostrava City were selected 78 volunteers- working in the office, as controls were city policemen from Prague (N=65). All volunteers were nonsmokers. The personal monitoring to c-PAHs was carried on in January-February 2010. The determined concentration of B[a]P was in the Ostrava region vs. Prague 14.8±13.3 vs. 2.80±1.87 ng/ m^3. The impact of these concentration to biomarkers as DNA adducts, chromosomal aberrations, 8-oxodG, lipid peroxidation, and gene expression profiles are followed. DNA adducts were analysed in lymphocytes by ^{32}P-postlabeling assay, chromosomal aberrations by fluorescent in situ hybridization (FISH) by whole chromosome painting #1 and #4, and by the determination of micronuclei, oxidative damage as 8-oxodG and 15-F2t-IsoP.
Results: Obtained results indicate no differences between the level of biomarkers determined in the Ostrava region and Prague. Multivariate analyses revealed that subjects living in Ostrava had increased odds of having above-median levels of *XRCC5* expression (OR; 95% CI: 3.33; 1.03-10.8; q=0.046). Above-median levels of 8-oxodG were associated with decreased levels of vitamins C (OR; 95% CI: 0.37; 0.16-0.83; p=0.016) and E (OR; 95% CI: 0.25; 0.08-0.75; p=0.013), which were elevated in subjects from Ostrava.
Conclusions: We may speculate, that high environmental exposure to B[a]P does not correspond to DNA damage according to dose effect relationship in a population affected by these concentrations for years, probably due to a possible adaptive response.
Supported by the Czech Ministry of Environment (SP/1b3/8/08) and the Czech Ministry Education (2B08005).

ENVIROMENTAL EXPOSURE TO CADMIUM IS ASSOCIATED WITH INCREASED RISK OF CANCER

Aviad Zick, *Sharett institute of oncology, Hadassah - Hebrew University Medical Center, Jerusalem ,Israel*

Yakir Rottenberg, *Sharett institute of oncology, Hadassah - Hebrew University Medical Center, Jerusalem ,Israel*

Moshe Shirav-Schwartz, *Geo -Information Division, Geological Survey of Israel, Jerusalem, Israel*

Micha Barchana, *Israel Cancer Registry, Ministry of health, Jerusalem, Israel*

Tamar Peretz, *Sharett institute of oncology, Hadassah - Hebrew University Medical Center, Jerusalem ,Israel*

Background and Aims: Association between environmental exposure to Cadmium and cancer incidence was reported by few studies with conflicting results. The aim of the current study was to evaluate the association between Cadmium exposure and cancer incidence in a cohort of people living in an industrial subdistrict of Israel, followed for 13 years.

Methods: A historical prospective study, with cohort inception and baseline measurement of people participating in the Central Bureau of Statistics 1995 census, was designed. To asses Cadmium soil concentration possible contribution to cancer incidence, a geochemical survey was analyzed. Cadmium concentration in soil was analyzed in 1823 samples in Haifa and the West Galilee (total 162 km^2), which houses major industrial facilities. An Arithmetic mean of Cadmium measurements in a census block (aCd) was calculated. Cancer incidence was ascertained through the Israel Cancer Registry and was calculated after adjusting for age, sex, origin and years of education.

Results: 37,690 people were followed and 1759 developed cancer throughout the study's follow-up period. Of these 18,408 people live in areas with aCd above the limit of detection. Living in areas where aCd is detected was associated with increased cancer incidence (Hazard ratio (HR) 1.11 95% CI: 1.01-1.23, *P*=0.038). People age 41-65 living in areas where aCd is detected were found to have an increased cancer incidence (HR 1.21, 95% CI: 1.09-1.40, *P* =0.014). In this age group, people living in areas where aCd is 0.1-1.5 ppm show no difference in cancer incidence (HR 1.15, 95% CI: 0.96-1.36, *P* =0.118), where as in people living in areas where aCd is above 1.5 ppm an increase in cancer incidence is found (HR 1.27, 95% CI: 1.07-1.51, *P* =0.007).

Conclusion: We report an increase of cancer incidence in Cadmium rich areas in a dose dependent manner among people age 41-65.

STATISTICAL METHODS FOR EXPOSURE RESPONSE ANALYSIS OF HIGHLY CORRELATED EXPOSURES

Lutzen Portengen, *Institute for Risk Assessment Sciences, Utrecht University, The Netherlands*
Roel Vermeulen, *Institute for Risk Assessment Sciences, Utrecht University, The Netherlands*

Background and Aims: Standard multiple regression techniques for exposure response analysis may fail for highly to moderately correlated exposure data due to the strong co-linearity and resulting instability of effect estimates. To identify single polychlorinated biphenyls (PCBs) congeners causally related to Non-Hodgkin Lymphoma in a nested case-control study from among a mixture of 36 different PCBs we performed a simulation study to assess the utility of statistical techniques that were developed to deal with highly dimensional data.
Methods: We simulated 150 different datasets based on the observed standardized multivariate lognormal distribution of 36 PCBs in the JANUS nested case/control study. Of these 50 simulations used the observed means and covariance matrix, 50 used a reduced covariance matrix (off-diagonal entries scaled by 1/3), and 50 used a diagonal covariance matrix to simulate uncorrelated exposures. For every dataset we simulated 6 different exposure-response scenario´s corresponding to either two or four randomly selected PCBs related to the outcome with a weak (OR=1.2), medium (OR=1.5), or strong (OR=2.0) effect. All datasets were analyzed using standard univariate and (stepwise) multiple regression analysis as well as Sparse Partial Least Squares Discriminant Analysis (SPLS-DA), an elastic net for Generalized Linear Models (GLMNET), and a Bayesian hierarchical variable selection model. Models were compared using measures of sensitivity, specificity, and relative bias.
Results: With uncorrelated exposures, univariate analysis outperformed all others in sensitivity and specificity, and had lowest bias. With moderate and strong correlations, naive multiple regression often failed to identify the true causal agents, while more appropriate techniques were often more sensitive and only slightly less specific. No method was uniformly best, but the elastic net appeared to offer a good compromise.
Conclusions: More sophisticated statistical techniques may be needed to identify causal agents in exposure response analysis of highly and moderately correlated exposure data. However, the lack of a formal inference framework for some of these methods may hamper more widespread use.

CANCER INCIDENCE AND CAUSE-SPECIFIC MORTALITY FOLLOWING BALKAN DEPLOYMENT

Dieneke Schram-Bijkerk, *National Institute for Public Health and the Environment, Bilthoven, the Netherlands*
Rik P. Bogers, *National Institute for Public Health and the Environment, Bilthoven, the Netherlands*
Leo J. Schouten, *Maastricht University, Maastricht, the Netherlands*
Bart L.A.L.M. Kiemeney, *Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands*
Floor E. van Leeuwen, *the Netherlands Cancer Institute, Amsterdam, the Netherlands*

Background and aims: In 2000 the media reported on cases of leukaemia among Balkan-deployed soldiers, which some attributed to alleged exposure to depleted uranium (DU), originating from DU-containing ammunition. These media reports prompted questions about the occurrence of leukaemia, and its relationship with Balkan deployment and DU exposure in particular. Although the NATO reasoned the DU-related health risk to be very low, it was nevertheless recommended that the NATO countries would perform epidemiological studies on cancer among Balkan veterans. This study describes the results of analyses comparing the risk of different types of cancer and mortality among 18,000 Dutch Balkan-deployed military versus 140,000 non-Balkan-deployed military personnel. In addition, a comparison is made with cancer risk and mortality in the general population of the Netherlands.
Methods: A historical cohort study was performed, comparing military personnel deployed to the Balkans between 1993 and 2001 and their peers by using Cox regression analysis. In addition, expected numbers of cases of cancer and deaths in the Balkan-deployed group were computed according to the person-year method, based on rates for the general population in the Netherlands. Cancer and mortality data from 1993 to 2008 were provided by the Association of Comprehensive Cancer Centres and Statistics Netherlands, respectively.
Results: Final results will be presented at the ISEE. Results are strictly confidential until publication of the report in April 2011 (available at www.rivm.nl by that time, in English).
Conclusions: Similar studies have been performed in Denmark, Sweden and Italy, but this is the largest study with the longest period of follow-up.

EFFECTS OF MOTHER'S CONSUMPTION OF TRADITIONAL CHINESE HERBS AND LEAD AND CADMIUM CONCENTRATION IN MECONIUM IN TAIWAN

Chuen-Bin Jiang, *Department of Pediatrics, Taipei Mackay Memorial Hospital, Taipei, Taiwan*
Ching-Ying Yeh, *Department of Public Health, School of Medicine, Taipei Medical University, Taipei, Taiwan*
Bor-Cheng Han, *School of Public Health, Taipei Medical University, Taipei, Taiwan*
Ruey-Yu Chen, *School of Public Health, Taipei Medical University, Taipei, Taiwan*
Shu-Yu Lyu, *School of Public Health, Taipei Medical University, Taipei, Taiwan*
Chun-Hua Fan, *School of Public Health, Taipei Medical University, Taipei, Taiwan*
Ling-Chu Chien*, *School of Public Health, Taipei Medical University, Taipei, Taiwan*

Background and Aims: Traditional Chinese herbs have been used in Chinese society for thousands of years, and consequently family members would like to use herbal remedies to keep pregnant women in good health. Meconium is a matrix and is representative of a wide period of exposure in the fetus during gestation. The purposes of this study were to assess the relationship between mercury, lead, and cadmium concentration in meconium and the consumption of traditional Chinese herbs commonly used before and during pregnancy.
Methods: A total of 275 mother-infant pairs residing in Northern Taiwan were recruited for the study between January 2007 and March 2009. The parents were interviewed face-to-face by a trained interviewer after delivery in which information pertaining to the parents' and baby's demographic characteristics at birth were collected. Lead and cadmium concentrations in meconium were analyzed by ICP-MS.
Results: The geometric mean of lead and cadmium concentrations in all meconium samples (n = 275) was 117.2 ± 48.4 and 28.5 ± 4.0 ppb, respectively. The concentration of lead in the meconium of the consumption group (the mothers who consumed traditional Chinese herbs) was 491.9 ± 462.4 ppb, a level significantly higher than the level of 93.9 ± 52.1 ppb found in the control group (mothers who did not consume traditional Chinese herbs) before pregnancy. There was the same result during the pregnancy (923.4 ± 87.69 ppb vs.106.1 ± 49.5 ppb). The cadmium concentration in meconium was no significantly different between the two groups.
Conclusions: According to our findings, if the mother had consumed traditional Chinese herbs before or during pregnancy, it may be affect the body burden of lead in their fetus. The quality of raw material for traditional Chinese herbs may be affected by environmental contaminants and cultivated materials, so there should be frequent monitoring of purity.

CLIMATE CHANGE AND HEALTH IN THE DUTCH POLITICAL ARENA

Dieneke Schram-Bijkerk, *National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands*
Theo van Alphen, *CQ Consultancy, Leidschendam, the Netherlands*

Background and aims: In 2008, a Dutch report about climate change and health concluded that more research was needed in this area. In response, the Netherlands Organization for Health Research and Development (in Dutch: ZonMw) initiated the development of a research proposal. However, until now, a draft proposal has not been supported by the Dutch ministries involved due to a lack of sense of urgency and budget constraints. In order to enhance political support, ZonMw asked RIVM to investigate possibilities to link the proposal to policy needs.
Methods: RIVM interviewed policy makers of four Dutch Ministries to investigate existing policy priorities with regard to the four main themes of the draft research proposal; 1) heat stress and air pollution 2) allergies 3) vector-borne diseases and 4) water- and food borne diseases.
Results: According to policy makers, it is difficult to assess the urgency for policy making due to the many uncertainties about the extent of climate change related health impacts. Therefore, political attention is minimal. An exception is the so-called 'Delta Program', which is set to prepare the Netherlands for future climate change. A subprogram of the Delta Program considering new buildings and renovation of cities aims to take health effects into account. For example, several strategies to decrease heat stress in cities are under development. However, quite a few climate change mitigation and adaptation measures have been implemented without the evaluation of potential health effects.
Conclusions: From a policy perspective, research with regard to the extent of climate change related health impacts is required to give the theme priority and move it higher on the Dutch political agenda. Several ministries recognized that knowledge on health effects is required. It would support the implementation of the Delta Program and the translation of international research findings into (local) Dutch policy-making.

ASSESSMENT OF EXPOSURE TO POTENTIAL LUNG CARCINOGENS IN XUANWEI AND FUYUAN, CHINA: PARTICULATE EXPOSURE FROM COOKING AND HEATING STOVES

Qing Lan, Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, DHHS, Bethesda, MD, USA
Roel Vermeulen, Institute for Risk Assessment Sciences, Division of Environmental Epidemiology, Utrecht University, Utrecht, The Netherlands

Backgrounds and aims: Residents in Xuanwei, China have the highest lung cancer incidence rates in China for both men and women. Several lines of research have provided strong support that the excess lung cancer rate in this region is caused primarily by emissions from smoky coal exposure. In order to develop individual estimates of exposure to known or suspected lung carcinogens for an ongoing case-control study, we designed a comprehensive exposure assessment study of 163 households in this region to evaluate exposure to PAHs, $PM_{2.5}$, silica, and other exposures from coal and wood burning.
Methods: Homes that used three main fuel types (i.e., smoky coal, smokeless coal and wood), and eight stove types [e.g., firepit, fixed or portable stove, with or without ventilation] were identified and households were sampled on two consecutive days. The female head of each household was asked to wear a 24-hour personal $PM_{2.5}$ air sampler at the same time that 24-hour area air sampling was employed in the main living area. We also collected information on potential factors that could influence exposure, such as house characteristics, stove type, fuel type and use and amount of time spent in each room.
Results: Initial analyses showed that people using wood burned in firepits were exposed to the highest levels of $PM_{2.5}$ measured in area (536.3±370.5 $\mu g/m^3$) and personal samples (419.8±283.3 $\mu g/m^3$). Burning smokeless coal in a high stove with a chimney was associated with the lowest exposure to $PM_{2.5}$ (62.2±34.1 $\mu g/m^3$, 62.5±29.9 $\mu g/m^3$ for area and personal samples, respectively).
Conclusions: These data show that there is a wide range of exposure to $PM_{2.5}$ in this population. These data and other exposure information from this study will be used in the future to model environmental exposures and risk of lung cancer in this special, high risk population.

ASSOCIATIONS BETWEEN BLOOD LEAD AND KIDNEY OUTCOMES IN ADOLESCENTS FROM A SMELTER COMMUNITY

Background and Aims: Although environmental exposure to lead is common, few studies have examined its impact on kidney function in children. Analyses of associations between lead dose and glomerular filtration measures are especially scarce. Therefore, the extent of lead-related nephrotoxicity in children and adolescents remains uncertain.
Methods: Cross-sectional study of 512 adolescent (12-15 years of age) long term residents in Torreón, Mexico, who were chronically exposed to lead due to a large lead-zinc smelter located within city limits. Associations between blood lead and three kidney outcomes (serum creatinine and cystatin C, and urinary N-acetyl-β-D-glucosaminidase [NAG]) were examined using multiple linear regression.
Results: Median (5th – 95th percentiles) blood lead, serum creatinine and cystatin C, and urine NAG were 4.0 (1.7 – 9.8) µg/dl; 0.58 (0.45- 0.82) mg/dL; 0.76 (0.61 - 1.0) mg/L; and 220.5 (101.2 - 647.3) µmol/h/g creatinine, respectively. After adjustment for age, sex and body mass index, a doubling of blood lead was associated with increases of 0.02 mg/L (95% CI 0.01 to 0.03) in serum cystatin C, -0.01 mg/dL (95% CI -0.02 to 0.002) in serum creatinine, and 0.03 log(µmol/h/g creatinine) (95% CI 0.0002 to 0.06) in NAG.
Conclusions: These results provide support for nephrotoxicity due to environmental lead in chronically exposed children, but the lack of association with serum creatinine, a traditional measure of kidney function, deserves further investigation.

Background: Violence is a major public health problem, yet epidemiological studies on the occurrence of violence remains limited. We aimed at 1) estimating the scope of reported violence against older persons living in seven cities of seven countries, 2) assessing socio-demographic and economic factors correlated to reported VAO and 3) understanding between countries commonalities and differences in reported VAO.

Methods: To investigate the scope of VAO, we conducted a cross-sectional community study of N=4467 individuals in seven cities in Europe (Stuttgart, Germany; Athens, Greece; Ancona, Italy; Kaunas, Lithuania), Granada, Spain, Stockholm, Sweden) with inventories in local languages. The associations between socio-demographic and economic characteristics, health and mental health factors, and experiences of violence and perpetrators characteristics were assessed by calculating and comparing the VAO crude and adjusted Odds Ratios with the respective 95% confidence intervals (CI).

Findings: Mean response rate was 48.8%. Mean age was 70 years and 42.7% (N=1908) of the sample were male. The reported overall proportion of VOA was 12.7% (95% CI: 10.2-15.6) in Italy and 30.8% (95% CI: 27.2-34.6) in Sweden. The reported most common type of VAO was psychological violence 10.4% (95% CI: 8.1-13.0) in Italy and 29.7% (95% CI: 26.2-33.5) in Sweden followed by physical violence with 1.0% (95% CI: 0.4-2.1) in Italy and 4.0% (95%CI: 2.6-5.8) in Stockholm, Sweden. Reported prevalence rate of physical violence with injuries: 0.0% in Italy; 1.5% (95%CI: 0.7-2.8) in Lithuania. Reported prevalence rate of financial violence: 1.8% (95%CI: 0.9-3.2) in Sweden; 7.8% (95% CI: 5.8-10.1) in Portugal. Proportion of reported sexual violence: 0.3% in Lithuania and Spain (95% CI: 0.0-1.1); 1.5% (95%CI: 0.7-2.8) in Greece. The adjusted Odds ratio for psychological violence was for individuals from Germany 3.70 (95% CI 2.45-12.61), from Lithuania 2.60 (95% CI 1.83-3.70) from Porto, Portugal 1.91 (95% CI: 1.35-2.70) and for Sweden 3.70 (95% CI 2.61-5.23). Gender was associated with sexual and financial violence, not with psychological violence.

Interpretation: The present study suggested that older persons living in Stockholm, Sweden; Stuttgart, Germany, and in Kaunas, Lithuania report more often psychological

violence than people living in Ancona, Italy; Granada, Spain, Porto, Portugal. Disclosure of VAO is more likely in Northern urban centers than in Southern small cities. Further research on connections between social and cultural constructions of family, and different types of VAO risk, as well as on effective interventions for older persons, are urgently needed.

RELATIONSHIPS BETWEEN URINARY PHTHALATE METABOLITES AND POTENTIAL BIOMARKERS OF INFLAMMATION AND OXIDATIVE STRESS FROM NHANES 1999-2006

Kelly K. Ferguson, *Department of Environmental Health Sciences, University of Michigan School of Public Health, USA*
John D. Meeker, *Department of Environmental Health Sciences, University of Michigan School of Public Health, USA*

Background and Aims: Phthalate exposure has been associated with a wide range of adverse health outcomes in epidemiologic studies, and one hypothesized mechanism is potentially through induction of inflammation and oxidative stress. We recently reported associations between urinary phthalate metabolites and levels of serum gamma glutamyltransferase (GGT), an indicator of oxidative stress, and C-reactive protein (CRP), a marker of inflammation. In this study we expanded our analysis to investigate associations with other potential markers of oxidative stress (bilirubin) and inflammation (alkaline phosphatase, absolute neutrophil count [ANC], ferritin, and fibrinogen). We hypothesized that higher phthalate metabolite concentrations would be associated with elevations in the inflammation markers and decreases in bilirubin, an indication of increased oxidative stress.
Methods: In this exploratory analysis, we combined data from the National Health and Nutrition Examination Survey (NHANES) collected between 1999 and 2006 and performed multivariable regression analyses.
Results: After adjustment for covariates we found ANC to be significantly and positively associated with the metabolites mono-n-butyl phthalate (MnBP), mono-benzyl phthalate (MBzP), mono-(3-carboxypropyl) phthalate (MCPP), mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), mono-2-ethyl-5-carboxypentyl phthalate (MECPP), and a combined measure of the dibutyl phthalate metabolites ($p < 0.05$). We also observed significant positive associations between alkaline phosphatase levels and the metabolites MnBP, MBzP, MCPP, MEHHP, mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP), mono-isobutyl phthalate (MiBP), mono-(carboxynonyl) phthalate (MCNP), and the aforementioned combination measure ($p < 0.05$). Lastly, bilirubin was significantly and inversely associated with the metabolites MnBP, mono-(2-ethyl)-hexyl phthalate (MEHP), MBzP, MCPP, MEHHP, MEOHP, MiBP, MECPP, and the combined DBP metabolites ($p < 0.0001$).
Conclusions: Concentrations of some urinary phthalate metabolites are associated with increases in ANC and alkaline phosphatase levels, as well as decreased bilirubin levels, which may be indicative of increased inflammation and oxidative stress. These markers may be useful in other studies of low-dose exposure to environmental contaminants in NHANES and other datasets.

ESTIMATING CANCER RISK AMONG RESIDENTS LIVING IN PROXIMITY TO PETROLEUM STORAGE TANKS: THE CASE OF KIRYAT HAIM, ISRAEL

Marina Zusman, *Department of Natural Resource & Environmental Management, Graduate School of Management, University of Haifa, Israel*
Micha Barchana, *Israel National Cancer Registry, Ministry of Health, Jerusalem, Israel; School of Public Health, Faculty of Social Welfare & Health Sciences, University of Haifa, Israel*
Jonathan Dubnov, *Haifa District Health Office, Ministry of Health, Haifa, Israel; School of Public Health, Faculty of Social Welfare & Health Sciences, University of Haifa, Israel*
Boris Portnov, *Department of Natural Resource & Environmental Management, Graduate School of Management, University of Haifa, Israel*

Background and Aims: Cancer is the leading cause of mortality in Israel (both in men and women) and cancer incidence rates are especially high in the Haifa district, which is the main industrial district of the country (Barchana et al 2007; ICBS 2008; IMEP 2008). Although several petroleum storage facilities located in the area may present a considerable health risk, no epidemiological studies have been carried out to date to investigate their potential health effects.
Methods: Both traditional zonal approaches and recently developed Double Kernel Density (DKD) tools were used to investigate relative risks of lung and NHL cancers attributed to residential proximity to the petroleum storage tanks in the Kiryat Hiam residential area.
Results: While traditional zonal approaches failed to detect any association between residential proximity to the petroleum storage tanks and the two types of cancer under study ($P>0.6$), the DKD approach indicates that the relative density of both lung and NHL cancers declines with distance from the storage tanks. The results are found to be especially significant among the elderly (lung: $t= -14.058$; $P <0.01$; NHL: $t= -4.638$; $P <0.01$), controlled for residential proximity to main roads, average income and smoking.
Conclusions: Living near petroleum storage tanks appears to represent a significant health risk that can be detected by sensitive analytical tools, such as the DKD approach, whereas it may remain undetected by traditional zonal approaches commonly used in epidemiological studies.

Adonina Tardón, *University of Oviedo, CIBER Epidemiologia y Salud Pública (CIBERESP), Spain*

Background and aims: The INMA (Childhood and Environment Project) is a multi-centre prospective mother and child cohort study which aims to evaluate the impact of exposure to the most prevalent environmental pollutants on foetal growth and infant development This communication describes health inequalities on diet, health behaviours and self-caring during pregnancy among 2607 women.
Methods: Pregnant women were recruited at their first routine specialized antenatal care visit (10-13 weeks of gestation) to their health centre in four Spanish areas: Valencia, Sabadell (Catalonia), Asturias and Gipuzkoa (Basque Country). Information on maternal characteristics was collected through two questionnaires completed in the first and third trimester of pregnancy, including socio-demographic data, and variables describing monitoring and care received during pregnancy, as well as diet and life-style. Socioeconomic status (SES) was measured by means of occupation, coded using the four-digit Spanish Classification of Occupations (CNO94), closely related to the international ISCO88 coding system.
Results: The mean age of the women was 30.6 years old (range 15-43), 56.2% were primiparous, 98.9% were married and 8.5% were foreigners. A total of 33.5% had university level education and 47% were from a high occupational class. Women with highest SES reported significantly healthier lifestyle habits and had greater skills for self-care, monitoring and planning their pregnancy, and they had fewer pregnancy-related complications and fewer problems in previous pregnancies. Dietary habits were negatively correlated with maternal SES, with higher intake of protein, carbohydrates, fats and total calories in pregnant women with lower SES. On the other hand, we did not find any statistically significant differences in the intake of dietary supplements.**Conclusions**: Adequate care during pregnancy, apart from monitoring all the usual clinical variables, requires an understanding and consideration of the socioeconomic circumstances of the pregnant woman, which determine her behaviour, habits and self-care during this period.

DI (2-ETHYLHEXYL) PHTHALATE EXPOSURE DURING CATHETERIZATION

Ken-Pen Weng, *Kaohsiung Veterans General Hospital, Taiwan*

Wei-Hsiang Chang, *National Cheng-Kung University, Taiwan*

Shi-Hui Huang, *Fooyin University, Taiwan*

Kai-Sheng Hsieh, *Kaohsiung Veterans General Hospital, Taiwan*

Ching-Chang Lee, *National Cheng-Kung University, Taiwan*

Background and Aims: Diethylhexyl phthalate (DEHP) may produce potential toxicity in human bodies. Medical devices containing DEHP are widely used in patients undergoing catheterization, but data on catheterization exposures are limited. In this prospective study, we will investigate the difference of DEHP level before and after catheterization.

Methods: A total of 16 patients (M/F 12/4, mean age 15.7±10.4 years) with congenital heart disease who underwent catheterization were enrolled. Urine samples were collected on admission, pre-catheterization, post-catheterization, and discharge times for assessment of urinary DEHP. We measured mono-(2-ethylhexyl) phthalate (MEHP) and two oxidative DEHP metabolites, mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP) and mono (2-ethyl-5-hydroxyhexyl) phthalate (MEHHP). Exposures to DEHP, such as plastic container, catheters, and intravenous tubing systems were recorded.

Results: Distribution of creatinine-adjusted phthalate metabolites is shown in Table 1. There were significant differences between admission and pre-catheterization times in terms of MEHP (p=0.01), MEHHP (p=0.005), and MEOHP (p=0.001). There were significant differences between pre-catheterization and post-catheterization times in terms of MEHP (p=0.004), MEHHP (p=0.003), and MEOHP (p=0.002). There were no significant differences between post-catheterization and discharge times in terms of MEHP, MEHHP, and MEOHP. There were significant differences between admission and discharge times in terms of MEHHP (p=0.01), and MEOHP (p=0.005) except MEHP. DEHP metabolites on four different times were not significantly associated with PVC-containing systems except MEHHP on discharge ($r=-0.564$, $p < 0.05$). After a multivariate logistic regression, MEHHP levels were associated with intravenous tubing systems (p=0.07).

Conclusions: Use of intravenous tubing systems in catheterization may result in higher exposure to DEHP as reflected by elevated urinary levels of MEHP.

DITHIOCARBAMATE PESTICIDE EXPOSURES, ALDEHYDE DEHYDROGENASE INHIBITION, AND RISK OF PARKINSON'S DISEASE

Beate Ritz, *UCLA, USA*
Shannon L. Rhodes, *UCLA, USA*
Arthur G. Fitzmaurice, *UCLA, USA*
Myles Cockburn, *USC, USA*
Jeff M. Bronstein, *UCLA, USA*

Background and Aims: Chronic exposure to pesticides has been associated with increased risk of sporadic PD in humans. A hallmark of PD is the selective degeneration of dopaminergic neurons in the substantia nigra. Several studies have suggested that 3,4-dihydroxyphenyl-acetaldehyde (DOPAL), the MAO-B product of dopamine metabolism, is toxic to dopaminergic neurons. We hypothesized that exposure to certain pesticides can potentiate this toxicity by inhibiting aldehyde dehydrogenase (ALDH) which would otherwise oxidize DOPAL to the less toxic DOPAC. Furthermore, human genetic variability in ALDH might influence susceptibility to PD in the presence of pesticide exposure.
Methods: To investigate this hypothesis we used both biochemical and epidemiologic approaches. Spectrophotometrically we determined the ALDH inhibiting activity of 30 pesticides in mitochondrial preparations containing rat hepatic ALDH and exposed primary neuronal cultures to these pesticides to determine the loss of dopaminergic neurons. In parallel, we performed genotyping of the ALDH2 gene on DNA samples from a case-control study of 363 incident PD patients and 427 population controls recruited in a region of California with extensive commercial agriculture. A geographical-information systems computer model we developed was used to assess each subject's exposure to commercial pesticides for the years 1974-1999, using state-mandated pesticide use reports, land use maps, and residential/occupational addresses.
Results: Age, gender, and smoking adjusted odds ratios of PD were estimated in logistic regression models including average lifetime exposure to specific pesticides, ALDH2 clade, and an interaction term. We found 50-200% increases in PD risk associated with exposure to fungicides identified in our biochemical screens (e.g. thiram, mancozeb, maneb) and observed a suggestive interaction between the ALDH2 clade and pesticide exposures.
Conclusions: Our results suggest that certain pesticides can impact ALDH function and may lead to increased PD risk. Furthermore, genetic variability in the ALDH2 gene appears to potentiate this effect.

WATER CONSUMPTION HABITS AND LEVELS OF NITRATE AND TRACE METALS IN MUNICIPAL WATER OF SPAIN. MULTI CASE CONTROL STUDY MCC- SPAIN

Background and Aims: Several health effects including cancer have been linked to nitrate and metals in drinking water, although the evidence is not conclusive for many associations. Information about the type of water consumed in Spain and levels of these contaminants in drinking water is limited. The aim of this study is to describe levels of nitrate and metals in municipal water and drinking water habits among the controls of a multicase-control population-based study of cancer in Spain (MCC-Spain).
Methods: Study areas include Asturias, Barcelona, Cantabria, Guipúzcoa, Granada, Huelva, León, Madrid, Murcia, Navarra and Valencia. Individual information about water consumption in all residences since 18 years old was obtained in personal interviews. Here we describe water consumption in the current residence among controls (N=2340). Tap water samples were collected between March and June 2010 in 207 sampling points. Nitrate, arsenic, nickel, chromium, cadmium, lead, selenium and zinc were measured at Laboratory of Public Health in Guipúzcoa.
Results: Overall, 71%, 25% and 3% of subjects consumed, respectively, municipal, bottled and private well water in the current residence. Municipal water consumption was highest in Madrid (94%) and lowest in Murcia (65%). Correspondingly, bottled water consumption was highest in Murcia (65%) and lowest in Madrid (5%). Proportion of private well water consumption was highest in León (36%). Mean levels of nitrate ranged from 2.7 mg/l (Guipuzkoa) to 9.8 mg/l (Barcelona). Trace metals were mostly below the detection limit (on average, 94% of samples). Arsenic was detected in Barcelona, León and Madrid (maximum levels were 1.0, 3 and 4.0µg/l, respectively).
Conclusions: Considerable differences in water consumption are observed between regions. Levels of nitrate and metals were below the regulated limits in municipal water. It is necessary to assess these contaminants in bottled and private well water, given their high consumption in some areas.

IN-UTERO ORGANOCHLORINE EXPOSURE, GENE EXPRESSION OF AROMATASE, AND ABNORMAL PAP SMEARS

Chen Wang, *Michigan State University, USA*
Janet Rose Osuch, *Michigan State University, USA*
Wilfried Karmaus, *University of South Carolina, USA*
Pamela Haan, *Michigan State University, USA*
Dorota Mickuki, *Michigan State University, USA*

Background and Aims: We have previously demonstrated that prenatal exposure to organochlorines is associated with gene expression of aromatase, an enzyme in estrogen synthesis. It is also known that aromatase is overexpressed in HPV positive cervical cancer cells. Estrogen activates HPV in cervical carcinogenesis. The objective of this study is to determine the association between prenatal exposure to organochlorines and abnormal Pap smear, mediated by altered gene expression of aromatase.
Methods: Female offspring of the Michigan Fisheater's Cohort (recruited 1973-1991) were contacted in 2001/2 and 2006/7. Interview variables included age and reproductive history. Leukocyte gene expression was determined and standardized with RNA Polymerase II. Generalized estimation equations and path-analyses were used to investigate the link between prenatal organochlorine exposure, gene expression, and Pap smear results.
Results: 139 women birthed by 93 mothers were identified. Of 134 women with complete data, 22 reported abnormal Pap smears. The average age at interview was 40 years (20.2 – 52.8) and of menarche, 13 years (11.0-16.0). Ninety-eight were premenopausal, 11 perimenopausal, and 24 postmenopausal.

Mean values of gene expression for *CYP19* were higher (p=0.03) in women with abnormal Pap smears and marginally different for *ESR1,* (p=0.09), which codes for ERα. No difference was found for 17-α-hydroxylase or *ESR2.* The path analysis showed no direct effect between prenatal organochlorine exposure and abnormal Pap smears, but a significant indirect effect via higher expression of *CYP19*.
Conclusions: These results demonstrate an association between abnormal Pap smears and the gene expression of *CYP1* that is not directly related to in-utero organochlorine exposure. This may reflect an indirect effect via gene expression, initiated earlier in life or a true negative effect. If the former is the case, the association between the gene expression of *CYP19* and abnormal Pap smears will need an alternative explanation.

EXTREME AIR POLLUTION EVENTS FROM BUSHFIRES AND CARDIO-RESPIRATORY HOSPITAL ADMISSIONS IN SYDNEY, AUSTRALIA 1994-2007

Fay Johnston, *Menzies Research Institute, University of Tasmania, Australia*
Ivan Hanigan, *University of Tasmania and the Australian National University, Australia*
Kara Martin, *Menzies Research Institute, University of Tasmania, Australia*
Sarah Henderson, *University of Tasmania and the British Colombia Centre for Disease Control, Canada.*
Geoffrey Morgan *North Coast Area Health Service and the University of Sydney, Australia.*

Background and aims: Extreme air pollution events due to bushfire smoke are expected to increase as a consequence of climate change, yet little has been published about their population health impacts. We examined the association between bushfire smoke pollution events and hospital admissions in Sydney from 1997-2004.
Methods: Events were defined as days for which smoke from bushfires caused the 24 hour city-wide average concentration of PM_{10} to exceed the 99^{th} percentile. We used a time-stratified case-crossover design with conditional logistic regression modeling adjusted for daily meteorology, flu epidemics and holidays. Odds ratios (OR) and 95% confidence intervals (CI) for admissions on event compared with non-event days were estimated. We assessed admissions for all cardiovascular conditions, ischaemic heart diseases, hypertensive diseases, cerebrovascular diseases, all respiratory conditions, asthma, chronic obstructive pulmonary disease (COPD), bronchitis and pneumonia.
Results: There were 52 days during the study period in which the extreme particulate pollution was attributable to bushfire smoke. On the day of the smoke events all respiratory hospital admissions increased by 7% (OR 1.071, 95%CI, 1.033,1.112). Admissions for COPD increased 16% (OR 1.168, 95%CI 1.080, 1.263) and asthma by 14% (OR 1.145, 95%CI 1.036, 1.265). Results were similar at a lag of one day. No associations were observed with other respiratory diagnoses or with cardiovascular admissions.
Conclusions: Bushfire smoke pollution events were associated with increases in admissions for respiratory, rather than cardiovascular conditions.

EXPOSURE TO PARTICULATE AIR POLLUTION AND COGNITIVE DECLINE IN OLDER WOMEN

Joel Schwartz, *Harvard School of Public Health, Boston, MA, USA; Channing Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA*
Jeffrey D. Yanosky, *Penn State University College of Medicine, Hershey, PA, USA*
Francine Laden, *Harvard School of Public Health, Boston, MA, USA; Channing Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA*
Francine Grodstein, *Harvard School of Public Health, Boston, MA, USA; Channing Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA*

Background and Aims: Chronic exposure to particulate air pollution may accelerate cognitive decline in older adults. We examined long-term exposure to thoracic (PM_{10}) and fine ($PM_{2.5}$) particulate air pollution in relation to cognitive decline.
Methods: Our investigation included 17282 US women, aged 70-81 years, who were participants in the Nurses' Health Study. We used geographic information systems (GIS)-based spatio-temporal smoothing models to estimate recent (1 month) and long-term (6-13 years) exposures to PM_{10}, and $PM_{2.5}$ for women residing in the contiguous US. We evaluated the women's cognition using validated telephone assessments of cognition, administered 3 times at approximately 2-year intervals, including tests of general cognition, verbal memory, category fluency, and attention. We used generalized estimating equation regression to estimate differences in the rate of cognitive decline over 4 years, across levels of PM_{10} and $PM_{2.5}$ exposures preceding cognitive testing.
Results: Higher levels of long-term exposure to both PM_{10} and $PM_{2.5}$ were associated with significantly faster cognitive decline. Decline on a global score, combining results of all 6 tests, was 0.017 standard units worse per 10 $\mu g/m^3$ increment in PM_{10} exposure (95% confidence interval, -0.027 to -0.007) and and 0.036 units worse per 10 $\mu g/m^3$ increment in $PM_{2.5}$ exposure (95% confidence interval, -0.064 to -0.008). These differences in cognitive trajectory were similar to the differences in trajectories between women in our cohort who were 1.5 and three years apart in age, respectively, indicating that the long-term effects of particulate air pollution are cognitively equivalent to aging by up to three years. Recent exposures to PM_{10} and $PM_{2.5}$ were not significantly associated with cognitive decline.
Conclusions: Long-term exposure to PM_{10} and $PM_{2.5}$, at levels typically experienced by many persons in the US, is associated with significantly worse cognitive decline in older women.

ESTIMATED GLOBAL HUMAN MORTALITY FROM VEGETATION FIRE SMOKE

Fay Johnston, *Menzies Research Institute, University of Tasmania, Australia*
Sarah Henderson, *University of Tasmania, British Columbia Centre for Disease Control, Canada.*
Yang Chen, *Dept of Earth System Science, University of California, Irvine, USA*
James T Randerson, *Dept of Earth System Science, University of California, Irvine, USA*
Miriam Marlier, *Columbia University, USA*
Ruth S Defries, *Columbia University, USA*
Patrick Kinney, *Columbia University, USA*
David Bowman, *University of Tasmania, Australia*
Michael Brauer, *University of British Columbia, Canada*

Background and Aims: Vegetation fires annually release an average of approximately 2 petagrams of carbon to the atmosphere causing recurring episodes of severe regional air pollution and contributing to greenhouse gas emissions. We aimed to assess global mortality attributable to particulate matter in vegetation fire smoke (VFS).
Methods: We followed the methods of the WHO Global Burden of Disease, Comparative Risk Assessment studies (Ezzati *et al.* 2002). Ambient concentrations of particulate matter (1997-2006) were estimated at a resolution of 2 (lat) X 2.5 (long) degrees using satellite-based observations of fire activity, atmospheric aerosol loadings and a global atmospheric chemical transport model. We applied previously published exposure-response coefficients for VFS and acute all-cause mortality in WHO regions where smoke exposure was sporadic. In regions with chronic VFS exposure we used a conservative coefficient from studies of urban air pollution and all-cause mortality as studies of chronic VFS exposure are lacking. Coefficients were applied to population-weighted mortality rates to produce global and regional mortality estimates. We conducted sensitivity analyses to assess the influence of effect size coefficients, acute vs chronic exposure scenarios, and counterfactual VFS pollution estimates.
Results: We estimated that 480,000 deaths/yr were attributable to VFS. In sensitivity analyses the estimate ranged from 300,000 to 820,000 with the assumed counterfactual exposure having the greatest influence on results. Regions most severely affected were Sub-Saharan Africa and South East Asia.
Conclusions: Fire emissions are an important contributor to global mortality, although lower than that estimated for urban air pollution (800,000/yr) and indoor air pollution from cooking fires (1.6 million/yr) (Ezzati *et al.* 2002). Rapid improvements in health outcomes could be achieved through the cessation of deliberate burning of biomes that rarely naturally burn, such as tropical rainforests. The potential to reduce overall fire emissions from highly flammable biomes such as savannas, the primary source of firesmoke in sub-Saharan Africa, warrants further investigation.

FROM SCIENCE TO POLICY: ADDRESSING HEALTH IMPACTS OF INSTITUTIONAL AND LARGE-SCALE WOODY BIOMASS BURNING

Molly Jacobs, *University of Massachusetts - Lowell, Lowell, MA USA*,
Polly Hoppin, *University of Massachusetts – Lowell, USA*
Richard Clapp, *University of Massachusetts – Lowell, USA*

Background and aims: Renewable energy credits, grants, and the low cost of wood have led to the proliferation of woody biomass electrical utility plants and institutional units to heat schools/universities and hospitals in the Northeast U.S. Potential health impacts of biomass burning are not systematically taken into account in energy policy decision-making. While "healthy renewable energy" is a goal shared by policy makers and the public, policy and practice changes are needed to achieve it. The objective of this project is to review the state of the science regarding health impacts from mid-sized biomass burning units as well policy gaps and opportunities for health-promoting energy policy decisions.
Methods: Literature reviews included a comprehensive search of the peer-reviewed literature, reviews of regulatory/permit policies and key informant interviews with air regulatory staff in nine Northeast U.S. states. Input and clarifying policy recommendations came from meetings with national health experts during Spring 2011. A policy symposium with leaders from energy, economic development, environment and public health agencies is scheduled later in the year to communicate key project findings and to begin a constructive dialog about policy solutions.
Results: Evidence of health risks to workers from the production of wood-chips, wood pellets and associated delivery, and community health impacts from diesel truck traffic and emissions from industrial and institutional wood-fired units will be presented. Preliminary policy opportunities identified include the adoption of health impact assessment during the permit process, and "Prevention through Design" policies that make available cleaner-burning technologies and safer workplaces. The case for stricter air permit regulations requiring emission controls on small institutional units will also be presented. Lessons-learned from meetings with experts and with policy leaders will be highlighted.
Conclusions: Health impacts of woody biomass burning have not been fully addressed to date. Scientific information can inform future policy decisions that will reduce public health risks.

Contribution of individual risk factors to the international variation in wheeze prevalence in children: a meta-analytic approach

Gudrun Weinmayr, *Institute of Epidemiology and Medical Biometry, Ulm University, Germany*
Andrea Kleiner, *Institute of Epidemiology and Medical Biometry, Ulm University, Germany*
Francesco Forastiere, *Department of Epidemiology, ASL Roma E, Italy*
David Strachan, *Division of Population Health Sciences and Education St George's, University of London, UK*
and the ISAAC Phase Two Study Group

Background and Aims: We investigate how much international differences in individual risk factors assessed in our study contribute to the high international variation in the prevalence of wheeze using a meta-analytic approach.
Methods: In Phase Two of the International Study of Asthma and Allergies in Childhood, cross-sectional population-based studies of children (8-12yrs) were performed in 30 centres in 22 countries worldwide according to a standardized protocol. Asthma symptoms and a wide range of potential risk factors were assessed by parental questionnaires as well as atopic sensitization by skin prick testing.
For each centre we fitted a logistic regression. Based on the resulting centre-specific beta estimates, we predicted the expected centre prevalence of wheeze at the global average level of exposure to each of the risk factors (equivalent to direct standardization).
Between centre heterogeneity was quantified by a random effects meta-analysis on the predicted prevalences. After running bivariate models, the risk factors that reduced most markedly the heterogeneity were combined in a multivariate model.
Results: The observed prevalence of wheeze ranged from 0.8% to 25.6%.
The most prominent individual risk factors to reduce the variation were parental allergic disease, feather bedding, a smoking mother, damp housing and skin prick test reactivity. When accounting for these factors, the predicted prevalence for the centres ranged from 1.0% to 19.3%. The variance of the combined estimate of the prevalence after adjustment was 64% of the variance for the observed prevalence.
Conclusions: Only a limited proportion of the variation between the centres could be eliminated by adjusting for the investigated individual risk factors. Quantification proves difficult because heterogeneity measures from meta-analysis are susceptible to increases in the standard error after multivariate modeling. In the future we aim to explore multilevel modeling.

EARLY DRY COUGH AND DYSPNOEA AS MARKERS OF ALLERGIC AND INFECTIOUS BRONCHIAL OBSTRUCTIVE PHENOTYPES IN INFANCY: RESULTS FROM THE FOLLOW-UP OF THE PARIS BIRTH COHORT

Fanny Rancière, *Université Paris Descartes, EA 4064, France*
Bénédicte Clarisse, *Université Paris Descartes, EA 4064, France*
Lydia Nikasinovic, *Université Paris Descartes, EA 4064, France*
Jocelyne Just, *Université Paris Descartes, EA 4064, France*
Isabelle Momas, *Université Paris Descartes, EA 4064, France*

Background and Aims: Asthma diagnosis during infancy is difficult: wheezing is quite frequent, notably due to respiratory infections, but all wheezers will not develop asthma. Thus, identification of phenotypes based on different respiratory symptoms has become one of the current challenges. We previously identified two bronchial obstructive phenotypes during the first year of life in 2632 infants from the PARIS birth cohort, using an unsupervised statistical approach: G1, presenting dry night cough, and G2, suffering from nocturnal dyspnoea. The present study aims to follow the evolution of the G1 and G2 children between 1 and 3 years and to examine whether the identified bronchial obstructive phenotypes are stable and whether they differ with regard to comorbidity and associated environmental factors.
Methods: Data about children's health and their mode/environment of life were gathered by self-administered questionnaires parents filled in 5 times during the first year of life, and at 2 and 3 years. Risk factors associated to G1 and G2 phenotypes were studied using polytomous logistic regression in comparison to the asymptomatic group G0.
Results: G1 and G2 phenotypes were persistent at 3 years, and comorbidity was quite different between both groups. G1 infants suffered significantly more often from allergic diseases such as eczema, food reactions, and nose disorders associated with itchy-watery eyes, whereas the G2 group was dominated by upper/lower respiratory infections. The analysis of associated factors corroborated these two distinct profiles. Parental history of allergy and potential contact with allergens were associated to G1. Conversely, exposure to chemicals, through prenatal and postnatal ETS exposure, renovation of the child's bedroom or acquisition of particleboard furniture, was significantly more frequent in G2, suggesting a synergistic effect on infections.
Conclusions: Early dry cough and nocturnal dyspnoea appear as markers of two distinct stable profiles, respectively allergic (G1) phenotype and infectious (G2) phenotype.

GPS AND GIS FOR ASSESSMENT OF PHYSICAL ACTIVITY BEHAVIOUR OF CHILDREN WITHIN THE URBAN ENVIRONMENT

Frank Pierik, *Expertise center Earth, Environmental and Life Sciences, TNO, The Netherlands*
Jamie Graham, *Expertise center Earth, Environmental and Life Sciences, TNO, The Netherlands*
Reinier Sterkenburg, *Expertise center Earth, Environmental and Life Sciences, TNO, The Netherlands*
Carien Caljouw, *Expertise center Earth, Environmental and Life Sciences, TNO, The Netherlands*
Jantine Slinger, *Expertise center Lifestyle, TNO, The Netherlands*
Sanne de Vries, *Expertise center Lifestyle, TNO, The Netherlands*

Background and Aim: The built environment may have a role in preventing obesity by stimulating physical activity (PA) levels. Knowledge of which environmental factors affect PA, and how, is sparse. This study aims to gain insight into locations where children are physically active, using innovative GPS, accelerometer and GIS techniques, and to analyze the willingness to travel from home to school by active transport, as a function of the distance.

Methods: 88 school children (aged 5-11 years) in 5 cities in the Netherlands participated for a maximum of 7 days. The locations and intensity of their activities were recorded by GPS and accelerometer and linked with geographical information on 1) green areas, 2) surface water, 3) playgrounds, and 4) schoolyards. The actively travelled (i.e. walked or bicycled) distance between home and school was assessed using GPS and GIS data.

Results: On average children spent 1 hour and 49 minutes a day outdoors. During this time, children were often near green areas (27%) or water areas (11%). The highest PA levels were found at or around playgrounds and schoolyards.
Children walked or bicycled a mean distance of 4.5 km per day. The majority of the actively travelled trips between home and school were < 500 meters long. Up to a distance between home and school of 350 meters, the willingness to travel by means of active transport is nearly 100%. At distances beyond 400 meters, the willingness decreases rapidly.

Conclusions: These findings provide better insight into the question where within the urban environment do children spend their time, where they are physically active, and how far they are willing to travel by foot or bicycle. Urban planning may provide a means to stimulate physical activity levels and health. GPS technology, in conjunction with GIS, is an insightful and promising addition to this field of research.

MATERNAL RESIDENCE NEAR AGRICULTURAL PESTICIDE APPLICATIONS AND AUTISM: A FOLLOW-UP STUDY

Eric M Roberts, *Public Health Institute, Oakland, CA USA*
Paul B English, *California Department of Public Health, Richmond, CA USA*
Liang Guo, *Public Health Institute, Oakland, CA USA*
Craig Wolff, *Public Health Institute, Oakland, CA USA*
Meredith Anderson, *Impact Assessment, La Jolla CA USA*
Gayle Windham, *California Department of Public Health, Richmond, CA USA*

Background and Aims: Our previous work documented associations between maternal residence near organochlorine pesticide applications during the approximate period of brain embryogenesis (gestational days 21 through 49) and mid-infancy (months 4 through 6 of life) with the development of autism spectrum disorders (ASD). We sought to confirm these findings using a larger sample, to examine differences in associations for male and female children, and to consider other pesticides having toxicological mechanisms theorized as being relevant to autism in the literature.
Methods: We identified 2,553 males and 523 females with ASD born during 1996-2005 in California's Central Valley using the California Department of Developmental Services (DDS) electronic files. These were matched them by sex and maternal date of last menstrual period to 46,140 live-born, normal birthweight, term infants as a comparison group. We determined proximity (residence recorded at delivery within 500 meters) to applications of organochlorine, organophosphate, pyrethroid, and anilide pesticides using California Department of Pesticide Regulation records refined via Department of Water Resources land use polygons. Probability of ASD was analyzed using conditional logistic regression controlling for maternal age, educational attainment, race/ethnicity, and DDS Regional Center responsible for ASD classification.
Results: Proximity to organochlorine applications during brain embryogenesis was associated with ASD for males (OR for ten-pound increase 4.81 [95%-confidence interval 2.41-9.54]) but not for females (0.90 [0.29-2.84]). For applications occurring during mid-infancy, these ratios were 1.76 (1.37-2.26) and 1.18 (0.53-2.67), respectively.
Conclusions: Proximity to organochlorine pesticides during each time-period of interest was associated with ASD in a linear fashion among males but not females. We conduct further analysis to understand (a) the sensitivity of these findings to chosen definitions of time period for each pesticide class, and (b) the potential for spatial confounding.

MATERNAL EXPOSURE TO MAGNETIC FIELDS (MFS) DURING PREGNANCY IN RELATION TO THE RISK OF ASTHMA IN OFFSPRING

De-Kun Li, Division of Research, Kaiser Permanente, USA
Hong Chen, Division of Research, Kaiser Permanente, USA
Roxana Odouli, Division of Research, Kaiser Permanente, USA

Background and Aims: Asthma is the most common chronic disease in children, and the prevalence has been increasing for decades. Yet, its etiology is large unknown. This study examined a new potential etiological factor: whether maternal exposure to high MF level during pregnancy increases the risk of asthma in offspring.

Methods: A prospective cohort study was conducted among members of Kaiser Permanente Northern California. Participating pregnant women carried a meter measuring their MF levels during pregnancy and 626 of their children were followed up to 13 years for their clinical diagnosis of asthma.

Results: A higher maternal MF exposure level during pregnancy was associated with significantly higher prevalence of clinically diagnosed asthma in offspring. After adjustment for potential confounders, a statistically significant linear dose-response relationship was observed between increasing maternal median daily MF exposure level in pregnancy and an increased risk of asthma in offspring (adjusted hazard ratio (aHR)=1.26, 95% confidence interval (CI) 1.10-1.44). Using the categorical MF level (low, medium and high), the results showed a similar dose-response relationship: compared to those whose mothers had a low MF exposure during pregnancy, children whose mothers had a high MF level had more than 3.5 fold increased risk of developing asthma (aHR=3.52, 95%CI: 1.68-7.35), while children whose mothers had a medium MF level had a 74 percent increased risk of asthma (aHR=1.74, 95% CI: 0.93-3.25). There was also a statistically significant synergistic interaction between other asthma risk factors, maternal history of asthma and birth order (first-born), and the MF effect on the asthma risk.

Conclusions: Our finding provides the new epidemiologic evidence that high maternal MF exposure in pregnancy may be associated with the risk of asthma in offspring.

METHODOLOGICAL APPROACHES AND CHALLENGES IN PROJECTING HEALTH IMPACTS ASSOCIATED WITH AIR POLLUTION AND CLIMATE CHANGE

Sarunya Sujaritpong, *Australian National University, Australia*
Keith Dear, *Australian National University, Australia*
Martin Cope, *The Centre for Australian Weather and Climate Research, Australia*
Sean Walsh, *Environmental Protection Authority Victoria, Australia*

Background and Aims: Quantifying the health impacts of climate change has been an active area of research in recent years. Different methods have been developed to estimate the magnitude of a number of diseases potentially modified by climate change. The focus of this review is on methodological approaches and challenges in projecting future health impacts associated with air pollution under a changing climate.
Methods: The review is limited to studies published between 2000 and 2010. In addition to examining approaches and challenges in projecting the effects of climate change on health outcomes related to air quality, we also compared them with projections of potential health effects attributable to climate change such as temperature-related deaths and food-borne disease.
Results: Approximately 90% of the published articles used epidemiological approaches where reference dose-response functions of pollutants were linked with projected air quality concentrations generated from climate-air pollution modelling systems. Recently a study proposed a combination of synoptic weather typing and statistical downscaling as an alternative approach. Factors other than climate change, for example, emissions of ozone precursors, population growth, age structure, and disease incidence, were mostly held constant to reduce uncertainty in the model predictions. Such simplified future scenario has been commonly found in estimating various disease outcomes under a changing climate. Challenges identified in the past studies include correlation of multiple air pollutants, interrelated air pollution-temperature health burdens, application of air pollution health thresholds, future demographic characteristics, and adaptive actions.
Conclusions: Developing models and realistic scenarios to minimise bias and uncertainty in predictions are the key challenges for future research. Similar to approaches in studying future impacts of climate change of heat on mortality, incorporating insights gained from historical air pollution episodes during extreme weather events can potentially help improve estimating future health effects of air pollution and climate change.

AN INTERACTIVE DISCUSSION OF THE NEWLY-REVISED DRAFT ISEE ETHICS GUIDELINES: KEY PRINCIPLES, CASE STUDIES, AND APPROACHES TO ETHICAL CHALLENGES

Shira Kramer, PhD, ***Epidemiology International, Inc., USA***

Background and Aims: The opportunity to positively contribute to the health and well-being of humans is a fundamental tenet of the field of epidemiology. Environmental epidemiologists are responsible for identifying environmental health threats which may have far-reaching implications, including multi-generational effects and global impacts. In order to meet the challenge of protecting public health, it is essential that funders, institutions, and researchers be committed to the pursuit of objective epidemiological evidence in protecting public health, and recognizing forces that subvert or undermine such work. However, there has been a growing threat to the impact and the legitimacy of our research due to increasing pressures and control from political and economic interests. These forces work to shape the research agenda, methodology, reported outcomes, and policy. The ensuing ethics issues add to the spectrum of other ethics challenges posed by research on humans.

Methods: In this presentation, I will discuss the newly-updated ISEE Ethics Guidelines, highlighting modifications that were deemed to reflect issues in the current research climate. One important addition is an invitation to ISEE members to contribute case studies. The Guidelines are organized according to four major areas:

- Obligations to Individuals and Communities Subjected to Research
- Obligations to Society
- Obligations Regarding Funders/Sponsors and Employers
- Obligations to Colleagues

Results: The new draft Guidelines reflect growing concern about conflicting interests; funding of heretofore independent institutions by private industry; political influence on the research agenda; restrictions on the flow of information; informed consent (including international differences regarding authority over decision-making); the fate of bio-specimens; editorial bias; and the implications of improper ("junk") science for public health policy.

Conclusions: The true value of the Ethics Guidelines will rest upon their active incorporation into professional practice, and into the dialogue among all stakeholders.

MATERNAL CONSUMPTION OF COFFEE AND TEA DURING PREGNANCY AND RISK OF CHILDHOOD ALL: RESULTS FROM AN AUSTRALIAN CASE-CONTROL STUDY

Bruce Armstrong, *Sydney School of Public Health, The University of Sydney, New South Wales, Australia*

Background: Little is known about the origins of childhood acute lymphoblastic leukaemia (ALL). Several studies have reported an increased risk of childhood acute leukaemia with higher levels of maternal coffee consumption during pregnancy, while others have reported no association. One positive study also examined maternal tea consumption and found no effect. Both coffee and tea contain naturally occurring topoisomerase II inhibitors, which have been associated with chromosomal damage of the type seen in infant leukaemia The aim of this study was to investigate whether maternal coffee and/or tea consumption during the last six months of pregnancy was associated with risk of childhood ALL.
Methods: Data on coffee and tea drinking during pregnancy from 337 case mothers and 697 control mothers were analyzed using unconditional multivariable logistic regression. A meta-analysis of our findings with those of previous studies was also conducted.
Results: There was little evidence of an overall association between maternal coffee consumption and risk of ALL: OR 0.89 (95% CI 0.61, 1.30), although there was some suggestion that higher levels of intake might increase risk in children of non-smoking mothers: OR for 2+ cups/day = 1.44 (95% CI 0.85, 2.42); this was supported by our meta-analysis. Risk was also elevated among cases with chromosomal translocations. The overall OR for maternal tea consumption was 0.82 (95% CI 0.56, 1.18), although the OR for T-cell ALL was 0.21 (95% CI 0.08, 0.51). Among ALL cases with translocations, the ORs for tea consumption tended to be elevated: OR=1.70 (95% CI 0.79-3.68) for 2+ cups/day.
Conclusions: The observed increased risk associated with coffee and tea consumption may be confined to ALL with translocations. These associations should be explored further in large international consortia.

AN INTERACTIVE DISCUSSION OF THE NEWLY-REVISED DRAFT ISEE ETHICS GUIDELINES: KEY PRINCIPLES, CASE STUDIES, AND APPROACHES TO ETHICAL CHALLENGES

Shira Kramer, PhD, ***Epidemiology International, Inc., USA***
Wael K Al-Delaimy, MD, PhD, ***University of California San Diego, USA***

Background and Aims: The final thirty minutes of the Symposium will be a moderated, interactive discussion of the draft of the revised ISEE Ethics Guidelines.
Methods: The discussion will reflect on the five presentations and the case studies presented, and how they are relevant to the mission of the ISEE and environmental epidemiologists. Feedback will be elicited from attendees on the content of the Guidelines; the value of case studies in illustrating the relevance of the Guidelines in actual practice; and on developing solutions for preventing and managing ethical conflicts.
Results: A paper will emerge from these proceedings for wider dissemination among environmental epidemiologists, with a view towards the ISEE's eventual adoption of the revised Ethics Guidelines.
Conclusions: It is our goal to increase awareness of the ISEE Ethics Guidelines, and to engage members of our profession in a positive dialogue about ethics issues that are so vital to the positive impacts of our work.

LOCAL NEIGHBORHOOD DEPRIVATION: NEW METHODS TO DEFINE NEIGHBORHOODS AND MEASURE DETERMINANTS OF POVERTY IN THE FRESNO ASTHMATIC CHILDREN'S ENVIRONMENT STUDY (FACES)

Gale, Sara, *University of California, Berkeley, US*
Padula, Amy, *University of California, Berkeley, US*
Tager, Ira, *University of California, Berkeley, US*

Background and Aims: Previous studies have demonstrated an association between neighborhood deprivation (often measured by the US Census), exposure to air pollution and asthma outcomes. However, what constitutes a neighborhood and how best to characterize local environments is subjective and evolving. A neighborhood is defined by a geographic boundary and thus, the appropriate scale and aggregation units must be considered in epidemiologic analyses. We aim to create individual neighborhoods based on walking distances from children's residences in the Fresno Asthmatic Children's Environment Study (FACES) and to describe quantitatively neighborhood deprivation at the individual level.
Methods: This study uses a geographic information system (GIS) to define neighborhoods and measure local, area-level deprivation in Fresno, CA from 2000-2008. Markers of deprivation in FACES include low grocery store availability, high density of alcohol outlets and cigarette sales permits, lack of schools and parks, inadequate public transit, lack of daycares, and eight census-derived variables. We use item response theory (IRT) with maximum likelihood estimation to develop a deprivation scale for study subjects' neighborhoods (n=518) where geographic attributes are converted to positive and negative neighborhood influences.
Results: The median IRT score for FACES participants is 0.16 (where scores range from -5 to 5 for low to high deprivation). The scores are correlated positively with census defined poverty (Spearman correlation rho=0.2) and may give a more complete picture of area-level deprivation than the census.
Conclusions: IRT helps summarize multiple GIS inputs and describe more precisely local deprivation with a composite score. The advantage of using individual neighborhoods defined by walking distances versus census defined boundaries is that the individual neighborhoods partly solve the problem of non-identifiabilty, an issue of insufficient covariate overlap that plagues neighborhood research. Our future research will employ the IRT scores to determine if there is a relation between neighborhood deprivation and exposure to traffic and lung function among asthmatics in FACES.

RELATIONSHIP BETWEEN BLOOD LEAD LEVELS AND PULMONARY FUNCTION

Sujin Park, *Korea Forest Research Institute, Republic of Korea*
Su Ryeon Noh, *School of Public Health Seoul National University, Republic of Korea*
Ae Ri Oh, *School of Public Health Seoul National University, Republic of Korea*
Domyung Paek, *School of Public Health Seoul National University, Republic of Korea*

Background and Aims: Lead is an environmental and public health hazard of global proportions. In case of lead, respiratory intake is a major route of exposure. But there are few studies on the relation between respiratory health and blood lead level. This study was performed to examine the influence of lead on the pulmonary function of local residents.
Methods: For this study, 800 local residents (353 men, 447 women) near an industrial complex were surveyed from July to August in 2008. All of the subjects completed the interview questionnaire and performed PFT (pulmonary function test) and blood lead tests.
Results: The mean blood lead level was 1.32±0.5ug/dl. The blood lead levels of men were higher than that of women. The results of %FVC, %FEV_1, FEV_1/FVC% in PFT were 94.9±13.1, 93.7±13.0, 84.3±8.5. Smoking, Income and traffic intensity was environmental factors of pulmonary function. There was a significantly negative correlation between PFT results and blood lead levels. For children under the age of nine, the pulmonary function significantly decreased as the blood lead levels rose, despite adjusting the factors age, sex, height, weight, smoking, and traffic intensity.
Conclusions: This study suggests that pulmonary function may be related to blood lead level, especially for children under nine years of age. This means that exposure to lead might decrease the function of respiratory system. Further study will be needed to indentify more association between blood lead levels and pulmonary function.

CORRELATION BETWEEN MAXIMUM TEMPERATURES AND ACUTE RESPIRATORY INFECTIONS IN THE METROPOLITAN AREA OF GUADALAJARA, MEXICO

Maria Guadalupe Garibay-Chavez, *Masters' Program on Environmental Health. Environment and Human Communities Institute. University of Guadalajara, Mexico*
Arturo Curiel-Ballesteros, *Masters' Program on Environmental Health. Environment and Human Communities Institute. University of Guadalajara, Mexico*
Tania Parada-Gallardo, *Masters' Program on Environmental Health. Environment and Human Communities Institute. University of Guadalajara, Mexico*
Arturo Perez Romero, *Jalisco Department of Health, Mexico*

Background/Aims: It is recognized worldwide that there is a link between increases in temperature and heat waves, and respiratory morbidity and mortality rates. In Guadalajara's Metropolitan Area (GMA) temperatures have increased and Acute Respiratory Infections (ARIs) ranks first in morbidity rates. The relationship between maximum observed temperatures and ARIs in the GMA between1996 and 2009 is analyzed.
Methods: Observational, retrospective, longitudinal and comparative study undertaken from 1996-2009. Variables analyzed were maximum observed daily temperature, heat waves and their duration and morbidity due to ARIs.
Maximum temperatures during the period from 1996 to 2009 were identified with respect to those observed from 1960-1980 considered as the baseline, in order to identify the highest levels of ARIs cases.
Heat waves was defined as observing a daily maximum temperature equal or above 32 °C for three consecutive days.
Correlation analyses were conducted between the maximum observed temperature and the total ARIs cases each week.
Results: The highest temperatures in the GMA from 1996-2009 are registered from April to June; the greatest increases with respect to the baseline occurred from November to February. The greatest frequency and duration of heat waves occurred in April and May; 2009 was atypical with respect to maximum temperatures and equally for ARIs, which showed an unusual increase in cases from April to June. The correlation between these two variables was found to be 0.49.
Conclusions: The maximum observed daily temperatures in 2009 are found to have increased within GMA with respect to those registered during the period from 1960 to 1990. 24% of the increase in ARIs in 2009 is determined by the increase in temperature.
The increase in ARIs during the periods of greater heat is a tendency recently observed in 2009, which makes it of great relevance, in the face of climate change scenarios, to maintain monitoring activities which provide daily data.

RELATIONSHIP BETWEEN BLOOD MANGANESE AND BLOOD PRESSURE IN THE KOREAN GENERAL POPULATION ACCORDING TO KNHANES 2008

Byung-Kook Lee, *Institute of Environmental & Occupational Medicine, Soonchunhyang University 646 Eupnae-ri, Shinchang-myun, Asan, Choongnam Korea*

Yangho Kim, *MD, Department of Occupational and Environmental Medicine, Ulsan University Hospital, University of Ulsan College of Medicine, Ulsan, Korea*

Background and Aims: Human studies on the relationship between blood pressure and Mn overload are limited or conflicting, and those studies have been performed on a small scale. We present data on the association of manganese (Mn) level with hypertension in a representative sample of the adult Korean population who participated in the Korean National Health and Nutrition Examination Survey (KNHANES) 2008.

Methods: This study was based on data obtained by KNHANES 2008, which was conducted for three years (2007–2009) using a rolling sampling design involving a complex, stratified, multistage, probability-cluster survey of a representative sample of the noninstitutionalized civilian population of South Korea.

Results: Multiple regression analysis after controlling for covariates, including gender, age, regional area, education level, smoking, drinking status, hemoglobin, and serum creatinine, showed that the beta coefficients of log blood Mn were 3.514, 1.878, and 2.517 for diastolic blood pressure, and 3.593, 2.449, and 2.440 for systolic blood pressure in female, male, and all participants, respectively. Multiple regression analysis including three other blood metals, lead, mercury, and cadmium, revealed no significant effects of the three metals on blood pressure and showed no effect on the association between blood Mn and blood pressure. In addition, doubling the blood Mn increased the risk of hypertension 1.828, 1.573, and 1.567 fold in women, men, and all participants, respectively, after adjustment for covariates. The addition of blood lead, mercury, and cadmium as covariates did not affect the association between blood Mn and the prevalence of hypertension.

Conclusion: Blood Mn level was associated with an increased risk of hypertension in a representative sample of the Korean adult population.

MOSQUITO-OVITRAP INDEX AND DENGUE FEVER EPIDEMICS IN GUANGDONG PROVINCE, CHINA: A SPATIOTEMPORAL ANALYSIS

Weizhong Yang, *Chinese Center for Disease Control and Prevention, China*
Zhongjie Li, *Chinese Center for Disease Control and Prevention, China*
Wenwu Yin, *Chinese Center for Disease Control and Prevention, China*
Archie Clement, *University of Queensland, Australia*
Gail Williams, *University of Queensland, Australia*
Dan Zhao, *Chinese Center for Disease Control and Prevention, China*
Hang Zhou, *Chinese Center for Disease Control and Prevention, China*
Wenbiao Hu, *University of Queensland, Australia*

Background and Aims: This study aims to use spatiotemporal analysis methods to describe the spatial distribution and clustering of dengue fever (DF) cases and explore the possibility of developing a time series forecast model of DF based on an index on Aedes larval density in Guangdong Province, China.
Methods: We obtained a data set containing numbers of notified monthly DF cases in Guangdong Province, China for the period of January 2005 – December 2010 from Chinese Center for Disease Control and Prevention. Monthly data on the mosquito-ovitrap index (MOI) on Aedes larval density and population data were obtained from the National DF Surveillance Sites in Guangdong province and China CDC, respectively. Geographical information system (GIS) and Kulldorff's spatial scan statistic were used to uncover spatial clustering of DF at prefecture level. Time series regression model was used to estimate independent contribution of MOI on incidence of DF in this study.
Results: There were 1658 DF cases (locally-acquired: 1599 (94.03%); overseas-acquired cases: 99 (5.97%)) in Guangdong between 2005 and 2010. The incidence rates of DF in spring, summer, autumn and winter were 0.0018, 0.0647, 0.2259 and 0.0023/100,000, respectively. High incidence clusters of DF were concentrated in Zhuhai (1.6178/100,000), Guangzhou (1.3524/100,000) and Shantou (0.5723/100,000), China, which have humid subtropical climate and the large amount of foreign tourism. Our results showed that there appeared to be an upward trend of geographic range of DF transmission in Guangdong, China. Monthly MOI at lag of 1 – 2 months may trigger DF outbreak in high incidence clusters of DF.
Conclusions: The geographic range of notified DF cases seems to be expanded in Guangdong, China over recent years. MOI warrant further investigation as a mediator/predictor of the DF cycles. The findings suggested the surveillances of vector should be taken at early stage. However, more research is needed to explore the possibility of developing early warning system for DF.

IS THE ASSOCIATION OF AIR POLLUTION WITH INCIDENT CORONARY HEART DISEASE OR ALL CAUSE MORTALITY MODIFIED BY A HEALTHY LIFESTYLE?

Jaime E Hart, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Department of Epidemiology, Harvard School of Public Health, Boston, MA, USA*
Diane Feskanich, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA*
Robin C Puett, *South Carolina Cancer Prevention and Control Program and Departments of Epidemiology and Biostatistics and Environmental Health Sciences, Arnold School of Public Health, University of South Carolina, Columbia, SC, USA*
Jeff D Yanosky, *Department of Public Health Sciences, and Department of Medicine, Division of Cardiology, Penn State University College of Medicine, Hershey, PA, USA*
Francine Laden, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Departments of Epidemiology and Environmental Health, Harvard School of Public Health, Boston, MA, USA*

Background and Aims: Chronic exposures to particulate matter (PM) have been associated with increased morbidity and mortality. Few studies, however, have been able to examine the impacts of a healthy lifestyle on these associations.
Methods: Monthly PM_{10} levels 1988-2006 were assigned to the residential address history of 101,307 members of the all-female Nurses' Health Study and were used to calculate time-varying average exposure in the previous 12 months. Information on confounders and diet and physical activity was available from mailed questionnaires. Effect modification of the association of PM_{10} with risk of incident coronary heart disease (CHD) and all-cause mortality by diet, alcohol consumption, and physical activity was assessed in stratified Cox proportional hazards models. All models were adjusted for calendar month, season, current age, region, family history, high cholesterol or high blood pressure, BMI, diabetes, cigarette smoking, median census tract income and home value.
.**Results:** Each 10 $\mu g/m^3$ increase in 12 month average PM_{10} was associated with an all-cause hazard ratio (HR) of 1.07 (95%CI: 1.04-1.11) and an incident CHD HR=1.04 (95%CI: 0.97-1.12). We observed suggestions of effect modification of the all-cause mortality associations by total antioxidant intake and physical activity. Similar patterns were seen for incident CHD with additional effect modification by the prudent diet pattern, fruit consumption, and alcohol consumption. Overall, increasing consumption of healthy foods was associated with a lower risk per unit increase of PM_{10}, while increasing physical activity levels were associated with higher risks.
Conclusions: These results suggest that individuals with moderate alcohol consumption and increased consumption of healthy foods may be at a lower risk of incident CHD and all-cause mortality per 10 $\mu g/m^3$ increase in PM_{10}. Individuals with higher levels of physical activity may be at a higher risk, possibly due to additional time outdoors.

PLASMA FLUORESCENT OXIDATION PRODUCTS AND SHORT-TERM AMBIENT AND OCCUPATIONAL PARTICULATE EXPOSURES

Jaime E Hart, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Department of Epidemiology, Harvard School of Public Health, Boston, MA, USA*
Tianying Wu, *Division of Epidemiology and Biostatistics, Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH*
Francine Laden, *Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School and Departments of Epidemiology and Environmental Health, Harvard School of Public Health, Boston, MA, USA*
Eric Garshick, *Pulmonary and Critical Care Medicine Section, Medical Service, VA Boston Healthcare System and Channing Laboratory, Brigham and Women's Hospital and Harvard Medical School, Boston, MA*

Background and Aims: Experimental evidence suggests that exposure to fine particulate air pollution results in oxidative induced tissue damage. To assess whether ambient and occupational particulate exposure in humans results in systemic oxidative stress, we used a novel fluorescent oxidation products (FLOx) assay measured in plasma samples.
Methods: Blood samples were collected from a total of 236 nonsmoking, Caucasian, male trucking industry workers either before, during, or after their work shifts. FLOx was measured as relative fluorescent intensity (FI) units per milliliter (FI/ml) of plasma. County-level ambient $PM_{2.5}$ exposures on the day of blood draw and the proceeding two days were determined based on US EPA monitors. Occupational exposures to $PM_{2.5}$ were based on job-specific area-level sampling, weighted by time worked prior to blood draw. Generalized linear models were used to determine associations between FLOP levels and the ambient and occupational exposures, adjusted for each other and age, alcohol consumption, aspirin, and cholesterol medications.
Results: Participants were 51.0 (SD=8.8) years old on average, had mean FLOx levels of 265.9 FI/ml (SD=96.0), and spent an average of 5 hours (range 0 to 17 hours) working prior to blood draw. Ambient $PM_{2.5}$ levels on the day of blood draw varied from 3.6 to 18.8$\mu g/m^3$ (mean=10.2$\mu g/m^3$) and occupational $PM_{2.5}$ levels varied from 0 to 87.0$\mu g/m^3$ (mean=16.4$\mu g/m^3$). Only 40 of the workers came in before work (occupational $PM_{2.5}$=0$\mu g/m^3$). In fully adjusted models, FLOx was positively associated with average ambient $PM_{2.5}$ levels on the day of blood draw, increasing 3.1 FI/ml (95%CI:0.6, 5.5) for each 1$\mu g/m^3$ increase in $PM_{2.5}$. No associations were observed between FLOx and occupational $PM_{2.5}$ levels.
Conclusions: Our results suggest a small, but positive association of recent ambient exposure to $PM_{2.5}$ with this novel marker of systemic oxidative stress. However, we did not observe the same relationship with occupational $PM_{2.5}$ exposures.

THE ASSOCIATION BETWEEN AGRICULTURAL ORGANOPHOSPHATE PESTICIDE EXPOSURE AND AUTISM SPECTRUM DISORDERS IN THE CHARGE STUDY

Janie Shelton, *University of California, Davis, USA*
Irva Hertz-Picciotto, *University of California, Davis, USA*

Background and Aims: Prenatal organophosphate (OP) exposure has been associated with an increased risk of cognitive and behavioural abnormalities in children. In California, two studies have reported an association between organophosphate exposure and autism spectrum disorders (ASDs).
Aim 1: Evaluate the association between ASD and organophosphate pesticide application within township sections 500m of the birth residence of CHARGE study participants.
Aim2: Evaluate the relationship between timing of exposure and the odds of having a child with an ASD.
Methods: The study population includes participants from the Childhood Autism Risks from Genes and Environment (CHARGE) study, a population-based case-control study. Using pesticide use report data from the California Department of Pesticide Regulation, agriculturally applied organophosphate exposure was summed in the 500m radius of each residence. Non-zero quartiles of exposure were calculated for residences where at least one trimester of pregnancy occurred during the application year. Multivariate logistic regression models were constructed to assess the relationship between living within the two highest quartiles of exposure and ASD.
Results: Children with ASDs were more likely to live in close proximity to the two highest non-zero quartiles of OP pesticide application. 7.9% of cases were in the 3rd and 4th quartiles of exposure compared to 1.54% of non-cases. In logistic regression modelling, the unadjusted odds ratio (OR) was 1.28 (95% confidence interval (CI) 0.81-2.04). After adjustment for potential confounders (regional center, gender, age of the mother, education level of the mother), the OR was approximately the same aOR=1.34 (95%CI 0.79-2.25).
Conclusions: These results suggest families of ASD children may live in closer proximity to agriculturally applied organophosphates, but a larger sample size will be analyzed prior to deriving meaningful results with regard to timing of exposure. Because only two of twelve years of CHARGE study participants (2000 and 2001) have been analyzed, these results should be considered strictly preliminary.

RESIDENTIAL PROXIMITY TO AGRICULTURE AND GOLF-COURSES IN THE CHARGE STUDY

Janie Shelton, *University of California, Davis, USA*
Irva Hertz-Picciotto, *University of California, Davis, USA*

Background and Aims: Autism spectrum disorders (ASD) have been diagnosed with increasing frequency throughout the US. Despite changes to diagnostic criteria and younger age at diagnosis, causes for the rise are unexplained. In California, two studies have suggested a positive association between gestational pesticide exposure and ASD's.
Aim 1: Evaluate the association between ASD and developmental delay (DD) and residential proximity to agriculture and golf courses.
Aim 2: Validate self-reported proximity to within ¼ mile of an agricultural field or golf course using land use reports comparing ASD and DD groups o typically developed (TD) children.
Methods: Utilizing data from the population-based case-control study of Childhood Autism Risks from Genes and Environment (CHARGE), birth addresses were geo-coded and mapped to land use report data. Self-reported residential proximity was spatially evaluated for validity. Discordant responses were evaluated for differential recall in logistic regression. Kappa statistics were calculated to evaluate agreement between self-report and spatial validation.
Results: TD children were more likely to live near agriculture or golf courses than case children. 34.9% of parents of children with ASDs reported proximity with ¼ mile, while only 23.17% did live within ¼ mile of agriculture or golf courses. Similarly 36.2% TDs reported proximity compared with the 27.6% that were spatially validated. 30.6% of parents of children with developmental delay (DD) reported proximity, and 18.9% were spatially validated. Parents of ASD and DD cases more often incorrectly reported proximity (OR=1.38 95% confidence interval (CI) 0.88-2.17) (OR=1.35 (95% CI 0.79-2.33) than parents of TD children. Kappa statistics were 0.47 (95% CI 0.36-0.58) for TD children, 0.33 (95%CI 0.234-0.43) for ASD's and 0.30 (95% CI 0.13-0.48) for DD.
Conclusions: Inaccurate recall of self-reported proximity to pesticide application sites was higher in the case groups than noncase group. Agreement between the variables was fair, indicating a moderate reliability of self-reported residential proximity.

ASSOCIATIONS OF SOURCE-RESOLVED PARTICULATE AIR POLLUTION MIXTURES AND CARDIORESPIRATORY EMERGENCY DEPARTMENT VISITS IN ST. LOUIS, MO-IL

Stefanie Ebelt Sarnat, *Emory University, United States*
Jeremy A. Sarnat, *Emory University, United States*
Andrea Winquist, *Emory University, United States*
Jay R. Turner, *Washington University, United States*
James J. Schauer, *University of Wisconsin-Madison, United States*
Mitchel Klein, *Emory University, United States*
Paige E. Tolbert, *Emory University, United States*

Background and Aims: Substantial evidence supports an association between broad measures of particulate matter (PM) and cardiorespiratory illnesses, but less is known regarding specific PM sources, components and mixtures that contribute to this association. We used source-indicative tracer and source apportionment analyses in a time-series investigation of emergency department (ED) visits in St. Louis, MO-IL to more fully examine the role of PM mixtures on acute health response.
Methods: Daily speciated $PM_{2.5}$ data were obtained from the St. Louis - Midwest Supersite for a 2-year period, and were used in an 11-factor positive matrix factorization analysis to obtain daily source contribution estimates. We selected a subset of elemental and organic molecular marker species as source tracers. Gaseous pollutant data were obtained from the adjacent U.S. Environmental Protection Agency site. Individual-level ED visit data were obtained from 36 acute-care hospitals in the study area. We used Poisson generalized linear models, controlling for long-term trends and meteorology, to examine associations between air quality parameters and ED outcomes.
Results: Asthma ED visits were strongly associated with ozone, nitrogen dioxide, and PM_{25}. In models using $PM_{2.5}$ species and source factors, we observed non-significant positive associations with elemental carbon (EC), organic carbon (OC), and sulfate, and strong positive associations with diesel, biomass, and carbon-rich sulfate source factors. For cardiovascular outcomes, associations with EC and OC were observed, particularly for congestive heart failure (CHF). Further CHF analyses indicated non-significant associations with diesel and gasoline factors and strong warm-season associations with mobile-source related organic markers, including benzo(a)pyrene.
Conclusions: Our analyses suggest that pollutant mixtures associated with both mobile-source emissions and regional sulfate production are associated with cardiorespiratory morbidity in St. Louis. Our approach of investigating pollutant sources is one of several methods for modeling complex pollutant mixtures in epidemiologic settings.

IMPORTANCE OF THE INTERINSTITUTIONAL DIALOGUE IN THE PREVENTION AND THE EPIDEMIOLOGICAL SURVEILLANCE OF DISEASES RELATED TO ENVIRONMENTAL ISSUES: REPORT OF ACTIVITIES OF THE DIVISION OF DISEASES OCCASIONED BY THE ENVIRONMENT OF THE CENTER OF EPIDEMIOLOGICAL MONITORING - SES/SP – BRAZIL

Introduction: The degradation of the environment around the planet is closely tied to increased demand for natural resources by human society. The increasing and rapid process of urbanization in developing countries especially in Brazil has helped the impacts of the processes associated with industrialization. Since ancient times were found specific sites of environmental contamination, but currently these areas occupy almost the entire planet.

The main risks to human health generated by these degradations relate to exposure to substances present in the effluents of large urban areas from organic matter and those caused by pollutants from industry, motor vehicles, mining, etc. These changes are now factors changes in various environments including soil, air, water, strengthening the need for new forms of considerations in prevention and health promotion.

Discussion : Established in 80 years, the Division of Disease Caused by Environmental - DOMA has among its tasks to coordinate epidemiological surveillance activities in environmental health at the SP state, involving population exposure to environmental contaminants and chemical and physical properties in water, air and solo. Has an multidisciplinary team of Doctors Health experts, labor, sanitary engineer, architect.

The coordination and conduct of epidemiological studies, preparation of protocols, guiding activities of several municipalities are the focus of activity in this Division which has as its main strategy the dialogue of epidemiological surveillance in environmental health numerous other institutions (environment, transportation, water, etc.) and areas of health.

Conclusion: This research initiatives developed by the Division focused on health impacts of population, highlighting the actions institutions facing the recent situations such as mercury metallic poisoning 100 people living in the municipality; accident with chemical spill after accident on highway and biomass burning by approximately 32 consecutive days after accident, reveal the importance of inter-institutional dialogue to action in environmental health.

BIOLOGY AND ENVIRONMENTAL HEALTH, REPORTS OF DISCUSSIONS EARLY AND SURVEYS BIBLIOGRAPHIC IN THE STATE OF SP - BRAZIL AND MISSOURI / USA

Telma Nery, *Secretary of State for Health – SP- Epidemiological Surveillance Center – CVE- Division of Diseases caused by Environmental DOMA-CVE-SES, SÃO PAULO/SP, Brazil*
Ivan Cardoso, *Student of University State Of Campinas, Campinas/Sp, Brazil*
Priscila Ricardi, *Student of University State Of Campinas, Campinas/Sp, Brazil*
Daniel Cardoso, *Student of Missouri Valley College, Marshall/Missouri, United States*

Intoductions: The discussion about environmental health, indicate knowledge of indicators. Several have been studied. It is necessary to have an indication of the health indicators related to environmental damages. This study addresses survey bibliographic performed by 3 students, and a doctor sanitary.
Objectives: The main objective **is** identify studies comprising environmental markers like plants that may contribute to the approach of environmental impacts and health of the population of more than 40 million people who live state SP .The secondary are:
1. know and identify environmental markers - Plants impctos related to environmental and health
2. Identify markers in Brazil and in USA
Methodology: The study includes literature review by students of two universities in Brazil and USA. Two students of the University Biology course of Campinas - Unicamp, located in SP / Brazil and one student of the Missouri Valley College, located in Marshall – Missouri/ USA, under the supervision of the of division of diseases due to the environment department of health state of Sao Paulo.
The survey was conducted sources of considering several countries, and existence of studies reveals that may serve as a markers.
Conclusions : Surveys indicated the presence of more than 50 environmental markers that can be used in health studies, revealing preventive impacts on human health and diseases caused by alterations of environmental air, soil and water

ASSOCIATION BETWEEN OZONE EXPOSURE AND PREVALENCE OF ASTHMA RHINITIS AND RESPIRATORY SYMPTOMS IN URBAN ELEMENTARY SCHOOL CHILDREN IN TORREÓN COAHUILA MÉXICO.

Backgorund/Aims: The aim of this study was to determine the prevalence of asthma, rhinitis and respiratory symptoms and relationship between high ozone levels and low ozone levels in urban elementary school children aged 6 - 12 years. **Methods:** A cross sectional study of the history of asthma, rhinitis and respiratory symptoms and ozone exposure among children was conducted using the ISAAC (the International Study of Asthma and Allergies in Childhood) questionnaires which were completed by the parents. A total of 2780 children aged 6 – 12 years in 2006 (response rate: 94.2%) were included in the study. To associate ozone exposure, models was calculated using 8 and 24 hours concentration. Children with high exposure were school located in zones with 80 – 160 ppb ozone concentrations (Typical Children) and low exposure school in zones with 20 – 50 ppb ozone concentrations (Atypical Children).
Results: Total Prevalence of Asthma, Rhinitis, Sibilance, Snot and Tearing was 8.0 (95% CI 6.7 – 9.4), 7.6 (95% CI 6.7 – 9.4), 23.3 (95% CI 21.3 – 25.4), 37.0 (95% CI 34.9 – 39.0) respectively. To Atypical Children Prevalence Rate (8 hours ozone exposure): Asthma 7.1 (95% CI 5.36 – 8.4), Rhinitis 6.9 (95% CI 5.2 – 7.8), Sibilance 21.9 (95% CI 16.1 – 24.4), Snot and Tearing 34 (95% CI 23.4 – 36.7). To Typical Children Prevalence (8 hours ozone exposure): 3.9 (95% CI 2.66 – 4.3), 5.5 (95% CI 5.1 – 7.2), 12.4 (95% CI 9.16 – 14.4 95%CI), 29.6 (95% CI 20.0 – 33.4) respectively.
Conclusion: This study showed that the Prevalence in Atypical Children are modified to ozone exposure compared with Prevalence in Typical Children affected and air quality could be reason to shoot respiratory pathologies.

THE BIOLOGICAL EFFECTS OF AMBIENT FINE PARTICLES ON CARDIOVASCULAR RISK IN CITY RESIDENTS

Jinzhuo Zhao, *Department of Environment Health, School of Public Health, Fudan University, the Key Laboratory of Public Health Safety, Ministry of Education. Shanghai , China.*

Background and Aims: Several studies have found that long-term exposure to particulate matter is an important environmental risk factor for cardiopulmonary disease morbidity and mortality, especially for particles with aerodynamic diameters under 2.5 micron fine particles. It is a challenge to elucidate the underlying pathophysiological mechanisms linking specific characteristics of fine particles and cardiovascular toxicity. The study aims to explore the association between long-term exposure to traffic-related fine particles air pollution and biological effects in cardiovascular system.

Methods: The participants included 420 men and women aged from 45-75. The distances between participants' residences and major roads were categorized as • 50 m, 51–100 m, 101–200, and > 200 m. Concentration of fine particles were measured using SIDEPAKTM AM510 (TSI, USA) in 2010. Personal exposure to traffic particle was measured using AM510. Aortic augmentation index (AI) and heart rate variability (HRV) were determined using Model SKY-A4 Bioelectric Signals Processing System. Meanwhile, heart rate and blood pressure were measured. The association between long-term exposure to fine particles and AI, HRV, heart rate and blood pressure were analyzed with sex-stratified multiple linear regression analyses.

Results: The results showed that the concentrations of fine particles were 125, 94, 57 and 67• g/m^3 in January, April, July and October, respectively. Meanwhile, fine particles concentrations were correlated with residential proximity to major road. The concentrations were 108, 99, 71 and 64 • g/m^3, respectively. In the adjusted analysis, fine particle exposure was associated with the decrease of HRV and increase of AI and blood pressure.

Conclusions: Traffic-related fine particles air pollution was associated with the cardiovascular risk. These results added to the evidence that long-term exposure to ambient fine particles associated with increased cardiovascular injury.

A STUDY ON THE RISK FACTORS OF THE PIPELINE DIRECT DRINKING WATER QUALITY IN A DISTRICT OF SHANGHAI

Lihong HUANG, Chuan WU, Lifang WANG, Deguang CHENG, *Institute of Health Inspection, Changning Health Bureau, Shanghai, China*
Renjie CHEN, Weimin SONG, *Department of Environmental Health, School of Public Health, Fudan University, Shanghai, China*

Background and Aims: To explore the risk factors of pipeline direct drinking water quality.
Methods: The system of pipeline direct drinking water in a district of Shanghai was sampled and the water quality was detected in August and December of 2008. Multiple linear stepwise regression models were fitted to the measured values of specific indices and the evaluation value of comprehensive index with various potential risk factors as the independent variables.
Conclusions: The whole water quality of pipeline direct drinking water could be influenced significantly by use of time, opening rate and disinfection process. The comprehensive value decreased 0.044 corresponding to an increment of 1 year of use of time,0.202 corresponding to an increase of 1 household with access to this direct drinking system, and 0.229 corresponding to a switch of disinfection process form, a combination of micro-electrolysis and UV disinfection to single ozone. Except manganese and zinc, the measured values of various specific indicators were all significantly correlated with the corresponding risk factors.

POLYCHLORINATED BIPHENYLS AND ORGANOCHLORINE PESTICIDES PREDICT DEVELOPMENT OF TYPE 2 DIABETES IN THE ELDERLY: THE PROSPECTIVE INVESTIGATION OF THE VASCULATURE IN UPPSALA SENIORS (PIVUS) STUDY

Duk-Hee Lee, *Kyungpook National University, Korea.,*
P Monica Lind, *Uppsala University, Sweden.,*
David R Jacobs, Jr, *University of Minnesota, U.S.,*
Samira Salihovic, *Örebro University, Sweden.,*
Bert van Bavel, *Örebro University, Sweden.,*
Lars Lind, *Uppsala University, Sweden.*

Background and Aims: Persistent Organic Pollutants (POPs), lipophilic chemicals that accumulate mainly in adipose tissue, has recently been linked to type 2 diabetes. However, evidence from prospective studies is sparse. This study was performed to evaluate prospective associations of type 2 diabetes with plasma concentrations of selected POPs among the elderly.
Methods: Twenty POPs (including 15 polychlorinated biphenyl (PCB) congeners, 3 organochlorine (OC) pesticides, 1 brominated diphenyl ether (BDE), and 1 dioxin) were measured in plasma collected at baseline in 725 participants aged 70 years of the Prospective Investigation of the Vasculature in Uppsala Seniors (PIVUS).
Results: After adjusting for known risk factors of type 2 diabetes including obesity, odds ratios (ORs) for incident type 2 diabetes (n=36) according to quintiles of a summary measure of plasma concentrations of PCBs (vs. the lowest quintile) were 4.5, 5.1, 8.8 (95% CI: 1.8-42.7), and 7.5 (1.4-38.8) (P_{trend} <0.01). Among 3 OC pesticides, adjusted ORs across concentrations of trans-nonachlor showed P for trend=0.03. Adjusted ORs across quintiles of the sum of 3 OC pesticides were 1.1, 1.6, 1.5, and 3.4 (1.0-11.7) (P_{trend} =0.03). Neither BDE47 nor dioxin was significantly associated with incident diabetes. The strength of prediction of incident diabetes was stronger for the sum of PCBs than it was for BMI or waist circumference. The sum of PCBs improved reclassification significantly when added to traditional risk factors for diabetes.
Conclusions: This study found that environmental exposure to some POPs substantially increased risk of future type 2 diabetes in an elderly population.

ASSOCIATIONS BETWEEN CADMIUM AND COGNITIVE FUNCTION IN THE ELDERLY

Moyeol Kang, *Seoul National University, Seoul, south Korea*
Soohun Cho, *Seoul National University, Seoul, south Korea*
Younhee Leem, *Seoul National University, Seoul, south Korea*
Jinhee Kim, *Seoul National University, Seoul, south Korea*
Sanghyuk Bae, *Seoul National University, Seoul, south Korea*
Yunchul Hong, *Seoul National University, Seoul, south Korea*

Background and Aims: We conducted this study to investigate on the relationship between blood concentration of cadmium and cognitive function in elderly Koreans.
Methods: This study is a part of the Korean Elderly Environmental Panel study (KEEPS). We enrolled the subjects from August 2008 through August 2010 and total 403 subjects were analyzed. Information such as demographic factors, medical history, dietary habits, smoking and alcohol consumption was obtained by a questionnaire. We measured blood concentration of cadmium and conducted Mini-Mental State Examination(MMSE) with Functional Activities Questionnaire(FAQ) for each subject. For statistical analysis, linear multiple regression models were used to estimate the effects of cadmium on the cognitive function parameters (MMSE) and functional scale(FAQ), controlling for age, gender, level of education, smoking and drinking habits. Because the distributions of biomarker concentrations were right skewed, we used log-transformed data for blood concentration of cadmium in the models.
Results: The mean age of subjects was about 70.67 (SD 5.18, n=403). 72% of them were female. Mean blood cadmium level was 1.22 • g/dl (SD 0.56), mean MMSE score 25.12 out of 30 and mean FAQ score 2.03 out of 30. At first we conducted linear regression analysis between blood cadmium concentration and MMSE or FAQ. We observed significant relationship between log transformed values of blood cadmium levels with MMSE scores ($p<0.002$) and FAQ score ($p=0.005$). After adjusting age, sex, level of education, drinking and smoking habits, the relationship f blood cadmium concentration with MMSE scores and FAQ score are still statistically significant. ($p=0.033$ and 0.029 respectively)
Conclusions: These results suggest that blood concentration of cadmium is strongly associated with cognitive function and the functional activity of the elderly.

COGNITIVE IMPAIRMENT FOLLOWING CHILDHOOD EXPOSURE TO MODERATE DOSES OF IONIZING RADIATION

Fabienne Sikron, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Tova Amitai, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Hadas Even-Nir, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Angela Chetrit, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Siegal Sadetzki, Cancer & Radiation Epidemiology Unit, Gertner Institute, Sheba Medical Centre, Israel
Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

Background and Aims: Exposure to high doses of ionizing radiation results in a spectrum of cognitive deficits but the impact of lower doses is much less clear. The aim of this study was to investigate the effect of childhood exposure of the head to a mean dose of 1.5 Gy on reported memory problems and attention deficit after about 50 years.
Methods: The study population included a subsample of individuals derived from the tinea capitis cohort, of which 253 irradiated and 162 non-irradiated subjects were interviewed (compliance rate 79.1% and 48.2% respectively, among those who could be located). Subjects completed a questionnaire covering socio-demographic and health topics. A section concerning memory problems and attention deficit (including details on symptoms, severity, and treatments) was incorporated using closed and free-text fields. To assess the effect of radiation on cognitive problems, multivariate Poisson regression models were performed.
Results: About half of the study population was females and most individuals (73%) were aged between 55-64 years at interview. The mean age at irradiation was 7.4 years (range 1-15) and the average follow-up period was 52 years (range 44-63). More irradiated subjects than non-irradiated subjects reported memory problems (55.7% vs 35.8%, p<.001) and attention deficit (33.2% vs. 14.8%, p<.001). Controlling for age, gender, and SES level, irradiated subjects had a higher risk of having moderate-high severe memory problems (RR=2.00, 95%CI: 1.19-3.26) and moderate-high severe attention deficit (RR=3.48, 95%CI: 1.77-6.85) compared to the non-irradiated. Female gender and low SES level were found to be independent risk factors for memory problems.
Conclusions: This study suggests that cognitive impairment may be a health outcome of exposure to moderate ionizing radiation in childhood. The long term effects of this exposure continue to be a public health concern considering the growing use of diagnostic modalities involving this exposure (primarily CT).

THE EFFECTS OF PFOS AND PFOA IN MATERNAL SERUM ON MATERNAL AND INFANT THYROID HORMONES

Reiko Kishi, *Hokkaido University Centre for Environmental and Health Sciences, Sapporo, Japan*

Background and Aims: Perfluorooctanesulfonate (PFOS) and Perfluorooctanoate (PFOA) are widely used in variety of industrial products and have been alleged persistent organic pollutants due to the chemical stability. However, there was no epidemiological report addressing the effects of these compounds on human thyroid hormones among mothers and their infants. The aim of this study was to examine the association of the concentrations of PFOS and PFOA in maternal serum with thyroid hormones, TSH and FT4, in maternal and infant serum.
Methods: 514 women who took prenatal health care at the Toho hospital (Sapporo, Hokkaido, Japan) were selected to participate in this study. We obtained the perinatal information from the questionnaire and medical records. PFOS and PFOA concentrations in maternal serum were measured after the second trimester of pregnancy or after delivery by LC/MS/MS, and TSH and FT4 in maternal and infant serum were measured by ELISA. The univariate and multiple linear regression analyses were performed to investigate the relationships between PFOS and PFOA levels and thyroid hormones.
Results: The concentration levels of PFOS and PFOA in maternal serum after delivery decreased compared to those before delivery. The thyroid hormone levels of infants were approximately twice as much as those of mothers. In the analyses of the correlations of PFOS and PFOA and thyroid hormones, there were significant association between PFOS and TSH of mothers and only male infants. No association between PFOS and FT4 in maternal serum was seen. PFOA had no effect on even maternal thyroid hormones.
Conclusions: This study showed that there was significant association between PFOS and TSH in maternal serum at low level exposure. PFOS also had an effect on infants' TSH. These results also indicate the possibility that PFOS and PFOA may have the ability of placental transfer.

MODELLING AND FORECASTING DENGUE FEVER INCIDENCE IN MALAYSIA BY INTERPOLATING ENVIRONMENTAL DATA

Balvinder Gill, *School of Biomedical, Biomolecular and Chemical Sciences, University of Western Australia, Australia*
Jianguo Xiao, *Epidemiology Branch, Department of Health Western Australia, Australia*
Grace Yun, *Epidemiology Branch, Department of Health Western Australia, Australia*
Shannon Carter, *Epidemiology Branch, Department of Health Western Australia, Australia*
Allison Imrie, *School of Biomedical, Biomolecular and Chemical Sciences, University of Western Australia, Australia*
Geoffrey Shellam, *School of Biomedical, Biomolecular and Chemical Sciences, University of Western Australia, Australia*

Background and Aims: In the literature on dengue fever in Southeast Asia, a variety of relationships between disease incidence and environmental factors have been suggested. Environmental factors and climatic conditions are known to strongly influence vector biology, its survival and the transmission of dengue. By linking spatial epidemiological data on disease incidence to environmental data on rainfall, temperature and humidity, this study describes the spatial and temporal patterns of dengue cases in relation to the environment factors and explores methods to predict future dengue outbreaks.
Methods: Monthly rainfall, mean temperature and relative humidity data collected at 26 locations in Peninsular Malaysia from 2005-2010 were interpolated to the surface data using the Inverse Distance Weighted (IDW) method in a geographical information system. The interpolated environmental data were then overlayed with dengue incidence data based on districts in Peninsular Malaysia that experiences the two different monsoon patterns. Monthly dengue incidence data and interpolated environmental variables were modelled using the Seasonal Autoregressive Integrated Moving Average (SARIMA) models. The best fit SARIMA models for 2005-2009 were applied to predict and validate dengue incidence in 2010.
Results: SARIMA models for different districts were found to have different patterns, with monthly rainfall identified as the only significant predictor of dengue incidence (β=0.009, t=0.104, p=0.038). The model identified were SARIMA$(1,1,0)(0,0,0)_{12}$ with the Ljung-Box test (Q18=15.205 and p=0.58). There was no significant seasonality pattern identified for the study period.
Conclusions: The IDW method is useful in interpolating environmental factors for large areas when climate information is not readily available. The SARIMA model is a valuable tool to model and forecast dengue fever incidence using environmental factors and to assist in developing effective disease prevention strategies.

RESPIRATORY HOSPITALIZATIONS OF CHILDREN AND RESIDENTIAL EXPOSURE TO TRAFFIC AIR POLLUTION IN JERUSALEM

Ronit Nirel, *The Hebrew University of Jerusalem, Israel*

Michal Bino Schiff, *Hebrew University – Hadassah Braun School of Public Health and Community Medicine, Israel*

Ora Paltiel, *Hebrew University – Hadassah Braun School of Public Health and Community Medicine, Israel*

Background and Aims: Although previous research on adverse health effects related to outdoor air pollution in Israel has focused on coastal areas adjacent to power stations, Jerusalem, an inland city, reports violations of air quality standards due to traffic occurring on more than 5% of the days. This case-control study examined whether pediatric hospitalization for respiratory diseases in Jerusalem is related to long-term exposure to traffic-related air pollution.
Methods: Cases (N=4844) were Jerusalem residents aged 0-14 years hospitalised for respiratory illnesses between 2000 and 2006. These were compared to children admitted electively (N=2161) or urgently (N=3085) for nonrespiratory conditions. Using Geographic Information Systems, subjects' addresses were linked to traffic data obtained from municipal records. Individual exposures were based on the total length of main roads, traffic volume, and bus load within three buffers around each address (radii of 50, 150, and 300 meters). The association between hospitalisation and exposure to transport pollution was examined by logistic regressions controlling for gender, age (0-4, 5-14) and socio-economic status (SES, high-low).
Results: Children hospitalised for respiratory diseases were more likely to have any bus traffic passing within 50m of their home (odds ratio (OR): 1.15 and 1.13; 95% confidence intervals: 1.01-1.30 and 1.01-1.25 for the elective and emergency controls, respectively). Other models indicated statistically significant interactions between age, SES and exposure (p-values <0.03 for road length and bus load models), and significant gender-age-exposure terms. For example, associations of total road length within 150 meters of residence with respiratory hospitalisations were highest among younger girls of lower SES (ORs: 1.07, 1.11).
Conclusions: Findings suggest exposure to bus traffic within 50 m of residence contributes to childhood respiratory hospitalisation and increased risk of respiratory hospitalisation for younger girls of low SES living near main roads. Further research into varying risks among different subpopulations is needed.

PLASMA AND EXHALED BREATH CONDENSATE NITRITE/NITRATE LEVEL IN RELATION TO ENVIRONMENTAL EXPOSURES IN ADULTS. THE EGEA STUDY

Rachel Nadif, *Inserm, CESP U1018, Villejuif, France*, *University Paris-Sud 11, Paris, France*

Background and Aims: Nitrites and nitrates, stable end products of NO synthesis, are generated from endogenous and environmental sources but the association with environmental exposures has been poorly investigated in epidemiology. The aim was to evaluate the associations between tobacco smoke, diet, air pollution, occupational and domestic exposures to chlorine agents with total nitrite/nitrate level (NO_2-/NO_3-) in plasma and exhaled breath condensate (EBC) among adults from the French Epidemiological case-control and family-based study on Genetics and Environment of Asthma (EGEA).
Methods: Total NO_2-/NO_3- level was measured using the Griess Reaction in 956 subjects (48.4% men, 43 yrs, 45% asthmatics) both in plasma and EBC. Smoking and dietary habits were assessed using standardized questionnaires, exposure to ambient air pollutants was estimated by using geostatistical models and occupational exposure was assessed with a job exposure matrix. All the estimates were obtained through generalized estimating equations (GEE) for linear regression models to account for family dependence.
Results: Geometric means (Interquartile Range) of NO_2-/NO_3- level were 35.6 µM (25.6, 51.1) in plasma and 1.9 µmol/mg (0.9, 3.9) in EBC. Total plasma NO_2-/NO_3- level was positively associated with age in women (b=0.12, p<0.001) and with a high consumption of leafy vegetables (b=0.05, p=0.02), while it was negatively associated with smoking status (b=-0.07, p=0.004). In EBC, negative associations were found with smoking (b=-0.11, p=0.01) and with ambient annual ozone concentrations (b=-0.16, p<.001). Multivariate analyses confirmed these results.
Conclusions: Besides smoking, the effect of environmental exposures was not similar in plasma and EBC. Environmental exposures probably activate different mechanisms at the systemic and lung level, and they should be taken into account in future epidemiological studies.

THE EFFECT OF ORGANOCHLORINE PESTICIDES (OCPs) POLLUTION ON THE ANTIBIOTIC RESISTANCE OF *BACILLUS ANTRACIS*

Rakhmanbek Toichuev, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*

Saparbai Zholdoshov, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*

Background and Aims: An increasing rate of microbial resistance is generally associated with the misuse and over use of antibiotics, yet the effect of environmental factors on antibiotic resistance of soil - zoonotic - anthropogenic microbes, primarily, the effect of organochlorine pesticides (OCPs) remains unstudied. Objective: To study the effect of OCPs pollution on antibiotic resistance of *Bacillus anthracis.*
Materials and methods: 137 strains of *Bacillus anthracis* isolated from biological media (carbuncle and the blood samples of patients) and 32 samples isolated from the soil were subjected to analysis. Of them, 36 samples of biomedia were taken from urban area, 86 – from "pesticide" zone and 15 – from ecologically clean area and 9, 19, 4 soil samples, respectively.
Antibiotic response of microbes to 12 antibiotics (gentamycin, Biseptol, ampicillin, chloramphenicol, streptomycin, penicillin, rifampin, ciprofloxacin, doxycycline, cephalexin, Amoksiklav and ophloxin) was evaluated by disco-diffusion method.
Results: *Bacillus anthracis* was found to be resistant to gentamycin: in urban area - 33.3%, pesticide zone - 36% and 18.75% - ecologically claen area; Biseptol - 30.6%, 34.9 and 6.25%, respectively; ampicillin – 50%, 50% and 12,5%; chloramphenicol-36,1%, 29,1% and 18,75%; streptomycin- 13,9%, 9,3% and 12,5%; penicillin- 19.4%, 16.3% and 6.25%; rifampin - 8.3%, 4.6%, and 6.25%; ciprofloxacin - 8,3%, 4,6% and 6,25%; doxycycline - 8,3%, 1,1%, and 0%. At the same time, low resistance was found in 11,1%, 8,1% and 12,5% to cephalexin; in 8,3%, 4,7% and 12,5% to Amoksiklav and in 5,6% 5,8% and 12,5% to ophloxin. As for soil samples, *Bacillus anthracis* isolated from the soil contaminated by organochlorine pesticides was found to be resistant to doxycycline, cephalexin, Amoksiklav and ophloxin in 5%-15.8%.
Conclusions: Thus, organochlorine pesticides are thought to be one of the major causes of high antibiotic resistance of soil - zoonotic - anthropogenic microbes and *Bacillus anthracis*.

INFLUENCE OF DEMOGRAPHIC CHARACTERISTICS AND PLACE OF RESIDENCE ON CANCER PATIENTS SURVIVAL INEQUALITIES IN LITHUANIA

Giedre Smailyte, *Institute of Oncology Vilnius University*
Birute Aleknaviciene, *Institute of Oncology Vilnius University*
Karolis Ulinskas, *Institute of Oncology Vilnius University*

Background and Aims: Health disparities exist according to an individual's place of residence and demographic characteristics. We evaluated the influence of demographic characteristics and place of residence on cancer patient's survival in Lithuania.
Methods: In the study group were used individual cancer registry records of patients who were diagnosed with stomach, colorectal, lung, breast and prostate cancers in the period 1998-2002. Survival rates were obtained through the Kaplan-Meier estimation method and compared using the log-rank test. Adverse influences on survival were investigated using Cox proportional hazards models.
Results: Survival outcomes of patients with cancer in Lithuania were associated with demographic characteristics and place of residence. Better survival was associated with female sex, younger age of patients and urban residence. Highest mortality risk was found for rural residents and for patients 65 years and older.
Conclusions: The findings suggest that patients who live in rural areas and are elderly have poorer chances of survival from stomach, colorectal, lung, breast or prostate cancer. High-risk patients from rural areas and elderly patients may benefit from better coordination of care.

SPATIAL ANALYSIS OF DRINKING GROUNDWATER AND BLADDER CANCER RISK IN SOUTHWESTERN TAIWAN: APPLICATION OF GENERALIZED ADDITIVE MODELS TO CASE-CONTROL DATA

Ya-Yun Cheng, *Department of Environmental and Occupational Health, Medical College, National Cheng Kung University, Tainan, Taiwan*

Yi-Ching Yang , *Department of Family Medicine, National Cheng Kung University Hospital, Tainan, Taiwan*

Hong-Lin Cheng , *Department of Urology, National Cheng Kung University Hospital, Tainan, Taiwan*

Chun-Hao Chen, *Division of Urology, Department of Surgery, Chi Mei Medical Center, Tainan, Taiwan*

How-Ran Guo, *Department of Environmental and Occupational Health, Medical College, National Cheng Kung University, Tainan, Taiwan*

Background and Aims: According to a governmental survey, more than half a million residents in Taiwan had drank water containing arsenic levels higher than 0.05 ppm, and therefore health effects of arsenic in drinking water are important public health issues especially in southwestern Taiwan. We conducted a study to evaluate the association between arsenic exposure in groundwater and bladder cancer risk geographically in southwestern Taiwan with application of generalized additive models to case-control data.

Methods: We conducted a hospital-based case-control study and recruited participants through two teaching hospitals in southwestern Taiwan. We interviewed the participants using a standard questionnaire to collect data on demographic characteristics, smoking habits, drinking water history, and potential confounders. Arsenic levels were assessed using the data from a governmental nationwide census survey of wells. We applied generalized additive models (GAMs), statistical models that combine smoothing Kriging with the ability to analyze binary outcome data and adjust for covariates, to analyze the data. We converted outcome data from log odds to adjusted odds ratios (ORs) and then located participants' residences and continuous ORs into WGS84 map using the GSLIB to identify the "hot spot."

Results: A total of 78 bladder cancer patients and 201 controls without any cancers participated in the study. We found that old age, male gender, low educational level, and cigarette smoking were associated with the risk of bladder cancer. In addition, we found that drinking groundwater over 15 years (as a latency period) and a history of drinking water with high arsenic concentration were also risk factors of bladder cancer. We also observed a high correlation between "hot spots" of bladder cancer and high arsenic levels in drinking water exposure.

Conclusions: Our results observed the association between arsenic exposure and bladder cancer and demonstrated the application of the GAM to analyzing data at an individual level.

Background and Aims: Environmental epigenetic is emerging in asthma. Early-life exposure to dichlorodiphenyldichloroethylene (p,p'-DDE) impacts the immune system development and the risk of asthma by unknown mechanisms. We investigated if prenatal exposure to p,p'-DDE induces epigenetic reprogramming involving aberrant DNA methylation of specific genes mechanistically related to asthma.
Methods: Data came from 404 children of a population-based birth cohort of the INMA Project. p,p'-DDE was measured in cord blood. Wheezing phenotype at age 6 years was defined according to parental report of wheezing episodes on each interviewer-led annual questionnaire. The coding variant Ile105Val from *GSTP1* was genotyped. In a subset (n=128), gene-specific methylation was screened along 1505 genomic CpG loci using Illumina GoldenGate panel in DNA from peripheral blood cells collected at age 4 years. Subsequently, a pyrosequencing assay was used to validate the results from the Illumina screening.
Results: Higher levels of p,p'-DDE were associated with higher risk of persistent wheeze among *GSTP1* Val carriers (OR for an interquantile range increase in p,p'-DDE=1.77; 95% CI 1.17-2.68), but not among the Ile homozygotes (OR=1.05; 95% CI 0.80-1.39; p for interaction=0.069). Higher levels of p,p'-DDE were associated with a decrease in methylation of a CpG site in arachidonate 12-lipoxygenase (*ALOX-12*) (beta(sd) for an interquantile range increase in p,p'-DDE =-1.7(0.6), p=0.060). The decrease in methylation was accounted for *GSTP1* Val carriers compared with the Ile homozygotes (beta(sd)=-4.1(0.8) vs. -0.8(0.8); p for interaction=0.007). Higher levels of methylation in *ALOX-12* at age 4 years were associated with a lower probability of being classified as persistent wheezing at age 6 years (OR=0.94; 95% CI 0.90-0.98).
Conclusions: Epigenetic changes in *ALOX-12*, a gene involved in the immune response of the airway, could mediate the lifelong effect of in utero exposure to p,p'-DDE on the risk of asthma in childhood.

RADON AIR POLLUTION IN URANIUM BIOGEOCHEMICAL AREAS OF THE TOWN OF MAILUU-SUU, KYRGYZ REPUBLIC

Rakhmanbek Toichuev, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*
Enver Soodanbekov, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*
Janyl Madykova, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*
Gulnara Toichueva, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*
Aigul Alybekova, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*

Background and Aims: To study the radon air pollution in uranium biogeochemical area and to search for possible ways to reduce air pollution.
Materials and methods: The present study was carried out in the town of Mailuu-Suu, Kyrgyzstan. There was an ore mining and processing enterprise in Mailuu-Suu that mined uranium between 1946 and 1966. Charcoal traps were used to detect radon concentration in the air.
Results: A total of 120 premises were examined. An increased radon concentration (>200 Bq/m^3) was revealed in 112 cases (85%). The results of examination of radon air concentration in the town of Mailuu-Suu were as follows: M = 511.23 Bq/m^3, max -3704.0 Bq/m^3, min-92.50 Bq/m^3, • -917.19 Bq/m^3, m-290.04 Bq/m^3, P< 0,00 and p Ci/I values: • = 12.23; •••- 28.20; • in-4.6; • -7.44 • -2.35, • < 0.001.
To reduce radon air pollution level in this area the following activities were suggested to local population: arrangement of green spaces (planting of trees and shrubs) in the area, use of sprinkler installation for garden watering, removal of uranium-containing boulders from the area, regular cleaning and ventilation of premises. On completion of the activities proposed the radon air concentration values were as follows: M = 704,39, max -2714,0, min-126,9 Bq/m^3, • -717,19 Bq/m^3, m-260.04 Bq/m^3, P< 0,00 and p Ci/I values: • = 10,23; •••- 25.20; • in- 3.6; • -6.44 • -2.05, • < 0.001.
Conclusions: Thus, arrangement of green spaces (planting of trees and shrubs) in the area, use of sprinkler installation for garden watering, removal of uranium-containing boulders from the dumps, regular cleaning and ventilation of premises are of great help in reducing radon air pollution level under the conditions of the town of Mailuu-Suu.

TIME-LOCATION PATTERN, HOUSEHOLD ENVIRONMENTAL TOBACCO SMOKE EXPOSURE AND URINARY COTININE IN NON-SMOKING CHILDREN

Kuan-Yen Tung, *Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan - Research Center for Genes, Environment and Human Health, College of Public Health, National Taiwan University, Taipei, Taiwan*

Kuen-Yuh Wu, *Institute of Occupational Medicine and Industrial Hygiene, College of Public Health, National Taiwan University, Taipei, Taiwan*

Yungling Leo Lee, Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan - *Research Center for Genes, Environment and Human Health, College of Public Health, National Taiwan University, Taipei, Taiwan*

Background and Aims: Environmental tobacco smoke (ETS) is an important exposure of indoor air, and may increase the risk of respiratory disease in children. The level of household ETS exposure may be associated with the time-location pattern for children. In this study, we will explore the association between the indoor time, household ETS exposure and urinary cotinine level in non-smoking children.

Methods : Total of 429 children were recruited in Genetic and Biomarker for Childhood Asthma (GBCA). We will utilize parental report method to measure household ETS exposure in children using structure questionnaires. Indoor and outdoor time for non-smoking children was administrated by the time-location pattern questionnaires. The urinary cotinine level was measured using a sensitive high-performance liquid chromatographic (HPLC) technique and the level of household ETS exposure will be assessed using the cotinine/creatinine ratio (CCR).

Results: Children exposed to ETS in household had higher cotinine level and CCR when compared with those children expose to ETS in outdoor environment. The CCR also showed a significant trend when children exposed to different amount of ETS in household. When the time-location pattern were considered in our analysis, we have found a significant trend of average CCR increased with indoor time for children in the groups of currently household ETS exposure, amount of household ETS exposure per day and number of smokers at home.

Conclusions: We found a dose-response relationship between urinary cotinine level and indoor time for non-smoking children. Our study suggested that the major source of ETS exposure for Taiwanese children was from family members in the household.

ORGANOCHLORINE EXPOSURE DURING PREGNANCY AND NEURODEVELOPMENT IN PRESCHOOL CHILDREN

Background and Aims: Persistent organochlorine compounds (POCs) were widely used until they were banned in the nineteen-seventies. Published findings on POCs exposure and neurodevelopment in children are inconsistent. The aim of this study was to assess the effects of prenatal organochlorine exposure on neurodevelopment.
Methods: A total of 2250 mother and 14-month-old child pairs from the cohorts of Valencia, Sabadell and Gipuzkoa of the INMA project (www.proyectoinma.org) participated in this study. Data were collected during pregnancy, birth and at 14 months of age. Socio-demographic data including residency and information concerning lifestyle, medical and reproductive history, and diet were collected using standardised questionnaires, while cognitive and psychomotor development of the children was assessed using the Bayley Scales of Infant Development. The concentrations of polychlorinated biphenyls (PCBs), and organochlorine pesticides (HCB, • -HCH, • -HCH, p,p'-DDE and p,p'-DDT) were measured in serum samples collected in the first visit (weeks 10-12 of gestation). General additive models were used to explore the shape of the relationship between log-transformed POCs and infant neurodevelopment, and, subsequently, multivariable linear regression models were developed to further assess this relationship.
Results: A total of 632 mother and infant pairs were excluded from the analysis, due to missing data on POCs or Bayley scales, or because preterm delivery , so overall 1518 cases were analysed. We found a significant relationship between level of PCBs (sum of PCB 138+153+180) and psychomotor development • (95%Confidence Interval): -2.19 (95%CI -3.87,-0.51)). However, for the other POCs we did not find any significant association with neurodevelopment.
Conclusions: Prenatal exposure to PCBs may play a negative influence on psychomotor development at early stages in children. In line with this, we believe that it is important to analyse the influence of this type of factor at older ages, as it would be possible to assess more complex cognitive functions using more accurate and reliable instruments.

THE EFFECT OF PESTICIDE POLLUTION LOAD ON THE PREVALENCE OF BREAST CANCER IN OSH REGION (KYRGYZ REPUBLIC)

Rakhmanbek Toichuev, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*
Zaripahon Paizova, *Osh Interregional Cancer Center, Osh, Kyrgyz Republic*

Background and Aims: To study the effect of pesticide pollution load on the prevalence of breast cancer (BC).
Materials and Methods: A total of 826 patients with breast cancer, 330 breast milk and 90 tumor tissue specimens were subjected to analysis. To determine the concentration of OCPs in breast milk and tumor tissues the authors employed gas chromatography. According to the OCPs pollution concentration all patients were allocated to 4 groups. Group I consisted of women living in urban areas, where people consume vegetables, melons, legumes grown in areas contaminated by OCPs, Group II comprised women from cotton-growing areas, where pesticides dab been used but residents of these areas cultivated vegetables, melons and legumes on ecologically clean fields Group III was made of women living in ecologically clean areas and Group IV consisted of women living near the pesticides warehouses with OCPs residues
Results: In group I the incidence of breast cancer per 100 thousand of the female population was 26.8. In Group II - 11.9, Group III – 7.3 and in Group IV- 20.2 cases (90 % were pluripara). To determine the effect of OCPs on the development of breast cancer the authors studied the concentration of OCPs in breast milk (BM). In Group I, concentration of OCPs in breast milk was detected in 58.65% of patients, in Group II - 37%, Group III - 21%, Group IV - 100%. Concentration of OCPs in tumor tissues specimen were found in 84%, 100%, 50% and 100% of patients, respectively.
Conclusion: Thus, organochlorine pesticides are thought to be one of the main causes in the prevalence of breast cancer in Osh region.

LONG-TERM EXPOSURE TO TRAFFIC-RELATED AIR POLLUTION, BLOOD PRESSURE AND RISK FOR SELF-REPORTED HYPERTENSION

Mette Sørensen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*
Barbara Hoffmann, *Institute for Medical Informatics, Biometry and Epidemiology, University of Duisburg-Essen, Essen, Germany*
Martin Hvidberg, *National Environmental Research Institute, Aarhus University, Roskilde, Denmark*
Matthias Ketzel, *National Environmental Research Institute, Aarhus University, Roskilde, Denmark*
Steen Solvang Jensen, *National Environmental Research Institute, Aarhus University, Roskilde, Denmark*
Zorana Jovanovic Andersen, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*
Anne Tjønneland, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*
Kim Overvad, *Department of Epidemiology, School of Public Health, Aarhus University, Aarhus, Denmark- Department of Cardiology, Centre for Cardiovascular Research, Aalborg Hospital, Aarhus University Hospital, Aalborg, Denmark*
Ole Raaschou-Nielsen*, Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen, Denmark*

Background and aims: Previous studies have indicated that few days' exposure to air pollution might be associated with changes in blood pressure (BP) and the frequency of emergency hospital visits for hypertension. Little is known about the effects of long-term exposure to traffic-related air pollution on BP and risk for development of hypertension. The aims were to study whether long-term exposure to air pollution affected BP and risk for hypertension.
Methods: In 1993-1997, 57 053 participants aged 50-64 year were enrolled in the Danish population-based cohort study, Diet, Cancer and Health. At enrolment, systolic and diastolic BP were measured. Incident hypertension during a mean follow-up of 5.3 years was assessed by questionnaire. Residential long-term NO_x, a marker of traffic-related air pollution, was estimated for the 1- and 5-year periods prior enrolment and prior a diagnosis of hypertension with AirGIS, a validated dispersion model. We conducted a cross-sectional analysis of associations between air pollution and BP at enrolment with linear regression in participants without anti-hypertensive medication (N=44,436), adjusting for traffic noise, measured short-term NO_x, meteorology and potential lifestyle confounders. Incident hypertension was analyzed with Cox regression, adjusting for traffic noise and potential lifestyle confounders.
Results: We found that a doubling in NO_x exposure during the one and five year periods preceding the enrolment was associated with a -0.55 (95% CI: -0.89; -0.20) and a -0.52 mm Hg (95% CI: -0.85; -0.18) lower systolic BP, respectively. Long-term exposure to NO_x was not associated with risk for development of hypertension; however living close to a major road increased the risk by 13% (95% CI: -3; 32%).
Conclusions: Long-term exposure to traffic-related air pollution was associated with a slightly lower BP, whereas it did not affect the risk for self-reported hypertension. More studies are warranted before any conclusions can be made.

TEMPERATURE EFFECTS ON THE TRANSPORT-RELATED INJURIES IN KOREA

Yoonhee Kim, *Graduate school of public health, Seoul National University, South Korea*
Ho Kim, *Graduate school of public health, Seoul National University, South Korea*
Sang-Do Shin, *Seoul National University College of Medicine, Seoul National University, South Korea*
Yun-Chul Hong, *Seoul National University College of Medicine, Seoul National University, South Korea*

Background and Aims: Several studies reported that the occurrence of injury has seasonality. Although climate change may be associated with the increased risk of traffic-related injuries, there have been little studies investigating temperature effect on the type of transportation. The aim of this study is to evaluate the association between outdoor temperature and transport-related injury.
Methods: Data on injury were derived from emergency ambulance delivery database of the National Emergency Management Agent in Korea from 2006 to 2007. We counted daily ambulance delivery in major seven cities and Gyeonggi Province according to sub-categories of transport injury, such as motor vehicle drivers, motor cyclists, and pedal cyclists. Generalized additive models (GAM) were used to examine the association between transport injury and mean temperature, adjusting for relative humidity, effect of holidays, and long-term trends in seven cities. Then city-specific estimates were combined using a meta-analysis. In addition, the analysis only for injury of pedal cyclists in metropolitan area was performed to evaluate temperature effect on injury by the deprivation index grouped into three levels that was calculated by using 2005 Census in Korea.
Results: Daily injuries of motor and pedal cyclists showed seasonality, higher in summer and lower in winter, but motor vehicle drivers were relatively steady across season. City-combined change in injuries of motor and pedal cyclists associated with a 1 • increase in mean temperature were 1.23% (95% CI 1.01, 1.46) and 2.89% (95% CI 2.13, 3.65), respectively, while the estimate for motor vehicle drivers was -1.19% (95% CI -1.73, -0.66). For the analysis by deprivation index, the temperature effect on injury of pedal cyclists during high temperature (above about 23 •) was positive in more deprived areas while the effect was negative in less deprived areas.
Conclusions: The occurrence of transport-related injury attributable to outdoor temperature depends on the type of transportation and area-level deprivation.

ELIMINATION OF ORGANOCHLORINE PESTICIDES FROM THE BODY BY USING HERBAL MEDICINES

Rakhmanbek Toichuev, *Institute of Medical Problems, Southern Branch of the National Academy of Sciences of the Kyrgyz Republic, Kyrgyz Republic*

Backgrounds and Aims: The aim of the present study was to evaluate the efficacy of herbal medicinal products obtained from the local herbs and fruits for neutralization and elimination of OCPs from the body.
Materials and methods: A total of twenty two patients were studied. All patients were allocated to 2 groups. Group I consisted of 11 nursing mothers (OCPs were detected in breast milk), Group II comprised 11 men with male infertility (OCPs were detected in testicular fluid). The authors employed gas chromatography for detection of OCPs (DDT, DDE, DDD, GCCG) in breast milk and testicular fluid before and after the treatment.
Results: For neutralization and elimination of OCPs from the body the authors suggested administration of herbal medical products, obtained from the herbs and fruits grown in Kyrgyzstan which are rich in vitamins, biologically active substances, pectins and microelements, having sorbent, choleretic and diuretic actions.
Herbal medicines were administered as a tea and food additives during 10-12 days in group I and during a month in Group II.
Before the treatment, concentration of GCCG in breast milk was 0,006238±0,0042 mg/l, after the treatment they were found in 10 patients (0,0031 ± 0,0006), DDE 0,0278 ± 0,0004 and detected in 8 (0,0135 ± 0,006) P<0,05.
Concentration of DDE in testicular fluid was 0,00257 ± 0,0006, GCCG 0,026744 ± 0,009934 mg/l P <0,05 before the treatment
After the treatment with the suggested medicines DDE were not detected, GCCG was found in 1 patient.
Conclusions: Thus, the herbal medicines obtained from local herbs and fruits grown in the Kyrgyz Republic were proved to be efficient in neutralization and elimination of OCPs from the body. But this field is an open way to further research.

HEALTH EFFECT OF FINE PARTICULATE MATTER ON DAILY EMERGENCY ROOM VISITS OF CARDIOVASCULAR DISEASE: A TIME-SERIES STUDY

Chang Su, *Peking University School of Public Health, China*

Background and Aims: Beijing, as the host of Olympics 2008, is developing quickly in economic and social areas. The air pollution pattern has been changing from the traditional coal burning pollution to complex pollution with vehicle exhaust, biomass combustion, dust from nature and construction, energy power and others. To evaluate the association between air particulate matter and daily hospital emergency room visits (HERVs) of cardiovascular disease, we performed a time-series analysis on health effects of air pollution. in Beijing.

Methods: A Poisson regression for the association of the daily air pollutants with daily HERVs for cardiovascular disease in Beijing from 2007.1.1-2008.12.31 was performed using generalized additive model. The effects of time trend, seasonal variations, temperature and humidity were adjusted by smooth functions. Daily mean concentration of SO_2, NO_2, PM_{10} and $PM_{2.5}$ were introduced into the core model. Relative risks (RR) of cardiovascular disease (per10ug/m3 increase in air pollutant concentration) were calculated. Lagged effects of air pollutants and multi-pollutant model were concerned as well.

Results: The results showed consistent correlation between air pollutants and daily HERVs. The increase of daily number of HERVs for cardiovascular disease for a 10ug/m3 increase in SO_2, NO_2, PM_{10}, $PM_{2.5}$ were: 0.36% (0.29%~1.01%), 1.02% (0.00%~1.74%), 0.32% (0.09%~0.55%), and 0.41%(0.19%~0.90%), respectively. The relative risks for daily HERVs in sub-categories and elderly were slightly higher. The multi-pollutants models showed the effects of SO_2 were the most stable, while the $PM_{2.5}$ had small increase when the gases were introduced into model. This study also found lagged effect of particulate matter on daily HERVs for cardiovascular disease.

Conclusions: The current air pollution in Beijing has a harm effects on daily cardiovascular emergency room visits. The effects of particulate matter were more considering, while the elder population is the most sensitive.

SUITABLE METHODS FOR COLLECTING HOUSE DUST SAMPLES FOR MEASUREMENT OF HOUSE DUST MITE ANTIGENS

Takeo Fujiwara, *National Research Institute for Child Health and Development, Tokyo, Japan*

Kenji Matsumoto, *National Research Institute for Child Health and Development, Tokyo, Japan*

Maiko Osawa, *National Research Institute for Child Health and Development, Tokyo, Japan*

Ikuko Takamatsu, *National Research Institute for Child Health and Development, Tokyo, Japan*

Kenji Tamura, *National Institute for Environmental Studies, Ibaraki, Japan*

Background and Aims: Genetic and environmental factors are known to be involved in the development of allergic diseases and/or allergic sensitization. In particular, the daily exposure level to airborne antigens is critically important. However, precise and convenient methods for accurately measuring airborne antigens in a large cohort study have yet to be identified. To remedy this, we compared 3 different methods of collecting house dust samples for measurement of house dust mite antigens.

Methods: We collected house dust samples from 7 different homes by vacuuming futons using 3 different methods: 1) We visited each home and used the same vacuum cleaner; 2) We sent dust collection packs and asked the householders to use them with their own vacuum cleaners; and 3) We sent the same handy vacuum cleaners and asked the householders to use them. The levels of major Japanese indoor allergens, i.e., house dust mite Der p1 and Der f1, were measured with specific ELISA kits. The data were analyzed using Spearman's correlation test.

Results: The total weights of house dust samples did not differ among the three collection methods. The amounts of both Der p1 ($p=0.037$) and Der f1 ($p<0.001$) showed significant correlations between home-visit vacuuming (Method 1) and sending the same vacuum cleaners (Method 3). In contrast, the results using the householders' own vacuum cleaners (Method 2) did not correlate with the results of the other two methods.

Conclusions: Home-visit vacuuming and sending the same vacuum cleaners are likely to be suitable methods for collecting house dust samples. For a large epidemiological study, sending handy vacuum cleaners can be a feasible method for accurately assessing the exposure levels to mite antigens in homes.

TRANSPORTATION, AIR POLLUTION AND PHYSICAL ACTIVITIES (TAPAS), A 6-CITY INTEGRATED HEALTH RISK ASSESSMENT PROGRAM OF ACTIVE TRAVEL POLICIES: THE BASEL CASE STUDY

Martina S. Ragettli, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Chantal Wullimann, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Leticia Grize, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Audrey de Nazelle, *Centre for Research in Environmental Epidemiology, Barcelona*
Nino Künzli, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
L.-J. Sally Liu, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland, University of Washington, Seattle, USA*
Charlotte Braun-Fahrländer, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
On behalf of the TAPAS consortium

Background and Aims: Within the TAPAS research program, quantitative assessments are developed for six case study cities in Europe, linking determinants of active travel to potential co-benefits and co-risks of modal shifts from motorized to non-motorized modes of travel. We describe here the Basel, Switzerland case study.
Methods: We identified local sources of information from government agencies describing active travel and environmental conditions. We aimed at selecting policies of local and international interest, with quantifiable or demonstrated effectiveness. We reviewed local and regional governmental policy documents. We are also conducting experimental work generating new data to help fill research gaps in current framework.
Results: The city of Basel has about 170'000 inhabitants. Since the 1980s, Basel has actively promoted sustainable forms of transportation. Especially the improvement of public transport (low-priced regional pass, expansion of network, customer convenience), reduction of car use (restriction of parking space, promotion of car-sharing), and the promotion of active transport (safe and coherent bicycle and pedestrian networks) are major themes of traffic policy. Almost 50% of the households are non-car owning and public transportation is the main travel to work mode of trips within the city (30.5%). The proportion of active transport on the total distance of trips to work is higher in Basel (12.4%) than the Swiss average (4.8%). Annual average concentrations of PM_{10} and NO_2 have been stable in the last decade (PM_{10}: 22$\mu g/m^3$, NO_2: 30$\mu g/m^3$). However, street levels for NO_2 still exceed Swiss federal standards. As a special contribution to the overall project, we develop a multi-modal commute model which is able to simulate both travel patterns and commute exposure to traffic-related air pollution in the region of Basel.
Conclusions: With its long tradition of active transport promotion, Basel is an interesting case while addressing challenging environmental conditions to mitigate risks.

EXPOSURE TO LOW DOSES OF BENZENE AND ALTERATIONS IN MITOCHONDRIAL DNA COPY NUMBER: A MULTI-CENTER STUDY

Angela Cecilia Pesatori, *Department of Occupational and Environmental Health, Università degli Studi di Milano, and Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy*

Background and Aims: Benzene is a widespread environmental chemical that has been associated with increased risk of leukemia. Though potential carcinogenic mechanisms are still unknown, recent evidences suggest that high benzene exposures might be associated with increased mitochondrial DNA copy number (mtDNAcn), possibly due to benzene-induced oxidative DNA damage. Whether benzene determines mtDNAcn alterations even at low doses remains uncertain.
Methods: The study enrolled 519 participants from three Italian cities (Genoa, Milan, Cagliari), including 341 individuals with low-level benzene exposures (bus drivers [BD], police officers [PO], gas-station attendants [GSA], petrochemical plant workers [PPW]), and 178 referents. Blood samples and lifestyle information were collected at enrollment. We measured individual exposure to benzene with personal passive samplers during the work shift, and blood relative mtDNAcn by real-time PCR. For the Milan participants, DNA methylation information were also available. We fitted linear regression models, adjusted for age, sex, smoking habit, and number of cigarettes/day, to investigate association between benzene and mtDNAcn.
Results: In each city, mtDNAcn was significantly higher in benzene-exposed subjects than in referents: 0.90 relative units in Genoa BD and 0.75 in referents ($p=0.019$); 0.90 in Milan GSA, 1.10 in PO, 0.75 in referents (p-trend=0.008); 1.63 in Cagliari PPW, 1.25 in referents close to the plant, 0.90 in farther referents (p-trend=0.046). In multivariate analyses an interquartile range (IQR) increase in personal airborne benzene exposure was associated with a mtDNAcn increase of 10.3% in all subjects combined ($p<0.001$), 10.5% in Genoa ($p=0.014$), 8.2% in Milan ($p=0.008$), 7.5% in Cagliari ($p=0.223$). In Milan, an IQR increase in mtDNAcn was associated with LINE-1 hypomethylation (-2.41%, $p=0.007$) and p15 hypermethylation (+15.95%, $p=0.008$).
Conclusions: Our study shows a mtDNAcn increase with low-level exposure to benzene and mtDNAcn-related variations in DNA methylation markers associated with leukemogenesis; it thus indicates potential toxicity of benzene even at low doses.

DOES TEMPERATURE MODIFY THE MORTALITY EFFECTS OF AMBIENT PARTICLE POLLUTION IN GUANGZHOU CITY, CHINA

Guoxing Li, *Occupational & Environmental Health Sciences Department, School of Public Health, Peking University Health Science Center,P.R.China.*

Maigeng Zhou, *Center for Public Health Surveillance and Information Service, Chinese Center for Disease Control and Prevention, P.R.China.*

Yajuan Zhang, *Occupational & Environmental Health Sciences Department, School of Public Health, Peking University Health Science Center,P.R.China.*

Yue Cai, *Center for Public Health Surveillance and Information Service, Chinese Center for Disease Control and Prevention, P.R.China.*

Xiaochuan Pan, *Occupational & Environmental Health Sciences Department, School of Public Health, Peking University Health Science Center,P.R.China.*

Background and Aims: Adverse health effects of PM_{10} and high temperature on mortality are widely accepted. However, only a few studies have focused on evaluating the temperature medication effects on the association of PM_{10} and mortality in Asia. The aim of this study was to explore the modification effects of temperature on the association between PM_{10} and cause-specific mortality for cardiovascualr, respiratory, cardiopulmonary, stroke, as well as non-accidental mortality in Guangzhou from 2008 to 2009.

Methods: This present study used a generalized additive model to analyse PM_{10}, mortality and covariate data. The estimates of temperature modification on PM_{10} effects on mortality were obtained from the main effects and PM_{10}-temperature interaction models.

Results: The PM_{10} effects were strongest on extremely high temperature days, less strong on extremely low-temperature days, and weakest on normal-temperature days.The interactions between PM_{10} and high temperature were found statistically significancent on daily non-accidental, cardiovascular, cardiopulmonary mortalities. The effect estimates of the mean percentage of change in daily mortality per 10-ug/m3 increase in PM_{10}concentrations at the average of lags 0 and 1 day in hot temperature level were 3.01%(95% CI:0.93-5.14) for non-accidental, 4.26%(0.92-7.70) for cardiovascular, 5.26%(1.14-9.55) for respiratory, 4.67%(1.90-7.52) for cardiopulmonary, 5.35%(-0.04-11.04) for stroke mortalities.

Conclusions: This suggests that extreme temperature can modify the effects of particulate matter on mortaliy, and it is important to control and reduce the emission of air particles in Guangzhou, particularly in extremely high/low temperature days.

EFFECT OF POLY-AROMATIC HYDROCARBONS ON CARDIOVASCULAR AND OXIDATIVE STRESS MARKERS IN ELDERLY KOREANS

Hye Yin Park, *Department of Preventive Medicine, Seoul National University College of Medicine, Republic of Korea*
Jin Hee Kim, *Institute of Environmental Medicine, Seoul National University Medical Research Center, Republic of Korea*
Youn-Hee Lim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, Republic of Korea*
Sanghyuk Bae, *Department of Preventive Medicine, Seoul National University College of Medicine, Republic of Korea*
Yun-Chul Hong, *Department of Preventive Medicine, Seoul National University College of Medicine; Institute of Environmental Medicine, Seoul National University Medical Research Center, Republic of Korea*

Background and Aims: Some researches have shown the effect of PAHs exposure on cardiovascular and oxidative stress markers in occupational settings. We aimed to evaluate this relationship among elderly in community exposure levels in a panel study.
Methods: Repeated measurements of blood pressure, SDNN, urinary 1-hydroxypyrene, 2-naphthol and malondealdehyde(MDA) were taken from 509 Korean individuals over 60 years old residing in Seongbuk-gu, Seoul, from August 2008 to August 2010.
Mixed model analysis was used to investigate the relationship between log-transformed urinary 1-hydroxypyrene, 2-naphthol levels with systolic and diastolic blood pressure, SDNN, urinary MDA levels. Selected adjustment variables were age, sex, body mass index and cotinine levels (model 1) or all the variables in model 1 plus temperature, humidity and amount of sunshine in Seongbuk area on the day each subject visited for measurements.
Results: Mean values of log-transformed 1-hydroxypyrene and 2-naphthol levels were -2.315±1.2674μg/g crt and 1.817±1.1266 μg/g crt, and mean levels of systolic and diastolic blood pressure were 127.8±16.47mmHg and 71.9±100.04mmHg. Mean SDNN was 3.2±0.54ms2, and mean urinary MDA level was 0.47±0.492μg/g crt.
Significant associations were found between urinary 1-hydroxypyrene levels with systolic blood pressure(model 1: estimate=0.8207, p-value=0.0011; model 2: estimate=0.5373, p-value=0.0313), diastolic blood pressure(model 1: estimate=0.8345, p-value<0.0001; model 2: estimate=0.6262, p-value<0.0001), SDNN(model 1: estimate=-0.7302, p-value=0.033; model 2: estimate=-0.749, p-value=0.0304) and MDA levels(model 1: estimate=0.0535, p-value<0.0001; model 2: estimate=0.05249, p-value<0.0001). Urinary 2-naphthol also showed significant associations with systolic blood pressure(model 1: estimate=0.7677, p-value=0.0133; model 2: estimate=0.5938, p-value=0.0513), diastolic blood pressure(model 1: estimate=0.5167, p-value=0.0072; model 2: estimate=0.3989, p-value=0.0337) and MDA levels(model 1: estimate=0.07543, p-value<0.001; model 2: estimate=0.07555, p-value<0.001), but not with SDNN(model 1: estimate=0.2096, p-value=0.6167; model 2: estimate=0.1972, p-value=0.6389).
Conclusions: Urinary 1-hydroxypyrene and 2-naphthol levels are significantly associated with cardiovascular and oxidative stress markers, systolic and diastolic blood pressures, SDNN and urinary MDA levels in elderly Koreans.

COMMUTE BEHAVIOR ASSESSMENT, SIMULATION OF COMMUTE PATTERNS AND EXPOSURE TO AIR POLLUTION IN THE REGION OF BASEL, SWITZERLAND

Martina S. Ragettli,*) Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Harish C. Phuleria, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Charlotte Braun-Fahrländer, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Laura Perez, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
Nino Künzli, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland*
L.-J. Sally Liu, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Switzerland, University of Washington, Seattle, USA*

Background and Aims: Our aim is to develop a multi-modal commute model which is able to simulate both travel patterns and commute exposure to traffic-related air pollution in the region of Basel. This study is part of the project "Transportation, Air Pollution, and Physical Activities (TAPAS)"; a 6-city integrated health risk assessment program of active travel policies.
Methods: Firstly, travel patterns are simulated by means of a Geographic Information System (GIS) model using extensive information from the Swiss 2005 Microcensus database, which provides temporally and spatially resolved data on travel behavior. Secondly, environmental parameters of the built environment and personal factors that may influence adults' choice of active and passive transportation modes are investigated on a route scale. Finally, exposure to air pollution is estimated by combining the commute patterns with predictions from air pollution models. Exposure in different commute modes and microenvironments are validated with personal measurements of $PM_{2.5}$ and ultrafine particles (UFP) (10-300nm) in three different seasons for typical commute routes. Simulating variations of commute patterns will allow us to test scenarios of change in commute behavior on exposure distribution.
Results: The proportion of active transport on the total distance of trips to work within the study area is 29.2%. Our first results of 24-hours personal $PM_{2.5}$ measurements reveal significantly higher exposures during commuting than outdoor urban background exposure levels. Average commute exposure to $PM_{2.5}$ (59.7±35.0 µg/m^3) was about three-fold higher than average daily $PM_{2.5}$ exposure (21.3±18.6 µg/m^3). UFP measurements similarly show higher exposures during commuting as well as indoor cooking events.
Conclusions: Preliminary results indicate significantly higher air pollution exposures during commuting in Basel. Results will be further examined and commuter exposure will be quantified. Thus, the study will contribute to a better understanding of population's commute behavior and exposure to harmful air pollutants during daily commuting.

EXPOSURE ASSESSMENT TO AIR POLLUTION IN FOUR SPANISH AREAS. LAND USE REGRESSION APPLICATION

Background and Aims:

Geographical Information Systems (GIS) are powerful tools to assess air pollution exposure in epidemiological studies. The aim is to describe the methodology used to assign levels of exposure to outdoor air pollution (NO_2 and benzene) in pregnant women from four cohorts of the Spanish INMA (Environment and Childhood) study.

Methods:

A total of 2644 pregnant women were recruited between November 2003 and February 2008. Air pollution concentrations were obtained for 302 locations in the four study areas by using passive samplers that were placed during several periods of 7 days. Land use regression (LUR) models were used to predict air pollution levels in the study areas. A GIS was established based on the data: land use, road traffic (traffic intensity and distances), altitude, and distance to industry. Seasonality was assigned to the pregnancy period of each woman by using daily levels of air pollution from the routine monitoring networks.

Results:

Predictor variables were different among cohorts and pollutants. In all the cohorts, models included traffic variables and land use (urban, industrial or agricultural). Other predictor variables were: topography, population density, and distance to industry. Within each cohort, urban levels were higher than rural ones. Exposure estimates by trimester of pregnancy presented medium to high correlations (Spearman rho 0.4-0.8). Residential NO_2 levels throughout the entire pregnancy period correlated well with benzene levels in Gipuzkoa, Sabadell, and Valencia (rho≈0.7) whereas in Asturias, the correlation was moderate (rho: 0.3).

Conclusions:

This work illustrates the possibilities offered by methods that combine spatial modeling and temporal correction in the identification of spatial and temporal patterns of air pollution levels. Assessment of individual air pollution exposure during pregnancy will allow analyzing its effects on health, e.g., fetal growth, neurodevelopment and respiratory problems.

Isabelle Kousignian, *Université Paris Descartes. EA 4064, Laboratoire Santé Publique et Environnement. Paris, France*

Chantal Guihenneuc-Jouyaux, *Université Paris Descartes. EA 4064, Laboratoire Santé Publique et Environnement. Paris, France*

Jocelyne Just, *Université Paris Descartes. EA 4064, Laboratoire Santé Publique et Environnement. Paris, France. Centre de l'Asthme et des Allergies, Groupe Hospitalier Trousseau – La Roche Guyon, Assistance Publique – Hôpitaux de Paris, France*

Isabelle Momas, *Université Paris Descartes. EA 4064, Laboratoire Santé Publique et Environnement. Paris, France Mairie de Paris. Direction de l'Action Sociale de l'Enfance et de la Santé. Cellule Cohorte. Paris, France*

Background and Aims: Lower respiratory tract infections (LRI) are common in infants, and are mainly induced by viral exposure. Association between exposure to certain chemical pollutants and LRI has been previously described. Although formaldehyde is ubiquitous indoors, its impact on infant health is uncertain. The aim of this study was to determine the impact of formaldehyde exposure on the incidence of LRI during the first year of life of babies from the PARIS *(Pollution and Asthma Risk: an Infant study)* cohort.

Methods: The PARIS cohort enrolled 3840 healthy newborns. Formaldehyde exposure was assessed by modeling in an environmental investigation including formaldehyde repetitive measurements into a random sample of 196 infants'homes from the cohort (at 1, 6, 9, 12 months) and data about potential formaldehyde level determinants (particleboard, varnished parquet floor, wall coating), home characteristics (number of inhabitants, construction date), aeration (mechanical ventilation, length of window opening). Health data were collected by regular self-administered questionnaires (at 1, 3, 6, 9 and 12 months). Multinomial logistic regression model was used to examine relations between formaldehyde exposure and the occurrence of (wheezy) LRI adjusting for potential confounders/risk factors.

Results: Around 40% of infants were exposed all the first year of life to formaldehyde levels above 19.5µg/m^3.

Well-known risk factors associated with LRI were confirmed in our study (child gender, parental history of asthma, presence of older siblings, day-care attendance, signs of humidity, prenatal/postnatal exposure to environmental tobacco smoke, and the protective effect of breastfeeding and furry pets). After adjustment for these risk factors, an interquartile increase of FA levels (P_{25}-P_{75}: 14.4-26.8µg/m^3) was associated with a 32% increase in risk of LRI (adjusted OR[95%CI]=1.32[1.11-1.55], *p=0.001*), and the strength of the association was slightly higher for wheezy LRI (aOR=1.41[1.14-1.74], *p=0.002*).

Conclusion: Infants exposed to formaldehyde are more likely to have an increased incidence of LRI.

TRENDS OF NOISE EXPOSURE IN BRATISLAVA AGGLOMERATION AT DIFFERENT TIME INTERVALS (10, 15, 20 YEARS)

Lubica Argalasova-Sobotova, *Comenius University, Bratislava, Slovakia*
Jana Jurkovicova, *Comenius University, Bratislava, Slovakia*
Zuzana Stefanikova, *Comenius University, Bratislava, Slovakia*
Katarina Hirosova, *Comenius University, Bratislava, Slovakia*
Ludmila Sevcikova, *Comenius University, Bratislava, Slovakia*

Background and aims: Noise is currently one of the most widespread environmental and occupational pollutants. It has become a serious problem in recent years, with significant development of industry and transport. The aim of the study is to objectively and subjectively evaluate and to follow the time trends of noise load of selected population groups in Bratislava agglomeration at different time intervals (10, 15, 20 years).
Methods: We used the validated methodology for the subjective assessment of "annoyance" and psychosocial well-being, as well as the objectification of noise levels by direct measurement method using sound analyzer with a module for frequency analysis. Statistical and epidemiological elaborations have been based on bivariate, stratified and multivariate analyses (multiple logistic regression).
Results: Based on the results of measurements of noise exposure in internal and external environments in the exposed and control site, we found a continuous increase in traffic noise burden in the exposed area at intervals of 10, 15 and 20 years beyond the health risk zone. Subjectively, we observed an increase of value risks causing road traffic noise annoyance and interference with several activities in the exposed group of university students over 20 years (OR=2.56 (95 % CI=1.93-3.42) vs 5.41 (95 % CI=4.28-7.25). In addition to road traffic noise we observed an increase in noise annoyance and disturbance from neighboring apartments (OR=1.71 (95 % CI=1.29-2.27) vs 2.48 (95 % CI=1.99-3.19), the entertainment facilities (OR=1.51 (95 % CI=0.90-2.52) vs 3.60 (95 % CI=2.85-4.90), from home construction sources, railway and industrial noise.
Conclusions: The contribution of our work is in the analysis of noise burden population trends and the elaboration of methods for environmental noise exposure assessing risk and the possibility of using this methodology for other physical factors such as suitable methodology in the practice of public health authorities.

CHILDHOOD LEAD POISONING SCREENING ACTIVITY IN FRANCE: A FIFTEEN-YEAR EXPERIENCE (1995-2009)

Camille LECOFFRE, *Institut de Veille Sanitaire, Saint-Maurice, France*
Philippe BRETIN, *Institut de Veille Sanitaire, Saint-Maurice, France*
Robert GARNIER, *Centre antipoison et de toxicovigilance, Paris, France*
Frédéric DE BELS, *Institut de Veille Sanitaire, Saint-Maurice, France*

Background and Aims: Lead poisoning is responsible for neurodevelopmental damage in children. In 1995, a Nationwide Monitoring System began in France recording blood lead levels (BLL) and characteristics of children who had blood lead (BL) tests. This study provides an overview of children screening for lead poisoning and a description of children's characteristics and risk factors.
Methods: Were included in the study, all the children under 18 who had one or more BL tests (within a screening framework) performed in France between 1995 and 2009.
Results: More than 83 600 children had at least one test during the study period. A peak of annual activity was observed in 2004 (10 060 children). From 1995 to 2001, the screening activity was stable: each year around 3 000 children had a first BL test. From 2004 to 2009 a stabilization of the activity was observed around 7 000 tested children per year. Most of the children were under 7 (80-90%). Most of them were screened because they lived in old housing (79.1% in 2005-2007). More than 60% of the children lived in the Greater Paris area even though the children population in this area was less than 20% of the French children population.
In 1995, 24.3% of screened children had a BLL ≥ 100µgL. They were 3.3% in 2009. From 1995 to 2009, the BLL geometric mean decreased from 59.2µg/L to 22.4µg/L in screened children.
Conclusions: The incidence of lead poisoning in screened children decreased regularly since 1995. The policies of old housing improvement, the leaded gasoline phase-out and the implementation of local prevention actions have taken part in this decrease. However the screening activity remained exceedingly area-dependant; so some children, exposed to lead, are not screened. The future evolution of the screening strategy and therefore of the surveillance system are currently being discussed.

USING THE NATIONAL HEALTH INSURANCE RESEARCH DATABASE TO ANALYZE THE RISK OF OCCUPATIONAL INJURIES/ DISEASES IN REGISTERED NURSES

Ya-Hui Yang, Department of Occupational Safety and Hygiene, Fooyin University, Taiwan
Trong-Neng Wu, Graduate Institute of Biostatistics, China Medical University, Taiwan
Saou-Hsing Liou, Division of Environmental Health and Occupational Medicine, National Health Research Institutes, Taiwan

Background and Aims: As indicated by the National Occupational Hazard Survey conducted in the United States, registered nurses (RN) are of a high risk group for occupational injuries and illnesses, incurring an annual incidence rate as high as 10.9%. A complete investigative report on the occupational injuries and illnesses in RNs is yet lacking. Moreover, previous studies have mostly been based on questionnaire surveys whose results were very much influenced by recall bias of studied subjects. This may disallow interventions to be implemented within an accurate and proper timeframe. Hence, the National Health Insurance Research Database (NHIRD) was used in this study to comprehensively examine RNs for occupational injuries, and to infer the time frame of initial occupational injuries.
Methods: This study used a retrospective prospective study, using the NHIRD of National Health Research Institutes, including registry for medical personnel (PER), and ambulatory care expenditures by visits (CD) files. The data provided by the National Health Research Institutes in Taiwan, the International Classification of Diseases, 9th revision, clinical modification (ICD-9-CM) code of the disease diagnosed from 2002 to 2008.
The ID numbers in the PER file were linked to the CD file. In Taiwan, there were 156,881 RNs in 2008 according the PER file. The subjects served as nurses from 2002 to 2008 were selected in this study.
Results: There were 23,898 subjects. From 2002 to 2008, three thousand six hundred eighty (15.4%) of 23,898 suffered occupational injuries/diseases. The RNs had a higher cumulative incidence in the following systems: there were 2,671 (11.2%) in injury and poisoning (ICD-9-CM code: 800-999, E800-E999); three hundred and three in diseases of the musculoskeletal system and connective tissue (ICD-9-CM code: 710-739), two hundred twenty-four in infectious and parasitic diseases and late effects of infectious and parasitic diseases (ICD-9-CM code: 001-139, 7713, 320-322), one hundred seventy-six in diseases of the digestive system (ICD-9-CM code: 530-579).
Conclusions: The occupational injuries/diseases in registered nurses are a matter worthy of note.

DIFFERENTIAL EXPRESSION OF MICRORNAS IN SUBJECTS EXPOSED TO METAL RICH PARTICULATE MATTER

Background and Aims: Altered patterns of gene expression mediate the effects of particulate matter (PM) on human health, but mechanisms through which PM modifies gene expression are largely undetermined. MicroRNAs (miRNAs) are highly conserved, noncoding small RNAs that regulate the expression of broad gene networks at the posttranscriptional level. We evaluated the potential effects of exposure to PM and PM metal components on microRNAs expression in 10 workers at an electric-furnace steel plant in Brescia, Italy.
Methods: We measured expression in blood leukocyte RNA on the first day of a workweek (baseline, after two days off work) and after 3 days of work (postexposure). All subjects in the study were no smokers with a means age of 46y and a characterized exposure to metal rich PM (about 3 times greater than environmental levels in the same area). Gene expression was profiled at baseline (n=10) and postexposure (n=10) using an Affymetrix GeneChip miRNA Array. Differential expression of miRNAs was determined with Limma (R-based Bioconductor package), which employs an empirical Bayes approach to calculate a moderated t-statistic. miRNAs with $p < 0.05$ and the absolute value of FC >2 were considered as differential miRNAs (DEMs). Predicted miRNA targets were determined using the miRanda algorithm, DEMs were subjected to pathway exploration using the Ingenuity Pathway Analysis (IPA) software.
Results: Four miRNAs – hsa-miR-421, hsa-miR-29, hsa-miR-146, hsa-let-7g – were found to be up-regulated. Bioinformatics analysis on these selected miRNAs showed as top ranked network RNA Post-Transcriptional Modification and Cell Morphology whereas the main diseases and disorders involved were Genetic Disorder, Cardiovascular Disease and Neurological Disease.
Conclusions: Changes in miRNAs expression may represent a novel mechanism mediating responses to PM and its metal components.

EFFECTS OF ENVIRONMENTAL FACTORS ON INFLUENZA SEASONALITY IN THE SUBTROPICS

Lin Yang, *The University of Hong Kong, Hong Kong Special Administrative Region, China*
King Pan Chan, *The University of Hong Kong, Hong Kong Special Administrative Region, China*
Ping Yan Chan, *Southern Medical University, China*
Jian Feng He, *Guangdong Provincial Center for Disease Control and Prevention, China*
Chun Quan Ou, *Southern Medical University, China*
JS Malik Peiris, *The University of Hong Kong, Hong Kong Special Administrative Region, China*
Chit Ming Wong, *The University of Hong Kong, Hong Kong Special Administrative Region, China*

Background and Aims: Environmental factors have been identified as an important driving force for influenza seasonality. But the results from previous studies were neither consistent nor conclusive. Almost all the studies were conducted in the temperature regions, which can barely apply to the subtropical and tropical regions with a distinct seasonal pattern of influenza. In this study, we assessed the dose-response relationship between environmental factors and influenza seasonality in two subtropical cities: Guangzhou and Hong Kong.
Methods: Influenza seasonality was measured by proportions of specimens positive for influenza from the surveillance networks of these two cities (termed influenza virus activity). We adopted a generalized additive model with variables for temperature, relative humidity and influenza virus activity, which allowed quantification of both linear and nonlinear relationships between these variables. The interaction between temperature and humidity on their effects on influenza virus activity was measured by a nonparametric bivariate response model.
Results: We did not find significant interaction between temperature and relative humidity in both cities. Influenza virus activity increased as temperature decreased and this linear relationship was consistent between these two cities. A positive linear relationship between relative humidity and influenza activity was found in Hong Kong, whereas a curvelinear relationship was found in Guangzhou with a turning point at 50%.
Conclusions: This study confirmed that seasonal environmental factors played an important role in determining influenza seasonality and for the first time revealed the dose-response relationship between environmental factors and influenza virus activity. Our findings provide key evidence for a future forecast model on influenza seasonality.

GREEN SPACE AND PHYSICAL ACTIVITY: RELATIONSHIPS IN SCOTLAND

Katherine Ord, *University of Glasgow, Scotland*
Richard Mitchell, *University of Glasgow, Scotland*
Jamie Pearce, *University of Edinburgh, Scotland*

Background and Aims: Epidemiological studies suggest that levels of green space in a neighbourhood are negatively associated with residents' mortality and morbidity rates. One mechanism proposed for this association is that green space is a venue for, and therefore encourages, physical activity. Few studies, however, have examined whether neighbourhood levels of green space are associated with physical activity actually in green space. New data have become available in Scotland, which permit this analysis.
Methods: A cross sectional study of 4167 adults (16+) living within an urban setting in Scotland. Logistic regression analysis established the association between respondents' green space exposure and their use of green space for physical activity (hereafter, green physical activity), controlling for relevant confounders, including age, sex, economic activity status and area level socio-economic deprivation. Green space was modelled as a categorical variable, with sensitivity analysis determining the impact of categorisation.
Results: Respondents with high levels of green space in their area of residence were 2.39 (95% CI, 1.11-5.11) times more likely to participate in green physical activity than those with very low levels of green space in their area. However, there was no evidence of a dose-response effect and results were highly sensitive to the definition of 'very low levels' of green space. Relatively high levels of green space in a neighbourhood held no real advantage over modest levels, for participation in green physical activity. The relationship between green space exposure and green physical activity did not differ by area level socio-economic deprivation.
Conclusion: Whilst green physical activity rates are very low among those who live in neighbourhoods where levels of green space are low, there is little difference in green physical activity rates between those residents' in areas with modest or high levels of green space.

ENVIRONMENTAL FACTORS AND MORTALITY RISKS ASSOCIATED INFLUENZA

Lin Yang, *The University of Hong Kong, Hong Kong Special Administrative Region, China*
King Pan Chan, *The University of Hong Kong, Hong Kong Special Administrative Region, China*
Ping Yan Chan, *Southern Medical University, China*
Jian Feng He, *Guangdong Provincial Center for Disease Control and Prevention, China*
Chun Quan Ou, *Southern Medical University, China*
JS Malik Peiris, *The University of Hong Kong, Hong Kong Special Administrative Region, China*
Chit Ming Wong, *The University of Hong Kong, Hong Kong Special Administrative Region, China*

Background and Aims: The subtropical and tropical regions exhibit a distinct seasonality of influenza incidence from the temperate regions, and the mechanism behind it remains unclear. Environmental factors have been related to the transmission and survival of influenza viruses but no studies have ever explored the role of environmental factors on regulating severity of influenza infection.
Methods: We applied a Poisson regression model to the mortality data of two Asian metropolitan cities located at the subtropical zone, Guangzhou and Hong Kong. Interaction between environmental factors (temperature, relative and absolute humidity) and influenza virus activity on their effects on mortality was assessed by Poisson regression models with product terms of environmental factors and influenza variables. The influenza associated excess mortality risks were also calculated for each period with different levels of temperature and humidity.
Results: Significant interactions ($p<0.05$) between absolute humidity and influenza were consistently found for mortality risks of all-cause and cardiorespiratory in both cites, with an increasing trend from low to high absolute humidity periods, but no significant interaction was found for pneumonia and influenza deaths. An increasing trend was also observed over strata of relative humidity, but the interaction between relative humidity and influenza was significant only in a few outcomes. The results for temperature were less consistent between two cities, and the interaction between temperature and influenza was only significant for cardiorespiratory mortality in Hong Kong.
Conclusions: The results suggest that environmental factors not only affect transmission of influenza viruses but also could be involved in pathogenesis of virus infections. The higher relative risks of influenza associated cardiorespiratory deaths in the hot and humid days highlight a need for people with chronic conditions to take extra caution against influenza in the subtropics.

PREDICTORS OF ENVIRONMENTAL EXPOSURE TO POLYCYCLIC AROMATIC HYDROCARBONS AMONG PREGNANT WOMEN

Kinga Polanska, *Nofer Institute of Occupational Medicine, Poland*
Wojciech Hanke, *Nofer Institute of Occupational Medicine, Poland*

Slawomir Brzeznicki, *Nofer Institute of Occupational Medicine, Poland*
Danuta Ligocka, *Nofer Institute of Occupational Medicine, Poland*

Background and Aims: Polycyclic aromatic hydrocarbons (PAH) are a group of compounds, comprising two or more fused aromatic rings, that are formed as a result of incomplete combustion of organic matter. Sources of environmental contamination can be both industrial and nonindustrial, the most common sources being cigarette smoke, grilled and smoked food processes, coal-fired utilities, steel plants, coke-oven plants, graphite electrode manufacturing plants, vehicle exhaust, wood-burning ovens and fireplaces. The aim of the study was to characterize the PAH exposure level based on 1-hydroxypyrene (1-HP) in urine of Polish pregnant women.
Methods: The study population consisted of 449 pregnant women who had been the subjects of the prospective Polish Mother and Child Cohort study performed in 8 regions of Poland. The women were interviewed three times during pregnancy (once in each trimester). 1–HP concentration in urine was chosen as the biomarker of exposure to PAH. The urine sample was analysed using high performance liquid chromatography (HPLC). The active and passive smoking exposure was verified by saliva cotinine, analysed by high performance liquid chromatography coupled with tandem mass spectrometry/positive electrospray ionisation (LC-ESI^{+}MS/MS) and isotope dilution method.
Results: 1-HP concentration in urine ranged from 0.02 to 10.2 • g/g creatinine with the geometric mean (GM) 0.4 • g/g creatinine. The significantly higher concentration of urinary 1-HP in pregnant women was observed for summer collection (GM ratio 1.1; $p = 0.01$), among smokers (GM ratio 1.7; $p < 0.001$) and for the women living in big cities (GM ratio 1.3; $p = 0.001$).
Conclusions: The significantly higher concentration of urinary 1-HP in pregnant women was observed for summer collection, among smokers and those living in big cities.

HEALTH OF MOTHERS IN RELATION TO HOUSEHOLD SMOKING EXPOSURE IN SLOVAKIA

Ľubica Argalasova-Sobotová, *Comenius University Bratislava, Slovakia*

Jozef Kajaba, *Health Center Medisyl Bratislava, Slovakia*
Zuzana Štefániková, *Comenius University Bratislava, Slovakia*
Michael Weitzman, *New York University, USA*

Background and Aims: According to the WHO, there are over 700 million children worldwide exposed to secondhand smoke and there is also a significant population of pregnant women and young women exposed to passive smoking in the world. Only a few studies specifically examine the association of living with smokers and maternal physical and mental health. The aim was to assess the physical and mental health of non-smoking mothers in relation to household smoking in Slovakia similar to a previous study we conducted using data from the USA.
Methods: A sample of 230 mothers with at least one child was surveyed at the OB/Gyn Department of Comenius University Faculty of Medicine. The Medical Outcomes Short Form-12 (SF-12) and its Mental Component (MCS) and Physical Component (PCS) Scale, were used to assess the mental and physical health of mothers. Bivariable and multivariable statistical analyses were performed (multiple linear regression).
Results: The average age of mothers was 30.75 ± 5 years (range of 14 - 46 years), 22 % of mothers were pregnant, 66 % were never-smokers, 29 % were ex-smokers, 5 % were smokers (95 % non-smokers); 47.35 % of non-smoking mothers live in households with at least one adult smoker. The presence of an adult smoker in a household was significantly negatively associated with the mother's MCS score in bivariable analysis. Adjusting for age, education, occupation and marital status in multiple linear regression analysis, the presence of a smoking partner in the household is independently associated with decreases of MCS, i.e. worse mental health (β= - 3.13; p=0.02). The association with PCS score was not significant.
Conclusions: Living with smokers had a negative influence especially on the mental health of non-smoking mothers in our sample. Future goals are to complete the sample and to enroll more pregnant women into the study.

DEVELOPMENT OF A QUALITY ASSESSMENT TOOL FOR 'DOORSTEP' GREEN SPACE IN DEPRIVED URBAN COMMUNITIES

Christopher Gidlow, *Staffordshire University, UK*
Naomi Ellis, *Staffordshire University, UK*

Background and Aims: Green space is a fundamental aspect of health-promoting neighbourhood environments. Despite evidence that the potential health benefits of green space are greatest for those in deprived and urban areas, in the UK, the most accessible local or 'doorstep' green space in these communities tends to be neglected and underused. As quality is a necessary precursor to use (and associated health benefits), it is important to understand relevant quality characteristics. We describe the development of a green space audit tool for use in 'doorstep' green space in deprived urban areas.
Methods: An existing tool (Foster et al. 2006) was adapted in two phases. A pilot phase in a deprived neighbourhood in Stoke-on-Trent, UK, used focus groups (35 adults; 23 children) and a postal survey (n=170) to capture key facilitators and barriers to using green space. The original items and scoring protocols were adapted and piloted in nine green spaces in deprived neighbourhoods (recreation areas; ≥2 hectares; unrestricted public access) to test protocols, utility and scoring. The second phase (ongoing) involved onsite user surveys to finalise items and appropriate domain weights to reflect the relative importance of different green space characteristics.
Results: Pilot work indicated that antisocial behaviour (and associated markers/'incivilities') and inadequate facilities were the greatest barriers to use. The piloted tool comprised six domains weighted on the basis of preliminary analysis: Access (10%), Recreation facilities (25%), Amenities (15%), Incivilities (25%), Usage (10%) and Overall impression (15%). Ongoing surveys and re-analysis of pilot data will verify these domain weights, with subsequent testing in further deprived urban areas (n~20 sites) to test feasibility, content validity, and inter-rater reliability.
Conclusions: The final audit tool and development process will be presented and made available for further testing in other areas of the UK and Europe.

EUROPEAN BIRTH COHORTS WITH ENVIRONMENTAL EXPOSURE DATA: THE ENRIECO INVENTORY AND RECOMMENDATIONS

Martine Vrijheid, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain - Hospital del Mar Research Institute (IMIM), Barcelona, Spain - Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain*
Mark Nieuwenhuijsen, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain - Hospital del Mar Research Institute (IMIM), Barcelona, Spain - Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain*
Maribel Casas, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain - Hospital del Mar Research Institute (IMIM), Barcelona, Spain - Spanish Consortium for Research on Epidemiology and Public Health (CIBERESP), Spain*

for the ENRIECO consortium*

Background and Aims: Many birth cohorts in Europe study the effects of early-life environmental exposures on pregnancy and child health, but data are often of fragmented nature and no overview of existing studies and their results is available. Therefore, the EU funded ENRIECO (Environmental Health Risks in European Birth Cohorts) to inventorize and synthesize birth cohort research in this area.
Methods*:* ENRIECO has created a detailed inventory of birth cohorts in Europe with data on environmental exposures, which can be searched on www.birthcohortsenrieco.net. Further, ENRIECO working groups in specific exposure and outcome topics have evaluated available data and methods used in the cohorts and developed recommendations. Lastly, case studies have examined areas in which pooling of data across cohorts may be feasible.
*Results***:** 36 birth cohorts in 19 European countries are studying a total of more than 350,000 mother-child pairs. The sizes of the cohorts vary considerably. Most of the cohorts are still young, with children under the age of 10 years. All cohorts have collected biological specimens of children and/or parents. Passive smoking, maternal occupation, outdoor air pollution, and allergens/biological organisms are assessed in many cohorts (>26). Fewer cohorts (12 to 16) collected information on water contamination, ionizing or non-ionizing radiations, noise, metals, persistent organic pollutants, or other, emerging, pollutants. Common and continuously measured health outcomes are well covered: birth weight, childhood growth, asthma and allergies, and child neurodevelopment. Methods and protocols differ considerably, but combined studies have proven feasible already for certain topics (e.g. PCBs and birth weight, and passive smoking and respiratory outcomes).
Conclusions: Combining forces in this field will yield more efficient and conclusive studies and ultimately improve causal inference. The impressive resource of existing birth cohort data should form the basis for a long-term infra-structure for cohort research on environmental exposures and child health.

* ENRIECO partners: Jens Peter Bonde, Sylvaine Cordier, Ulrike Gehring, Joachim Heinrich, Thomas Keil , Manolis Kogevinas, Remy Slama, Magnus Wickman, and representatives from all ENRIECO cohorts.

SPATIAL DISTRIBUTION OF ULTRAFINE PARTICLES IN GIRONA, SPAIN: A LAND USE REGRESSION MODEL

Gerard Hoek, *Institute for Risk Assessment Sciences (IRAS), Division of Environmental Epidemiology, Utrecht University, Utrecht, The Netherlands*

Background and aims: Ultrafine particles (UFP) are studied recently with increasing concern because of their toxic and pathogenic effects. A stronger association of cardiovascular and respiratory outcomes and UFP as compared to $PM_{2.5}$ has been reported. However, the epidemiological evidence is still insufficient and studies on the long term effects of UFP are needed. Given the high spatial variation of UFP, the assignment of exposure levels in epidemiological studies requires a fine spatial scale.

Methods: We measured UFP during 15min on the sidewalk of 652 participants' homes in 12 towns of Girona Province (Spain). The measurements were done during non-rush traffic hours 9:15-12:45 and 15:15-16:45 in 32 days during June 15–July 3, 2009. In parallel, we counted the number of vehicles driving in both directions. Potential predictor variables like building density, distance to bus lines and land uses were collected in GIS format. We adjusted for temporal variation using NO_X measurements at a central monitor. The model with highest adjusted R^2 was derived by supervised forward linear regression. Performance of other methods (GAM, regression trees, random forests) was tested.

Results: Individual models for groups of neighboring towns performed better than a general model for the study area. Adjusted R^2 varied from 0.16 to 0.76 across groups of towns. The most frequent determinants were traffic, traffic load (product of traffic and road length in a given radius) and household density. Other regression techniques improved the fit of the linear regression only marginally. Adjusted R^2 at a subset of sites in Girona city improved from 0.46 to 0.76 when the average of two repeated measurements was used.

Conclusions: Land use regression models of UFP for 12 towns in Girona were successfully developed using short-term data from a high density monitoring network. These are the first LUR models of the spatial variation of UFP in the Mediterranean area.

WHICH ASPECTS OF THE PERCEIVED URBAN ENVIRONMENT ARE ASSOCIATED WITH SELF-RATED HEALTH AND PHYSICAL ACTIVITY IN THE CITY OF GRAZ (AUSTRIA)?

Willibald J. Stronegger, Institute of Social Medicine and Epidemiology, Medical University of Graz, Austria
Sylvia Titze, Institute of Sport Science, University of Graz, Austria
Pekka Oja, UKK Institute, Tampere, Finland

Background and aims: Neighborhood characteristics have been shown to be associated with health and health-promoting behavior. The aim of our study was to identify perceptions of the urban residential environment and their association with physical activity for specific purposes and with self-rated general health.
Methods: A cross-sectional survey of inhabitants of Graz (a mid-sized Austrian city) aged 15–60 years was conducted in 2005. Self-reported data were obtained by means of computer-assisted telephone interviews. Participants (n=997) completed structured interviews including Likert-type scaled questions on neighborhood conditions, physical activity for specific purposes and self-rated general health. The questions concerning the neighborhood were factor-analyzed in order to generate primary measures of perceived neighborhood characteristics.
Results: We found that a perceived high socio-economic quality of the residential environment is associated with higher levels of self-rated health and leisure time physical activity. The better self-rated health among individuals who were more satisfied with their quarter is not due to increased levels of sport and exercise. Both, sport and satisfaction with environmental quality are independently linked with self-rated health.
Conclusions: Our results suggest that a high level of satisfaction with the individual's local infrastructure may urge the residents to engage in higher levels of physical activity for transportation, whereas the preferred mode of transportation may be gender-specific: men tend to use the bicycle while women walk. We found no clear relationship between satisfaction with the individual's social cohesion in his quarter and his/her physical activity. The results of our study may serve as a basis for devising structural preventive measures in urban environments (urban planning and design).

ASSESSMENT OF SPATIOTEMPORAL EXPOSURE ESTIMATES IN SMALL AREA EXPOSURE STUDIES

Daniela Fecht, *Imperial College London, United Kingdom*
Federico Fabbri, *Imperial College London, United Kingdom*
Linda Beale, *Imperial College London, United Kingdom*

Background and Aims: Exposure to air pollutants is often estimated based on location. Either ambient pollutant concentrations measured at the nearest monitoring station or modelled concentrations are, thereby, assigned to a specific location such as residential address. Mobility and time spent in locations away from home, however, greatly influence people's exposure. Ignoring this spatiotemporal element can result in inaccurate exposure estimates, but the magnitude and spatial distribution of the expected exposure error is largely unknown.
Methods: An urban simulation environment was used to compare a location-based exposure proxy to personal exposure. Exposure misclassification due to the use of ambient PM_{10} concentration measurements nearest to the home instead of personal exposure was quantitatively and spatially assessed for a cohort of 500 children. Personal exposure was modelled by predicting daily activity patterns using a probabilistic time-activity model and overlaying the visited locations and trips between locations with hourly PM_{10} concentration surfaces. Indoor particle concentrations were modelled using a stochastic mass-balance model.
Results: Personal exposure varied greatly between weekdays and the weekend due to a shift in the outdoor/indoor activity ratio, although that variation disappeared when averaging personal exposure over a two-week period. Using a location-based exposure proxy over-predicted exposures for those children with the lowest and highest exposures and the accuracy of the location-based proxy strongly depended on the activity patterns of individuals.
Conclusions: The spatial patterns of personal exposure showed that children are exposed to much higher levels of particles when away from home. A location-based proxy offers a reasonable estimate of exposure for children living in inner city areas, however, for children living in suburban areas, where ambient concentrations vary greatly, a single location will introduce spatially biased exposure error. There is a need to characterise this error in future exposure studies and analyses should include spatiotemporal detailed exposure information.

USING HEALTH INDICATORS IN A HEAT WARNING SYSTEM

Mathilde Pascal, *Institut de veille sanitaire, Saint-Maurice, France*
Aymeric Bun Ung, *Institut de veille sanitaire, Saint-Maurice, France*
Karine Laaidi, *Institut de veille sanitaire, Saint-Maurice, France*
Christophe Declercq, *Institut de veille sanitaire, Saint-Maurice, France*
Vérène Wagner, *Institut de veille sanitaire, Saint-Maurice, France*
Sabira Smaili, *Institut de veille sanitaire, Saint-Maurice, France*
Annamaria Antics, *Institut de veille sanitaire, Saint-Maurice, France*
Magali Corso, *Institut de veille sanitaire, Saint-Maurice, France*
Pascal Beaudeau, *Institut de veille sanitaire, Saint-Maurice, France*

Background and Aims: Since 2004, France operates a National Heat Wave Plan to reduce heat-related impacts. Preventive actions are implemented during summer and are reinforced in case of a heat wave warning. A monitoring of the health situation in the impacted regions can provide useful elements for the decision-makers to select the measures to be activated in priority. However, due to the short time available during a warning, the nature and the use of the health indicators must be clearly defined.
Methods: Based on a literature review and an expert consultation, we selected a limited number of morbidity and mortality indicators, taking into account their reactivity and data availability and quality. They were analyzed using two statistical methods to detect health impacts of heat waves: historical mean if at least two years of data are available and a control chart method if there is less than two years of data available.
Results: We initially identified 20 morbidity and mortality indicators, and restricted this list to one mortality indicator and five morbidity indicators: total mortality; total emergency admissions, for all ages and >75 years-old (which are the most vulnerable group); emergency admissions for heat-related diseases; number of calls to "*SOS médecins*", a 24-hour medical service; and number of calls to the emergency medical service centre. All are available on a daily basis, with a lag of 1 to 7 days.
Conclusions: Health indicators used during the warning must be able to rapidly identify a possible impact, in order to orientate preventive actions. They must be considered as tools for decision-makers and do not substitute to further epidemiological studies, which are necessary to better understand the vulnerability to heat, the dynamics of the health impact of heat waves, and to optimize the long-term response.

ASSOCIATION BETWEEN A URINARY BIOMARKER OF PRENATAL EXPOSURE TO DISINFECTION BY-PRODUCTS AND ADVERSE PREGNANCY OUTCOMES

Costet N., *INSERM U625, University of Rennes I, GERHM, IFR 140, Rennes, France*

Chevrier C., *INSERM U625, University of Rennes I, GERHM, IFR 140, Rennes, France*

Cordier S., *INSERM U625, University of Rennes I, GERHM, IFR 140, Rennes, France*

Background and aims: The microbiological control of drinking water through chlorinated disinfectants produces a large number of disinfection by-products (DBPs) suspected to have adverse reproductive effects. Most epidemiological investigations of the effect of prenatal exposure to DBPs on pregnancy outcomes used indirect measures of exposure combining estimated residential levels of trihalomethanes (THM) or haloacetid acids (HAAs) in tap water and eventually personal uses of water. Urinary trichloroacetic acid (TCAA) (one of the HAAs) has been validated as a biomarker of chronic exposure to DBPs via ingestion of chlorinated drinking water. We used it to study the association of DBP exposure with fetal growth and duration of gestation.
Methods: The PELAGIE birth cohort included 3,421 pregnant women in early pregnancy (<19 weeks of gestation) between 2002 and 2006. At inclusion, women were asked to complete a self-administered questionnaire and to provide a urine sample. Maternal urinary levels of trichloroacetic acid (TCAA) were assessed in a nested case-control study comparing 174 cases of fetal growth restriction, 114 preterm births, and 399 controls. Odds ratios were estimated with logistic models adjusted for high blood pressure, tobacco, alcohol, and coffee consumption, marital and employment status.
Results: TCAA was detected in 7% of the 611 maternal urine samples tested. The limit of detection was 0.01 mg/L. Women with detected TCAA in their urine had a significantly higher risk than others of fetal growth restriction (adjusted odds ratio=2.07; 95% confidence interval (CI): 1.00, 4.26). No association was found with preterm birth.
Conclusions: Prenatal exposure to DBPs as measured by detected urinary TCAA seems to affect fetal growth. This biomarker should however be considered as a marker of the whole mixture of DBPs and the causal agent(s), if any, remain to be identified.

OUTDOOR EXPOSURE TO FORMALDEHYDE (CH2O) IS ASSOCIATED WITH AN INCREASED RISK OF HOSPITALIZATION FOR RESPIRATORY DISEASES IN CHILDREN

Paolo Ricci, *Unit of Epidemiology, NHS Mantua, Italy*

Background and aims: Children living near wood industries have an increased risk of developing respiratory diseases.
We aimed at assessing if residential outdoor exposure to NO2 and CH2O was associated with the risk of hospitalization for respiratory diseases in children.
Methods: In 2006, all the children (3-14 years) living in the Viadana district (the largest wood manufacturing areas in Northern Italy) were surveyed through a parental questionnaire (n=3854) and their home addresses were geocoded. Their history of hospitalization for respiratory diseases (ICD-IX: 460-519) was assessed from January 2007 to December 2009, using discharge records obtained from the local Health Unit. To assess the outdoor exposure to NO2 and CH2O, 63 passive samplers were installed in the area using a Partitioning Around Medoids (PAM) algorithm. Pollutants were monitored twice, both in winter and in summer 2010. Kriging interpolation was used to attribute the average annual concentration of pollutants to each child. Poisson regression models were used to assess the association between the hospitalization rates (HR) and the average concentration of pollutants.
Results: By December 2010, 3798 (98.5%) children had been traced. During the 3 years of follow-up, 121 hospital admissions, caused by respiratory diseases, occurred (annual HR = 10.8/1000/year). The HR for respiratory diseases slightly increased with increasing outdoor exposure to NO2 ($\mu g/m^3$) (RR:1.02; 95%CI: 0.95-1.10), while they were strongly associated to CH2O outdoor concentration ($\mu g/m^3$) (RR:2.41; 95%CI: 1.07-5.43).
Conclusions: Emissions from wood industries apparently have a serious impact on children's health.

EXTRACELLULAR HISTONES AFFECT BLOOD COAGULATION IN SUBJECTS EXPOSED TO METAL-RICH AIR PARTICLES

Pier Alberto Bertazzi, *Università di Milano and IRCCS Maggiore Hospital, Mangiagalli and Regina Elena Foundation, Italy*

Background and Aims: Epidemiological findings suggest an association between particulate matter (PM) exposure and hypercoagulability and thrombosis. The underlying mechanism for PM-related procoagulative effects is still unknown, but recently, elevated levels of extracellular histones have been indicated as possible mediators in inflammatory conditions. In 63 steel workers, we evaluated the effects of exposure to PM and PM metal components on two extracellular histone modifications (histone H3 lysine 4 trimethylation: H3K4me3; histone H3 lysine 9 acetylation: H3K9ac), and the association between both H3K4me3 and H3K9ac and coagulation markers.
Methods:H3K4me3 and H3K9ac were determined in plasma samples through ELISA (enzyme-linked immunosorbent assay). Prothrombin time (PT), activated partial thromboplastin time (APTT), endogenous thrombin potentials (ETPs) with/without exogenous triggers and with/without soluble thrombomodulin, tissue-type plasminogen activator (t-PA) antigen, D-dimer, C-reactive protein (CRP) were measured as coagulation markers. Exposure to inhalable metal components (aluminum, manganese, nickel, zinc, arsenic, lead, iron), and to particle mass (PM with aerodynamic diameters <10µm [PM10], <1µm [PM1] and coarse PM [PM10- PM1]) was estimated for each study subject.
Results: Both H3K4me3 and H3K9ac were increased in association with PM1(β[H3K4me3]=0.34, P=0.01; β[H3K9ac]=0.27, P=0.02). H3K4me3 was increased in association with air levels of zinc (β=0.25, P=0.04) and iron (β=0.38, P=0.01). H3K9ac showed borderline positive association with air level of zinc (β=0.18, P=0.07). Histone modifications also showed significant association with ETP TM+ (β[H3K4me3]=355.27, P=0.05; β[H3K9ac]=389.03, P=0.05), and borderline association with t-PA antigen (β[H3K4me3]=-3.42, P=0.06; β[H3K9ac]=-3.23, P=0.06).
Conclusions: Our results indicate a potential role of extracellular histones in hypercoagulability induced by PM exposure.

INTERNATIONAL EXPERIENCE IN REGIONS WHERE THERE IS NO REQUIREMENT FOR AN IRB (RESEARCH ETHICS BOARD), AND HOW UNETHICAL RESEARCH MAY ENSUE

Adetoun Mustapha, *MRC-HPA Centre for Environment and Health, Imperial College London, UK*

Research activities are sparse in resource-poor settings and developing countries such as Nigeria and other parts of sub-Saharan Africa. Reasons include not only lack of funding, but also the practical difficulties of conducting research in an uncertain political and economic context, and conditions of poor literacy, lack of infrastructure (including reliable electricity supply) and administrative obstacles. Universities are not adequately funded to carry out meaningful research. Education is generally in a deplorable state in many instances. The practice of environmental epidemiology is in its infancy. Very few studies are from donor agencies or part of international collaboration or postgraduate theses. Some local universities constitute Grants and Ethics committees for such. However, there are reports that the committees may not be effective. Private consultants often carry out environmental studies for the industry without the need for ethics approval.

Application of ethics principles from the Western developed countries to the least developed countries that has different values and priorities and in the absence of Institutional Review Boards is challenging. For example, informed consent as an underlying principle of ethical research implies the individual research participant's ability to understand and make a decision autonomously. However, the reality is that in many low SES regions, the literacy levels are low and the family structure/community norms are complex. It may be the prerogative of a community leader or a male head of household to make decisions for others in some regions. The concept of individual consent may be seen as challenging an established structure in customs where the head of the extended family takes decisions for widows and orphans.

This presentation will use published examples to review the importance of applying key elements of the newly revised international ethics guidelines and the process by which the guidelines can be implemented by Institutional Review Boards.

GENOMIC DNA METHYLATION ALTERATIONS DUE TO METAL-RICH AIR PARTICLE EXPOSURE: POTENTIAL LINKS WITH INFLAMMATION AND COAGULATION MARKERS

Background and Aims: DNA methylation alterations have been proposed as a novel molecular mechanisms linking inhalable particular matter (PM) exposure to cardiovascular effects. However, data showing relations among PM exposure, DNA methylation and cardiovascular-related outcomes, such as inflammation and blood coagulation, are limited. We investigated global DNA methylation, inflammation and coagulation markers in foundry workers with well-characterized exposure to a wide range of metal-rich PM.
Methods: We recruited 63 male workers (mean age 44 years) in an electric-steel plant in Italy. Individual exposure to PM with diameter<10 µm (PM10) and its metal components was estimated using work-area measurements and time spent in each area. DNA methylation analysis of Alu and LINE-1 was performed trough bisulfite-pyrosequencing on blood DNA obtained on two different work days. We measured PT, aPTT, t-PA antigen, D-dimer, and CRP. Endogenous thrombin potentials (ETPs) were assessed with (TM+) or without (TM-) soluble thrombomodulin, but without exogenous triggers. Covariate-adjusted linear mixed-effect regression was used to evaluate associations between PM or metal exposure and methylation; and between methylation and coagulation/inflammation markers.
Results: Workers were exposed to a wide range of PM10 (between 73-1220 • g/m3) and metal components (PM10 metal content between 2%-94%). PM10 showed a negative association with Alu (• =-0.18, p=0.05) and LINE-1 (• =-0.37, p=0.04) methylation. Zinc had a marginal negative association with Alu methylation (• =-0.17, p=0.06). Aluminum was negatively associated with LINE-1 methylation (• =-0.19, p=0.04). Lower Alu methylation was associated with activated coagulation and inflammation, as indicated by shorter PT (• =-0.18, p=0.02), and increased ETP TM+ (• =87.17, p=0.03), ETP TM- (• =144.82, p=0.02), and CRP (• =0.58, p=0.01). No associations were found with other markers.
Conclusions: We found novel associations of coagulation markers with Alu repetitive element methylation. DNA methylation was associated with specific metal components, suggesting a possible common path linking PM exposure, methylation, and blood coagulation.

SEROPREVALENCE OF TOXOPLASMA GONDII ANTIBODIES AMONG VETERINARY STAFF FROM A VETERINARY DEPARTMENT IN TRANSYLVANIA

Ligia Stoica, *National Institute of Public Health, Regional Center of Public Health, Cluj-Napoca, Romania*
Mihai Cristescu, *University of Agriculture Sciences and Veterinary Medicine, Cluj-Napoca, Romania*
Nina Coroiu, *National Institute of Public Health, Regional Center of Public Health, Cluj-Napoca, Romania*

Background and Aims : Toxoplasmosis is an infectious disease caused by a parasite Toxoplasma gondii that spreads from animals to humans, veterinarians being at high risk for this zoonotic disease. The risk is more dangerous for women because this infection is embryotoxic.
Methods : A cross-sectional survey was carried out among 59 veterinary doctors (40 males and 19 women), age average 42,9 $\pm$ 10.4 years , in order to assess their risk through occupational exposure to Toxoplasma gondii. A special medical questionnaire was individualy applied regarding occupational and medical history, past and actual animal exposure, work-related symptoms and diseases. Clinical examination was performed and Toxoplasma gondii IgG and IgM antibodies were determined using ELISA method.
Results : No symptoms and signes suggesting an actual or past toxoplasmosis were found, in medical history no diagnosis of toxoplasmosis was mentioned.
Seroprevalence of IgG antibodies was 45,8% and of IgM antibodies was 1,7% among all analized samples. IgM titres exceeding 250 UI/ml in 29,6% of the Ig G positive samples were found.
Males doctors had a higher seropositivity prevalence (50%) as compare to women doctors (36,8%). The group aged up 40 years had a higher seroprevalence (56,25%) as compare to the group aged under 40 years (33,3%).
Conclusions : This findings suggest that veterinary doctors are at high risk of exposure to toxoplasmosis during their occupational activity, the degree of risk being related with increase of age, length of activity and in male doctors.

LONG TERM EFFECTS OF IN-UTERO EXPOSURE TO PERFLUORINATED CHEMICALS ON FEMALE REPRODUCTION

Susanne Lund Kristensen, *Aarhus University Hospital, Denmark*

Cecilia Høst Ramlau-Hansen, *University of Aarhus, Denmark*

Erik Ernst, *Aarhus University Hospital, Denmark*

Sjurdur Frodi Olsen, *Statens Serum Institut, Denmark*

Jens Peter Bonde, *Bispebjerg Hospital of Copenhagen University, Denmark*

Anne Vested, *Aarhus University Hospital, Denmark*

Thorhallur Ingi Halldorsson, *University of Iceland, Reykjavik, Iceland*

Georg Becher, *Norwegian Institute of Public Health, Norway*

Line Smaastuen Haug, *Norwegian Institute of Public Health, Norway*

Gunnar Toft, *Aarhus University Hospital, Denmark*

Background and Aims: The perfluorinated chemical perfluorooctanoate (PFOA) is detected in human blood worldwide. Limited data exist on the possible effect of PFOA on human female reproduction and particularly on the implications of in-utero exposure. There are potential adverse effects on the development of the foetus since PFOA crosses the placental barrier and may act as endocrine disruptor.
The aim of this population-based study was to investigate the effects of in-utero exposure to PFOA on female reproduction.
Methods: The participants were female offspring from a Danish pregnancy cohort established in 1988-89. Maternal serum concentrations of PFOA during pregnancy were related to reproductive parameters of the adult daughters: menstrual cycle characteristics, levels of reproductive hormones and ultrasonographic appearance of the ovaries.
Results: The 246 participants had a median (range) age of 20.1 (19.5-20.8) years. Median (range) PFOA concentration in the mother's serum was 3.7 (0.1-19.8) ng/ml. The cohort was divided into three groups according to PFOA levels (n=82 in each group). When comparing to the reference group of low exposure, the group of medium exposure had a higher median level of sex hormone-binding globulin (110 vs. 147 nmol/l, p=0.01), and a lower median value of free androgen index (1.2 vs. 0.7, p=0.02), of anti-müllerian hormone (2.8 vs. 2.4 ng/ml, p=0.03), and number of follicles/ovary (13.5 vs. 11.5, p=0.03). Compared to the reference group, the high exposure group had a higher median level of sex hormone-binding globulin (110 vs. 150 nmol/l, p=0.04) and a later mean (SD) age at menarche (12.7 (1.2) vs. 13.1 (1.2) years, p=0.03).
Conclusions: Preliminary results showed possible effects of PFOA on levels of reproductive hormones, number of ovarian follicles and age at menarche. Future analyses including control for confounders will provide more information on whether in-utero exposure to PFOA may have adverse long-term effects on female reproduction.

APPLICATION OF A NEW METHOD FOR TRICHLORAMINE DETERMINATION IN AMBIENT AIR OF INDOOR SWIMMING POOLS

Guglielmina Fantuzzi, *Department of Sciences of Public Health*, *University of Modena and Reggio Emilia, Italy*
Guerrino Predieri, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Pierluigi Giacobazzi, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Katia Mastroianni, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Elena Righi, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*
Gabriella Aggazzotti, *Department of Sciences of Public Health, University of Modena and Reggio Emilia, Italy*

Background and Aims: Trichloramine (NCl_3) is a volatile disinfection by-product (DBP) which is formed when chlorine in water reacts with nitrogen-containing compounds. NCl_3 is a strong mucous membrane irritant and it has been recently linked with respiratory symptoms and asthma in swimmers, mainly in children, and in pool attendants. However, there are some issues to clarify about NCl_3 exposure in indoor swimming pools and one of them deals with the analytical determination of NCl_3 in ambient air. The aim of this study was to investigate the feasibility of a new modified DPD/KI colorimetric method, recently proposed in literature, for the analysis of airborne NCl_3 in indoor swimming pools. The relationships between NCl_3 ambient air levels and some other DBPs in these environments were also evaluated.
Methods: Airborne NCl_3 levels were investigated in 20 indoor swimming pools. Technical characteristics and disinfection treatments were collected together with physical and chemical parameters in water. Trihalomethanes (THMs) levels in water and air were also investigated.
Results: The airborne NCl_3 levels ranged from 204 to 1020 $\mu g/m^3$ and the mean value was 648.7 ± 201.4 $\mu g/m^3$. High levels of combined chlorine in water were observed: only 25% of the investigated swimming pools showed levels ≤ 0,4 mg/l, which is the Italian limit value. The average and highest THMs levels in water were 41.4 and 134 µg/l, respectively. Mean ambient air THMs value was 86.0 ± 47.9 $\mu g/m^3$ and 187 $\mu g/m^3$ was the maximum value. Airborne NCl_3 levels were found associated only with combined chlorine ($r= 0.441$; $p < 0.05$) and with THMs levels in ambient air ($r= 0.554$; $p < 0.05$).
Conclusions: Airborne NCl_3 levels are in line with other studies in literature. However more than 50% of the investigated indoor swimming pools showed NCl_3 levels higher than the recommend provisional value of 500 $\mu g/m^3$, as suggested in WHO guidelines.

ANALYSIS OF HOSPITAL DISCHARGE DATA TO DESCRIBE HEALTH STATUS OF RESIDENTS IN ITALIAN POLLUTED SITES

Susanna Conti, *Istituto Superiore di Sanità, Rome,Italy*
Giada Minelli, *Istituto Superiore di Sanità, Rome, Italy*
Grazia Rago, *Istituto Superiore di Sanità, Rome, Italy*
Valerio Manno, *Istituto Superiore di Sanità, Rome, Italy*
Roberta Pirastu, *Sapienza Università di Roma, Italy*
Pietro Comba, *Istituto Superiore di Sanità,Rome, Italy*

Background and Aims: This study derives from SENTIERI Project, aimed at implementing a multi-disciplinary and multi-phase process leading to a full epidemiological characterization of Italian Polluted Sites (IPSs). SENTIERI Project analyzed mortality of residents in 44 IPSs for 63 causes of death, for which the epidemiologic evidence indicated a potential association with pollution in IPSs. The aim of the present study is to analyze hospital discharge data of residents in IPSs, with special focus on causes already studied in SENTIERI Project.
Methods: Hospital Discharge Record (HDR) is a synthesis of the patient's medical record and it is mandatory for both in-patients and out-patients and contains, for each hospital discharge in Italy, social and demographic data of the patient (i.e. age, gender, place of birth, place of residence) and clinical data ("main" diagnosis and up to 5 other diagnoses, procedures, outcomes). Diagnoses and procedures are coded using the International Classification of Diseases, 9th revision, Clinical Modification (ICD-9 CM). HDR data referring to year 2008 were analyzed calculating standardized hospitalization rates and relative risks (RR) using as reference the Region where the IPS is situated.
Results: As an example, Gela area (South of Italy), where a large chemical/petrochemical complex is located, shows significantly increased risks of hospitalization for all causes (RR=1.29, 95%CI 1.26-1.31), all tumors (RR 1.10, 95%CI 1.04-1.18), circulatory (RR=1.25, 95% CI 1.20-1.30) and respiratory diseases (RR=1.24, 95% CI 1.17-1.31), as also found for the mortality analysis.
Conclusions: In order to characterize the health status of IPSs residents, besides mortality data, HDR have to be analyzed. HDR have been created for administrative purposes and thus not necessarily contain complete clinical data but they do have potentials, such as the international system of codification used and the routinely and exhaustive collection, with no additional resources necessary.

PRENATAL EXPOSURE TO PERSISTENT ORGANOCHLORINE POLLUTANTS AND DEVELOPMENETAL MILESTONES IN GREENLANDIC YOUNG CHILDREN

Birgit Bjerre Hoeyer, *Department of Occupational Medicine, Aarhus University Hospital, Aarhus, Denmark*
Cecilia Hoest Ramlau-Hansen, *Department of Epidemiology, Institute of Public Health, Aarhus University, Aarhus, Denmark*
Henning Sloth Pedersen, *Centre for Arctic Environmental Medicine, Nuuk, Greenland*
Jens Peter Bonde, *Department of Environmental and Occupational Medicine, Copenhagen University Hospital Bispebjerg, Copenhagen, Denmark*
Gunnar Vase Toft, *Department of Occupational Medicine, Aarhus University Hospital, Aarhus, Denmark*

Background and aim: Polychlorinated biphenyls (PCB) and dichlorodiphenyldichloroethylene (DDE) are ubiquitous lipophilic environmental compounds that bio-accumulate through the food chain via consumption of contaminated sea mammals. Inuit populations are among the populations with the highest exposure to these compounds. Small-scale studies have shown an association between PCB and DDE and delays in childhood motor skills. This paper will present the results of a large-scale follow-up study of the association between prenatal exposure to PCB and DDE and motor developmental milestones like crawling, standing and walking in early childhood.
Methods: A total of 572 pregnant women from Greenland were enrolled in a cohort within the INUENDO study in 2002-2004. The follow-up, CLEAR, was conducted in 2010-2011. PCB and DDE were measured in maternal blood samples drawn when the women were on average 24 weeks pregnant. Developmental milestones were reported by mothers in a structured interview-based questionnaire when the child was 6-9 years old.
Results: The collection of field data is ongoing and is expected to be completed during the summer of 2011. Results will be presented on the poster.
Conclusions: The paper will be the first of its kind to present robust data owing to inclusion of a large study population living in an environment with high exposure to lipophilic environmental compounds.The study expects to provide strong evidence for or against the hypothesis of delayed developmental milestones after in utero exposure to PCB and DDE.

PROMOTING FOOD SAFETY IN THE KYRGYZ REPUBLIC

Maksat Kudayarova *Scientific and Production centre for Preventive Medicine, Bishkek, Kyrgyz Republic (sultashev@yahoo.com)*

Background and Aims: The Kyrgyz Republic is reforming the system on technical regulations and standards in the area of food safety. To promote the reform the European Commission has established the project "Support to Implementation of the Partnership and Cooperation Agreement – Phase III" (PSA). One of the main objectives of the project is to provide food safety along the chain of the food product turnover. The aim of this study was the informing of the population of the Kyrgyz Republic on the " PSA – Phase III" project to create preconditions for adopting and implementing international standards on food safety.
Methods: Population survey was conducted twice - at the beginning and at the end of the study. A total sample of 1000 households across the republic were surveyed. Booklets, posters and placards and mass media materials were developed for the campaign.
Results: The study was carried out in 3 stages. First, a baseline questionnaire on food safety was conducted which showed poor knowledge of the population on food safety measures. Then a large scale informational campaign was conducted with the involvement of mass media and with the use of the developed promotion materials. The campaign informed the population about international standards on food quality and safety, principles of national legislation on technical regulation, the main food poisoning prevention measures, requirements on biological additives and gene engineering products, foodstuff safety in agriculture. The second survey allowed assessment of the efficiency of the campaign.
Conclusions: The informational campaign led to an increase in the food safety awareness of the population and knowledge of respondents about food safety measures implemented by the Government of the republic and the international community.

STABILITY OF LAND USE REGRESSION MODELS AND MEASURED SPATIAL PATTERNS FOR NO2, PM2.5 AND PM2.5 ABSORBANCE

Ursula Krämer, *Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany*
Dorothea Sugiri, *Leibniz Research Institute for Environmental Medicine, Düsseldorf, Germany*
Joachim Heinrich, *Institute of Epidemiology, Helmholtz Center Munich, Germany*
Bert Brunekreef, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, The Netherlands*
Gerard Hoek, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, The Netherlands*

Background and Aims: Within the ESCAPE project outdoor air pollution concentrations are being estimated using harmonized Land Use Regression (LUR) models in 37 study areas in Europe. LUR models are being developed for concentrations measured in 2008-2011, but the cohort studies started much earlier. The aim is therefore to evaluate the stability of measured spatial patterns and LUR models using data and models from a European study conducted in 1999 (TRAPCA).
Methods: In each ESCAPE study area, 20 to 40 locations were monitored in the period October 2008 – April 2011. We also re-sampled sites used in the 1999 TRAPCA study in Munich, Stockholm and The Netherlands. For both TRAPCA and ESCAPE NO_2, $PM_{2.5}$ and $PM_{2.5}$ absorbance were measured, and LUR models were developed.
Results: The measured concentrations at the same locations in both periods correlated generally well, with Pearson correlations 0.98, 0.81 and 0.99 for the Netherlands (N=15), and 0.89, 0.46 and 0.75 for Stockholm (N=25) for NO_2, $PM_{2.5}$ and $PM_{2.5}$ absorbance, respectively. In both areas, concentrations decreased with largest decrease for $PM_{2.5}$ absorbance. In the Netherlands, the ESCAPE LUR models explained 89% (NO_2), 70% ($PM_{2.5}$) and 91% ($PM_{2.5}$ absorbance) of the spatial variance in measured concentrations in 2008-2011, and explained 94% (NO_2), 59% ($PM_{2.5}$) and 93% ($PM_{2.5}$ absorbance) of the spatial variance in concentrations measured in 1999. LUR model development is ongoing and results for other areas will also be shown.
Conclusions: The correlations between the measured spatial contrasts for $PM_{2.5}$ and especially NO_2 and $PM_{2.5}$ absorbance in 1999 and 2008-2011 were high. The ESCAPE models predicted the measured spatial contrast in 1999 well especially for NO_2 and $PM_{2.5}$ absorbance in The Netherlands. If corroborated by the analyses for the other study areas, this supports that the ESCAPE LUR models can be used to represent historical concentration contrasts.

SPATIO-TEMPORAL VARIATION OF PARTICLE NUMBER CONCENTRATIONS IN A SWISS URBAN CITY

Harish C. Phuleria, *Swiss Tropical and Public Health Institute, Basel, Switzerland - University of Basel, Switzerland*
Ming E. Tsai, *Swiss Tropical and Public Health Institute, Basel, Switzerland - University of Basel, Switzerland*
Elisabetta Corradi, *Swiss Tropical and Public Health Institute, Basel, Switzerland,- University of Basel, Switzerland*
Nino Künzli, *Swiss Tropical and Public Health Institute, Basel, Switzerland,- University of Basel, Switzerland*
L.-J. Sally Liu, *Swiss Tropical and Public Health Institute, Basel, Switzerland,- University of Basel, Switzerland,- University of Washington, Seattle, USA*

Background and Aims: This study is part of the Swiss Cohort Study on Air Pollution and Lung and Heart Diseases in Adults (SAPALDIA), a nearly 20-year old cohort study spread in 8 geographically diverse areas in Switzerland. Innovative exposure modeling has been conducted in SAPALDIA earlier for PM_{10} and NO_2, however, exposure to specific traffic related pollutants such as ultrafine particles and PM constituents has not been assessed. The overarching aim is to provide the estimates of individual long-term outdoor traffic-related air pollution exposures of the cohort participants. This paper focuses on the spatial and temporal variation of home outdoor particle number concentration (PN) in one of the SAPALDIA area, Basel.
Methods: The PN measurements will be conducted at 20 residences each in four of the eight areas in three seasons over a period of 2 years, 2011-2012. Indoors and outdoors monitoring will be conducted biweekly for $PM_{2.5}$, PM_{10}, NO_2 and weekly for PN. Particle counts are measured using a particle counting device, miniDiSC (miniature diffusion size classifier). It is a portable device and measures nanometer sized (10-300nm) particles with a resolution of one second.
Results: Mean weekly averaged PN levels are observed 14529±3296, 13659±1878 and 11545 particles/cm^3 at street, urban and regional background locations respectively. Median correlation coefficient for all sites is 0.70 (range 0.36-0.91) and 0.83 (range 0.39-0.99) for hourly and daily PN respectively. Median coefficient of divergence, a measure of spatial heterogeneity, for all site pairs is 0.15 (range 0.05-0.27), showing a low to mid spatial heterogeneity in daily PN in Basel. These winter season observations will be compared across seasons and further with concurrent $PM_{2.5}$, PM_{10} and NO_2 measurements.
Conclusions: Our first results show significant differences in PN levels in home outdoor locations and document the differential impact of traffic on PN levels in the city.

PRENATAL EXPOSURE TO ORGANOCHLORINE COMPOUNDS (OCs) IN RELATION TO BIRTHWEIGHT AND DURATION OF GESTATION: THE SPANISH INMA PROJECT

Marieta Fernández, *University of Granada, San Cecilio Universitary Hospital, Granada, Spain*

Background and aims: To evaluate associations between prenatal organochlorine compounds (OC) exposure and birthweight and duration of gestation in a population with low exposure levels.
Methods: The analysis included 1527 mother-child pairs from three sub-cohorts of the INMA project (www.proyectoinma.org) recruited during pregnancy between 2003-2008. Polychlorinated biphenyls (PCBs 138, 153, 180 and the total), p,p´-dichlorodiphenyldichloroethylene (p,p'-DDE), hexachlorobenzene (HCB) and • -hexachlorocyclohexane were measured in maternal serum obtained in weeks 10-13 of gestation. Multivariable linear regression was used to assess the association between the exposure to these compounds and birthweight and gestation duration adjusting for potential confounders.
Results: The mean (sd) gestational age was 39.7 (1.6) weeks and mean birthweight 3254.8 (465.7) grams. After multivariate adjustment including other OCs, the increase levels of p,p'-DDE were significantly negatively associated with gestation duration among male infants (• =-0.129; 95%CI: -0.251 to -0.007), but not among females. Among infants of both sexes whose mothers smoked during pregnancy (31,7% of the sample), p,p'-DDE was also associated with shorter gestation duration after multivariable adjustment (• =-0.192; 95%CI: -0.356 to -0.028) and PCBs were associated with significant reductions in birthweight among infants (• =-50.474; 95%CI: -99.442 to -1.506); these associations were marginally non-significant after adjusting for other OCs. When OCs were categorized in quartiles, the main differences were found betwen the first and the fourth quartile (p,p'-DDE: • 0.43 vs. >0.16 • g/L; • PCBs: • 0.43 vs. >0.91 • g/L).
Conclusions: Results suggest infants of women who smoke during pregnancy may be vulnerable to adverse effects of low-level p,p'-DDE exposure on the duration of gestation and to effects of PCB exposure on birthweight. Overall, boys also appeared to be more susceptible than girls to negative effects of p,p'-DDE on the duration of gestation.

OUTDOOR NO_2 EXPOSURE IS ASSOCIATED WITH PERSISTENT COUGH DURING THE FIRST YEAR OF LIFE

Ana Esplugues, *CIBER Epidemiologia y Salud Pública (CIBERESP), Centre for Public Health Research (CSISP), Valencia, Spain*
Ferran Ballester, *University of Valencia, Centre for Public Health Research (CSISP), CIBER Epidemiologia y Salud Pública (CIBERESP), Spain*

Jesús Vioque, *Departamento de Salud Pública, Universidad Miguel Hernández, Spain*
Carmen Iñiguez, *Centre for Public Health Research (CSISP), CIBER Epidemiologia y Salud Pública (CIBERESP), Spain*

Background and Aims: Because children's lungs and immune system are not completely developed they are more susceptible to respiratory disease as well as more vulnerable to ambient pollution. We assessed the relation between prenatal and postnatal NO_2 levels and the development of Lower Respiratory Tract Infections (LRTI), wheezing and persistent cough during the first year of life.
Methods: Study population were 352 children from a birth cohort in Valencia, Spain. Prenatal exposure to NO_2 was measured at 93 sampling sites spread over the study area during four different sampling periods of 7 days each. It was modelled for each residential address through land use regression using the empirical measurements and geographic information systems data. Postnatal exposures were measured indoor and outdoor the residence with passive samplers during 14 days once in each home. Outcomes studied were any episode of LRTI during the child's first year of life diagnosed by a doctor (bronchitis, bronchiolitis or pneumonia), wheezing (defined as whistling sounds coming from the chest), and persistent cough (more than three consecutive weeks). Outcomes and potential confounders were obtained from structured questionnaires. Multiple logistic regression was used to explore associations.
Results*:* Cumulative incidence (CI) was 30.40% for LRTI (23.01% bronchiolitis, 11.93% bronchitis and 1.42% pneumonia), 26.14% for wheezing and 6.25% for persistent cough. Adjusted odds ratio (95% confidence interval) per 10 $\mu g/m^3$ increment in postnatal outdoor NO_2 concentration was for persistent cough 1.40 (1.02-1.92). We also found evidence of an association with bronchiolitis, bronchitis and persistent cough in different prenatal periods, although it was not statistically significant.
Conclusions: Our results support that exposure to outdoor NO_2 during first year increase the risk of persistent cough.
Support statement: "Instituto de Salud Carlos III" (G03/176), FIS-FEDER 03/1615, 04/1509, 04/1112, 06/1213, RCESP C03/09, the fellowship for research training FI05/01109, "Enrique Nájera 2006" prize for young researchers and Conselleria Sanitat GV 16/2009.

BUILT ENVIRONMENT AND HEALTH: ANALYSIS OF NEIGHBOURHOOD ENVIRONMENT WITHIN 5- AND 10-MINUTE WALKING DISTANCE OF THE HOME

Christopher Gidlow, *Staffordshire University, UK*
Graham Smith, *Staffordshire University, UK*
Thomas Cochrane, *Staffordshire University, UK*
Rachel Davey, *University of Canberra, Australia*
Jon Fairburn, *Staffordshire University, UK*

Background and Aims: Recent research has highlighted the potential importance of the individual-neighbourhood interaction in determining population health and physical activity. Environment has often been considered on a relatively large scale, but there is increasing interest in the influence of 'neighbourhood' environment. This is often defined as the area within walking distance of people's homes, but inconsistency in how this is defined (Smith et al. 2010) has implications for environmental measurement and possible relationships with health.
Methods: A representative random adult sample from 10 neighbourhoods in Stoke-on-Trent, UK, participated in a computer-assisted personal interview, including health (SF12) and physical activity (IPAQ) outcomes. Geographical Information Systems were used to: geocode participants' homes and create two network buffers around each to represent 5- and 10-minute walking distances (400m and 800m respectively): create individual-level environmental indices for each participant (e.g., connectivity; land use mix; transport; traffic; safety and crime) for each buffer size. Multiple linear regression and multi-level analysis will be used to examine the effects of using the different neighbourhood definitions on relationships between health and neighbourhood environment.
Results: Productive interviews were obtained from 761 adults (49% response; 16+ years; 55% women). Most were overweight (65%), of low educational attainment (72%), and on modest income, consistent with much of the city. Self-reported health data were comparable with available normative data for England and were linked to perceived environment (Gidlow et al. 2010). Proposed analysis will explore the relative importance of individual-level environmental indices that capture GIS-defined environment indictors within 5- and 10-minute walking distances of individuals' homes.
Conclusions: Findings from novel analyses exploring differences in the relationships with health of a range of environmental indicators calculated using two commonly used neighbourhood definitions will be presented.

Background and Aims: This study is part of the Projet Tri-national Trafic, Air, Bruit et Santé (TRITABS), a tri-national study on traffic-related air pollution, noise and cardiovascular health. Disentangling cardiovascular effects of road traffic noise and air pollution require city-specific analyses, as their spatial distribution varies between cities. Moreover, traffic-specific air pollution and noise exposure models use similar traffic and land-use predictors, which may impede identification of the true relationship between the two. Our primary aim is to compare and contrast the spatial characteristics of traffic related air pollution and noise in Basel (CH), Grenoble (FR) and Girona (ES). This paper focuses on the spatial distribution of measured road traffic noise and particle number concentration (PN) in Basel.
Methods: Synchronized 15-minute measurements are being conducted at 60 locations in Basel for traffic volume, road traffic noise and PN. Measurements are done during non-rush traffic hours (9:30-16:00h) and repeated at least once at each of the locations. PN are measured using a miniDiSC (miniature diffusion size classifier), a portable device measuring nanometer sized (10-300nm) particles. Traffic-related noise is measured using a class 1 sound level meter, Pulsar 30. Detailed records of all non-traffic events during the measurements are made and excluded in the subsequent analysis.
Results: Mean PN and road traffic noise levels (as LAeq) are 24,180±13,949 particle/cm^3 (range, 5,232-51,387) and 57.2±8.6 dBA (range, 43.3-71.6) respectively. The observed PN-noise correlation is 0.73. Comparison of these short-term measurements to existing noise maps and concurrent weekly PN levels in Basel is underway. Local determinants of the spatial correlations will be further investigated, and compared within and across Basel, Girona and Grenoble.
Conclusions: Our first results show a high correlation between measured PN levels and road traffic noise in Basel, however, the validity of the same for longer time-windows is yet to be investigated.

METAL-RICH PARTICULATE MATTER INFLUENCE EPSTEIN-BARR VIRUS METHYLATION IN PERIPHERAL BLOOD LEUKOCYTES.

Background and Aims: Epstein-Barr virus (EBV), after primary infection, persists in most individuals as a lifelong asymptomatic infection of B-lymphocytes. The expression of latent viral oncogenes is under epigenetic control by DNA methylation. DNA methylation inhibits expression of viral latency proteins which are recognized by cytotoxic T cells. We aimed at evaluating effects of PM exposure on EBV DNA methylation in workers in an electric furnace steel plant with well-characterized exposure to metal-rich particulate matter.
Methods: We measured EBV DNA methylation content (in Wp promoter) through bisulfite PCR Pyrosequencing on EBV-positive, leukocytes DNA obtained from 48 workers on the first day of a work week (baseline, after 2 days off work) and after 3 days of work (post-exposure). We determined individual exposure to inhalable particles and metals for all subjects. Paired t-test was used to compare baseline and post-exposure samples. Linear mixed models were fitted to evaluate the association between metal-rich particle exposure and EBV DNA methylation.
Results: Our date showed a change between EBV methylation measured at the baseline and at the post-exposure (difference postexposure-baseline=-9.5%, p-value=0.009). Multivariable mixed models adjusted for age, body mass index and smoking, Nickel, Arsenic and Lead had a positive association with EBV methylation (Nickel: • =16.16, p-value<0.001; Arsenic: • =13.0, p-value=0.02; Lead: • =16.53, p-value<0.001).
Conclusions: The difference observed comparing baseline and post-exposure samples may be suggestive of a rapid change in EBV methylation induced by air particles, while correlation between EBV methylation and metal exposure may represent an adaptive mechanism. These results, however, should be further characterized in future investigations on the effects air particles.

Background and aims: Human exposure to chemicals through multiple pathways is classically estimated by the so-called 'multimedia models', calculating the distribution of contaminants among products of interest for humans (like drinking water, inhaled air, vegetables, meat, milk, etc). Combined to data describing human behavior (diet composition, time spent outside, etc), such multimedia models provide an estimation of the daily quantity inhaled or ingested by the population of interest. Once the exposure scenario is identified, the dose-response assessment is typically achieved by comparing exposure outputs (*e.g*, the daily intake) to reference doses, estimated from toxicological data. Coupling multi-media models for different exposure pathways with a generic physiologically based pharmacokinetic (PBPK) model for the human population enables to assess directly the impact of the exposure scenarios on the chemical's concentration in the target tissues.
Methods: One aim of the European 2-FUN project (Full-chain and UNcertainty Approaches for Assessing Health Risks in FUture ENvironmental Scenarios) was to develop an integrated 'multimedia-PBPK' toolbox that also incorporates uncertainty and inter-individual variability analyses and different kinds of sensitivity analysis.
Results: In the present study, an integrated modeling approach was demonstrated for predicting internal tissue concentrations of chemicals by coupling a multimedia environmental model and a PBPK model. A case study was designed for a region situated on the Seine river watershed, downstream of the Paris megacity and for some chemicals (for example benzo(a)pyrene or lead) emitted from industrial zones in the region. In order to take into account the parametric uncertainty in the model inputs, some input parameters relevant for the multimedia model were given by probability density functions (PDFs); some generic PDFs were updated with site-specific measurements by a Bayesian approach.
Conclusions: This case study demonstrated the feasibility of a full-chain assessment combining multimedia environmental predictions and PBPK modeling, including uncertainty analysis.

Manuel Haro, *Guàrdia Urbana de Barcelona, Spain*
Mercè Navarro, *Àrea de Prevenció, Seguretat i Mobilitat de l'Ajuntament de Barcelona, Spain.*

Background and Aims: In Barcelona, 5 areas with a speed limit of 30 km/h were implemented in 2007 and further more up to 300km in 2009. This paper aims to assess the effectiveness of 30 km/h zones in reducing the number of people injured in a road traffic collision in the city of Barcelona. Preliminary analysis of the first 5 areas is presented in this abstract.
Methods: A pre-post evaluation study was performed using an interrupted time-series design with comparison groups. The study population include people injured in a road traffic crash in Barcelona from January 2002 to March 2010 obtained from the Crash Register of the Local Police. The intervention were zones with a 30k/h speed limit implemented in 2007 and the comparison group the adjacent zones to the intervention areas. Quasi-Poisson regression models were fitted adjusting for time trend and seasonality. Relative risks (RR) and their 95% confidence intervals (95% CI) were derived from the adjusted models which indicate the change in the mean number of injured during the post-intervention period compared to the pre-intervention period.
Results: The speed zones implemented in 2007 showed a change in the time trend of injured, from a stable to a significant 12.2% annual decrease. After adjusting for time trend and seasonality, the overall monthly average number of injured in 2009 was significantly lower than that in the pre-intervention period (-28.6%, 95%CI: -43.9%, - 8,9%), as well as for two-wheel users injured (-40.5%, 95%CI: -56.9%, -19.0%) and for the number of injured at intersections (-4.8%, 95%CI: -56.1%, -3.2%). In the adjacent areas there was no significant change.
Conclusions: The implementation of 30 km/h speed zones in 2007 has had a significant impact in reducing the number of people injured in a traffic crash. Data of the overall zones evaluation will be presented.

THE EFFECT OF A SMOKING BAN INTRODUCTION TO ENVIRONMENTAL TOBACCO SMOKE EXPOSURE IN SWISS HOSPITALITY WORKERS

Sarah Rajkumar, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland*
Cong Khanh Huynh, *Institue for Work and Health, Lausanne, Switzerland*
Georg Bauer, *Institute of Social and Preventive Medicine, University of Zürich and Center for Organizational and Occupational Sciences, ETH Zurich, Switzerland*
Martin Röösli, *Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland*

Background and Aims: To protect the population from environmental tobacco smoke (ETS) Switzerland introduced a nationwide rather heterogeneous smoking ban in May 2010. The exposure situation of non-smoking hospitality workers before and after implementation of the new law is being assessed in a prospective cohort study.
Methods: Exposure to ETS was measured using a novel method developed by the Institute for Work and Health in Lausanne. It is a passive sampler called MoNIC (Monitor of NICotine). The nicotine of the ETS is fixed onto a filter and transformed into salt of not volatile nicotine. Subsequently the number of passively smoked cigarettes is calculated. Badges were placed at the workplace as well as distributed to the participants for personal measuring. Additionally a salivary sample was taken to determine nicotine concentration.
Results: At baseline Spearman's correlation between workplace and personal badge was 0.47. The average cigarette equivalents per day at the workplace obtained by badge significantly dropped from 5.1 (95%- CI: 2.4 to 7.9) at baseline to 0.3 (0.2 to 0.4) at first follow-up (n=29) three months later ($p<0.001$). For personal badges the number of passively smoked cigarettes declined from 1.5 (2.7 to 0.4) per day to 0.5 (0.3 to 0.8) (n=16).Salivary nicotine concentration in a subset of 13 participants who had worked on the day prior to the examination was 2.63 ng/ml before and 1.53 ng/ml after the ban ($p=0.04$). Spearman's correlation of salivary nicotine was 0.56 with workplace badge and 0.79 with personal badge concentrations.
Conclusions: Workplace measurements clearly reflect the smoking regulation in a venue. The MoNIC badge proves to be a sensitive measuring device to determine personal ETS exposure and it is a demonstrative measure for communication with lay audiences and study participants as the number of passively smoked cigarettes is an easily conceivable result.

DIFFERENCE IN PERSONAL EXPOSURE TO PARTICULATE AIR POLLUTANTS IN USERS OF DIFFERENT TRANSPORT MODES (AUTOMOBILE, BUS, SUBWAY AND BICYCLE) IN SANTIAGO, CHILE: STUDY DESIGN

Pablo Ruiz, *School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile*
Dante Cáceres, *School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile*
Verónica Iglesias, *School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile*
Paulina Pino, *School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile*
Stephanie Mesías, *School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile*

Background and Aims: Daily, people can be exposed to high levels of air pollutants during their home-work trips because of their closer proximity to traffic emissions and their exposures may vary according to the mode of transport used (bus, automobile, subway and bicycle). Little is known about exposure to air pollutants in transport´s users in Chile, and even less is known regarding difference in exposure by transport mode. Here, we present a study that compares air pollutant exposures in users of different modes of transport in Santiago, Chile.
Methods: (Arial, 8pt, bold) We will conduct a first, observational cross-sectional study of personal exposure to air pollutants in users of different modes of transport in their normal routes. 68 volunteer subjects that have similar home-work routes will be recruited, allocating about 17 subject to each mode (bus, automobile, subway and bicycle). Each participant will perform its morning and evening trips as usual except that they will carry personal monitors to measure particulate air pollutants PM2.5 and ultrafine particles. Additionally, both PM fractions will be measured at a central site in order to separate the contribution of the transport microenvironment from the background. This study will be complemented with a second cross-sectional study where exposure in the different modes will be evaluated in an assigned route (Alameda Street in downtown Santiago) during morning trips. Data will be analyzed using regression models to compare the modes, and determine the effects of environmental factors such as temperature, meteorology, traffic density, and so on, on personal exposure levels.
Results: Some preliminary results are expected by the time of the conference.
Conclusions: identification of environmental factors that determine increases in pollutant's exposure may guide actions aimed to reduce people's exposure to air pollutants during their home-work trip.

EFFECTS OF METAL-RICH PARTICULATE MATTER EXPOSURE ON EXOSOME-ASSOCIATED MICRORNAS.

Background and Aims: Epidemiological studies have reported an increased risk for cardiovascular disease (CVD) in relation to exposure to metal-rich particulate matter. Cell-derived membrane vesicles (exosomes) are released in plasma and transfer microRNAs. Exosomes might mediate the effects of air pollution, since potentially they could be produced by the respiratory system, reach the systemic circulation and lead to the development of CVD. The aim of the present study was to identify effects of exposure to metal-rich particulate matter on exosomes-associated microRNAs expression in workers of an electric furnace steel plant with well characterized exposure.
Methods: Plasma exosomes were isolated by ultracentrifuge from 55 steel workers on the first day of a workweek (baseline) and after three days of work (post-exposure). We measured the expression of the 88 most abundantly expressed and best characterized micro RNA sequences by SYBR green chemistry. The relative expression of miRNAs was measured by real-time PCR using SNORD48, SNORD47, SNORD44 and RNU6-2 as endogenous controls. Relative quantification of miRNA expression was calculated using the $2^{-\Delta Ct}$ method. Paired t-tests were used to compare baseline and post-exposure samples.
Results: Expression profiling of 88 human miRNAs extracted from baseline and paired post-exposure blood samples identified 6 miRNAs which showed significant differential expression between the two samples. Among the most notable changes were miR-302c and miR-128 which were up-regulated by 13.9- and 5.6-fold respectively ($p<0.001$), and miR-28-3p and let-7g which were up-regulated by 3.6- and 2.26-fold ($p=0.01$), miR-125a-5p and miR-181a that were up-regulated 3- and 1.7-fold ($p<0.02$).
Conclusion: These results propose a new role for exosomes in mediating the effects of air pollution exposure on CVD risk. Our findings, if confirmed, could lead to the identification of potentially reversible alterations that might be also considered as potential target for new diagnostic and therapeutic interventions.

Occupational activities and a reported history of Malaria among women working in small-scale agriculture in South Africa

Naidoo S, MBChB,[1] London L, MD,[2] Burdorf A, PhD,[3] Naidoo R, PhD,[1] Kromhout H, PhD [4]

[1] Department of Occupational and Environmental Health, School of Family and Public Health Medicine, Nelson R Mandela, School of Medicine, University of KwaZulu-Natal, Congella, South Africa
[2] Occupational and Environmental Health Research Unit, Department of Public Health, University of Cape Town, Cape Town, South Africa
[3] Department of Public Health, Erasmus MC, University Medical Centre, Rotterdam, the Netherlands
[4] Institute for Risk Assessment Sciences, Environmental Epidemiology Division, Utrecht University, Utrecht, the Netherlands

Background and Aims: Malaria remains a persistent and major public health challenge in the developing world despite improvements in malaria control methods. Agricultural communities in malaria endemic regions may be at high risk for disease transmission with crop production and agricultural activities being associated with increased disease transmission. A better understanding of this association and particular risk activities and crop types can assist malaria control interventions.

Methods: A cross-sectional study using a questionnaire survey, compared a self-reported history of malaria among women (n=911) working in small-scale agriculture on the Irrigation Scheme and Drylands of the Makhatini Flats of northern KwaZulu-Natal South Africa. Associations between demographics, crop production and agricultural activities and a history of having malaria while working in agriculture were explored.

Results: Approximately 15% (n= 98) of 644 women reported malaria while working in agriculture with more Dryland as compared to Irrigation Scheme women reporting disease (18.4 % vs. 10.9%; $p<0.05$). Working on a self-owned or family owned farm (PR: 2.6; 95% CI: 1.3-5.2), spraying pesticides (PR: 2.3; 95% CI: 1.4-3.8), cultivating sugar cane (PR: 1.6; 95% CI: 1.1-2.3), cotton and mangoes (PR: 1.7; 95% CI: 1.1-2.6) were significantly associated with a history of having malaria when working in agriculture.

Conclusion: Agricultural work in general, and specific work tasks and crops appear to increase the risk of malaria infection in endemic areas. Future interventions by the SA Malaria Control Programme should

include educating rural populations on how to protect themselves during certain agricultural activities which could result in increased malaria transmission.

IN-UTERO EXPOSURE TO DIOXINS AND DIOXIN-LIKE COMPOUNDS AND ANOGENITAL DISTANCE IN NEWBORNS OF THE RHEA STUDY IN CRETE

Background and Aims: Maternal exposure to dioxins and dioxin-like compounds has been related to adverse health outcomes in infants (Halldorsson et al 2009). The toxicity of these compounds is mostly traced to their blocking of the aryl hydrocarbon receptor (AhR) in part by modulating estrogen and androgen signaling (Carlson et al 2002). In animals, anogenital distance is used as a measure of fetal androgen action, tracks through life and varies by dose of antiandrogen (Longnecker et al2007). Although anogenital distance is scarcely used in human studies, results show that prenatal phthalate exposure decreases male anogenital distance (Swan et al 2005). We evaluated the association between *in-utero* exposure to dioxins and dioxin like compounds, using the DR-Calux bioassay and anogenital distance in newborns of the Rhea birth cohort in Crete.
Methods: Anogenital distance (AGD: anus to upper penis), anoscrotal distance (ASD: anus to scrotum) and penis width (PW) were measured in 64 boys. Anoclitoral (ACD: anus to clitoris) and anofourchetal distance (AFD: anus to fourchette) were measured in 62 girls. Ratios of anogenital distances divided by body weight were calculated. Maternal blood samples were collected at delivery and dioxin-like activity was measured in plasma using the DR-CALUX bioassay.
Results: Anogenital distances were wider in males (mean AGD= 50,46mm) than females (mean ACD=35,03mm). Plasma dioxin-like activity was negatively associated with AGD in males. The estimated change in AGD per 10 pg CALUX-TEQ/g lipid increase was -1.12mm (95%CI:-2.12,-0.12) and -0.39 mm/kg for the AGD weight ratio (95%CI:-0.74,-0.05) after adjusting for potential confounders. Negative but not statistically significant associations were observed for ASD and PW; no associations were found for ACD or AFD in females.
Conclusions: Male infants may be susceptible to endocrine-disrupting effects of dioxins. This is the first study that appears to replicate in humans, experimental animal evidence used by WHO/FAO for setting recommendations on human dioxin intake.

EFFECT OF THE NUMBER OF MEASUREMENT SITES ON LAND USE REGRESSION (LUR) MODELS OF AIR POLLUTANTS

Xavier Basagaña, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
David Agis, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Inma Aguilera, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Marcela Rivera, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Maria Foraster, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Audrey de Nazelle, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Nino Künzli, *Swiss Tropical and Public Health Institute Basel, Switzerland*

Background and Aims: Land use regression (LUR) models used in epidemiologic studies on air pollution usually rely on air pollution measurements at a few locations across a city. The number of locations commonly varies from 20 to 100. Our aim is to explore the effect of the number of locations (N) on LUR model performance.
Methods: The REGICOR-AIR study measured NO_2 in 159 locations in the two adjacent cities of Girona and Salt (Spain). A total of 102 potential predictors like traffic, road type and land cover entered a supervised forward selection procedure to derive the final model. Training datasets of 20, 50, 80, 110 and 140 points were obtained by randomly sampling the original dataset. The remaining points were used as validation datasets. The process was repeated 200 times for each N. Adjusted R^2 (R^2a) and leave-one-out cross-validation R^2 (R^2cv) were calculated in the training datasets, and validation R^2 was obtained from the validation datasets. The median value over the 200 iterations was reported.
Results: With 20 points, the median R^2a and R^2cv were 79% and 71% but the validation R^2 was negative, indicating that the regression equation resulted in a worse prediction than assigning the overall mean to each point of the validation sample. Both R^2a and R^2cv decreased with increasing N to reach R^2a=54% and R^2cv=52% for N=140. Conversely, the validation R^2 increased with increasing N, from negative values (N=20) to 44% (N=140). The most frequent predictive variable entered in only 32% of the models for N=20, while for N=140 four variables appeared in more than 90% of the final models.
Conclusions: Increasing the number of measurement points increases both the predictability and the stability of the models. Leave-one-out cross-validation R^2 overestimates the predictive ability of the model. This bias is more important at small sample sizes.

DETERMINANTS OF NONADHERENCE TO COMMUNITY-DIRECTED IVRMECTIN TREATMENT FOR ONCHOCERCIASIS CONTROL IN MANNA DISTRICT OF JIMMA ZONE, OROMIYA REGION, SOUTHWEST ETHIOPIA

Wondwossen Birke Eshete, *Jimma University, Ethiopia*
Bishaw Deboch, *Jimma University, Ethiopia*
Benyam Negesse, *Jimma Teachers Training College, Ethiopia*

Background and Aims: Though a few empirical studies from endemic regions identified some determinants of nonadherence to ivermectin treatment for onchocerciasis control, no attempt was made in Ethiopia in general and Mana district in particular. The present study assessed the demographic, host behaviours, social and service related factors of why some people adhere and others not in Mana district of Jimma zone, southwest Ethiopia.
Methods: Community based unmatched case-control study was conducted. 552 (185 cases and 367 controls) eligible individuals who were registered to take ivermectin annually from 2004-2008 in 7 randomly selected Kebeles out of 25 and chosen based on lottery method through multistage sampling technique constituted the study population. Data were collected using a pre-tested structured questionnaire and interview guide, entered into a computer, edited and analysed using SPSS version 16.0. Stepwise logistic regression model was used to calculate the Odds ratios and 95% confidence interval for the different risk factors.
Results: Out of 552 sampled individuals, 536 participated in the study giving a response rate of 97.1%. Therapeutic coverage and individual adherence rate were found to be 78.2% and 59.7%, respectively. In the bivariate analysis, except the socio-demographic variables (P>0.05), ten of the host behaviours, social and service related variables were statistically significant associations with nonadherence. However, only six factors such as unsatisfactory knowledge of disease signs and symptoms, lack of participation in distributor selection (P< 0.05), and lower perceived risk of acquiring the disease, believing height not to be the best dose determination, perceiving distributor performance as poor or very poor, and family not being supportive toward taking ivermectin, were the only significant variables on multivariate analyses (<0.001).
Conclusions: As some host behaviour, social and service related factors influenced individual nonadherence, appropriate intervention programs targeting health education, community participation and empowerment should be designed.

USE OF FINGERSTICK BLOOD COLLECTION FOR THE MEASUREMENT OF BLOOD ARSENIC

Christine Marie George, *Columbia University, New York, New York, USA*

Background and Aims: In Bangladesh millions of people are exposed to naturally occurring arsenic concentrations exceeding the World Health Organization's standard of 10 µg/L (Ahmed et al 2006). Recently a method has been developed to measure blood arsenic concentrations. Blood arsenic (BA) has the advantage of not needing to be normalized for creatinine. It also represents an internal dose, and in the case of chronic steady state exposure blood arsenic has the potential to serve as a biomarker of past exposure. A previous study conducted in Araihazar, Bangladesh has demonstrated that blood arsenic is strongly correlated with both water arsenic (r=0.76) and urinary arsenic adjusted for creatinine (r=0.85) (Hall et al. 2006). However in Bangladesh because of their cultural perceptions of blood, people often feel extremely uncomfortable giving blood by venipuncture.

Methods: In this study we employed fingerstick blood sampling, commonly used in the United States for screening blood lead levels in children, for the measurement of blood arsenic in 10 study participants. Collecting blood by fingerstick requires less blood then traditionally used venipuncture measurements. In this study, the precision of venous and capillary blood collection methods for measuring blood arsenic were compared. Whole blood samples were analyzed for arsenic using Inductively Coupled Plasma Mass Spectrometry (ICP-MS).

Results: Arsenic measured by venous and fingerstick sampling methods were found to be highly correlated (r=0.97) with a mean difference between fingerstick and venous methods of 1 µg/L.

Conclusions: Fingerstick blood collection is an acceptable alternative to venipunture for measuring blood arsenic concentrations. Blood arsenic is a useful biomarker of arsenic exposure that has the potential to help better understand the mechanisms behind arsenic toxicity. The fingerstick method of blood collection allows for this biomarker to be used in Bangladeshi populations that for cultural reasons prefer not to provide venous blood samples.

Background and Aims: Previous research suggests that chronic low-level lead exposure is associated with impaired cognition, but little research has considered this association in women. We examined this association in expanded repeated outcome assessment data in a subset of participants in the Nurses' Health Study.
Methods: We measured lead concentrations in blood, indicating recent exposure, and patella and tibia bone, indicating chronic exposure. Women completed up to four cognitive assessments. Cognitive test scores were z-transformed. We used linear mixed models to evaluate the test-specific and global association between cognition and each lead biomarker.
Results: 584 women who were, on average, 61 (SD: 6) years old at lead measurements (mean (SD) in blood: 2.9 (1.9) µg/dL, patella: 12.6 (11.7) µg/g bone, tibia: 10.5 (9.7) µg/g bone) completed at least one cognitive assessment (average: 2.1 assessments, 3.0 years apart). In our global analysis, for each SD increase in tibia bone lead concentration, we observed a 0.044 SD lower cognitive test score (95% CI: -0.088, 0.001), an effect similar to a difference of 3 years of age. Associations were weaker for patella and blood lead concentrations. Previous work with more limited data suggested a positive association between lead exposure and performance on the letter fluency task; this suggestion did not persist in the expanded data. Preliminary evaluation of the association between lead and change in cognitive function did not suggest an association.
Conclusions: In expanded data, we confirmed previous findings that lead is related to level of cognitive function in women. Our analysis suggests the previous finding that higher lead was associated with better performance on the letter fluency task was spurious. Although we did not see an association between lead and change in cognitive function, these preliminary analyses are limited by short duration of follow-up, learning effects, and our participants' good health.

The Mobil phone use and the early childhood neurodevelopment

Ching-Chun Lin , *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University College of Public Health, Taipei, Taiwan*

Department of Public Health, National Taiwan University College of Public Health, Taipei, Taiwan;

Department of Environmental and Occupational Medicine, National Taiwan University College of Medicine and Hospital, Taipei, Taiwan

Background and Aims: The effect of exposure to the RF-EMF of mobile phone still not inconsistent and need to be investigates. Our study is to explore the association between the prenatal and postnatal exposure of mobile phone use and early childhood neurodevelopment.

Methods: Our study recruited 192 children in Taiwan. All study subjects were evaluated by Movement Assessment Battery for Children (Movement ABC) at five years old and their parents also completed mobile phone use questionnaires. Multiple linear regression models were employed to assess the potential effects of the mobile phone exposure of three trimesters of pregnancy and at postnatal ages up to 60 months old on the Movement ABC score after adjusted for maternal nationality, educational level, family income, and child sex.

Results: There were borderline significantly lower (worse) scores in manual dexterity in children of frequent mobile phone users during the preconception period, second trimester and the age of children before 12 months. However, there were significantly higher (better) scores in balance in children of headsets users during the preconception period, pregnancy and the age of children up to 60 months.

Conclusions: The exposure of mobile phone may be associated with the early childhood neurodevelopment. Further research is needed to elucidate the causal relationship.

TRADITIONAL USE OF MOSQUITO REPELLENT PLANTS AND TESTING THEIR REPELLENCY IN FIELD TRIALS AROUND GILGELGIBE RESEARCH CENTRE, JIMMA ZONE, SOUTHWEST ETHIOPIA

Wondwossen Birke Eshete, *Jimma University, Ethiopia*
Dante Santiago, *Jimma University, Ethiopia*
Getinet Fetene, *Jimma Teachers Training College, Ethiopia*

Background and Aims: Although local plants as mosquito repellents are known and used among the different cultures of Africa and beyond, little effort is done to document about the knowledge, usage pattern and their repellency potential in Ethiopia in general and specifically around Gilgelgibe Field Research Centre, Jimma Zone, Southwest Ethiopia. This study was aimed to assess the ethno botanical knowledge and usage custom of traditional mosquito repellent plants among the inhabitants of Gilgelgibe Field Research Centre, and evaluating the mean percentage repellency of candidate plants.
Methods: Community based cross-sectional quantitative study and pilot field repellency test using candidate five potted mosquito repellent plants was conducted from January 19 to April 10, 2010. The total sample consisted of 417 households for quantitative study. Data were collected using a pre-tested interviewer administered structured questionnaire and by vector collectors for field test. The quantitative data were cleaned, edited and entered into SPSS version 16.0 and analyzed. Repellency of plants to mosquitoes was evaluated by using mean percentage repellency.
Results: The study identified eleven species of mosquito repellent plants. Besides, 85.9% and 73.14% of the respondents had knowledge and usage practice of mosquito repellent plants, respectively. The mean percentage repellency of Lantana camara, Cymbopogen citrates, Ocimum sanctum, Chrysanthemum cinerariaefolium and Tagetes minuta to all mosquitoes were found to be 57.0%, 56.0%, 50.7%, 46.7% and 37.0%, respectively.
Conclusions: Mosquito repellent plants are widely known and used among the inhabitants of the study area. Field evaluation on the repellent activity of plants showed that repellent plants reduced natural population of mosquitoes significantly as compared to the control house, showing repellency on the range of 37-57%. This study, therefore, provides valuable information to all stakeholders who are involved in mosquito born disease control, particularly for malaria vector control.

INVESTIGATION OF DYSENTERY OUTBREAK AND ITS CAUSES, JIMMA CITY, SOUTHWEST ETHIOPIA

Wondwossen Birke Eshete, *Jimma University, Ethiopia*
Fessehaye Alemseged, *Jimma University, Ethiopia*
Alemshet Yami, *Jimma University, Ethiopia*
Zewdineh S/Mariam, *Jimma University, Ethiopia*
Kenate Worku, *Jimma University, Ethiopia*

Background and Aims: Although bloody dysentery commonly caused by Shigella is wide spread globally and occurs in outbreaks, epidemiological studies regarding shigellosis are rare in Ethiopia in general and none for Jimma City. Investigation team aimed to confirm, control and prevent further spread of suspected dysentery epidemic was formed after several cases visited Jimma University Specialized Hospital and private clinics in the city on 12th December 2008.
Methods: A data collection format containing address, demographic variables, risk factors and laboratory findings was prepared and distributed to all health facilities in Jimma City. Stool samples were collected from suspected cases and cultured to identify the causative organism and determine its antimicrobial susceptibility. Inspection of facilities and collection of water samples for bacteriological analyses was done from suspected sources. Data was analyzed using SPSS version 16 and results were presented in tables and figures.
Results: A total of 566 cases were seen in different health facilities in Jimma City in a period 29 days. Out of this, 299 (52.8%) were Jimma University students and 56 (11.7%) were residents of Jimma. Shigella flexinneri was identified from some of the stool specimens and was sensitive to most antimicrobial agents. There was a sudden increase in the number of cases starting from December 9, 2008 with a peak (161 cases) on December 12, 2008. The epidemic curve then fell down slowly with one small peak during the decline. 344 (60.8%) of the cases reported that they had consumed food prepared by Mars food factory located in the town.
Conclusions: There was dysentery epidemic from December 12-22, 2008 due to Shigella flexinneri most likely caused by food contamination at Mars food factory. To prevent future occurrence, regular health education and screening of food handlers with strong supervision of food establishments should be undertaken.

LEAD LEVELS IN TEETH AS A MEASURE OF LIFE-TIME LEAD EXPOSURE IN CHILDREN

Charuwan Manmee[1], Susan Hodgson[1], Wendy Dirks[2], Thomas Shepherd[3] and Tanja Pless-Mulloli[1]
[1]Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom; [2]Oral Biology, School of Dental Sciences, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]School of Earth and Environment, University of Leeds, Leeds, United Kingdom

Background and Aims: Lead exposure has irreversible health effects in children who are susceptible even at very low levels of exposure. The usual test for lead exposure is blood lead level (BLL), but this indicates only recent exposure. This study aimed to develop a method to assess the use of tooth lead levels as a histological marker to reveal the history of lead exposure during the child's life-time. We will ascertain whether milk teeth are suitable biomarkers of lead exposure.
Methods: Two deciduous molars each were collected from 15 children aged 6-8 years living in Northeast England. Using histological sections, the distribution of lead in different growth layers was quantified by Laser Ablation Inductively Coupled Plasma Mass Spectrometry (LA-ICP-MS). BLLs were measured using ICP-MS. Calcium normalised lead ratios ($^{208}Pb:^{44}Ca$) were measured as lead body burden. For each tooth surface, five ablation transects (minimum 10 points/line) were sampled. Incremental growth lines in enamel and dentine were used to determine the ages and time interval of exposure at each point. The data were grouped into age intervals of 42 days, based on the mean time interval sampled. Lead intensities were plotted for each interval along each transect.
Results: BLLs ranged from 0.5-6.8μg/dl, none of the children had a BLL above the WHO threshold (10μg/dl). Lead ratios vary across individual teeth. Comparatively low intensities were observed in enamel, higher ratios were found around the dentine close to the pulp cavity. In the initial four teeth examined, $^{208}Pb:^{44}Ca(x10^{7})$ in primary dentine ranged from 1.65-95.96 (median=4.45), Standard sigma errors ranged from 0.15-13.88 (median=2.08).
Conclusions: Preliminary results indicate that lead ratios in primary dentine are consistent between teeth from the same child, and at the same age within each tooth, indicating that the history of exposure may be determined using one ablation transect in primary dentine.

TRANSPORTATION, AIR POLLUTION AND PHYSICAL ACTIVITY: INTEGRATED HEALTH IMPACT ASSESSMENT OF THE BIKE SHARING SYSTEM "BICING" IN BARCELONA, SPAIN

David Rojas-Rueda, *Center for Research in Environmental Epidemiology (CREAL), C. Doctor Aiguader, 88, 08003 Barcelona, Spain.*
Audrey de Nazelle, *Researcher, Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain.*

Mark Nieuwenhuijsen, *Research Professor, Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain.*

Background and Aims: Motorized transport is associated with negative impacts on health and the environment. Active travel is promoted as an alternative to mitigate such impacts and increase physical activity rates in the population. We assessed health impacts of `Bicing´´, the bike sharing system implemented in Barcelona, Spain, in 2006.
Methods: We constructed a model to quantify the health risk and benefits in terms of all-cause mortality associated with traveling by Bicing compared to the car for three main domains, physical activity, air pollution and traffic accidents. Travel and safety information was obtained from institutions and agencies of local and regional government. We used dose-response functions obtained from a review of the scientific literature. We performed uncertainty and sensitivity analyses. We also conduct an economic evaluation of mortality, and quantification of CO2 emissions.
Results: The estimated annual excess mortality in the population of regular Bicing users assumed to have shifted from car travel (n=25,426) was 0.03 deaths from traffic accidents, 0.15 deaths from PM2.5 and 0.05 deaths from black smoke exposure, while 14.25 deaths were avoided due to physical activity (Benefit: risk ratio =79). The total annual number of deaths avoided was therefore 14.05 deaths, resulting in 21,088,385 million € saved per year. This represented an economic benefit greater than the initial Bicing investment and annual maintenance costs. We estimated a reduction of 9,062,344 kilograms of CO2 as a result of Bicing journeys each year.
Conclusions: The results presented demonstrate the potential health benefits of infrastructure dedicated to encouraging active commuting. In particular, short trips within the city by bicycle have benefits not only in health, but also represent a cost savings and reduced emissions of greenhouse gases.

GROWING SOCIAL AND GEOGRAPHIC INEQUALITIES IN ALL-CAUSE MORTALITY, JAPAN, 1970 to 2005

Etsuji Suzuki, *Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan*
Saori Kashima, *Hiroshima University Graduate School of Biomedical Sciences, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan*
Ichiro Kawachi, *Harvard School of Public Health, USA*
S V Subramanian, *Harvard School of Public Health, USA*

Background and Aims: While Japan has the lowest mortality in developed world, the magnitude and patterning of health inequalities remains less understood. We examined trends in social and geographic inequalities of all-cause mortality from 1970 through 2005.
Methods: We used the Vital Statistics and the Census data among those aged 25 or older and less than 65. For each sex, we estimated odds ratios (ORs) and 95% confidence intervals (CIs) for mortality by using multilevel logistic regression models with "cells" (cross-tabulated by age and occupation) at level 1, eight survey year at level 2, and 47 prefectures at level 3.
Results: Adjusting for age and survey year, compared with production process and related workers, ORs ranged from 0.97 (95% CI: 0.96-0.98) among administrative and managerial workers to 2.22 (95% CI: 2.19-2.24) among service workers in men. By contrast, in women, the lowest odds for mortality was observed among production process and related workers (reference) while the highest OR was 12.22 (95% CI: 11.40-13.10) among security workers. The degree of social inequality appeared to increase since 1970 in both sexes; ratios of the highest OR divided by the lowest OR for men were 2.48 and 3.97 in 1970 and 2005, respectively, and the corresponding ratios for women were 11.43 and 16.25. Conditional on individual age and occupation, overall geographic inequality of mortality were relatively small in both sexes; the ORs ranged from 0.87 (Okinawa prefecture) to 1.13 (Aomori prefecture) for men and from 0.84 (Kanagawa prefecture) to 1.11 (Kagoshima prefecture) for women. Although overall geographic inequalities of mortality were relatively small, we found growing inequalities in mortality across prefectures since 1995 in both sexes.
Conclusions: The present findings demonstrate that both social and geographic inequalities in all-cause mortality have increased recently in Japan.

ASSOCIATION BETWEEN OCCUPATIONAL NOISE EXPOSURE, BEHAVIORAL FACTORS, AND TOTAL CARDIOVASCULAR RISK

Jana Jurkovicova, *Comenius University Bratislava, Slovakia*
Zuzana Stefanikova, *Comenius University Bratislava, Slovakia*
Lubica Argalasova-Sobotova, *Comenius University Bratislava, Slovakia*
Ludmila Sevcikova, *Comenius University Bratislava, Slovakia*

Background and Aims: Noisy occupational environment presents an increasing hazard to health. Its effects are insidious in development, particularly the non-auditive effects and/or effects on cardiovascular system. Cardiovascular diseases involve multiple biomedical risk factors. Specific aspects of the occupational environment are embedded in a large, complex matrix of their influences. The aim of the study was to compare selected lifestyle characteristics, dietary habits and health determinants in relation to total cardiovascular risk in the exposed and unexposed samples.
Methods: 2,690 healthy employees (44.9% men and 55.1% women) in the mean age 41.5±9.6 years were examined for cardiovascular risk factors (serum lipid levels, blood pressure, anthropometric parameters on overweight and obesity) and completed a questionnaire on socioeconomic, demographic and behavioral factors, nutritional pattern, self-reported health status, and mental health. Relative cardiovascular risk was calculated using SCORE chart after the projection to the age of 60. 1,210 subjects (58.3% men) exposed to noise in their workplaces were compared to unexposed subjects; chi-square and multiple linear regression analysis were performed.
Results: Exposed subjects were younger (41.1 yrs vs. 41.8 yrs; NS), with lower educational level, they had higher physical (p=0.0000) and stress load (p=0.0417) at work, worse mental health score (NS), and higher relative cardiovascular risk (OR=1.80; 95%CI=1.51-2.14; p=0.0000). They reported more often exposure to second hand smoke at work as well as in privacy and self-reported poorer health status. Linear regression analysis (adjusted for age) showed positive association among SCORE60 and noise exposure (p=0.0000), physical load (NS), second hand smoke exposure (p=0.0000), smoked meats (p=0.0025) and alcoholic beverages consumption (p=0.0000), and negative association with educational level (NS), fruit (p=0.0000) and vegetable (p=0.0345) consumption.
Conclusions: Our results point out the possible combined adverse effects of noisy working conditions, wrong lifestyle and/or incorrect nutritional habits to total cardiovascular risk.

ASSOCIATIONS OF ENVIRONMENTAL MICROBIAL EXPOSURE WITH DEVELOPMENT OF ASTHMA AND ALLERGIES

Background and Aims: Studies on farms have suggested that environmental microbial exposure can decrease the risk of developing asthma and allergies. In contrast, studies in moisture damaged homes have shown adverse effects. The present aim was to try to disentangle the differing effects of different microbial species or types of microbes.
Methods: Birth cohorts of rural children, half from farmer families, were followed up in five European centers (n=1034). Associations of surface loads (amounts per m2 sampling surface) of house dust, endotoxin and extracellular polysaccharides (EPS) of Penicillium and Aspergillus spp. (with development of doctor-diagnosed asthma and wheezing by the age of 2 years were assessed using multivariate discrete-time hazard models and GEE. Within the same cohorts a nested case-controls study of current asthma at age 4 years was performed. Mattress dust samples (66 cases, 71 controls) were analyzed using denaturing gradient gel electrophoresis (DGGE) fingerprinting for bacterial community composition. Detected bands were dichotomized at level of detection.
Results: In the whole cohort, the risk of asthma was inversely associated with mainly increasing dust load on mother's mattress (aOR 0.76, 95%CI 0.64-0.90), especially among non-farmers (aOR 0.68, 95%CI 0.54-0.87). Weaker associations were observed for EPS and endotoxin. In the nested case-control study, 42 bands were detected in DGGE. Among these, there was a suggestion ($p<0.2$) for 4 bands for an inverses association and for 5 band for a positive association with asthma, out of which only one reached statistical significance (aOR 3.1, 95%CI 1.1-9.0). In contrast, 6 significant positive associations with sensitization (>0.7 kU/l) to any food allergen, but none with sensitization to any inhalation allergen were observed.
Conclusions: Present preliminary results suggest that methods for characterizing environmental microbial exposure in more detail may help to disentangle the differing effects of different microbes on development of asthma and allergies.

PESTICIDES EXPOSURE AND THE RISK OF CHILDHOOD ACUTE LEUKEMIA

Yan Zhang, *Shanghai JiaoTong University School of Medicine, China*
Yu Gao, *Shanghai JiaoTong University School of Medicine, China,*
Xiao-jin Wang, *Shanghai JiaoTong University School of Medicine, China*
Sha Zhu, *Shanghai KeyLab of Children's Environmental Health, China*
Tao Chen, *Shanghai KeyLab of Children's Environmental Health, China*
Rong Shi, *Shanghai JiaoTong University School of Medicine, China*
Ying Tian, *Shanghai JiaoTong University School of Medicine, China*

Background and Aims: Acute leukemia (AL) is one of the most common malignant tumors among children below the age of 15, and pesticide has been hypothesized as one of the risk factors for AL. In this study, the association between pesticide exposure and the risk of childhood AL is evaluated.

Methods: A total of 248 patients with newly diagnosed AL were recruited from four pediatric hospitals in Shanghai between January 1, 2006 and December 31, 2010, and 111 controls were matched with the cases based on gender and age. Pesticide exposure was determined by questionnaire and by measuring of organophosphate pesticide (OP) metabolites including Diethyl phosphrate (DEP), Dimethyl phophrate (DMP), Dimethyl thiophosphrate (DMTP), Diethyl thiophosphrate (DETP) and Diethyl dithiophosphrate (DEDTP) in the subjects' urine using gas chromatography with a flame photometric detector.

Results: Total environmental chemical exposure of children [odds ratio (OR)= 9.320, 95% confidence interval (CI):2.842-30.568], maternal chemical exposure during pre-gestation and pregnancy (OR=3.333; 95%CI:1.524-7.289), household use of pesticides (OR=1.786; 95%CI:1.128-2.830), and household use of mosquito insecticides (OR=2.225; 95%CI:1.304-3.796) increased the risk of childhood AL. Median concentrations of organophosphate metabolites (DEP, DMP, DMTP, DETP and DEDTP) in the cases (5.7296, 9.6673, 14.0634, 4.3642, 3.8472μg/gCr respectively) were significantly higher than those in the controls (1.6901, 1.6828, 0.8451, 0.7221, 0.7221μg/gCr respectively) ($P<0.05$).

Conclusions: This study found that chemical exposure and household use of pesticides, especially mosquito insecticides, might be associated with childhood AL, based on higher urine OPs levels in children with AL compared with those in the controls. Our findings add some evidence to the hypothesis that pesticides might be a risk factor for childhood AL. This association of AL risk with pesticide exposure merits further studies to confirm the association.

Nino Künzli, *Swiss Tropical and Public Health Institute, Switzerland*
Ursula Krämer, *IUF-Leibniz Institut für Umweltmedizinische Forschung, Germany*

Background and Aims: ESCAPE, the European Study of Cohorts for Air Pollution Effects, was initiated in 2008. Chronic obstructive pulmonary disease (COPD) is one of four respiratory outcomes to be investigated in five studies of adults. All studies were conducted 10-20 years ago while ESCAPE pollution models reflect current conditions. An association between COPD and particle pollution (1) was published for SALIA, one of the cohort studies included. We now investigate whether the SALIA-results found for the investigation 1985-1994 can be replicated using the newly developed PM_{10} land-use regression (LUR) models of ESCAPE instead of the former SALIA estimates.
Methods: Spirometry was performed in N=2593 women living in the Ruhr- and adjacent less polluted areas. We used GOLD criteria to define COPD (FEV_1/FVC ratio <0.7 and FEV_1 <80% of predicted). PM_{10} exposure was previously assessed by measurements from monitoring stations. In ESCAPE, PM_{10} was measured at 20 locations to derive a LUR. Logistic regression was used to determine the adjusted association between exposure and COPD. Effect-estimates were based on interquartile-ranges of exposure, thus being invariant to homogeneous linear time trends.
Results: Prevalence of COPD was 4.0%. The odds-ratio describing the association with PM_{10} using means of the 5 years before baseline was 2.63 (95% Confidence interval 1.37-5.06). Using PM_{10} from the new land use regression models the odds-ratio was 2.27 (1.61-3.19).
Conclusions: The association between COPD and particle pollution as observed in SALIA is not sensitive to the use of a more current LUR to assign exposure. The slightly different odds-ratios might be due to small deviations from simple linear trends or differences in the spatial resolution.

MEASURING PERSONAL EXPOSURE TO BLACK CARBON: THE IMPORTANCE OF BEING IN OR NEAR TRAFFIC

Evi Dons, *VITO / Hasselt University, Belgium*
Martine Van Poppel, *VITO, Belgium*
Jan Theunis, *VITO, Belgium*
Geert Wets, *Hasselt University, Belgium*
Luc Int Panis, *VITO / Hasselt University, Belgium*

Background and aims: To determine personal exposure, most epidemiological studies use proximity measures (e.g. distance of residence to a busy road) or concentrations measured by the nearest fixed AQ monitoring station; or develop land use regression models to determine the concentration at the home address. Unfortunately these exposure estimates provide only an indication of true personal exposure, since a large part of exposure during the day is not encountered outdoors at the place of residence. To improve on this, daily mobility and time-activity patterns should be taken into account, especially for air pollutants with a high temporal and spatial variability.
Methods: Real-time monitoring of personal exposure to black carbon, gives us an insight into the main drivers or activities responsible for human exposure to traffic related air pollution. The results presented here originate from two measurement campaigns monitoring weeklong personal exposure of participants using 12 portable µ-aethalometers and electronic diaries. There were 16 participants in summer 2010 and 46 participants in winter 2010-2011 resulting in over 12,000h of annotated BC measurements.
Results: In-vehicle concentrations were 5 times higher than the average concentration inside residences. Concentrations on trains, and during walking or cycling trips are lower, but still a factor of 2 higher than in the residence. Concentrations in buses were highest. For an average individual the transport microenvironment was one of the most important contributors to personal exposure: 6% of time is spent in transport but contributes over 20% of exposure. Proper transport mode or route choice, or changes to the activity pattern that reduce the total time in transport can lower exposure and will mitigate possible health effects.
Conclusions: Integrated personal exposure to black carbon is dominated by exposure in transport. Not taking into account daily mobility will thus significantly increase exposure misclassification in epidemiological studies.

CHLORINATION DISINFECTION BY-PRODUCTS AND RISK OF STILLBIRTHS AND CAUSE-SPECIFIC STILLBIRTHS IN ENGLAND AND WALES

Background and Objective: We investigated the association between still births and Trihalomethanes (THM) concentrations in tap water across a large population residing in 12 regions of England and Wales.
The study data cover the period 1993 – 2001 and include 2.79 million births with 14,265 stillbirths.
Two cause-specific subgroups of stillbirths, as defined by Wigglesworth codes, were also investigated.
Trihalomethanes are one of the main groups of disinfection byproducts and are widely used in epidemiological studies as a marker for DBPs as they are routinely collected by the water companies.
Methods: Routinely collected THM data from each water company were modelled using a hierarchical mixture model.
The modelled individual and total THM concentrations for the final trimester of the pregnancy were categorized into one of three predefined exposure categories and linked to the outcome data via the postcode of the maternal birth address.
Logistic regression was carried out with maternal age, split into 5 categories, and deprivation, as measured by quintiles of the Carstairs Index, included in the model as confounders.
Results: Analyses were conducted to investigate the relationship between total THMs and risk of stillbirths. Further analyses using individual THMs and also the cause specific subgroups of stillbirths were also undertaken. Full results will be presented.
Conclusion: This is the largest study to date worldwide. Previous studies have shown inconsistent evidence for the association between stillbirths and trihalomethanes.
Concern remains of the possible adverse impact of disinfection by products on births outcomes due to the large population at risk. More detailed exposure assessment including information on water consumption, showering and swimming diaries and, in particular, the use of urinary biomarkers is recommended to move this important field of research forward.

CROSS-SECTIONAL ASSOCIATION BETWEEN POLYFLUOROALKYL CHEMICALS AND TWO MEASURES OF COGNITVE FUNCTION IN THE NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (NHANES)

Melinda C. Power, *Department of Epidemiology, Harvard School of Public Health, USA and Department of Environmental Health, Harvard School of Public Health, USA*
Thomas Webster, *Department of Environmental Health, Boston University School of Public Health, USA*
Marc G. Weisskopf, *Department of Epidemiology, Harvard School of Public Health, USA and Department of Environmental Health, Harvard School of Public Health, USA*

Background and aims: Epidemiologic and animal research suggests that non-steroidal anti-inflammatory drugs, especially ibuprofen, may be protective against cognitive decline and Alzhiemer disease. The underlying mechanism is unclear but may be related to activation of peroxisome proliferator-activated receptors (PPARs). Polyfluoroalkyl chemicals (PFCs) also appear to activate PPARs; therefore we hypothesized that exposure to PFCs may be inversely related to measures of cognitive function in older adults.
Methods: We used data from participants 60 years and older from the 1999-2000 and 2003-2008 National Health and Nutrition Examination Surveys to evaluate the association between serum concentrations of four PFCs, perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorononanoic acid (PFNA), and perfluorohexane sulfonic acid (PFHxS), and two measures of cognitive function: performance on the Digit Symbol Substitution Task (DSST) (1999-2000 only) and self-reported functional limitation due to poor memory or periods of confusion (1999-2000 and 2003-2008).
Results: In multivariable adjusted models, higher exposure to PFCs was associated with reduced odds of self-reported functional limiation due to poor memory or periods of confusion (OR: 0.84 for a doubling in PFOS, 95% CI: 0.70, 0.99; OR: 0.82 for a doubling in PFOA, 95% CI: 0.66,1.01; OR: 0.84 for a doubling in PFNA, 95% CI: 0.71,0.99; OR: 0.95 for a doubling in PFHxS, 95% CI: 0.75, 1.16). However, there was little evidence to suggest an association between performance on the DSST and PFC exposure in multivariable adjusted models.
Conclusions: This cross sectional study suggests that there may be an inverse association between exposure to PFCs and self-reported functional limitation due to poor memory or periods of confusion. However, this study cannot establish temporality and further exploration in prospective analyses is warranted. No association was seen between PFCs and performance on the DSST.

PERSISTENT EFFECT OF PRENATAL DOCOSAHEXAENOIC ACID ON HEART RATE VARIABILITY AND COGNITIVE DEVELOPMENT IN CANADIAN INUIT CHILDREN

Natalia Poliakova, *CHUQ Research Center, Laval University, Canada*

Beatriz Valera, *CHUQ Research Center, Laval University, Canada*
Sandra Jacobson, *Wayne State University School of Medicine, USA*
Joseph Jacobson, *Wayne State University School of Medicine, USA*

Background and Aims: Docosahexaenoic acid (DHA), an *n*-3 polyunsaturated fatty acid (PUFA), has been shown to be beneficial for the development of the central nervous system and cognitive functioning in adults and youth. This effect may be mediated by influences of DHA on cardiac autonomic function (CAF), which is a physiological substrate of numerous cognitive processes. Beneficial impact of DHA on cardiovascular function is well documented in adults, but information on the association between pre- and postnatal PUFA and CAF in youth is scarce. Aims: (a) to evaluate the effect of prenatal DHA on child CAF, estimated by heart rate variability (HRV); (b) to test the hypothesis that the effect of DHA on child cognition is mediated by its effect on HRV.
Methods: A sample of 278 Inuit children (138 boys, 140 girls) from Nunavik (Arctic Canada) was assessed at birth and at school age. Prenatal DHA (3.7±1.2 % phospholipids, *M*±*SD*) was obtained from cord blood at birth. HRV, estimated from 2-hour electrocardiograms, assessing high and low frequencies (HF, LF), and a vocabulary test (Boston Naming Test, BNT) were obtained at age 11 years. Direct and mediation effects were tested using path analyses.
Results: Cord DHA was positively associated with BNT scores (• =.14, *p*=.009) as well as with HF HRV (• =.12, *p*=.03) and the effect on LF HRV fell short of statistical significance (• =.11, *p*=.06). No HRV measures were significantly associated with BNT scores (• =.01, *p*=.81 and • =.05, *p*=.40 for HF and LF, respectively). Thus, the effect of DHA on the BNT was not mediated by either of the HRV measures.
Conclusions: Prenatal DHA provided lasting beneficial effects on HRV and cognitive function later in childhood. Although the effect of DHA on the BNT was not mediated by HRV, effects on other cognitive processes might be partially mediated by CAF.

DEMOGRAPHIC & SOCIO-ECONOMIC FACTORS INFLUENCING RURAL WOMEN'S PERCEPTION OF DEFORESTATION THE CASE OF SEKA DISTRICT SOUTH WEST ETHIOPIA

Abebe Gbremariam Hailu, *Jimma University, Ethiopia*
Wondwossen Birke, *Jimma University, Ethiopia*

Background and Aims: Globally and in developing countries in particular, women experience a major role as farmers, animal tenders, and water and fuel collectors. Studies on the knowledge, attitude and perception of women towards deforestation are scarce in the study area. There fore, the aim of this study is to assess the demographic and socio-economic factors influencing rural women's perception towards deforestation, in Seka district Southwest Ethiopia.
Methods: Cross sectional population based study was conducted from September to November 2009, to identify the demographic and socio-economic factors influencing rural women's perception of deforestation. A sample of 426 female households selected applying a multi-stage sampling were included. The information collected includes variables on socio-demographic and economic, questionnaire on the knowledge and attitude towards deforestation, was collected through, multiple methods: house to house surveys, secondary data focus group discussions, key informants and observations to gather the required information. Data was analyzed using SPSS/PC version 12.8. Statistical techniques like frequency, percentages, cross-tabulation, bivariate and multivariate analysis were used.
Results: Four hundred twenty six women were interviewed making a response rate of 100%. Out of the total studied subjects 294 (69.0%) showed low perception towards deforestation. Among the demographic factors: age and household size; and the socio-economic factors: literacy status, farmland size and contact with conservation agents have an association with the dependent variable. The results of the multivariate analysis have shown that literacy status and farmland size significantly influence women's perception of deforestation.
Conclusions: From the study it can be concluded that women living in in the study area have good perception about deforestation, which is an important input for development plans, strategies and actions; as well as conservation movements to be carried out. Empowering women, participating them in forest conservation improves the overall ecosystem and lives of people.

Comparison of two methods for regression analysis for log-normal exposure data

Sara Gustavsson, *Sahlgrenska Academy, Gothenburg, Sweden*
Sandra Johannesson, *Sahlgrenska Academy, Gothenburg, Sweden*
Gerd Sallsten, *Sahlgrenska Academy, Gothenburg, Sweden*
Eva M Andersson, *Sahlgrenska Academy, Gothenburg, Sweden*

Background and Aims: Log-normally distributed variables are common in exposure data. One characteristic of the log-normal distribution is that the variance increases with the mean. Often it is of interest to analyze which background variables (e.g. time spent in traffic) that are associated with the personal exposure (e.g. particles). Often we want to estimate the absolute effect (of e.g. time spent in traffic on exposure) but by log-transforming data we instead estimate the relative effect.
We propose a new regression method for log-normal data, using a maximum likelihood approach (ML) by which we can account for the heteroscedasticity. The aim of this study was to compare this new ML-approach with ordinary Least-Squares regression (LS).
Methods: A large simulation study was performed, using a model in which expected personal exposure (MuY) is a linear function of the outdoor particle levels (x): $MuY=4.804+0.574 \cdot x$ In the model the variance (in personal exposure) increases with the exposure level. The bias of the estimated coefficients (b0 and b1) was assessed by comparing the estimated values to those in the model.
Results: Both ML and LS showed small bias for both b0 and b1 ($< 2 \cdot 10^{-4}$). However, the standard errors were larger for LS (about 54% larger for SE(b0) and 10% for SE(b1)). As a result the power of LS will be lower, especially regarding test of the intercept. The power for detecting a small effect was estimated by simulating the situation where beta1=0.10 (rather than 0.574). We found the power to be 77% (LS) and 80% (ML).
Conclusions: Both ML and LS give unbiased estimates of the regression parameter, but the larger standard errors for LS-regression means that the confidence intervals will be wider and it will be harder to detect small effects. Therefore ML-regression seems more suitable for estimating linear relationships in log-normally distributed data.

AN APPROACH TO STUDY HEALTH EFFECTS OF ENVIRONMENTAL CONTAMINATION FROM OIL REFINERIES IN A LONGITUDINAL PERSPECTIVE

Pasetto R, *Istituto Superiore di Sanità, Rome, Italy*
De Santis M, *Istituto Superiore di Sanità, Rome, Italy*
Sampaolo L, *Istituto Superiore di Sanità, Rome, Italy*
Settimo G, *Istituto Superiore di Sanità, Rome, Italy*

Background and Aims: In 2010 the world total number of oil refineries was more than 650, about 200 in Europe. Oil refineries are complex industrial sites that manage large amounts of raw materials and products. Refineries generate emissions of many different pollutants. Most of the emissions are into the air.
The aim of this contribution is to describe an approach developed to study the relationship between over-time emissions from oil refineries**,** and over-time health profiles of populations living near the plants. This approach was used to study refineries spread over the Italian territory.
Methods: For each plant constructed in Italy, the following data were collected: year of operation start off and close down; annual oil consumption; and, where available, type of refinery cycle. Estimates of emissions into the air of several pollutants were used to categorize plants. Populations to be studied through a small-area approach were identified by an *ad hoc* GIS model. Outcomes of *a priori* interest were selected through a review of the available epidemiological evidence.
Results: Forty-five refinery plants were constructed in Italy in the last century. Most of the plants started operations in the '60s, and some were closed down after one or more decades of activity. Oil consumption from 1948 up to 2007 was collected for each plant. Nearly 15 plants were selected to study time trends and time-related variables for risk of lung cancer, some hematopoietic neoplasms, respiratory system diseases, neurological diseases and perinatal conditions in selected populations.
Conclusions: The proposed approach has the potential to go beyond the limits of previous studies that could not evaluate refineries health impact over time. It could be used in other countries and is suitable to meta-analyses.

RELATIONSHIPS BETWEEN LEAD EXPOSURE AND MATERNAL CORTISOL CONCENTRATIONS DURING PREGNANCY

Joe M. Braun, *Department of Environmental Health, Harvard School of Public Health*
Robert O. Wright, *Department of Environmental Health, Harvard School of Public Health*
Adriana Mercado-García, *Center for Population Health Research, National Institute of Public Health, Mexico*
Lourdes Schnaas, *Division of Research on Public Health, National Institute of Perinatology, Mexico*
Howard Hu, *Department of Environmental Health, University of Michigan*
Rosalind Wright, *Department of Environmental Health, Harvard School of Public Health*
Martha María Téllez-Rojo, *Center for Population Health Research, National Institute of Public Health, Mexico*

Background and Aims: Gestational lead (Pb) exposure and stress may increase the risk of adverse maternal, neonatal, and childhood health outcomes. Some studies suggest that Pb may alter hypothalamic-pituitary-adrenal (HPA)-axis function. Correlates of psychological stress, like depression, may modify the effect of Pb exposure, increasing susceptibility to Pb-induced HPA-axis dysregulation. We examined the relationship between Pb exposure and HPA-axis function in a cohort of 850 pregnant women from Mexico City.
Methods: Blood Pb concentrations were measured during the second trimester. Tibia and patella bone Pb concentrations were measured 1-month postpartum and represented cumulative Pb exposures. Second trimester salivary cortisol concentrations were measured in 10-timed saliva samples collected over 2-days and used to characterize diurnal HPA-axis function. Cortisol concentrations were parameterized as the area-under-the-curve, morning rise slope, and diurnal slope. Maternal depressive symptoms were examined as a modifier of Pb-coritsol relationships, measured with the Edinburgh Postnatal Depression Scale (EPDS), and dichotomized as $\geq$13/<13). Linear mixed-effect models were used to account for repeated measurements.
Results: Median blood, tibia, and patella Pb concentrations were 3.3 □g/dL, 3.6□g/g and 3.1□g/g, respectively. After adjustment for confounders, parameter estimates between patella and blood Pb biomarkers and cortisol parameters were null in value. However, each 10 □g/g increase in tibia Pb concentrations was associated with a 20% increase (95% confidence interval [CI]:-7%, 55%) in morning rise slopes. This effect was greater among women with EPDS scores $\geq$13 (76%; 95% CI:13%, 175%, interaction p-value <0.05).
Conclusions: These results suggest that tibia, but not blood or patella Pb concentrations might be associated with some aspects of HPA-axis function during pregnancy. We observed evidence that depressive symptoms modify the associations between tibia Pb concentrations and maternal cortisol rhythms. Future studies should validate these findings and determine the clinical significance of altered maternal cortisol profiles in pregnancy on child development.

HIGH TEMPERATURES AND AIR POLLUTION: INVESTIGATING INTERACTIVE EFFECTS ON CARDIOVASCULAR MORTALITY

Background and Aims: Numerous studies have shown associations between human health and air pollution or air temperature. Whether both exposures have synergistic effects on health outcomes has so far only received limited attention. The aim of this study was to examine potential interactive effects of high air temperature and air pollution on cardiovascular mortality in Munich and Augsburg, Germany, as well as in Beijing, China.
Methods: We used data from Munich as well as Augsburg, Germany, for the period 1990 to 2006 (May to September), including daily cardiovascular death counts, meteorological variables, and air pollution concentrations (24-h averages of particulate matter with a diameter < 10µm (PM_{10}) and daily maximum 8-h ozone (O_3)). Additionally, we obtained cardiovascular death counts, meteorological variables, and PM_{10} concentrations from the urban area of Beijing, China, for the period 2004 to 2005. Data were analyzed using Poisson regression models adjusting for long-term trend, calendar effects, and other meteorological factors. We fitted bivariate models using tensor product smooth terms to explore joint response surfaces of 2-day average air temperature and 2-day means of PM_{10} or O_3. To quantify the interactive effects, we categorized air pollutant concentrations into three levels, and then included an interaction term for the pollutant categories and air temperature.
Results: A 1°C increase in 2-day average air temperature in Munich was associated with a 0.4% (95% confidence-intervals (95%-CI): -0.7%; 1.6%), 1.0% (95%-CI: 0.6%; 1.3%), and 1.3% (95%-CI: 0.5%; 2.1%) increase in mortality for low, moderate, and high 2-day average PM_{10} levels, respectively. Similar results were observed for Augsburg and Beijing. There were no interactive effects observed with O_3 in Munich and Augsburg.
Conclusions: Enhanced adverse temperature effects were found at higher levels of PM_{10}, which implies that it is important to evaluate synergistic effects and not only pure temperature or air pollution effects.

INTERACTIONS BETWEEN TRAFFIC AIR POLLUTION AND GLUTATHIONE S-TRANSFERASE GENES ON CHILDHOOD ASTHMA

Ching-Hui Tsai, *Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan*
Kuan-Yen Tung, *Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan; Research Center for Genes, Environment and Human Health, College of Public Health, National Taiwan University, Taipei, Taiwan*
Yungling Leo Lee, *Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan; Research Center for Genes, Environment and Human Health, College of Public Health, National Taiwan University, Taipei, Taiwan*

Background and aims: Ambient traffic-related air pollutants, such as nitrogen dioxide (NO_2), have shown adverse effects on respiratory health in children. However, few studies showed the interactive associations between traffic air pollution and genetic polymorphisms on childhood asthma. The aim of this study is to evaluate the role of glutathione S-transferase (GST) genetic polymorphisms potentially modifying the association between NO_2 and asthma in Taiwanese children.
Methods: We investigated 3714 seven-grade schoolchildren in Taiwan Children Health Study from 14 Taiwanese communities. Children's exposure and disease status were measured from questionnaire by parents. Multiple logistic regression models were fitted to estimate the effects of NO_2 exposures and GSTs polymorphisms on the prevalence of asthma and wheeze.
Results: Compared with children in low-NO_2 communities, those in high-NO_2 communities had significantly increased risks of asthma (OR=1.65, 95% CI=1.09~2.50), late-onset asthma (OR=2.26, 95% CI=1.11~4.62), active asthma (OR=1.85, 95% CI=1.03~3.34), asthma under medication (OR=2.65, 95% CI=1.27~5.52) and wheeze (OR=1.54, 95% CI=1.10~2.16) among GSTP1 Ile/Val or Val/Val genotypes. Significant interactions were found between NO_2 level and GSTP1 on asthma, late-onset asthma, asthma under medication and wheeze (p for interaction < 0.05).
Conclusions: Children under high traffic air pollution exposure are more susceptible to asthma, especially among those with GSTP1 Val allele.

MORTALITY ANALYSIS IN ITALIAN POLLUTED SITES (IPS) WITH INDUSTRIAL WASTE LANDFILLS AND DUMPING SITES

Lucia Fazzo, *National Institute of Health - Rome, Italy*
Fabrizio Minichilli, *National Research Council, Pisa, Italy*
Roberta Pirastu, *Sapienza Università di Roma, Italy*
Mirella Bellino, *National Institute of Health - Rome, Italy*
Fabrizio Falleni, *National Institute of Health - Rome, Italy*
Pietro Comba, *National Institute of Health - Rome, Italy*
Fabrizio Bianchi, *National Research Council, Pisa, Italy*

Background and Aims: SENTIERI project describes mortality in 44 Italian polluted sites (IPS) "of national concern" for their contamination documented in Ministerial Decrees. IPS are classified for the presence of environmental exposures: chemical industry/petrochemical plants&refineries/asbestos or other mineral fibers/steel plants/thermoelectric power plants/mines or quarries/landfills/incinerators. For each site, Standardised mortality ratios, crude and deprivation adjusted, were calculated for 63 groups of causes (reference regional population, 1995-2002). We aim at estimating the health impact of residents in 24 sites (205 municipalities; 3,964,425 inhabitants at 2001 census) where industrial waste landfills or illegal dumping sites are located.
Methods: Twelve mortality causes were selected for analysis on the basis of the epidemiological evidence evaluation completed in SENTIERI project. Metanalysis of mortality results, by SMR adjusted for Deprivation Index, was completed overall (24 sites) and separately for the two categories of industrial waste landfills (10 sites) and illegal dumping sites (14 sites). In the analysis presence/absence of other sources of environmental contamination were included as covariates when applicable (crude and adjusted SMR estimates). A negative binomial regression model by STATA 10 software was used.
Results: The main results are for illegal waste dumping sites. Significant increases (p-value<0.05) are observed for lung cancer among men (crude: SMR=1.12; adjusted: SMR=1.13) and in both genders for liver (men: SMR=1.13; women: SMR=1.21) and bladder cancer (men: SMR=1.05; women: SMR=1.12). Mortality for congenital malformations did not show significant increases. Same results are found when the largest waste illegal dumping sites were excluded from the analysis.
Conclusions: The results suggest a contribution of waste illegal dumping sites in the increased mortality for lung cancer. A role for bladder and liver cancers can be envisaged. The ecological approach, the diversity and mixtures of environmental exposures sources do not allow conclusions on specific etiological hypothesis and hinder a causal interpretation of study results.

THE CONTRIBUTION OF SHIPS TO MEASURED NO_x AND ULTRAFINE PARTICLE CONCENTRATIONS ALONG THE WATERWAYS IN AMSTERDAM

Saskia van der Zee, Municipal Health Service Amsterdam, the Netherlands
Jorrit van der Laan, Municipal Health Service Amsterdam, the Netherlands
Gerard Hoek, University of Utrecht, the Netherlands

Background and aim: Emissions from ships in waterways near residential areas might contribute significantly to local air pollution. The aim of this study was to assess the contribution of passing ships to short term concentrations NOx and ultrafine particles (UFP) near homes close to waterways.
Methods: Continuous measurements were made in 10 second intervals at two locations in the Amsterdam area, on different predefined days in June 2010 during a 4 hour period. One of the locations (Sumatrakade) was in central Amsterdam along the river IJ, in a street with medium traffic intensity (4000 veh/24h). The other location (Diemen) was in a low traffic zone in a suburban area along the Amsterdam-Rhine Canal. Measurements were performed near homes at 21 m from the waterside at Sumatrakade and 44 m in Diemen. Local wind direction was variable at Sumatrakade and from the canal side in Diemen. Time and type (cargo vs pleasure) of passing ships and road traffic were registered.
Results: A significant increase in NOx concentration was observed 10-90 seconds after passage of cargoships at Sumatrakade and 30-100 seconds in Diemen. Linear regression analysis showed that during those time periods, a cargo ship increased NO and NO_2 concentrations with on average 2,4 and 5,7 $\mu g/m^3$ at Sumatrakade and 20 and 11 $\mu g/m^3$ in Diemen. The effect on UFP was less clear at Sumatrakade and absent in Diemen. Mean NO_2 and NO concentration was respectively 42 and 9 $\mu g/m^3$ at Sumatrakade and 10 and 10 $\mu g/m^3$ in Diemen. Taking the number of passing ships into account, cargo ships contributed 2 $\mu g/m^3$ to the NO_2 concentration at Sumatrakade and 5 $\mu g/m^3$ in Diemen. The contribution to the NO concentration was 1 $\mu g/m^3$ at Sumatrakade and 8 $\mu g/m^3$ in Diemen.
Conclusion: Ship emissions contributed significantly to NO_2 and NO concentrations in Amsterdam.

DIVERGENT ASSOCIATIONS OF BLOOD AND URINE CADMIUM LEVELS WITH KIDNEY FUNCTION

Maria Tellez-Plaza, *Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, USA - Centro Nacional de Investigaciones Cardiovasculares, Madrid, Spain*
Ana Navas-Acien, *Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, USA*
Eliseo Guallar, *Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, USA - Johns Hopkins University School of Medicine, Baltimore, MD, USA*
Jeff Fadrowski, *Johns Hopkins University School of Medicine, Baltimore, MD, USA*
Bernard Jaar, *Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, USA - Johns Hopkins University School of Medicine, Baltimore, MD -USA*
Paul Muntner, *University of Alabama, Birmingham, Alabama, USA*
Ellen Silbergeld, *Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, USA*
Virginia Weaver, *Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, USA- Johns Hopkins University School of Medicine, Baltimore, MD, USA*

Background and Aims: Cadmium is nephrotoxic at high exposure levels. Lower level exposure is widespread but data on kidney impact at these levels are scarce. In the 1999-2006 National Health and Nutrition Examination Survey (NHANES), higher blood cadmium levels were related to reduced estimated glomerular filtration rate (eGFR; <60 mL/min/1.73 m^2). Our aim was to compare urine and blood cadmium with reduced eGFR in NHANES 1999-2008.
Methods: We included 6,231 NHANES 1999-2008 participants aged ≥ 20 years who had blood and urine cadmium available. eGFR was estimated using the Modification of Diet in Renal Disease (MDRD) equation.
Results: Geometric mean blood and urine cadmium and MDRD eGFR levels were 0.40 µg/L, 0.26 µg/g creatinine, and 86.8 ml/min/1.73 m^2, respectively. Blood and urine cadmium levels were correlated (r_s = 0.60). After adjustment, the odds ratio (95% CI) for reduced eGFR comparing the 75th to the 25th percentile of blood cadmium levels was 1.44 (1.15, 1.82). In contrast, for urine cadmium, the corresponding odds ratio (95% CI) was 0.47 (0.34, 0.66). Without adjustment for urine creatinine, the odds ratio was 0.97 (0.81, 1.16).
Conclusions: In this large, representative sample of US adults, blood and urine cadmium, although correlated, were associated in opposite directions with eGFR. Both dose measures reflect environmental exposure although blood cadmium incorporates current exogenous exposure and endogenous exposure from body burden. Potential mechanisms for these unexpected findings include the impact of adjusting urine cadmium for urine dilution with urine creatinine which is significantly associated with eGFR in this population; an impact of renal filtration on cadmium excretion; cadmium-related hyperfiltration with urine cadmium dose; and alterations in metal excretion due to protein binding. Prospective epidemiologic studies and experimental studies are needed to understand these cross-sectional findings.

ANATOMICAL LOCATION OF SCC TUMORS: TRENDS IN COASTAL AND INLAND AREAS IN SWEDEN

Eva M Andersson, *Sahlgrenska University Hospital and Sahlgrenska Academy Gothenburg, Sweden*

Background and Aims: The incidence of squamous cell carcinoma (SCC) has increased, both in Sweden and worldwide. The aim was to investigate if there had been an increase in all anatomical sites and if there had been any changes in the anatomical distribution of the tumors. Another aim was to compare the incidence in geographic areas with different sun exposure.
Methods: Yearly data on SCC incidence for the period 1990-2005 were obtained from the Swedish Cancer Registry. The number of tumors on head/neck, arms/legs and trunk were available, together with the incidence (cases per 100 000 inhabitants) for each anatomical site. The investigated area was the southwest part of Sweden, divided into a coastal area (over 1700 sun hours per year) and an inland area (up to 1700 sun hours per year). The statistical analyses were made using Cochran-Armitage tests, chi-square tests and regression analysis.
Results: Preliminary results showed no change over time in the distribution of tumors (on head/neck, arms/legs and trunk). No difference could be found between the growth rates for the site-specific incidence series.
Among men on the coast we found a larger percent of head tumors than in the inland (72% vs 68%), whereas no significant differences were found for women. The incidence was found to be significantly higher on the coast, for both men and women (all three anatomical sites).
Conclusions: The proportion of tumors on head, on arms/legs and on trunk has been fairly constant over time. The similar growth rates for the three anatomical sites do indicate a general increase in tumors at all sites, reflecting a general increase in exposure.
For each of the three anatomical sites a higher incidence was found on the coast compared to the inland. This mirrors the higher exposure on the coast (more sun hours).

Background and Aims: Aromatic hydrocarbons are environmental contaminants, found in gasoline and oil products, that exhibit mutagenic and/or pro-carcinogenic properties in humans. Among them, one of the more dangerous and known to be related to the risk of developing leukaemia is benzene, which is volatile and can be inhaled by the population. In Sao Paulo city there are about 2,300 gas stations, which are responsible for the contamination of soil and/or groundwater at 82.5% of the city contaminated areas (675). It is described in the literature that living near a gas station increases the risk of developing leukaemia in childhood. This aim of this study was to investigate whether there is an excess of leukaemia in children and adolescents from 0-14 years old who live in the vicinity of gas stations.
Methods: case-control design was adopted. Cases were all children and adolescents younger than 15 years old who died of leukaemia in Sao Paulo city, from January 1996 to December 2009 (548 deaths). Control group presented equal number of participants, with the same age range and gender distribution who did not die due to cancer, external and haematologic causes. Exposure was defined by distance between residences and gas stations (≤ 50 meters).
Results: Living at a distance of up to 50 meters from gas station can increase the odds of leukaemia death (OR of 2.64, 95% IC: 0.93-7.45).
Discussion: This exploratory study suggests the association between leukaemia deaths and living in nearby gas stations even using a 1:1 proportion. We controlled for age and gender characteristics and we are aware that other confounders have to be taken into account in our further investigations.

HUMAN HEALTH RISK ASSESSMENT OF POPs IN BACKGROUND SOILS IN THE CZECH REPUBLIC

Zdenka Bednarova, *Research Centre for Toxic Compounds in the Environment, Brno*
Pavel Cupr, *Research Centre for Toxic Compounds in the Environment, Brno*
Milan Sanka, *Research Centre for Toxic Compounds in the Environment, Brno*
Jiri Komprda, *Research Centre for Toxic Compounds in the Environment, Brno*
Klara Kubosova, *Research Centre for Toxic Compounds in the Environment, Brno*

Background and Aims: Persistent organic pollutants (POPs) cause serious problems, due to their persistence, lipophility and toxicity in the environment, for the whole ecosystem. Because of these properties they are still detectable in abiotic and biotic environmental compartments. Spatial concentrations of selected pollutants (PCBs, DDT, HCB and PAHs) in the soil and resulting human risks were modeled in high resolution network (1x1 km) for the area of the Czech Republic.
Methods: Datasets of 534 soil samples on arable land, grassland and forest land were used for analysis. Urban and industrial areas were not included in this study. We used nonparametric methods (random forests) for modeling spatial concentration in the soil. The exposure model approach was used for the risk evaluation. This method is usually used to identify areas, chemicals and exposure pathways that represent the potential risks to human health.
Results: The result of the model shows the highest concentrations for pesticides in lowlands and sites close to former application of these compounds. Human risks concerning these pesticides were determined as negligible. On the other hand the highest concentrations for PCBs were predicted in forest soils (mountain areas). Health risks resulting from exposure to PCBs do not show any important level. Concerning PAHs concentrations, the highest levels were modeled at sites close to industrial areas and at places with highest annual mean precipitation. Exposure to PAHs (especially to benzo(a)pyrene) was evaluated as the most important in health risk assessment.
Conclusions: The study shows that connection of the model techniques with monitoring give useful information about the behavior of the pollutants and their influence on human health.
The research was supported by the Czech Ministry of education project INCHEMBIOL (MSM0021622412) and by the CETOCOEN project from the European Regional Development Fund (No. CZ.1.05/2.1.00/01.0001).

IMPACT OF DUST FROM MULTIPLE MICROENVIRONMENTS AND DIET ON PENTA-BDE BODY BURDEN

Deborah J. Watkins, *Boston University School of Public Health, Dept. of Environmental Health, Boston, MA, USA*
Michael D. McClean, *Boston University School of Public Health, Dept. of Environmental Health, Boston, MA, USA*
Alicia J. Fraser, *Boston University School of Public Health, Dept. of Environmental Health, Boston, MA, USA*
Heather M. Stapleton, *Duke University, Nicholas School of the Environment, Durham, NC, USA*
Andreas Sjödin, *Centers for Disease Control and Prevention (CDC), National Center for Environmental Health (NCEH), Division for Laboratory Sciences (DLS), Atlanta, GA, USA*
Thomas F. Webster, *Boston University School of Public Health, Dept. of Environmental Health, Boston, MA, USA*

Background and Aims: Polybrominated diphenyl ethers (PBDEs) have been widely used as flame retardants in consumer products and are ubiquitous in residential indoor air and dust. Biological measurements of PentaBDEs have been shown to be associated with concentrations in house dust and dietary intake of animal fat. However, little is known about exposure to dust in other microenvironments. Our objectives were to determine relative contributions of diet and dust exposure from multiple microenvironments to PentaBDE body burden, and to explore the role of handwipes as a measure of personal exposure to PentaBDEs.
Methods: We collected serum, dust (office, main living area, bedroom, vehicle) and handwipe samples from 31 participants. A food frequency questionnaire was administered to collect dietary information.
Results: Geometric mean concentrations of PentaBDE in dust from offices, main living areas, bedrooms, and vehicles were 2,167 ng/g, 1,691 ng/g, 1,378 ng/g, and 2,607 ng/g respectively. The geometric mean of PentaBDEs in handwipes and serum were 70 ng and 27.7 ng/g lipid respectively. PentaBDEs in handwipes collected in the office environment were correlated with dust collected from offices ($r=0.35$, $p=0.06$) and bedrooms ($r=0.39$, $p=0.04$), but not with dust from main living areas ($r=-0.05$, $p=0.77$) or vehicles ($r=0.17$, $p=0.47$). PentaBDEs in serum were correlated with dust from main living areas ($r=0.42$, $p=0.02$) and bedrooms ($r=0.49$, $p=0.008$), but not with dust from offices ($r=0.22$, $p=0.25$) or vehicles ($r=0.20$, $p=0.41$). The final regression model included variables for main living area dust and handwipes, and predicted 55 percent of the variation in serum PentaBDE concentrations ($p=0.0004$). Diet variables were not significant predictors of PentaBDEs in serum.
Conclusions: Our research suggests that exposure to dust in the home environment may be the most important factor in predicting PentaBDE body burden in humans, and potential exposure pathways may involve PBDE residues on hands.

MATERNAL EXPOSURE TO ENVIROMENTAL TOBACCO SMOKE DURING PREGNANCY AND OFFSPRING'S GROWTH AND OBESITY

Chia-Jung Hsieh, *National Taiwan University College of Public Health, Taiwan*

Wu-Shiun Hsieh, *National Taiwan University Hospital and National Taiwan University College of Medicine, Taiwan*

Kuen-Yuh Wu, *National Taiwan University College of Public Health, Taiwan*

Yi-Ning Su, *National Taiwan University Hospital and National Taiwan University College of Medicine, Taiwan*

Hua-Fang Liao, *National Taiwan University College of Medicine, Taiwan*

Suh-Fang Jeng, *National Taiwan University College of Medicine, Taiwan*

Pau-Chung Chen, *National Taiwan University College of Public Health, Taiwan*

Background and Aims: The evidence of exposure to environmental tobacco smoke (ETS) on children's growth and obesity is limited and not sufficient to conclude a definitive relationship. The aim of this study was to examine whether maternal exposure to ETS will affect child grow or not.

Methods: We conducted a birth cohort study of 300 nonsmoking women who delivered normal birth weight singletons. We enrolled them before delivery, interviewed them with by a structured questionnaire, and collected umbilical cord blood. Cotinine in umbilical cord blood as an indicator of environmental tobacco smoke was analyzed by using HPLC-MS/MS and the detection limited of this method was 0.05 ng/mL. The child healthcare handbooks were used to record the child height, weight, head circumference and body mass index (BMI) from birth to three years of age. The information was measured by the doctor or nurse in each time to visit the clinic. Multiple linear regressions were used to explore the relation between maternal ETS exposure and child growth and obesity. Linear mixed model was used to explore the effect from birth to three years of age.

Results: Maternal ETS exposure was significantly associated with shorter child head circumference at birth (β = -0.389; P = 0.008) and 12 months (β = -0.475; P = 0.019) of age. Mixed model also showed adverse effect from birth to three years of age (β = -0.606; P = 0.003). In contrast,higher maternal ETS exposure showed significant higher body weight (β = 0.494; P = 0.050) and BMI (β = 0.630; P = 0.029) at 18 months of age.

Conclusions: It can be concluded that prenatal ETS exposure can cause adverse effect of child growth and future obesity.

EFFECTS OF IN UTERO EXPOSURE TO PFOA AND PFOS ON HUMAN SEMEN QUALITY AND HORMONE PROFILE

Anne Vested, *Aarhus University Hospital, Denmark*
Cecilia Hoest Ramlau-Hansen, *University of Aarhus, Denmark*
Sjurdur Frodi Olsen, *Statens Serum Institut, Denmark*
Jens Peter Bonde, *Bispebjerg Hospital of Copenhagen University, Denmark*
Susanne Lund Kristensen, *Aarhus University Hospital, Denmark*
Thorhallur Ingi Halldorsson, *University of Iceland, Iceland*

Line Smaastuen Haug, *Norwegian Institute of Public Health, Norway*
Emil Hagen Ernst, *University of Aarhus, Denmark*
Gunnar Toft, *Aarhus University Hospital, Denmark*

Background and Aims: Perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) are man-made compounds found globally in humans. They are suspected to act as endocrine disrupters and since they are able to cross the placental barrier, in utero exposure is inevitable. The aim was to investigate whether in utero exposure to PFOA and PFOS is negatively associated with adult semen quality and hormone profile.
Methods: We recruited 169 sons (median age 20 years) who were offspring from a Danish pregnancy cohort in Aarhus. The sons' semen samples were analysed for sperm concentration, total count, motility, volume, and morphology, and blood samples were assessed for reproductive hormone profile. Maternal blood samples from pregnancy week 30 were analysed for levels of PFOA and PFOS as a measure of prenatal exposure. Median (range) PFOA was 3.7 (1.3 - 16.6) ng/mL and median (range) PFOS was 21.4 (7.5 - 54.3) ng/mL. Based on tertiles of exposure, the sons were divided into three groups according to maternal PFOA and PFOS serum levels, and multiple regression analysis was used to evaluate possible associations.
Results: Higher in utero exposure to PFOA was associated with lower sperm concentration, total count, and percentage of progressive spermatozoa and higher levels of luteinizing hormone (LH) and follicle stimulating hormone (FSH). Trends on continuous PFOA were statistically significant for sperm concentration ($p=0.03$), total count ($p=0.02$), LH ($p=0.02$), and FSH ($p=0.01$). For progressive spermatozoa there was a statistically significant overall association ($p=0.03$).
There were no associations between in utero exposure to PFOS and any of the traditional semen parameters or any of the reproductive hormones.
Conclusions: The results indicate that in utero exposure to PFOA negatively affects adult human male semen quality and hormone profile. The results concord with earlier studies on adult exposure and emphasises the necessity of further research on this issue.

REVIEW OF EPIDEMIOLOGICAL STUDIES ON CANCER RISKS FOLLOWING DIAGNOSTIC RADIATION EXPOSURE IN CHILDREN

Hélène Baysson, *Institut de Radioprotection et de Sûreté Nucléaire (IRSN). France*
Marie-Odile Bernier, *Institut de Radioprotection et de Sûreté Nucléaire (IRSN). France*
Cécile Etard, *Institut de Radioprotection et de Sûreté Nucléaire (IRSN). France*
Dominique Laurier, *Institut de Radioprotection et de Sûreté Nucléaire (IRSN). France*

Background and aims: The question of cancer risks associated with postnatal diagnostic medical exposure involving ionising radiation in childhood is particularly relevant given the growing use of diagnostic examinations, especially computed tomography scans, in children. Although several studies have indicated that in utero exposure to radiation from diagnostic radiography is associated with increased risk of cancer, the association between postnatal diagnostic exposure and risk of cancer remains controversial (Linet, 2009, Schutz-Rath, 2008, Wakeford, 2008).
Methods A review of epidemiological studies, published in English between 1990 and 2011, on cancer risks following diagnostic radiation in children is proposed following the publication of 3 recent relevant studies (Ronckers, 2010, Bartley, 2010, Rajamaran, 2011).
Results 12 case-controls studies and 7 cohort studies have been identified**.** Heterogeneous results were found for postnatal diagnostic medical exposures and leukaemia. An excess of breast cancer has been observed in cohorts of girls and young women subjected to multiple diagnostic radiation exposures for spine deformities. No significant effect of postnatal exposures was observed for other cancer sites (Non–Hodgkin lymphomas, solid tumours and brain tumours). One of the key concerns is that results from most of the epidemiological studies on postnatal radiography are based on data from interviews with parents allowing for the possibly of bias. Besides, most studies have limitations in study size and involve very low exposure.
Conclusions
As the expected cancer risks are small, epidemiological studies require very large sample sizes and long periods of follow-up combined with a good dosimetry assessment. In this context, newly launched cohort studies on cancer risks associated with exposures to CT scans during childhood will provide new results in the future.

AIR POLLUTION HEALTH IMPACT ASSESSMENT USING TIME-ACTIVITY DATA: TIME AND LOCATION MATTER

Stijn Dhondt, *Vrije Universiteit Brussel, Belgium*
Cathy Macharis, *Vrije Universiteit Brussel, Belgium*
Koen Putman, *Vrije Universiteit Brussel, Belgium*

Background and Aims: Important differences in air pollutant concentrations can occur over a day and between different locations, e.g. higher pollution during rush hours in areas with high commuter traffic and employment facilities. At the same time, the location of individuals also varies over space and time. Previous studies have shown that exposure assessments that do not take into account this variability underestimate the exposure of the population. Choices about time and activity will therefore ultimately affect exposure and health effects.
Methods: The standard health impact assessment methodology is applied to Flanders and Brussels and modified with special attention given to the exposure assessment. Human exposure to air pollutants ($PM_{2,5}$, O_3, NO_2) is estimated by combining air quality data from a dispersion model at high temporal and spatial resolution with population data from an activity-based transport model. This model takes into account the activity-travel behaviour of individuals during the day and provides hourly population mobility data on suburban level. For children school locations are taken into account during school hours.
Results: Health effects are presented for both a dynamic and static exposure profile together with their health effects. The magnitude of the difference is compared for different population subgroups and pollutants.
Conclusions: A comparison of the dynamic with the static approach provides information on the sensitivity of the applied methodology for health impact assessment. Using a dynamic exposure assessment we argue to model the actual exposure and health impact of populations more accurately.

INVESTIGATING HEATWAVE EFFECTS THROUGH MULTI-LEVEL MODELING: THE ROLES OF HEATWAVE VARIABILITY AND HEATWAVE CHARACTERISTICS

G. Brooke Anderson, *Yale University, USA*
Michelle L. Bell, *Yale University, USA*

Background and Aims: Research that jointly investigates effects of heat and heatwaves often models heatwaves using a binary distinction (a day either belongs to a heatwave or does not). However, this approach fails to distinguish among different heatwaves. Here, we investigate heterogeneity in the characteristics and health effects of different heatwaves.
Methods: We identify all heatwaves in 43 US communities, 1987--2005, (heatwaves are defined as $\geq$ 2 days at $\geq$ 95th percentile of the community's May-September temperature). We use a Bayesian hierarchical model to quantify heatwave effects within each community. We explore heterogeneity between heatwaves both in heatwave characteristics (intensity, length, timing in summer) and in effects on human mortality.
Results: Heatwave intensities (measured as the average of mean daily temperature during the heatwave) ranged from ~80^{o}F to 103^{o}F (the most intense was in Phoenix, AZ, July 2003). Heatwaves ranged in length from 2 to 16 days (the longest heatwave was July 1998 in Dallas/Ft. Worth, Texas). Heatwaves also varied in their effects on human health: while many heatwaves had negligible added mortality effects (beyond effects explained by single days of heat), some heatwaves had substantial added effects. For example, the July 1995 heatwave was associated with a 134% increase in mortality beyond the effect expected for non-consecutive days of the same temperature.
Conclusions: Here we show substantial heterogeneity in heatwaves, both in heatwave characteristics and in their effects on human health. Our approach also helped identify unusual heatwave events (e.g., July 1995 in Chicago, IL; August 2003 in New York, NY) and generate new hypotheses based on these unusual events (in both cases, widespread power outages coincided with the heatwave).

NIGHT WORK AND BREAST CANCER RISK: CECILE STUDY

Patrick Arveux, *Jean-François Leclerc Center, Département d'informatique médicale, Dijon, France*
Farida Lamkarkarch, *Inserm, CESP Center for research in Epidemiology and Population Health, U1018, Environmental Epidemiology of Cancer Team, F-94807, Villejuif, France*
Pascal Guénel, *Inserm, CESP Center for research in Epidemiology and Population Health, U1018, Environmental Epidemiology of Cancer Team, F-94807, Villejuif, France*

Background and Aims: Epidemiological studies have suggested that night shift-work may increase the risk of breast cancer. Disruption of the normal circadian rhythm may explain this association. We investigated whether working at night may influence the incidence of breast cancer in a population-based case-control study in France.
Methods: The CECILE study was conducted in two administrative areas (départements). All female residents aged 25-75 years diagnosed in 2005-2007 with a cancer of the breast were eligible to the study. Population controls were frequency-matched by age group to the cases. A total of 1232 incident breast cancer cases and 1317 controls were included. An in-person interview was conducted using a standardized questionnaire to obtain information on risk factors for breast cancer, as well as on lifetime occupational history. For each job held for more than 6 months, information on night work schedules (defined as working at least one hour between 11pm and 5am) was elicited. Analyses were conducted using unconditional logistic regression adjusting for age and recognized risk factors for breast cancer.
Results: Thirteen percent of the cases and eleven percent of the controls had ever worked during night shifts (OR=1.27 [0.99-1.64]). The association was more pronounced for women who worked during overnight shifts (shift work from 11 pm to 5 am: OR=1.35 [1.01-1.80]) than for women with late evening shifts (ending before 3 am: OR=1.25 [0.79-1.98]) or early morning shifts (starting after 3 am: OR=0.90 [0.36-2.21]). Women who had worked at night for 4.5 or more years had an OR of 1.40 [1.01-1.92], but no further increase of the OR was observed for longer durations. Night work of less than 3 nights per week, implying frequent changes between night and day schedules, was associated with an OR of 1.43 [1.01-2.03]).
Conclusion: Our results support the hypothesis that working at night increases the incidence of breast cancer.

VARIABILITY OF URINARY PHTHALATE CONCENTRATIONS BEFORE AND DURING PREGNANCY

Joe M. Braun, *Department of Environmental Health, Harvard School of Public Health*
Antonia Calafat, *National Center for Environmental Health, Centers for Disease Control and Prevention*
Russ Hauser, *Department of Environmental Health, Harvard School of Public Health*

Background and Aims: Phthalates are a diverse class of chemicals used in a wide variety of consumer products. Gestational exposure to phthalates may increase the risk of adverse infant/child health outcomes. Urinary phthalate concentrations are variable and the ability of a single spot-urine sample to classify gestational exposure remains uncertain.
Methods: We collected 1,065 urine samples before and during pregnancy from 168 women who delivered live-born infants in Boston, MA. Women provided up to three urine measurements during each trimester of pregnancy. We measured concentrations of monoethyl phthalate (MEP), monobutyl phthalate (MBP), monobenzyl phthalate (MBzP), and four metabolites of di-2-ethylhexyl phthalate (DEHP). We used intraclass correlation coefficients (ICC) to characterize urinary phthalate concentration variability before and during pregnancy. We averaged phthalate concentrations from at least 2 pregnancy urine samples and estimated the sensitivity and specificity of trimester specific spot-urine samples to classify the top tercile of mean gestational exposure.
Results: The ICCs of most urinary phthalate metabolite concentrations were similar before and during pregnancy. During pregnancy, ICCs were low for DEHP metabolites (<0.16) and MBzP (0.28) and higher for MBP (0.43) and MEP (0.50). Third trimester urine samples had the highest sensitivity and specificity for classifying the upper tercile of mean MBP (sensitivity: 0.68, specificity: 0.84), MEP (sensitivity: 0.68, specificity: 0.95), and MBzP (sensitivity: 0.75, specificity: 0.86) concentrations during pregnancy. The sensitivity and specificity were variable depending on the DEHP metabolite examined.
Conclusions: Urinary phthalate concentrations were variable before and during pregnancy, but the magnitude of variability depended on the individual phthalate metabolite. Our results suggest that a single spot-urine sample in the third trimester may accurately rank-order exposure to some phthalates during pregnancy. These results may be related to unique features of the women studied and studies with serial urine measurements should conduct their own exposure assessments.

ADULT CANCERS NEAR HIGH VOLTAGE OVERHEAD POWER LINES

Mireille B. Toledano, Small Area Health Statistics Unit, MRC-HPA Centre for Environment and Health, School of Public Health, Imperial College London, St Mary's campus, London, UK

Background. Extremely low frequency electromagnetic fields are designated as possibly carcinogenic in humans based on an epidemiologic association with childhood leukemia. Evidence for associations with various adult cancers is inconsistent and currently considered inadequate to make causal judgements.
Aims. To investigate risks of adult cancers in relation to distance and extremely low frequency electromagnetic fields from high voltage overhead power lines.
Methods. Case-control study. Adult cancers identified through national cancer registry data in England and Wales, 1974-2003. 6069 leukemia, 5409 brain/central nervous system, 6218 malignant melanoma, 22,395 female breast cancer cases and 36,187 age-sex matched cancer controls (three controls/case except breast cancer, one control/case) ages 15-74 years living within 1000 m of an overhead power line. Distance measures based on a Geographical Information System of the national power line network. Calculated magnetic fields based on EM2D program, which takes into account distance from the power line, tower design, clearance above ground, phase arrangement and historical load data – mainly estimated for the winter peak and scaled to give an annual average.
Main outcome measures. Risks of leukemia, brain/central nervous system cancers, malignant melanoma and female breast cancer in relation to distance and calculated magnetic fields within 1000 m of high voltage overhead power lines, adjusted for age, sex (except female breast cancer), deprivation, and rurality.
Results. Full results including adjusted odds ratio for various adult cancers by distance from powerlines and for calculated magnetic fields, $\geq$1000 nT compared with <100 nT, will be presented at the conference (paper findings currently under peer review).
Conclusions. Our findings add substantive new evidence to the current inadequate and inconsistent body of research on low frequency magnetic fields and specific adult cancers.

SOURCE-SPECIFIC AIR POLLUTION AND SYSTEMIC INFLAMMATION IN ISCHEMIC HEART DISEASE PATIENTS

Timo Lanki, *National Institute for Health and Welfare (THL), Kuopio, Finland*

Background and Aims: Associations between particulate air pollution (PM) and cardiovascular health have been observed in numerous studies. Exposure to PM can accelerate systemic inflammation, which has been hypothesized to play an important role in the development of cardiovascular disease. Our aim was to evaluate the association between source-specific PM and systemic inflammation among ischemic heart disease patients.
Methods: Fifty-two ischemic heart disease patients were followed for six months with biweekly clinical visits (minimum of three) including a blood-withdrawal in Kotka, Finland, between November 2005 and May 2006. Blood levels of high-sensitive C-reactive protein (CRP) and fibrinogen were determined to be used as indicators of systemic inflammation. Daily levels of air pollution were measured at a central outdoor measurement site. Source-apportionment for fine particles (< 2.5 µm in diameter) was conducted using positive matrix factorization 3.0.2.2. by the U.S. Environmental Protection Agency. Immediate and delayed associations of source-specific air pollution with levels of fibrinogen and log-transformed CRP were analyzed using mixed models with random patient effects adjusting for time-trend, temperature and relative humidity.
Results: There were 507 successful repeated clinical visits in total. Looking at 5-day average concentration, CRP had stronger association with air pollution than fibrinogen. The %-changes for CRP were 2.9% (95%-confidence interval (CI): 0.3 to 5.5%) for long-range transported PM, 31.1% (95%-CI: -6.4 to 83.8 %) for traffic emissions, 2.3% (95%-CI: 0.2 to 4.5%) for biomass burning and -16.1% (95%-CI: -27.2 to -3.3%) for pulp industry per 1µg m^{-3} increase in pollutant concentration. We found no association for seasalt.
Conclusions: Our results suggest that several sources of ambient air pollution are associated with systemic inflammation, a risk factor for coronary heart disease.

WOMEN'S PESTICIDE EXPOSURE IN RURAL BRAZIL: CONTRIBUTIONS FROM RISK PERCEPTION STUDIES

Serena Arancibia, *Center for Studies in Workers Health and Human Ecology -National School of Public Health, The Oswaldo Cruz Foundation, Rio de Janeiro/RJ, Brazil*
Karla Meneses Rodrigues, *The Oswaldo Cruz Foundation, Rio de Janeiro/RJ BRAZIL*
Frederico Peres, *The Oswaldo Cruz Foundation, Rio de Janeiro/RJ BRAZIL*

Background and Aims: Brazil is the largest consumer of pesticides in the world and is highly dependent on agricultural production for economic sustainability. Agricultural workers and their families are at an increased risk of suffering from pesticide related illnesses due to their frequent exposure to these chemicals. Women are at an even greater risk and have been noted to suffer from reproductive health disorders and poor pregnancy outcomes resulting from pesticide exposure. This study examined the risk perceptions women had related to their occupational pesticide exposures, focusing on attitudes, behaviors, and knowledge.
Methods: This study focused on two rural communities of Rio de Janeiro State, Brazil. Rapid assessment procedure techniques were applied and a combination of questionnaires, a focus group, and toxicology exams were used to obtain data. Content analysis techniques were used to assess the results.
Results: Three themes were identified as influencing women's risk perception to pesticides: 1) invisibility of risks - women do not understand the risks involved in their work; 2) minimization of risks – some women understand there are a few risks involved in their work, however, they fail to understand the degree of harm and neglect major health risks; 3) women take on defensive strategies - even after knowing there is a risk present and understanding how harmful that risk can be, they deny there is any risk involved in order to continue working. Additionally, women did not associate their work with poor reproductive health and birth outcomes that they or other women in their community experienced.
Conclusions: Our study indicated that women do not attribute many of their work behaviors to poor reproductive and birth outcomes, or other health problems. This leads to the need for developing effective risk communication tools and incorporating risk perception studies to epidemiological and health situation analysis.

A RETROSPECTIVE ASSESSMENT OF OCCUPATIONAL EXPOSURE TO ELEMENTAL CARBON IN THE U.S. TRUCKING INDUSTRY

Mary E. Davis, *Exposure, Epidemiology and Risk Program, Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA - Department of Urban and Environmental Policy and Planning, Tufts University, Medford, MA, USA*

Thomas J. Smith, *Exposure, Epidemiology and Risk Program, Department of Environmental Health, Harvard School of Public Health, Boston, MA, USA*

Background and Aim: Despite considerable epidemiologic evidence about the health effects of chronic exposure to vehicle exhaust, efforts at defining the extent of risk have been limited by the lack of historical exposure measurements suitable for use in epidemiologic studies and for risk assessment. We seek to reconstruct exposure to elemental carbon (EC), a marker of diesel and other vehicle exhaust exposure, for a large national cohort of 55,000 US trucking industry workers enrolled in 1985 and evaluated for mortality in 2000.
Methods: Using a national set of measurements collected from 2001-2005, we identify the predictors of exposure in a statistical model, which is used to extrapolate exposures across the cohort nationally. These estimates are adjusted for changes in work-related conditions over time using a previous exposure assessment of this industry, and for changes in background levels with a trend analysis of historical air pollution data.
Results: We construct monthly estimates of EC exposure for each job and trucking terminal combination between 1971 and 2000. Occupational exposure to EC declined substantially over time, and there is significant variability in exposures both within and across job groups, trucking terminals, and regions of the US. Average EC exposures during a typical work shift ranged from less than 1 • g/m3 in the lowest exposed category in the 1990s to over 40 • g/m3 for workers in the highest exposed jobs in the 1970s.
Conclusions: Our results provide a framework for understanding changes over time in exposure to EC in the US trucking industry. Our assessment should minimize exposure misclassification by capturing between freight terminal differences, including across US regions and across time.

PRENATAL EXPOSURE TO HEAVY METALS AND COTININE IN A MOTHER-INFANT STUDY IN TAIWAN

Shih-hui Huang, *Graduate Institute of Occupational Safety and Health, Kaohsiung Medical University, Taiwan - Department of Nursing ,Fooyin University,Kaohsiung,Taiwan*

Ken-Pen Weng, *Department of Pediatrics and Medical Education and Research, Kaohsiung Veterans General Hospital*

Ching -Chiang Lin, *Department of Laboratory Medicine, Fooyin University Hospital, Pingtung ,Taiwan*

Chung-Cheng Wang, *Department of Gyn & OBS Fooyin University Hospital, Pingtung ,Taiwan*

Ming-Tsang Wu, *Graduate Institute of Occupational Safety and Health, Kaohsiung Medical University, Taiwan - Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan - Research of Excellence for Environmental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan*

Background and Aims: Prenatal exposure to toxic substances such as mercury, cotinine, etc can negatively affect fetal and post-natal growth and development. Taiwan is a country with a relatively high consumption of fish and percentage of exposure to smoking. However, there are only few studies reporting the effect of environmental toxins on the effect of neonatal growth and development during pregnancy in Taiwan. The purpose of this prospective study in south Taiwan is to evaluate the effect of mercury and cotinine on fetus and postnatal development.

Methods: This is a multi-center prospective cohort which enrolled pregnant women from Kaohsiung Veterans General Hospital (KVGH) and Fooyin Hospital (FH). The questionnaire was administered to the subjects after recruitment, to assess the exposure of environmental toxins during pregnancy. Whole blood and urine samples were collected for measurement of mercury(Hg), lead (Pb), manganese (Mn), and cotinine during pregnancy. The maternal chart during pregnancy were reviewed. Newborns were examined for body weight, body length, head circumference, and function of nervous system, etc.

Results: A total of 113 pregnant women (mean age 27.05±3.80 years) in FH (rural group) and 103 (mean age 31.18±4.60 years) in KVGH (urban group) were enrolled. There were significant differences between two groups in terms of age, education, occupation, and total weight gain after pregnancy. The prevalence of maternal exposure to smoking in KVGH and FH was 33.3% and 74.4% respectively. There were significant differences between two groups in terms of consumption of lean fish, and fried and mixed fish. There was significant association of Pb with cotinine in pregnant women ($p=0.006$). There was significant correlation between Mn and Pb ($p<0.0001$). There was no significant correlation between maternal heavy metals and birth outcome.

Conclusions: Exposure to smoking environment is high for pregnant women in south Taiwan. There is no risk of mercury toxicity in pregnant women in this series, but the contamination of heavy metals in our life is still an important issue.

THE BURDEN OF DISEASE RELATED TO INDOOR AIR EXPOSURE: A COMPARISON OF TWO METHODS

Dr Dieneke Schram-Bijkerk, *National Institute for Public Health and the Environment, the Netherlands*
Dr Elise van Kempen, *National Institute for Public Health and the Environment, the Netherlands*
Dr Anne Knol, *National Institute for Public Health and the Environment, the Netherlands*

Background and Aims: Recently, two European projects estimated the burden of disease related to exposure to indoor air pollutants –EBoDE and EnVIE. EBoDE's calculations were based on population exposure and exposure-response functions derived from epidemiological studies ('exposure-based approach'). EnVIE's calculations were based on (expert judgments of) the fractions of a disease burden that can be attributed to various risk factors ('outcome-based approach'). Our aim was to compare estimates from both approaches for exposure to environmental tobacco smoke (ETS), radon, dampness, CO and VOC's in the Netherlands.
Methods: We have reviewed the calculations as carried out in the two projects and compared the calculation processes and outcomes of both approaches.
Results: For ETS, the estimates were similar. Approximately half of the total burden of disease attributable to the 5 included risk factors could be attributed to ETS. In the exposure-based approach, radon was the second most important cause of disease burden, followed by dampness. In the outcome-based approach, dampness was more important than radon. The outcome-based approach only included radon from soils, which is the most important source of indoor radon in many European countries, but not in the Netherlands. This explains the difference with the outcome-based approach, in which total radon was included. For dampness, the lower estimate in the exposure-based approach can probably be explained by difficulties in identifying exposure-response functions which cover all possible effects. This problem was overcome in the outcome-based approach, in which experts estimated the attributable fraction. Contributions of CO and VOC's to the total burden of disease were relatively low in both approaches.
Conclusions: The two approaches used provided partly different results. This study illustrates that results should always be interpreted within the context of input data, methodology and assumptions used.

APHEKOM: HEALTH IMPACT ASSESSMENT OF SHORT AND LONG-TERM EXPOSURE TO OZONE AND PM IN 25 EUROPEAN CITIES

Mathilde Pascal, *Institut de Veille Sanitaire, France*

Sylvia Medina, *Institut de Veille Sanitaire, France*
on behalf of the Aphekom group

Background In Europe, improvements in air quality were observed between 1990 and 1997. Since then concentrations of particulate matter (PM) and ozone have not shown a significant decrease. European citizens are still exposed to concentrations exceeding the recommendations of the World Health Organization (WHO). The Aphekom project assessed the mortality and morbidity impacts of this pollution in 25 European cities: Athens, Barcelona, Bilbao, Bordeaux, Bucharest, Brussels, Budapest, Dublin, Granada, Le Havre, Lille, Ljubljana, London, Lyon, Malaga, Marseille, Paris, Rome, Rouen, Seville, Stockholm, Strasbourg, Toulouse, Valencia and Vienna, using standardized health impact assessments (HIA).

Methods HIAs were performed using routine health and air quality data. All cities used common guidelines to define the study area, the health and the exposure indicators. Concentration response functions, linking PM_{10}, $PM_{2.5}$ and ozone to mortality and hospitalizations, were selected from multicenter studies. They were applied to a scenario where the air pollutants levels are decreased to the WHO-air quality guidelines.

Results In the 25 cities, the largest health burden was attributable to the long-term impacts of chronic exposure to $PM_{2.5}$. The compliance with the WHO guideline of 10 • g/m^3 in annual mean would increase by 22 months the life expectancy for people aged 30 years and older, depending on the city. This corresponds to a burden on mortality of nearly 19,000 deaths per annum. Considering PM_{10}, in 22 cities the compliance with the WHO guideline of 20 • g/m^3 in annual mean would prevent more than 2500 hospitalizations for cardiac diseases and more than 5300 for respiratory diseases each year.

Conclusions Aphekom provided robust estimates confirming that further steps to reduce PM_{10} and $PM_{2.5}$ would result in significant health gains in Europe. This should be considered when revising the current EU legislation in 2013.

THE EFFECT OF BOILING AND FILTERING ON THE CONCENTRATION OF DISINFECTION BY-PRODUCTS IN TAP WATER

Background and aims: Disinfection by-products (DBPs) are ubiquitous contaminants in drinking tap water with potential to produce adverse health effects such as bladder cancer and adverse reproductive effects. Filtering and boiling tap water can lead to changes in the disinfection by-products levels and affect the exposure through ingestion.

Methods: Changes in the concentration of 4 Trihalomethanes (THM4), MX and bromate were tested when boiling and filtering high bromine-containing tap water from Barcelona. For filtering we used a pitcher-type filter and a household reverse osmosis filter. For boiling we used an electric kettle, a saucepan and a microwave. Samples were taken before and after each treatment to determine the change in the DBPs concentration. pH, conductivity and free and total chlorine were also measured. Trihalomethanes were measured in quadruplicate samples using gas chromatography/electron capture detection. MX was solid phase extracted from water samples, a volatile isopropyl derivative was formed and analysed by gas chromatography - high resolution mass spectrometry. Ion chromatography with suppressed conductivity detection was used for bromate.

Results: A high reduction of THM4 (reduction ranging from 97% to 48%) and MX (reduction ranging from 72% to 54%) was observed for all experiments. Bromine-containing trihalomethanes were most eliminated when filtering and chloroform when boiling water. Bromate was highly reduced with reverse osmosis but showed little effect in the other experiments.

Conclusions: These findings suggest that exposure to THM4 and MX through ingestion is reduced when using these household appliances while bromate reduction is device-dependent. This should be taken into account in exposure assessment of epidemiological studies.

AIR POLLUTION FROM TRAFFIC AND CANCER INCIDENCE IN A DANISH COHORT

Anne Tjønneland, *Institute of Cancer Epidemiology, Danish Cancer Society, Copenhagen Ø, Denmark*

Background and aims: Vehicle engine exhaust includes ultrafine particles with a large surface area and containing absorbed polycyclic aromatic hydrocarbons, transition metals and other substances. Ultrafine particles and soluble chemicals can be transported from the airways to other organs, such as the liver, kidneys, and brain. We have previously reported on air pollution and lung cancer and the aim of the present study was to investigate whether air pollution from traffic is associated with risk for other cancers than lung cancer.
Methods: We followed up 54 304 participants in the Danish Diet Cancer and Health cohort for 20 selected cancers in the Danish Cancer Registry, from enrolment in 1993–1997 until 2006, and traced their residential addresses from 1971 onwards in the Central Population Registry. We used modeled concentration of nitrogen oxides (NO_x) and amount of traffic at the residence as indicators of traffic-related air pollution. NO_x correlates strongly with particle number concentrations in Danish streets. We used Cox models to estimate incidence rate ratios (IRRs) after adjustment for potential confounders.
Results: NO_x at the residence was significantly associated with risks for cervical cancer (IRR, 2.45; 95% confidence interval [CI], 1.01;5.93, per 100 $\mu g/m^3$ NO_x) and brain cancer (IRR, 2.28; 95% CI, 1.25;4.19, per 100 $\mu g/m^3$ NO_x).
Conclusion: This hypothesis-generating study indicates that traffic-related air pollution might increase the risks for cervical and brain cancer, which should be tested in future studies**.**

POLLUTION CHARACTERISTICS AND RESIDENTIAL INDOOR-OUTDOOR RELATIONSHIPS OF PM_{10} ELEMENT IN ONE COMMUNITY IN TIANJIN

Fei He, *State Environmental Protection Key Laboratory of Urban Ambient Air Particulate Matter Pollution and Control, College of Environmental Science and Engineering, Nankai University, China*

Zhipeng Bai, *State Environmental Protection Key Laboratory of Urban Ambient Air Particulate Matter Pollution and Control, College of Environmental Science and Engineering, Nankai University, China*

Background and Aims: Studies on indoor-outdoor relationship are in need to better understand and calibrate exposure measurement errors when ambient concentrations are used as real exposure for epidemiological studies. The object is to characterize the influences of outdoor contribution and indoor sources on indoor PM_{10} and metals in Tianjin.

Methods: Residential indoor, outdoor airborne particulate matter (PM_{10}) were concurrently collected for total 55 families in Tianjin in summer of 2009, using personal exposure monitors (PEM). All the filter samples were cut into two halves and analyzed for 39 elements using ICP-MS and ICP-OES. The enrichment characteristics of elements were analyzed by enrichment factor and indoor-outdoor relationship and penetration were analyzed by regression models.

Results: Total 39 determined elements made up (19.4 ±12.8)%, (22.1 ±13.8)%, (18.7 ±7.2)% of the indoor, outdoor and community-central PM_{10}, respectively, of which 8 main elements (i.e.: Si>Ca>Al>Fe>K>Na• Mg>Ti)contributed 86.3%, 88.9%, 88.9% of their total elements. Cd, Bi and Zn were three most enriched metals in all microenvironments, of which corresponding Enrichment factors in indoor environment were 1290.80, 254.39, 252.77. The penetration rates of K, V, Mn, Cu, Zn, As, Cd, Pb were 0.51, 0.40, 0.44, 0.85, 0.58, 0.67, 0.58, 0.77.

Conclusions: By comparison of background value of soil elements, 13 metals including Cr, Ni, Cu, Zn, As were extremely enriched in indoor, outdoor and community-central PM_{10}, which indicating ubiquitous anthropogenic emission sources. Regression models were constructed for each metal, which showed high indoor-outdoor correlations and penetration rates among K, V, Mn, Cu, Zn, As, Cd, Pb, with low indoor sources contributions.

SOURCE APPORTIONMENT OF PM_{10} PERSONAL EXPOSURE OF AN ELDERLY POPULATION IN ONE COMMUNITY, TIANJIN

Nan Zhang, *State Environmental Protection Key Laboratory of Urban Ambient Air Particulate Matter Pollution Prevention and Control, College of Environmental Sciences and Engineering, Nankai University, China.*

Zhipeng Bai, *State Environmental Protection Key Laboratory of Urban Ambient Air Particulate Matter Pollution Prevention and Control, College of Environmental Sciences and Engineering, Nankai University, China.*

Background and Aims: Studies on personal exposure were in need to better understand and analyze source apportionment of PM_{10} personal exposure, especially for the elderly. The object of this study was to collect personal exposure samples to PM_{10} of the elderly livings in one community in Tianjin and to identify their potential personal exposure sources.

Methods: In this study, a total of 80 elderly participants were selected and monitored in August and September, 2009. 24-h average particulate matter personal exposure and simultaneously compared with residential indoor and outdoor PM_{10} concentrations were measured in Tianjin, China, together with 24-h time-activity patterns collected. Ratio method and PCA receptor model were implied to analyze related sources and contributions.

Results: Using ratio method, it was found that the ratio of OC and EC were more than 2, and the NO_3^-/SO_4^{2-} ratio were relatively lower, besides, PM_{10} indoor exposure contributed more to PM_{10} personal exposure than PM_{10} outdoor exposure. PCA receptor model showed that seven sources were resolved, namely metal smelting, motor vehicle emission and nitrate, combustion, soil, industrial sources (mainly steel-making), second sulfate and indoor re-suspended particulate matter.

Conclusions: The second organic pollution may be existed to personal exposure. The stationary emissions were a dominant source of PM_{10} personal exposure. Metal smelting, motor vehicle emission and nitrate, combustion were identified as principal sources of personal exposure to PM_{10}.

ASSOCIATION BETWEEN CONGENITAL HEART DEFECTS AND MATERNAL EXPOSSURE TO AMBIENT AIR POLLUTION AND TEMPERATURE IN AN ISRAELI BIRTH COHORT, 2000-2006

Keren Agay-Shay, *University of Haifa, Israel*
Michael Friger, *Ben-Gurion University, Israel*
Shai Linn, *University of Haifa, Israel*
Ammatzia Peled, *University of Haifa, Israel*
Yona Amitai, *The Hebrew University, Israel*
Chava Peretz, *Tel Aviv University, Israel*

Background and Aims: There are new concerns that air pollution may play a role in the causation of congenital anomalies, and such an effect is of public health importance. A recent meta-analysis reported evidence for an effect of ambient air pollutants (AP) on Congenital Heart Defect (CHD) risk. The potential influence of direct temperature effects on pregnancy outcomes is an area of emerging research. Therefore we examined associations between CHD and maternal exposure to ambient AP and temperature in an Israeli birth cohort.
Methods: We conducted a population-based cohort study on 138,675 newborns in Tel-Aviv region during 2000-2006. For each pregnant woman we used GIS to assess personal exposure to carbon monoxide, nitrogen dioxide, ozone, sulfur dioxide, particulate matter (PM10 and PM2.5) during weeks 3-8 of pregnancy; using inverse distance weighting method. In addition ambient temperature was considered. Logistic models were conducted to compare exposure levels between the 2087 CHD cases and the non-cases, adjusted for socio-demographic covariates and season.
Results: We did not find positive dose-response associations in both single and multi-pollutant models between exposure to air pollutants and CHD - for total CHD and for the major subgroups (Atrial Septal Defect (ASD), Ventricular Septal Defect (VSD) and Patent Ductus Arteriosus (PDA)). However, we found a positive association between ambient temperature quartiles (<16˚C, 16.1-20.4˚C, 20.5-25.2˚C, 25.3˚C<) and CHD risk, adjusted for multi-pollutant exposure. For total CHD, OR= 1.13 (95%CI: 1.05, 1.21), for ASD OR= 1.14 (95%CI: 1.04, 1.26), for VSD OR = 1.08 (95%CI: 0.98, 1.2), for PDA OR=1.13 (95%CI: 0.95, 1.34).
Conclusions: The positive relationship between ambient temperature exposure during weeks 3-8 of pregnancy and CHD risk found in this study should be further explored since there is biological plausibility for these results, and temperatures are expected to increase due to climate change.

AIR POLLUTION DECLINE, BODY MASS INDEX AND PULMONARY FUNCTION: THE ROLE OF GENDER

Background and Aims*:* Reduction in air pollution has been associated with an attenuation of lung function decline in adults[1]. Since obese people have an accelerated age-related decline in lung function we aimed to assess whether the impact of air pollution on the longitudinal course of lung function is modified by BMI and whether this effect differs by gender.
Methods: Data from the population-based SAPALDIA cohort was used. Baseline and follow-up assessments were in 1991 and 2002, respectively. Weight status was based on average BMI and change in BMI between surveys divided in four categories: underweight, normal, overweight and obese. Outcomes were the annual rates of change in different lung function (LF) parameters: FEV_1, FVC, FEV_1/FVC and forced expiratory flow between 25% and 75% of FVC (FEF_{25-75}). Exposure was the difference in PM_{10} at residence between follow-up and baseline. Mixed linear models with random area intercepts were used to estimate effects of air pollution and obesity on LF adjusted for potential confounders.
Results: Lung function data and complete information on potential confounders were available in 4729 participants. PM_{10} levels declined over the study period of 11 years (median: -5.3µg/m3). Among neversmokers, women had a higher benefit in lung function from a reduction in air pollution than men. The beneficial effect of declining air pollution decreased with increasing BMI. On average, a decline of PM_{10} by 10 $\mu g/m^2$ over the entire follow-up period was associated with an attenuation of the annual age-related decrease of FEF_{25-75} by 18.1% ($CI_{95\%}$= [31.3; 5.0]) in the normal weight women, whereas no attenuation was found in overweight or obese women.
Conclusion*:* First results suggest that overweight or obese women may not benefit from the previously published beneficial effect of a decline in PM_{10} on the small airways. However, overall men did not benefit to the same degree than women.

PUBLIC HOUSING PROGRAMS: POTENTIAL ENVIRONMENTAL HEALTH BENEFITS THROUGH INDOOR AIR QUALITY: A CASE STUDY IN SANTIAGO, CHILE

Soledad Burgos, *School of Public Health, Faculty of Medicine, University of Chile, Santiago, Chile*
Pablo Ruiz, *School of Public Health School, University of Chile, Santiago, Chile*
Rosalina Koifman, *School of Public Health*, *Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, Brazil*

Background and Aims: Housing interventions, as rehousing/relocation of families from deprived to improved houses, can impact public health through reducing several risk factors. One of the potential benefits of relocation, which have not been studied extensively, is the improvement of indoor air quality of the relocated families. The purpose of this study was to determine differences in indoor air quality between families living in slums and families relocated through a housing program, both living in a similar geographical area in Santiago, Chile, and identify likely determinants of this difference.
Methods: Using particulate matter $PM_{2.5}$ as an indicator of indoor air quality, in this study we sampled 169 houses cross-sectionally: 98 relocated families and 71 families living in slum houses. In each home, Indoor and outdoor 24-hour samples and questionnaire about home conditions were collected.
Results: . Indoor $PM_{2.5}$ concentrations inside slum homes were higher than in homes of relocated families (77.8 $\mu g/m^3$ vs. 55.7 $\mu g/m^3$, $p<0.001$). A regression model was used to identify determinants of indoor $PM_{2.5}$ concentrations. Outdoor $PM_{2.5}$ was the main predictor of indoor $PM_{2.5}$, explaining 26.0% of the total variance of the model. Also significant were the type of fuel used to heat water and the number of indoor cigarettes smoked, which increased the indoor $PM_{2.5}$, and the presence of infants, which was a protective factor. The intervention itself – comparing slum homes with relocated homes in the model–significantly decreased indoor $PM_{2.5}$
Conclusions: These results show that a housing program may improve indoor air quality which represents a clear health benefit.

DEVELOPMENT OF A PROBABILISTIC MODEL FOR PESTICIDE EXPOSURE THROUGH SHEEP DIPPING

Haytham Alhamwi: *University of Manchester, Great Britain*
Dr. Andrew Povey: *University of Manchester, Great Britain*
Dr. Frank De Vocht: *University of Manchester, Great Britain*

Background and Aims: Whereas probabilistic exposure modelling has been used in environmental epidemiology, its use in occupational settings remains limited. Sheep dippers are exposed to pesticides when they treat sheep for ectoparasites. Previous exposure assessment models have depended on a deterministic approach incorporating only few determinants, considering other uncollected variables known to be factors of exposure process as random error only. This study aims to explore whether a probabilistic model can result in a more realistic estimation of exposure intensity in sheep dipping.
Methods: A conceptual exposure model was developed to estimate pesticide exposure intensity during sheep dipping. Distributions of exposure variables were based on previously published data where possible; determinants without prior information available were set at 1 ('no effect'). Monte Carlo simulations generated 10,000 samples of semi-quantitative exposure intensity scores of different dipping tasks (plunger, chucker and helper) in the same dipping session. The probabilistic conceptual exposure model was applied to four dippers participating in the Study of Health in Agricultural Work (SHAW) and the results were compared with the deterministic estimates obtained from SHAW.
Results: Deterministic exposure scores for a plunger, chucker and helper in a same session were 3.51, 2.40, and 1.17, respectively whereas probabilistic estimates showed a considerable overlap with the 1st and 3rd quartiles (Q1,Q3) being (3.3,6.5), (2.0,5.2), and (1.0,2.9) respectively. Deterministic scores of four SHAW farmers were 13.84, 6.89, 7.38, and 3.89 respectively. In contrast, the probabilistic estimates resulted in similar exposure distributions for farmers 2 (10.2,14.5) and 4 (10.4,15.4), but higher scores for farmer 1 (19.1,22.2) and farmer 3 (14.3,19.7).
Conclusions: This study indicates that probabilistic models may give more comprehensive estimations for occupational exposures than deterministic estimations. Probabilistic models could be a solution to bridge the gap between conceptual models and applicable ones which can be used in epidemiological studies.

CONDITIONAL POISSON MODELS: A BETTER WAY TO ANALYZE CASE-CROSSOVER AND RELATED DATA?

Ben Armstrong and, *London School of Hygiene and Tropical Medicine, LSHTM, UK*
Antonio Gasparrini, *London School of Hygiene and Tropical Medicine, LSHTM, UK*

Background and Aims: Almost universally, case-crossover studies are analyzed using a conditional logistic regression model with aggregated data reconstructed to resemble case-control sets. This is somewhat laborious to program and inefficient computationally. It does not easily permit allowance for over-dispersion or auto-regression. Time stratified case cross-over studies may equivalently be modeled using Poisson models with indicator variable for time strata, but these models fit large numbers of nuisance parameters so are again inefficient, sometimes infeasible. Similar issues can arise in related spatio-temporal designs.
Methods: Poisson models with large numbers of indicator variables can alternatively be fit with conditional Poisson models (conditioning on numbers of events – for example deaths - in the time stratum). Despite this model's long life (Chapman 1954) it seems only very few researchers (Whitaker 2009) have considered it for purposes similar to this one. These models can incorporate both overdispersion and autocorrelation in the same ways that this can be done in unconditional Poisson models, though in both approaches problems arise if data are sparse. The models can be fit using R function *gnm* with the *eliminate* option or Stata command *xtpoisson* with option *fe*.
Results: Fitting case-crossover data for a 15-city 14-year time series study using conditional Poisson models stratified by city-month gave identical parameter estimates to unconditional ("regular") Poisson models or conditional logistic regression but in dramatically less computer time. Incorporating overdispersion and auto-correlation was straightforward.
Conclusions: Conditional Poisson models are easier and quicker to fit and more flexible than conventional methods for case crossover and related studies.

Marie-Odile Bernier, *Institut de Radioprotection et de Sureté Nucléaire (IRSN), DRPH, SRBE, Laboratory of epidemiology, Fontenay-Aux-Roses, France*

Background and aims: Interventional cardiologists are exposed to ionizing radiations which may induce radiation-induced cataracts. To test the existence of an increased risk of cataracts among interventional cardiologists compared with unexposed workers, the O'CLOC study (Occupational Cataracts and Lens Opacities in interventional Cardiology) was performed in France.
Methods:O'CLOC study includes an exposed group of interventional cardiologists and a comparable unexposed group (including non nterventional cardiologists and unexposed French workers). Individual risk factors of cataracts (age, diabetes, myopia, ...), were collected during a telephone interview. For the exposed group, in order to assess exposure level, a specific part of the questionnaire focused on their interventional practice (description of type of procedures , frequency, use of radiation protection tools). All participants underwent a clinical eye examination. The use of the international standard lens opacities classification – LOCS III, allowed detecting cataracts even at the early stages and for different localisation (nuclear, cortical or posterior subcapsular).
Results: Preliminary results were based on 92 interventional cardiologists, and 70 unexposed individuals. Mean age was 51.9 ± 7.3 years in the exposed group and 51.8 ± 7.5 years in the control group. Some posterior subcapsular lens opacities, known as radiation-induced eye lens damages, were observed in the exposed group and have to be analyzed more precisely. Complete analyses will be based on more than 200 individuals and final results will be presented during the congress.
Conclusion: The O'CLOC study is the largest study ever performed on lens opacities among interventional cardiologists. Preliminary results need further analyses, in particular to consider the level of exposure and means of protection against X-rays used by cardiologists.

THE IMPACT OF SECOND HAND SMOKE EXPOSURE ON THE HEALTH IN SLOVAK SCHOOLCHILDREN

Ludmila Sevcikova, *Comenius University Bratislava, Slovakia*
Lubica Argalasova-Sobotova, *Comenius University Bratislava, Slovakia*
Ying Hua Liu, *New York University, USA*
Jana Jurkovicova, *Comenius University Bratislava, Slovakia*
Zuzana Stefanikova, *Comenius University Bratislava, Slovakia*
Erika Machacova, *Comenius University Bratislava, Slovakia*
Kseniya Slobodyanyuk, *New York University, USA*
Michael Weitzman, *New York University, USA*

Background and Aims: The prevalence of smoking in adult Slovak population is high. The aim of the project is to analyze the situation in school age children exposure to SHS and to analyze the impact of exposure on their health status.
Methods: Study elaborates the representative data of the sample of 1478 Slovak schoolchildren in the age 6 - 15 years, the same number of boys and girls, using anonymous questionnaire filled in by parents. General questionnaire was aimed at children's health status and environmental conditions. Validated questionnaires CIS (Columbia impairment scale) and BPI (Behavior Problem Index) are focused on emotional and behavioral functions in children. Basic anthropometric variables were measured. SAS program was used for statistical analysis.
Results: From 7.8 to 27.6% of Slovak children are exposed to passive smoking. The significantly highest numbers were in big cities Bratislava and Kosice. There were 21.3 % of smoking and 8 % ex-smoking mothers; 36.5 % of fathers smoke and 12.2 % of fathers are ex-smokers. Lower family social status was reported by the almost 30% of families. Older school children have been more exposed to passive smoke. Exposure to passive smoke decreases with the level of parental education. The positive relationships with low socio-economic status and incompleteness of the family have been shown. The significantly higher prevalence of respiratory diseases in children exposed to passive smoke was confirmed ($p = 0.02$). Children exposed to SHS have worse eating habits and regimen, lower physical activity and sports. No relationship between overweight / obesity (BMI ≥ 90%) and exposure to passive smoking has been confirmed.
Conclusions: Results showed that 19% of Slovak children are exposed to passive smoking in family with health consequences. The results of the study contribute to the effective protection of children from exposure to toxic tobacco smoke.

FLU TRANSMISSION IN A SAHELIAN CITY: TEMPERATURE PLAYS A MAJOR ROLE AT NIAMEY, NIGER

JF Jusot, *Centre de Recherche Médicale et Sanitaire, Niamey, Niger*
L Adamou, *Centre de Recherche Médicale et Sanitaire, Niamey, Niger*
JM Collard, *Centre de Recherche Médicale et Sanitaire, Niamey, Niger*

Background and aims: Flu threatened the world during four pandemics that occurred within the last century and recently in 2009. Temperature and humidity seem the main climatic factors involved in flu transmission. This study aimed to provide insight on the role of meteorological factors on flu transmission in Niamey, a Sahelian city that exhibits climate particularities of a very long dry season with consistently hot temperatures.
Methods: In April 2009, a surveillance system for flu composed of ten sentinel sites in Niamey was set up by CERMES, the national research institute of Niamey, Niger. A nasopharyngeal swab was taken from subjects with influenza like illness or severe acute respiratory illness symptoms attending the sentinel sites and analyzed by RT-PCR. Long-term trend, seasonality, day of the week, holidays and religious periods were taken into account in a generalised additive model to link temperature, humidity, wind speed and visibility with daily counts of biologically confirmed influenza cases between 1st June 2009 and 31 May 2010.
Results: Seventy six among 319 subjects were positive (23.8%) for influenza virus, comprising 46 A/H1N1(2009), 19 A/H3N2 and 11 influenza B. Positive cases were detected more frequently during cold and rainy seasons, with respectively 46.9% and 34.4% of positive subjects. Minimal temperature between 13 and 22°C and visibility were significantly and positively correlated respectively three days and one day before the occurrence of flu cases ($\beta = 3.99$, $p = 0.022$ and $\beta = 3.30$, $p = 0.014$, respectively).
Conclusions: The occurrence of flu cases could be related to the lowest minimal temperatures mainly found during cold season and to the highest values of visibility occurring during rainy season. This work brought new evidence on the important role of temperature in the transmission of flu in a Sahelian tropical city like Niamey, Niger.

THE IMPACT OF CLIMATE CHANGE ON DENGUE TRANSMISSION IN NICARAGUA

Jessie Edwards, *University of North Carolina – Chapel Hill, USA*
Leah Sirkus, *University of North Carolina – Chapel Hill, USA*

Background/Aims: In 2007, 918,495 cases of dengue and dengue hemorrhagic fever occurred in Latin America (Barclay 2008). Climate change is projected to alter the transmission of dengue through changes in temperature and precipitation, which affect biological factors and human ecology. A sustained decline in precipitation could lead subsistence farmers to migrate to urban areas, where dengue can become hyperendemic due to poor living conditions and unsafe water storage (Campbell-Lendrum and Corvalán 2007). This study compared the incidence of dengue in Nicaragua under climate change and non-climate change scenarios using mathematical models.
Methods: The study used a deterministic Susceptible, Infectious, Recovered (SIR) compartmental model to compare dengue incidence projections over the next 100 years with and without climate change. Climate change was parameterized as a temperature increase of two degrees Celsius over 100 years and a decline in precipitation, resulting in urbanization. Incidence projections were compared between non-climate change, climate change, and intervention scenarios, which included 1) controlling mosquito population growth; 2) reducing the effective contact rate between mosquitoes and urban residents; 3) promoting sustainable agricultural practices (thus reducing urbanization); and 4) increasing mosquito mortality through vector control programs.
Results: The projected number of symptomatic dengue cases over the next 100 years (from 2010 to 2110) under the climate change scenario was 91% higher than under the non-climate change scenario. This increase was reduced to 89, 86, 44, and 27% by applying interventions one through four above, respectively.
Conclusion: Climate change mitigation will require strengthening public health infrastructure to address biological and socioeconomic determinants of infection. Future research should identify interdisciplinary interventions employing optimal combinations of strategies to reduce dengue transmission in the face of climate change.

PHTHALATES IN COW MILK: POSSIBLE CONTAMINATION PATHWAYS AT FARM LEVEL

Tine Fierens, *VITO - Flemish Institute for Technological Research, Belgium*
Mirja Van Holderbeke, *VITO - Flemish Institute for Technological Research, Belgium*
Hanny Willems, *VITO - Flemish Institute for Technological Research, Belgium*
Isabelle Sioen, *Ghent University – Department of Public Health, Belgium*
Stefaan De Henauw, *Ghent University – Department of Public Health, Belgium*

Background and Aims: Phthalates are organic lipophilic compounds which are mainly used as plasticizer in plastic polymers. Human exposure occurs mainly via food intake and can cause a wide range of negative health effects. Phthalates are not only present in food because of environmental contamination, but also as a result of migration from contact materials. This study investigated phthalates in cow milk in order to determine the contamination pathways at farm level.
Methods: The levels of eight phthalates were determined in raw milk samples collected during summer and winter at five farms located in 'The Kempen' (Belgium). Both manually obtained milk samples as milk samples milked by machine were collected. Analysis was performed by gas chromatography-mass spectrometry.
Results: The analysis of the milk samples milked by machine revealed a difference in average total phthalate level between the summer and the winter sampling period (572 versus 379 µg/kg fat). While the total phthalate levels of the different farms during winter were nearly of similar magnitude (291-587 µg/kg fat), a wide range could be observed during summer (95-1550 µg/kg fat). Comparing milk samples within a farm, lower total phthalate levels were found in the milk samples milked by hand than those by machine (100 versus 179 µg/kg fat). Di(2-ethylhexyl) phthalate which is the most commonly used plasticizer worldwide, was the most dominating one (79 % of the total concentration in milk from the central collecting tank).
Conclusions: The results indicate that the contamination pathways for phthalates in cow milk vary across seasons. An explanation therefore is that the feed composition is different during summer than during winter. In summer, cows are grazing in the fields where an extra phthalate contamination can occur via soil ingestion. Comparing the milk samples milked by hand with those by machine reveals that the milking equipment is another important contamination pathway.

COMPARISON OF PM MASS CONCENTRATION AND PM OXIDATIVE POTENTIAL EXPOSURE METRICS IN RELATION TO CAROTID INTIMA MEDIA THICKNESS WITHIN THE WHITEHALL II COHORT

Cathryn Tonne *Dept. of Social and Environmental Health Research, London School of Hygiene and Tropical Medicine, UK; MRC-HPA Centre for Environment and Health, King's College London, UK*
Jeff Yanosky *Dept. of Public Health Sciences, Pennsylvania State University College of Medicine, Hershey, Pennsylvania, USA*
Sean Beevers *MRC-HPA Centre for Environment and Health, King's College London, UK*
Paul Wilkinson *Dept. of Social and Environmental Health Research, London School of Hygiene and Tropical Medicine, UK*
Frank Kelly *MRC-HPA Centre for Environment and Health, King's College London, UK*

Background and Aims The epidemiological evidence that particulate matter (PM) can augment the progression of atherosclerosis remains limited and the specific attributes of PM responsible for observed health effects is unclear. We previously developed a model to predict exposure to PM10 mass concentration weighted by its oxidative potential (OP), a measure of particles' capacity to induce oxidative damage. Our present objective was to estimate the association between PM10 mass concentration and carotid intima media thickness (CIMT), a measure of subclinical atherosclerosis, and to compare the association with that of PM10 weighted by its OP (PM10xOP).
Methods Analysis was based on 2,348 participants of the Whitehall II cohort of British civil servants who had CIMT measured between 2003-05 and lived in Greater London. Weekly PM10 and PM10xOP were predicted at each participants' residence. Primary exposure metrics were defined as predicted PM10 and PM10xOP averaged over 52 weeks prior to CIMT scan. Associations between exposure metrics and CIMT were estimated using generalized linear regression models.
Results Median exposures were 24.4μgm^{-3} for PM10 and 15.6m^{-3} for PM10xOP. An interquartile range increase (5.2μgm^{-3}) in PM10 was associated with a 2.3% (95% CI 0.7%, 3.8%) increase in CIMT without adjusting for covariates. This association increased to 5.0% (95% CI 1.9%, 8.3%) after adjustment for age, sex, smoking, BMI, year and season. An interquartile range increase (1.6m^{-3}) in PM10xOP was associated with a 1.8% (95% CI 0.6%, 3.1%) increase in CIMT in the fully adjusted model. Although the association with CIMT was larger for PM10, the predictive value (AIC) of the two exposure metrics was comparable.
Conclusions This analysis adds to the evidence of the relationship between PM exposure and the extent of atherosclerosis, but also for the first time, incorporates information on the oxidizing characteristics of particles in this relationship.

HEALTH OF RESIDENTS LIVING NEAR INTENSIVE LIVESTOCK FARMS

Mariëtte Hooiveld, *Netherlands Institute for Health Services Research (NIVEL), the Netherlands*

Dick Heederik, *Institute for Risk Assessment Sciences (IRAS), Division of Environmental Epidemiology, the Netherlands*
Joris IJzermans, *Netherlands Institute for Health Services Research (NIVEL), Utrecht, the Netherlands*

Background and Aims: Swine and poultry farmers are at increased risk of developing adverse respiratory health effects. Research into the health of residents living near intensive livestock farms is sparse and repeatedly based on self-report, while the potential health effects of intensive livestock farm emissions are of great interest for public health. The aim of this study was to explore the health of neighboring residents based on medical information registered by their general practitioner, with focus on the respiratory and gastrointestinal tract and possible intertwining comorbidity.
Methods: Data were collected from routine electronic medical records of 28 general practices (total population of 122,542 patients) in an area with a high density of intensive pig, poultry, and cattle farms. A comparison was made with 22 practices (78,060 patients) in other rural areas with low density of these facilities. Information included patient characteristics and all registered health problems (in the Netherlands everyone is obliged to register with one general practice) during 2006-2009. Prevalences of symptoms and diagnoses were calculated by multilevel analyses accounting for differences between practices and the patient's age, gender and follow-up duration.
Results: The overall prevalence of respiratory diseases was similar or even lower compared to other rural areas, with the exception of pneumonia (OR=1.4; 95%CI=1.1–1.8). No increased prevalence of asthma was observed (OR=0.9; 95%CI=0.7–1.2). The most frequently presented reasons for encounter among patients with asthma were cough, upper respiratory tract infections and rhinitis. We found an increased prevalence of atopic eczema (OR=1.3; 95%CI=1.1–1.6). More detailed analyses are currently being performed, including the geographical distribution of diseases within the study area.
Conclusions: The first results showed no differences for respiratory diseases other than pneumonia. The prevalence of atopic eczema was increased compared to controls. Having data from general practice is an important addition to self-reported complaints.

IS PM_{10} ASSOCIATED WITH EMERGENCY AMBULANCE DISPATCHES?

Ester Alessandrini, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy; Department of Statistics, University of Bologna, Italy*
Stefano Zauli Sajani, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*
Stefano Marchesi, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*
Fabiana Scotto, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*
Rossella Miglio, *Department of Statistics, University of Bologna, Italy*
Paolo Lauriola, *Environmental Health Reference Centre, Regional Agency for Environmental Prevention, Emilia Romagna, Modena, Italy*

Background and Aims: Positive short-term associations between particulate matter and mortality has been well established. To investigate the impact of air pollution on non fatal events we analyzed for the first time the exposure-response curve of ambulance dispatches using a region-wide real time database.
Methods: Daily Emergency Ambulance Dispatches (EAD) for people aged 35 or older were collected for six chief towns of the Emilia-Romagna region between 2002 and 2006. In a first stage, Poisson regression models were used to assess the relationship between PM_{10} daily mean concentrations and EAD, controlling for potential confounders and including natural splines to adjust for trend and seasonality. City-specific estimates were obtained for three age groups (35-64, 65-74, 75+ years) and for non-traumatic, cardiovascular and respiratory disease. Cumulative lagged effect was investigated up to five days and temporal patterns were explored using distributed lag models. Hot and cold season effect modification was also verified in additional analyses. In a second stage, city-specific effects were combined in fixed effects meta-analyses.
Results: The percent change of EADs associated with 10 • g/m^3 increase in five-day mean exposure was 1.06% (95%CI: 0.74;1.38) for non-traumatic disease. Effects were larger during the hot season with significant effects for all-age cardiovascular and respiratory disease. The highest effects were found for respiratory 75+ EAD during the hot season for lag0-3 of exposure (3.38%, 95%CI: 1.06;5.7).
Conclusions: EADs data showed a strong relationship with PM_{10} with larger effects during the hot season. The effects were similar to those found in previous studies on mortality. EAD are relevant indicators in order to achieve a wider view of the effects of air pollution on human health and possibly to establish real-time surveillance systems.

LEAD CONCENTRATIONS IN CANDIES FREQUENTLY CONSUMED BY CHILDREN LIVING IN MEXICO CITY

Marcela Tamayo y Ortiz, *Harvard School of Public Health, U.S.A.*
Héctor Lamadrid Figueroa, *Instituto Nacional de Salud Pública, México*
Adriana Mercado García, *Instituto Nacional de Salud Pública, México*
Chitra Amarasiriwardena, *Harvard School of Public Health, U.S.A.*
Martha María Téllez-Rojo, *Instituto Nacional de Salud Pública, México*
Howard Hu, *University of Michigan School of Public Health, U.S.A.*
Robert Wright, *Harvard School of Public Health, U.S.A.*

Background and aims: For more than a decade Mexican candies have been found to have lead concentrations higher than the FDA recommendation of 0.1 ppm. A study that assesses the type, quantity, and frequency of candy that children eat has not been previously carried out in Mexico. This study aims to identify what candy brands are consumed by children, to measure the lead concentrations in the candies that children consume more frequently and to evaluate if the recent ingestion of these candies has an association with their blood lead concentrations.

Methods: We conducted a cross-sectional study nested in a cohort of children living in Mexico City. From June 2007 to July 2008 a recall questionnaire for recent candy ingestion was administered to 181 children between 1 and 6 years of age and their mothers. Children had a capillary blood lead test at the time of the interview. The most frequently consumed candy brands were analyzed for their lead concentrations.

Results: Children reported 171 different candy brands. We analyzed 137 samples of the top 30 brands reported. Three brands exceeded a lead concentration of 0.1 ppm and 9 candy samples exceeded 6 µg of lead (FDA's provisional total tolerable intake level for lead by small children of per day). The mean blood lead concentration was 4.96 µg/dL. After adjusting for sex and age, we found an association between blood lead concentrations and candy ingestion (*ß=0.025, p-value 0.025, 95% C.I. 0.003, 0.047*).

Conclusions: Eating candies with lead concentrations above 0.1 ppm may have an association with an increase of blood lead concentrations in children. The results of this study suggest that Mexican health authorities should further supervise the quality control of candy production and advice the general population with respect to candy intake by small children.

LIGNANS, FLAVONOLS, AND BREAST DEVELOPMENT

Nancy Mervish, *Mount Sinai School of Medicine, USA*

Frank Biro, *Cincinnati Children's Hospital Medical Center, USA*
Larry Kushi, *Kaiser Permanente Division of Research, USA*
Mary S. Wolff, *Mount Sinai School of Medicine, USA*
Breast Cancer and Environment Research Project, *www.bcerc.org*

Background and Aims: Phytoestrogens are dietary micronutrients with known hormonal activity. They have been associated with reduced cancer risk, and they alter pubertal onset in experimental animals and in some human studies. Lignans and flavonols are dietary phytoestrogens found at high levels in the western diet. The Breast Cancer and Environment Research Project (BCERP) cohort is investigating environmental exposures and puberty in females.
Methods: Breast stage, dietary recall data, body size, and other information were collected for 1239 girls enrolled at 3 US sites during 2004-2007, followed through 2010. Phytoestrogen intake was calculated for lignans and flavonols using a new micronutrient database. Associations between phytoestrogens and breast stage (pubertal [B2+] vs prepubertal [B1]) were investigated using bivariate comparisons and Hazards Ratios (HR) with 95%-confidence intervals (CI), adjusting for energy intake, body mass index, race, age and parental education. Data are currently available for 747 girls.
Results: Breast development was present in 81% (N=606/747) at the last visit. Mean level of lignan intake was 0.12 ± 0.07 mg/day; mean flavonol intake was 5.2 ± 3.6 mg/day, mainly quercetin. Energy and quercetin intakes were greater among girls at B2+ compared with B1. Age at B2+ was similar across quartiles of intake, for example HR 1.03 (CI 0.77-1.25) in the 4^{th} vs 1^{st} quartile of lignan intake. We found no attenuation of the BMI-effect on puberty by dietary lignans. Additional analyses will examine how associations may differ at different times during development.
Conclusions: Preliminary results from this longitudinal study suggest that dietary lignans and flavonols are not directly associated with pubertal developmental. Dietary intake during puberty may reflect different windows and duration of exposures than urinary biomarkers of phytoestrogens. Timing of dietary intake may influence associations of weak hormonal agents in relation to pubertal development.

AN ANALYSIS OF SPATIAL VARIABILITY IN DISINFECTION BY-PRODUCT CONCENTRATIONS FOR EXPOSURE ASSESSMENT APPLICATIONS

Amanda M. Evans, *Association of Schools of Public Health, USA*
Amy Meyer, *Oak Ridge Institute for Science and Education, USA*
Zorimar Rivera-Núñez, *National Research Council, USA*
J. Michael Wright, *US Environmental Protection Agency, USA*

Background and Aims: Many epidemiological studies of disinfection by-products (DBPs) in public water systems (PWSs) rely on system average trihalomethane (i.e., THM4; sum of chloroform, dibromochloromethane, bromodichloromethane, and bromoform) and haloacetic acid (i.e., HAA5; sum of monochloroacetic acid, dichloroacetic acid, trichloroacetic acid, monobromoacetic acid and dibromoacetic acid) concentrations as surrogates for chemical-specific personal exposures. The study objective is to assess intra-system variation and evaluate the utility of various methods for determining spatial variability of DBPs.
Methods: To determine the utility of system-averages in estimating DBP levels, we assessed spatial variability in THM4 and HAA5 monitoring data for 144 and 132 PWSs in Massachusetts from 1995-2004. High spatial variability was defined using three methods. Methods 1 and 2 consider a PWS to have high spatial variability if the absolute difference between at least two sampling locations is • 20 and • 30 • g/L, respectively. Method 3 categorizes concentrations based on cut-points of regulatory significance (<40 µg/L, 40-80 µg/L, >80 µg/L), and a PWS is defined as having high spatial variation if same-day sample concentrations fall into multiple categories.
Results: For THM4, 108 PWSs (75%) had high spatial variability according to Method 1, compared to 95 PWSs (66%) using Method 2. Results for HAA5 were lower with 79 PWSs (59%) and 60 PWSs (45%) based on Methods 1 and 2, respectively. Over half of these PWSs had high THM4 and HAA5 spatial variability for at least 25% of their sampling dates. Using only chlorinated surface water PWSs from 1996 (17 PWSs), we found comparable results from Methods 1 and 3, with 76% of PWSs having high spatial variation.
Conclusions: The spatial variability noted within PWSs could result in misclassification bias if system averages are used to estimate individual-level DBP exposures. Therefore, exposure assessment approaches should target systems with minimal spatial variability for epidemiological application.

EXPOSURE TO ENVIRONMENTAL POLLUTION IN THE GENERAL FLEMISH POPULATION: RESULTS OF THE SECOND FLEMISH ENVIRONMENT AND HEALTH STUDY

Background: The second Flemish human biomonitoring survey (2007-2011) generated information on the distribution of biomarkers for a large number of environmental pollutants in a representative sample of the Flemish population.
Methods: Between May 2008 and July 2009, 255 newborns and their mothers, 210 students (14-15 years old) and 204 adults (20-40 years old) were recruited as a representative sample of the Flemish population. Blood, urine and hair samples were collected; questionnaire data were obtained through self-assessment. For each biomarker, the detection frequency, geometric means and 90th percentiles were calculated as reference values for the Flemish population.
Results: Levels of historical compounds were compared with the first Flemish human biomontioring campaign. Persistent chlorinated compounds, cadmium and lead levels decreased over time, while 1-hydroxypyrene (metabolite of PAHs) and t,t-muconic acid (benzene metabolite) remained at similar levels.
New emerging pollutants such as perfluorinated compounds, bisphenol A, phthalates, musks, triclosan, *para*-hydroxybenzoic acid (a metabolite of parabens) and 2,5-DCP (a metabolite of *para*-dichlorobenzene) were detected in 80% or more of the samples. For metabolites of organophosphate pesticides, the detection frequency ranged between 5 (DEDTP) and 95 % (DMTP) of the individual urine samples. Levels of brominated flame retardants were under the limit of quantification in most blood samples.
Margins of safety (MOS) were calculated by dividing the 90th percentile by the available health based biomonitoring equivalants (BEs). MOS below 10 were observed for toxicologically relevant arsenic, cadmium, lead, methyl mercury, hexachlorobenzene and phthalates.
Conclusions: Flemish reference values for exposure to environmental pollutants were obtained, both for historical and new emerging chemicals. These reference values may be used to follow up time trends and to compare exposure of the general Flemish population with health based guidance values.

"Calculating the exposure of infants and children to particulate matter from biomass fuels in The Gambia"

Affiliations:
[1]Harvard School of Public Health, Boston, MA
[2]Medical Research Council Laboratories, Fajara, The Gambia
[3]Royal Veterinary College, London, UK
[4]Imperial College London, London, UK

Background and aims
Smoke from biomass fuels is a risk factor for pneumonia, the leading cause of child death worldwide. While particulate matter (PM) is the metric of choice when evaluating the health effects of biomass smoke, measuring children's exposure to PM is very difficult. Previous studies have used indirect methods to estimate children's PM exposure, including using carbon monoxide (CO) as a proxy for PM, and using time-location-activity budgets in combination with microenvironment PM monitoring. The validity and comparability of these indirect methods is not known. We report on a study which used multiple methods to quantify children's exposure to PM, and validated estimates from indirect methods against direct measurements.

Methods
Two estimates of personal exposure of children in The Gambia to PM were compared to a directly-measured personal PM exposure. A parsimonious mixed effects model was previously used to predict usual 72-h personal CO exposure for 1,200 children. 186 co-located 72-h cookhouse measurements of CO and PM were used to model the CO-PM relationship, with the model including a natural spline to account for non-linearity. In addition, for 60 children time-location-activity budgets and continuous PM measurement in the cookhouse were used to calculate a second estimate of personal PM exposure. For 25 children, these two estimates were compared to a direct measurement of personal PM exposure.

Results
72-h CO and PM concentrations in the cookhouse had a correlation coefficient of 0.85. Based on Bayesian model selection, the CO-PM relationship was best described by a model including CO with a natural spline with 2 degrees of freedom, type of fuel used, season of measurement, and study site. Preliminary results show a mean calculated 72-h PM exposure on children of 112 ± 32 $\mu g/m^3$.

Conclusion
Children's exposure to $PM_{2.5}$ in The Gambia is well above WHO Air Quality Guidelines. The results of multiple measurement methods can be combined to estimate children's personal $PM_{2.5}$ exposure.

DISINFECTION BY-PRODUCTS AND COLORECTAL CANCER IN SPAIN

Cristina M Villanueva, Nuria Aragonés, Itziar Zaldua, Estefanía Toledo, Adonina Tardón, Antonio José Molina, Concepción López Rojo, Esther Gracia-Lavedan, Marina Pollán, Manolis Kogevinas

Background and aims: Disinfection by-products (DBPs) are colorectal carcinogens in rodents exposed experimentally, but epidemiological evidence in humans is contradictory. A multi-case control study conducted in Spain (MCC-Spain) aims to evaluate the risk of colorectal cancer associated with long-term exposure to DBPs.

Methods: Incident cases 20-85 years old were enrolled and population-based controls were age- and gender-frequency matched to cases in Asturias, Barcelona, Gipuzkoa, León, Madrid, Murcia and Navarra. Study subjects were interviewed on residential history and water use (ingestion, showering, bathing, dishwashing and swimming in pools) and potential risk factors. Assessment of lifetime trihalomethane (THM) exposure is based on historical data on THM levels and determinants (water source and treatment) in the study municipalities.

Results: Among the 3762 study subjects included, water ingested at the longest residence (35 years on average) was mainly municipal water (65% cases, 75% controls), followed by bottled water (24% cases, 18% controls). Municipal water consumption at the longest residence, showering/bathing above the median (>35 min/week) and hand dishwashing above the median (>140 min/week) were not associated with colorectal cancer risk (odds ratios around 1 and not statistically significant). Stratified results by area showed consistent results. In a subset of Barcelona (488 cases, 422 controls), the study population was grouped in tertiles of lifetime residential THM concentration from age 16 years. Tertiles in μg/l were 7.5, 21.5 (chloroform); 22.7, 31.5 (bromodichlormethane), 13.9, 26.9 (dibromochloromethane) and 16.5, 49.2 (bromoform). In a model adjusting for the 4 THMs simultaneously, a decreased risk for colorectal cancer was observed for chloroform, and an increased risk for bromodichloromethane, both with statistically significant dose-response trends. No significant associations were found for dibromochoromethane and bromoform.

Conclusions: Results based on the questionnaire show consistent results among areas, with null associations. Results for THM exposure differ widely among specific THMs and need replication in other study areas.

SAHARAN DUST AND CAUSE-SPECIFIC MORTALITY IN EMILIA-ROMAGNA (ITALY)

Stefano Zauli Sajani, *Regional Agency for Environmental Protection of Emilia-Romagna, Italy*
Rossella Miglio, *University of Bologna, Italy*
Paolo Bonasoni, *Institute of Atmospheric Sciences and Climate (ISAC), Italy*
Paolo Cristofanelli, *Institute of Atmospheric Sciences and Climate (ISAC), Italy*

Carlo Alberto Goldoni, *Local Health Authority of Modena, Italy*
Gianfranco De Girolamo, *Local Health Authority of Modena, Italy*
Paolo Lauriola, *Regional Agency for Environmental Protection of Emilia-Romagna, Italy*

Background and Aims: There is a growing concern about the health effects of Saharan dust outbreaks but evidence is limited. We investigated the association between Saharan dust outbreaks and natural, cardiovascular and respiratory mortality.
Methods: A case-crossover design was adopted to assess the effects of Saharan dust days (SDD) on mortality in the Emilia-Romagna region of Italy. The population under study consisted of residents in the six main towns of the central-western part of the region who died between 2002 and 2006. Saharan events have been identified by using observations carried out at the Italian Climate Observatory at Mt. Cimone (2165 m a.s.l.). Based on previous analysis on particulate size distribution of Saharan air masses we decided to use PM_{10} data for particulate exposure instead of $PM_{2.5}$ and $PM_{2.5-10}$ separately. The association of Saharan dust outbreaks and PM_{10} concentration with mortality was estimated using conditional logistic regression, adjusted for apparent temperature, holidays, summer population decrease, flu epidemic weeks and heat wave days. The role of the interaction term between PM_{10} and SDD was analysed to test for effect modification induced by SDD on the PM_{10}-mortality concentration-response function. Separate estimates were undertaken for hot and cold seasons.
Results: We found some evidence of increased respiratory mortality for people aged 75 or older on SDD. Respiratory mortality increased by 22.0% (95% CI 4.0% to 43.1%) on the SDD in the whole year model and by 33.9% (8.4% to 65.4%) in the hot season model. Effects substantially attenuated for natural and cardiovascular mortality with ORs of 1.042 (95% CI 0.992 to 1.095) and 1.043 (95% CI 0.969 to 1.122), respectively.
Conclusions: Our findings suggest an association between respiratory mortality in the elderly and Saharan dust outbreaks. We found no evidence of an effect modification of dust events on the concentration response relationship between PM_{10} and daily deaths.

AMBIENT TEMPERATURE AND RISK OF CARDIOGENIC SHOCK – A CASE-CROSSOVER STUDY

Pei-Chun Chen, *China Medical University and Hospital, Taiwan.*

Ling-Ya Huang, *China Medical University and Hospital, Taiwan.*

Fung-Chang Sung, *China Medical University and Hospital, Taiwan.*

Background and Aims: Cardiogenic shock is a life-threatening medical condition. The authors investigated the association between ambient temperature and risk of cardiogenic shock.

Methods: This population-based case-crossover study used claims data from Taiwan National Health Insurance. We identified patients with an initial hospitalization for cardiogenic shock during 1996-2008 using the primary hospital discharge diagnosis. For each subject, we defined the date of hospitalization for cardiogenic shock as the case period. Ambient temperature was compared between the case period and the 14 control periods: 7th, 14th, 21st, 28th, 35th, 42ed and 48th day before and after the case period. We used conditional logistic regression models, mutually adjusted for mean daily temperature and daily temperature change, to assess the association between the two variables and risk of cardiogenic shock.

Results: During the 13-year period, 53352 patients had an initial hospitalization for cardiogenic shock. Mean daily temperature of 30°C and above presented in 3.9% of case periods and 3.6% of control periods (p=0.004), and the adjusted odds ratio (OR) was 1.16 (95% confidence interval [CI]=1.08-1.25), as compared with mean temperature of 20-24°C. The corresponding OR was 1.02 (95% CI=0.99-1.05) for mean temperature of 25-29 C, 1.00 (95% CI=0.97-1.03) for that of 15-19°C and 0.99 (95% CI=0.95-1.03) for that of <15°C. However, greater daily change in temperature was associated with increased risk of cardiogenic shock. Compared with the change of <5°C, the adjusted OR was greatest for the change of 15°C and above (OR=1.15, 95% CI=1.09-1.21), follow by the variation between 10-14°C (OR=1.09, 95% CI=1.04-1.15) and 5-9°C (OR=1.08, 95% CI=1.04-1.13).

Conclusions: Elevated ambient temperature and increased daily variation in temperature are associated with increased risk of cardiogenic shock in this study in Taiwan. We found no appreciably association between low temperature and the risk of cardiogenic shock.

RESIDENTIAL HISTORY, DURATION OF ENVIRONMENTAL AND NEIGHBORHOOD SOCIOECONOMIC EXPOSURES AND MENTAL AND CARDIOVASCULAR HEALTH

On behalf of the Heinz Nixdorf Recall Study Investigative Group

Background and Aims: High traffic at the residence has been linked to cardiovascular and mental health in cross-sectional analyses; however, the lack of a residential history to assess duration of exposure has limited prior analyses. We investigate the effect of exposure duration on disease prevalence.
Methods: We used baseline data (2000-2003) from the population-based prospective Heinz Nixdorf Recall Study in Germany. Residential history of 10 years before baseline examination was obtained from the city registries for 3,320 participants, aged 45-75 years. Proximity to state/federal highways, traffic noise (EU-directive; 2002/49/EC), and neighbourhood unemployment rate were assigned on a monthly basis to all of the participants´ addresses. Outcomes included depression, high coronary artery calcification (CAC), and hypertension. Logistic regression was used, adjusting for cardiovascular risk factors and traffic proximity (in models with noise and neighbourhood unemployment as main exposures).
Results: Full ten-year residential history was available for 95.3%, 20.7% changed their residence at least once. In the subset of participants with complete residential history (n=2,830), night-time noise exposure >60 dB for 1-60 months yielded ORs for depression (2.68; 1.08-6.64) and high CAC (1.67; 0.86-3.23); similar trends, but smaller effect sizes were observed for longer exposure duration. ORs for 1-60 and 61-120 months of residence in neighborhoods with high unemployment rate (upper quintile) were 1.20 (0.54-2.71) and 1.60 (1.10-2.31) for depression and 1.40 (0.87-2.28) and 1.01 (0.80-1.27) for high CAC, respectively. Marginal associations of residence within 100 m of a major road were observed for depression and high CAC, however, no consistent exposure-response relationship was found. ORs for hypertension were elevated, though inconclusive.
Conclusions: We found weak associations of long-term residential exposures with mental and cardiovascular health outcomes, but reductions in sample size due to out-of-area relocations and extrapolation of exposures into the past have to be considered.

INFLUENCE OF TRAFFIC-RELATED AIR POLLUTION ON BIOMARKERS OF OXIDATIVE STRESS AND INFLAMMATION IN HEALTHY ADULTS: SEASONAL FOLLOW-UP

Background and Aims: Traffic-related air pollution is known to induce oxidative stress and inflammation in humans. Our aim was to assess whether measurement of oxidative stress and inflammation markers are associated with exposure parameters.
Methods: The study population consisted of 48 healthy non-smoking adults. Following biomarkers for oxidative stress and inflammation were analysed in both Winter and Summer season: oxidative DNA damage in blood (comet assay, FPG sites), 15-F2T-isoprostane in plasma, 8-oxo-2'-deoxyguanosine (8-oxodG) in urine, and nitric oxide (eNO) in exhaled breath.
Exposure to traffic-related air pollution during the 2 seasons was assessed: NO_2, PM_{10} and O_3 concentrations at the home address (4x4 km grids) were calculated by interpolation of measured concentrations at stationary stations. A Geographical Information System (GIS) was used to calculate traffic-related parameters. Also, participants wore a personal dosimeter for NO_2.
Associations between exposure parameters (single pollutant/exposure model) and biomarkers, within each individual in Winter and Summer, were tested using multiple mixed-effects regression models.
Results: NO_2 and PM_{10} concentrations correlated positively with eNO ($p<0.10$ and <0.01, respectively). For ozone, positive associations were found with comet assay results, 15-F2T-isoprostane measurements, and 8-oxodG in urine ($p<0.05$, <0.10 and <0.10, respectively). No correlations with GIS data or personal NO_2 dosimetry were observed.
Further, multi-pollutant models will be analysed. Results will be presented at the ISEE meeting.
Conclusions: It is well known that traffic-related air pollution triggers inflammation and oxidative stress reactions in individuals with chronic diseases, such as cardiovascular patients, asthmatics and diabetics. In our study biomarkers measured in healthy adults correlated with background outdoor pollutants at home address.
Ackownledgements: This study was financed by the Flemish Government (Department of Environment, Nature & Energy, Environment and Health unit), and the EU-FP7 project INTARESE.

PULSE PRESSURE AND CONSTITUENTS OF PARTICULATE AIR POLLUTION IN ELDERLY

Lotte Jacobs, *K.U.Leuven, Belgium*
Anna Buczynska, *UA, Belgium*
Christophe Walgraeve *Ugent, Belgium*
Andy Delcloo, *RMI, Belgium*
Sanja Vermaak, *UA, Belgium*
Rene Van Grieken, *UA, Belgium*
Kristof Demeestere, *Ugent, Belgium*
Jo Dewulf, *Ugent, Belgium*
Herman Van Langenhove *Ugent, Belgium*
Hugo De Backer, *RMI, Belgium*
Benoit Nemery, *K.U.Leuven, Belgium*
Tim Nawrot, *Uhasselt, Belgium*

Background and Aims: An increased pulse pressure (Δ systolic – diastolic pressure) suggests aortic stiffening. New evidence also suggests that pulse pressure is a more sensitive measure of risk than other indexes of blood pressure in middle-aged and older persons. The objective of this study was to examine the acute effects of both particulate matter (PM) mass and composition on systolic blood pressure, diastolic blood pressure and pulse pressure, among a more susceptible population of elderly persons.
Methods: During the period June 2007 until October 2010, we carried out a panel study in persons living in elderly homes located in the province of Antwerp, Belgium. Blood pressure was measured and a blood sample was collected on two time points. Exposure to in- and outdoor 24 hour mean $PM_{2.5}$ mass concentrations was determined. The elemental content of the collected in- and outdoor $PM_{2.5}$ was measured. Oxygenated polyaromatic hydrocarbons (oxy-PAHs) sorbed onto outdoor PM_{10} were measured.
Results: We recruited 84 persons, 70 % women with a mean age of 83 years (SD: 5.2). Each interquartile range (IQR) increase of 21.1 µg/m³ in 24 hour mean outdoor $PM_{2.5}$ was associated with an increase in systolic blood pressure of 3.9 mmHg (95%CI:1.6 to 6.2) and in pulse pressure of 4.1 mmHg (95% CI: 1.8 to 6.5), in persons taking antihypertensive medication (n=54), but not in persons not using antihypertensive medication (p for interaction: 0.02). Vanadium, iron and nickel content of $PM_{2.5}$ were significantly associated with systolic blood pressure and pulse pressure, among persons on antihypertensive medication. Similar results were found for indoor concentrations. Of the oxy-PAHs, chrysene-5,6-dione, benzo[a]pyrene-3,6 and benzo[a]pyrene-6,12 were significantly associated with increases in systolic blood pressure and pulse pressure.
Conclusions: In elderly, pulse pressure was positively associated with acute increases in outdoor and indoor air pollution, among persons taking antihypertensive medication. These results might form a mechanistic pathway linking air pollution as a trigger of cardiovascular events.

MONETISING ROAD TRAFFIC NOISE AND AIR POLLUTION IMPACTS: DOES IT MATTER WHICH EFFECTS YOU SPECIFY?

Tifanny Istamto, Institute for Risk Assessment Sciences (IRAS), Utrecht University, the Netherlands
Danny Houthuijs, National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands
Erik Lebret, Institute for Risk Assessment Sciences (IRAS), Utrecht University, the Netherlands - National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands

Background and aims: There is an increasing trend to monetise environmental health impacts. Only few studies provided original data on the economic valuation of environmental health impacts in terms of public's willingness-to-pay (WTP) and willingness-to-accept (WTA). We studied how people value the impacts of road traffic noise and air pollution.
Methods: A web-based survey was conducted in the United Kingdom, Finland, Germany, the Netherlands, and Spain in 2010. Our objective was to gather 2,000 respondents per countries. There were 2 types of survey: one on air pollution and the other on noise. Respondents randomly received one of the two types of the survey. We inquired respondent's WTP and WTA to avoid or to accept the current level of road traffic noise and air pollution related to different types of health and wellbeing outcomes.
Results: Nearly 10,500 respondents answered the survey and 75% of them decided to answer the other type of survey. Circa 10% of the respondents rejected the concept of WTP and 2% rejected the WTA concept, with various motivations between countries. When the effects of road traffic noise and air pollution were specified, their WTP and WTA increased, compared to when the effects were unspecified. The annual WTP for separated effects summed up for noise and air pollution had an average between €40 and €200 for the participating countries. For the annual WTA of separated effects, the average was between €130 and €2,230.
Conclusions: When effects were presented as a combination of effects which occurred simultaneously, the amounts of WTP and WTA were much lower than the sum of the individually scored health outcomes. Specifying the impacts of road traffic noise and air pollution lead us to a higher amount of WTP and WTA, compared to valuation of traffic noise and air pollution in general.

VALIDATION OF EXPOSURE ASSESSMENT IN ESCAPE, THE VE3SPA PROJECT

Denise Montagne, *IRAS, Utrecht University, the Netherlands*
Mark Nieuwenhuijsen, *CREAL, Spain*
Timo Lanki, *THL, Finland*
Audrey de Nazelle, *CREAL, Spain*
Meritxell Portella, *CREAL, Spain*
Arto Pennanen, *THL, Finland*
Gerard Hoek, *IRAS, Utrecht University, the Netherlands*
Bert Brunekreef, *IRAS, Utrecht University, the Netherlands*

Background and aims Land use regression (LUR) models can be used to provide individual estimates of outdoor air pollution concentrations at the residential address. There is limited information on how closely these residential exposure estimates are related to personal exposure. The objective of the VE3SPA project is to measure the personal exposure to PM2.5 and NOx for volunteers living at a busy street, an urban background location or a suburban/regional background location. The results will be used to quantify the agreement between modelled outdoor concentrations at the home address and measured personal exposures.

Methods In Barcelona, Helsinki and Utrecht fifteen volunteers participated, five from each location type. Volunteers were asked to adhere to predetermined time activity patterns representative for schoolchildren and elderly adults. The volunteers participated for two weeks in three different seasons (winter, summer and spring/autumn). During every 2-week measuring period, three participants (one from every site type) were selected.
At the house of the volunteer, three identical PM2.5 filter sampling units and NOx/NO2 (Ogawa) badges were placed. One unit was placed outdoors, one indoors in the living room and another was a mobile unit placed in a backpack. The participants took the backpack to different locations for a prescribed amount of hours.

Results We will present the differences in outdoor, indoor and personal exposures between busy street, urban and suburban/regional background sites for the three cities. In the Netherlands, average PM2.5 concentrations were 14, 11 and 11 $\mu g/m^3$ for outdoor, indoor and personal exposure respectively. Average absorbance values (a marker for elemental carbon) were 1.1, 0.8 and 0.8 for outdoor, indoor and personal exposure.

Conclusions Measured personal and indoor exposure to PM2.5 and black carbon were slightly lower than measured outdoor concentrations. A comparison between exposure modeled with LUR and measured exposures will be presented at the conference.

THE IMPACT OF URBAN SPRAWL ON THE WALKABILITY OF SUBURBAN, TRADITIONAL, AND URBAN COMMUNITIES IN CINCINNATI, OHIO, USA

Dawn Ebron, *Wright State University, United States of America*
Naila Khalil, *Wright State University, United States of America*
Jennifer Weisser, *Wright State University, United States of America*
Caitlin Botschner, *Warren County Soil and Water Conservation District/Engineer's Office, United States of America*

Background and Aims: The prevalence of obesity in the United States of America (USA) has risen over the past 25 years. Participation in regular physical activity and adopting a healthy diet are recommended behaviors in preventing obesity. An individual's level of physical activity is influenced by the walkability of his or her environment which has been compromised by the trend of urban sprawl. This research addressed the effect urban sprawl has on physical inactivity of members of suburban Cincinnati, Ohio, USA, communities as well as the negative impact of urban sprawl on physical activity of members who remained in the urban communities.
Methods: Using geographic information systems (GIS) and field observations, the walkability of a suburban, traditional, and urban community was assessed using six walkability criteria. In each community, two residences were chosen and observations related to the walkability criteria were recorded within a 400 meter buffer zone of the house.
Results: The suburban community was considered safe with good path quality and context, but deficient land use mix, poor connectivity, and minimal access to other modes of transportation proved to be a barrier to walking. The neighborhoods in the urban community had good mix ofland uses, high connectivity of the path network, acceptable path quality, and multiple linkages to other modes of transportation. Safety and path context proved to be extremely poor attributes of this neighborhood. The traditional neighborhood could be deemed walkable based on all six walkability criteria.
Conclusions: City planners and public health practitioners must work together to evaluate their communities and plan improvements that will support walking and outdoor physical activity. Enhancing neighborhood walkability by adding sidewalks, addressing safety concerns, or improving neighborhood aesthetics can reduce the negative effects urban sprawl has had on physical activity and ultimately the rates of obesity.

ENVIRONMENTAL CONTAMINATION AND ITS IMPACT ON PREGNANCY FREQUENCY IN ESTUARY OF SANTOS AND SÃO VICENTE, SÃO PAULO, BRAZIL

Mariana Guimarães, *University of São Paulo Faculty of Medical Sciences, Brazil*
Michele Cunha, *Catholic University of Santos, Brazil*
Tatyana Ribeiro, *Catholic University of Santos, Brazil*
Daniele Carvalho, *University of São Paulo Faculty of Medical Sciences, Brazil*
Alfésio Braga, *University of São Paulo Faculty of Medical Sciences, Brazil*
Luiz Alberto Pereira, *University of São Paulo Faculty of Medical Sciences, Brazil*

Background and Aims: There are many sources of pollution like capital goods industries, port terminals and open air dump sites in the region of Santos and São Vicente Estuary. Heavy metals, organochlorine pesticides, polychlorinated biphenyl, dioxins and furans are stood out within toxic substances found in this region that are deleterious to health and cause mostly effects on reproductive system. The aim of this study was to evaluate occurrence of pregnancy in these contaminated areas comparing to a non contaminated area (control).
Methods: We adopted a cross sectional study. A structured and pre-tested questionnaire was applied to 820 families in each one of the five studied areas: four of them in the Estuary region and one in a control area without evidences of environmental contamination but with the same socioeconomic profile of the contaminated ones. We estimated the proportion of pregnant, controlling to important fertility risk factors (time of exposure in the area, occupational exposure, use of alcohol and tobacco), in those areas and tested differences among them and the control area using the Fisher's exact test and adopting a significance level of 5%. This study is part of a wide project which aims to estimate the effects to health associated to environmental contaminants exposure in the Santos and São Vicente Estuary Region.
Results: We found a significant association between living in contaminated areas in three of four areas and decrease of pregnancy percentage. Area 2 (Cubatão) 26,2% (133), Area 3 (São Vicente) 30,7% (125), Area 4 (Guarujá) 30,9% (141) compared to control area (Bertioga) 38,4% (128).
Conclusions: This study shows enough evidence in reducing number of pregnancies in contaminated areas and reinforces the necessity of deepening additional studies in the region of the Santos and São Vicente Estuary.

EARLY LIFE BPA EXPOSURE AND OBESITY AND METABOLIC SYNDROME IN CHILDREN

Con formato: Derecha: 0 cm

Kim G. Harley, *University of California, Berkeley, United States*
Raul Aguilar-Schall, *University of California, Berkeley, United States*
Michelle Vedar, *University of California, Berkeley, United States*
Antonia Calafat, *Centers for Disease Control and Prevention, United States*
Xiaoyun Ye, *Centers for Disease Control and Prevention, United States*
Brenda Eskenazi, *University of California, Berkeley, United States*

Background and Aims: Bisphenol A (BPA) is a widely used, endocrine disrupting compound detected in 93% of Americans. Prenatal and early postnatal BPA exposures are associated with increased weight gain in rats, but no published studies have examined early life exposure and obesity in children.
Methods: Participants were 313 children enrolled in the Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS), a longitudinal birth cohort study in northern California. We measured BPA concentrations in urine from mothers during pregnancy and children at 5 and 9 years of age. Children were examined at 9 years of age to measure height, weight, waist circumference, percent body fat, and blood pressure. Fasting blood was collected on a subset (n=119) of 9-year old children for measurements of glucose and lipids.
Results: Urinary BPA concentrations in pregnant mothers (median = 1.1 µg/L), and children at age 5 (median = 2.3 µg/L) and age 9 (median = 1.6 µg/L) were within U.S. national averages. Prenatal and age 5 BPA concentrations were unassociated with anthropometric measures at age 9. However, $\log_{10}$-transformed BPA concentrations at age 9 were associated with increased BMI (• =2.1 kg/m^2, 95% confidence interval (CI): 0.6, 3.6), waist circumference (• =6.0 cm, 95% CI: 2.0, 10.2) and percent body fat (• =4.3%, 95% CI: 0.4, 8.2) at age 9. Results were similar after adjustment for urinary creatinine and other covariates. Future analyses will examine associations with elements of metabolic syndrome, including blood pressure, glucose, and lipid levels.
Conclusions: Prenatal and early childhood exposures to BPA were not associated with BMI, waist circumference, and percent body fat at age 9 years, but concurrent BPA levels were. It is unknown whether BPA is causally related to obesity or whether the association is due to weight-related differences in storing or metabolizing BPA.

VALUING ENVIRONMENTAL HEALTH IMPACT OF TRAFFIC CIRCULATION PLAN IN THE HAGUE

Tifanny Istamto[1], Gerard Hoek[1], Hans Nijland[2], Elise van Kempen[3], Erik Lebret[1, 3]

[1] Institute for Risk Assessment Sciences (IRAS), Utrecht University, the Netherlands
[2] PBL Netherlands Environmental Assessment, Bilthoven, the Netherlands
[3] National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands

Background and aims: Within the framework of Integrated Assessment of Health Risks of Environmental Stressors in Europe (INTARESE), the impact of the traffic circulation plan (VCP) in The Hague during 2007-2010, was assessed. Our aim was to provide an overview of the relevant costs and benefits of different health endpoints related to the traffic exposure of this transport intervention.

Methods: The impact of VCP was quantified by selecting traffic-related exposure and health endpoints, modelling of population exposure, selecting exposure-effect relations, estimating the number of attributable cases, and assessing these outcomes in terms of Euros.
By applying the "revealed-preference" method using the existing market prices for cardio- and respiratory diseases, the perceived depreciation of property, and the aggregated health indicator for mortality, we derived economic values for persons with a certain disease/health end-point attributable to road traffic noise exposure or exposure to air pollution.

Results: Some 90,000 people live in the study area which covers about 8 km^2. The benefit of discounted mortality in the period between 2010 and 2115, which is the expected life period of a birth cohort in 2010, is approximately projected to be €7 million for 467.4 life years gained with the implementation of VCP. The annual gains in terms of less hospital admissions for cardiovascular- and respiratory diseases are circa €3,000. A reduction of noise to 50 dB and 55 dB increases the property values with approximately a range of between €120,000 and €105,000 annually in the housing areas influenced by VCP.

Conclusions: In the period up to 2020, the monetary value of the total health benefits from VCP implementation is projected to be approximately 1.5 to 2 million euros. Two thirds of this would be due to health benefits from noise reduction, while one third from cleaner air. For a longer time span, e.g. 2030, the benefits from cleaner air would be greater than from noise reduction.

AIR QUALITY MONITORING SYSTEM FOR A MORE COMPREHENSIVE LOOK AT TRANSPORTATION EMISSIONS

Emily Lord, *Trinity College Dublin, Ireland*
Dermot Geraghty, *Trinity College Dublin, Ireland*

Background and Aims:
Recent studies indicate that pedestrians are regularly exposed to high levels of sulfur dioxide (SO_2), nitrogen dioxide (NO_2), nitric oxide (NO), ozone (O_3) as well as carbon monoxide (CO) at street level, with peak concentrations during the rush hour commute. Many respiratory and cardiovascular issues for children under 18 years of age and elderly people have been linked to exposure to air pollutants. Current roadside monitoring of transportation emissions is irregular and subjective to the availability of personnel to remain on site, indicating the need for a more continuous system for data acquisition.
Methods: The unit under development is compact, unobtrusive, cost effective and easily installed at street level for continuous monitoring of air pollution to provide a more comprehensive data set on daily pedestrian exposure to air pollution. This system utilizes compact sensors and a unique Linux based operating system, facilitating a simple expansion protocol to a network of sensor nodes, allowing for regional comparison as well as the facilitation of modeling urban levels of carcinogenic gas. It currently has pressure, temperature and relative humidity sensors integrated in to the system, while lab testing continues on the selected gas sensors.
Results: The system is fully functional. The temperature, pressure and relative humidity sensors have been integrated and are producing accurate results. The system is functionally robust where any error occurs, the system is set to reboot and start anew. The units can be left running for months at a time without issues enabling them to continuously collect data 24 hours a day.
Conclusions: The system is created in order to minimise size and maximise performance to enable monitoring in close proximity to the breathing height of the public. Additional units deployed are easily integrated in to the network to facilitate mapping of pollution levels.

EPIDEMIOLOGY OF UNINTENTIONAL CARBON MONOXIDE FATALITIES IN THE UK

Alexandra de Juniac, *Centre for Radiation, Chemical and Environmental Hazards (London), Health Protection Agency, UK and St George University, London, UK*
Irene Kreis, *Centre for Radiation, Chemical and Environmental Hazards (London), Health Protection Agency, UK*
Judith Ibison, *St George University, London, UK*
Virginia Murray, Centre *for Radiation, Chemical and Environmental Hazards (London), Health Protection Agency, UK*

Background and Aims: Carbon monoxide (CO) is a colourless, odourless, tasteless, non-irritant gas, which is potentially lethal. We describe the epidemiology of unintentional non-fire related CO fatalities in the UK and where possible to link this to sources of CO.
Methods: Unintentional CO related deaths were as recorded on the CO-Gas Safety Society (COGSS) database. Results were compared to results from the English House Condition Survey (EHCS). Statistical tests included the calculation of relative risk and 95% confidence intervals.
Results: The COGSS database from 1 January 1996 to 31 December 2007 inclusive was used, covering 462 deaths. Patterns were mostly as expected with spikes of death in the colder season but some small changes over time occurred. The most striking results concerned those related to heaters which could not be tested against national usage data and gas vs non-gas heating fuels which was tested. By consulting the EHCS the overall relative risk for death due to non-gas vs gas fuels was found to be 10.52 (95% CI 7.71 – 14.34).
Discussion and Conclusion: The main weaknesses of the study lies in the heavily reliance on figures from an incomplete database. While confident in the broad observations there is the possibility of sample bias in the COGSS figures. There do not appear to be any other studies, which have examined CO-poisonings in a similar way. However, several of the more generic findings are corroborated in a few recent studies.
Despite possible apprehensions about the quality of the data, there is nonetheless a clear need for concern regarding CO-related deaths in the UK. In particular, the use of non-gas fuels has not before been highlighted as a significant cause of CO poisoning and the relative risk (although not the absolute risk) of CO-related fatalities from these fuels is substantial. Further investigation and more elaborate use of existing data is needed.

AGE AT PUBERTY IN RELATION TO PREPUBERTAL MEASURES OF PFOA – NEW FINDINGS

Background and Aims: Polyfluoroalkyl compounds (PFCs), such as perfluorooctanate (PFOA) and perfluorooctane sulfonate (PFOS), have been reported to change mammary gland structure in laboratory animals and pubertal timing in humans. We explored the relationships between serum PFOA and PFOS concentrations and pubertal maturation in young girls.
Methods: Within the NIH Breast Cancer and the Environment Research Program, we conducted a study of PFC environmental biomarkers, including PFOA and PFOS, in young girls (age 6-7 years at entry) from two sites (N=688 girls). Pubertal staging (breast and pubic hair) has been conducted by clinicians or trained research staff, every year or more frequently, for as long as six years. Using longitudinal analysis methods (time to event) we studied the relationship between PFOA and PFOS serum concentrations measured at the beginning of the study (2005-2006) with age at pubertal Stage 2.
Results: Median serum concentrations of PFOA and PFOS differed at the two sites (California: PFOA= 5.8 ng/ml, PFOS=12.5 ng/ml vs. Cincinnati PFOA =7.9 ng/ml, PFOS 14.0 ng/ml). Among girls at the Cincinnati site, we found a statistically significant relationship between PFOA serum concentration and age at Tanner breast Stage 2, and an inverse relationship between PFOS and age when Tanner pubic hair Stage 2 was first noted, with adjustment for race/ethnicity, body mass index percentile for age, caregiver education and mother's age at menarche. Neither of these relationships reached statistical significance among the girls at the California site.
Conclusions: PFOA and PFOS may act as endocrine disruptors, affecting the timing of pubertal maturation in humans.

Support for this project provided by the National Institute of Environmental Health Sciences and the National Cancer Institute, to the University of Cincinnati/Cincinnati Children's Hospital Medical Center, Breast Cancer & the Environment Research Center (U01 ES12770), and Center for Environmental Genetics (P30-ES06096).

PREVALENCE OF PREGNANCY OUTCOMES IN CONTAMINATED AREAS IN ESTUARY OF SANTOS AND SÃO VICENTE, SÃO PAULO STATE, BRAZIL

Mariana Guimarães, *University of São Paulo Faculty of Medical Sciences, Brazil*
Michele Cunha, *Catholic University of Santos, Brazil*
Tatyana Ribeiro, *Catholic University of Santos, Brazil*
Daniele Carvalho, *University of São Paulo Faculty of Medical Sciences, Brazil*
Alfésio Braga, *University of São Paulo Faculty of Medical Sciences, Brazil*
Luiz Alberto Pereira, *University of São Paulo Faculty of Medical Sciences, Brazil*

Background and Aims: The Estuary region hosts a large number of industries, based on petrochemical, steel and production of fertilizers since the 1950s. Epidemiology provides evidence that fetus and infants are probably more susceptible to environmental toxic substances than adults. Therefore, the aim of this study was to evaluate the occurrence of adverse pregnancy outcomes in these contaminated areas comparing to a non contaminated area (control).
Methods: We adopted a cross sectional study. A structured and pre-tested questionnaire was applied to 820 families in each one of the five studied areas: four of them in the Estuary region and one in a control area without evidences of environmental contamination but with the same socioeconomic profile. We estimated the prevalence of pregnancy outcomes (abortion, prematurity, low birth weight – LBW, stillbirth, congenital malformation), controlling to important pregnancy risk factors (time of exposure in the area, occupational exposure, use of alcohol and tobacco), in those areas and tested differences among them and the control area using the Fisher's exact test and adopting a significance level of 5%. This study is part of a wide project which aims to estimate the effects to health associated to environmental contaminants exposure in the Santos and São Vicente Estuary Region.
Results: We found a higher prevalence of pregnancy outcomes in contaminated areas. A significant association was found between living in contaminated areas and increase of spontaneous abortions prevalence; Area 1 (Pilões) 14.9% (20), and Area 3 (São Vicente) 17.8% (21) compared to control area (Bertioga) 7.3% (9). There was also a significant increase in prevalence of LBW in Area 1 (Pilões) 9.2% (12) compared with the control area (Bertioga) 3.3% (4).
Conclusions: This study shows evidence in increase number of pregnancy outcomes in contaminated areas and reinforces the necessity of additional studies in these regions.

Arsenic methylation is associated with breast cancer risk in northern Mexico

López-Carrillo Lizbeth, *National Institute of Public Health, México.*

Cebrián Mariano E., *Departamento de Toxicología. Centro de Investigación y Estudios Avanzados (Cinvestav), México.*

Background and Aims: Arsenic (iAs) exposure has been associated with several types of cancer (1). However, most studies to date have not yet implicated iAs as a cofactor for breast cancer (BC). BC incidence and mortality are 3-fold higher in Northern Mexico (NM) than in the rest of the country (2). iAs levels in drinking water are a source of concern since they have been above international standards (3). We hypothesized that iAs exposure and individual Arsenic-methylation ability are potential cofactors for BC risk.
Methods: We investigated 840 BC incident cases and 973 controls from a population-based case-control study performed in NM. Women were directly interviewed about dietary and reproductive BC covariables. iAs metabolites in urine were determined by HPLC/ICP-MS. Methylation capacity was assessed by calculating the percentage of iAs species and primary [MMA(V)/(As(III)+As(V)] (PMI) and secondary [DMA(V)/MMA(V)] methylation indexes (SMI).
Results: The range of total urinary Arsenic was 0.4-303.9 ug/L. Most women (91%) had values above 50 ugAs/L. %MMA(V) was significantly higher in BC cases while %DMA(V) was significantly lower. PMI was positively associated with BC (OR T3vsT1=1.47; 95%CI=1.17-1.84; p for trend=0.001), while SMI was negatively associated (OR T3vsT1=0.54; 95%CI=0.42-0.68; p for trend<0.001).
Conclusions: As exposure may pose a risk for BC, particularly in women with higher capacity to methylate iAs to MMA(V) and lower capacity to further methylate MMA(V) to DMA(V). This is consistent with studies indicating that the proportion of MMA(V) in urine was positively associated whereas that of DMA(V) was inversely associated with the risk of skin, bladder and lung cancer (4,5). Further research is needed about the temporal relationships between disease and methylation capacity and the presence of potential association modifiers, including environmental and genetic factors involved in one carbon metabolism.

MOTORISED TRIPS SUSCEPTIBLE OF BEING SUBSTITUTED BY WALKING IN CATALONIA, SPAIN

Marta Olabarria, *Agència de Salut Pública de Barcelona, Spain*
Katherine Pérez, *Agència de Salut Pública de Barcelona, Spain*
Elena Santamariña-Rubio, *Agència de Salut Pública de Barcelona, Spain*
Ana M Novoa, *Agència de Salut Pública de Barcelona, Spain*

Background and aims: Walking as a mean of transport is considered a moderate physical activity that can be integrated into daily life and suitable for achieving recommended activity levels. This study aims to quantify the number of people who could achieve recommendations by substituting short motorised trips (5 minutes or less) by walking.
Methods*:* A cross-sectional study was developed. Data come from individuals older than 3 years who reported, in the 2006 Daily Mobility Survey, having travelled on the referred working day (N=98,665). A bivariate and multivariate logistic regression analysis was carried out to determine the factors associated with making short motorised trips among those not reaching recommended physical activity levels through walking, by calculating odds ratios (OR) and their corresponding 95%CI.
Results: A total of 79% of men and 70.6% of women did not achieve recommended physical activity levels through walking. Of those, 16% of men [95%CI 15.6-16.4], and 14.5% of women [95%CI 14.1-14.9], could achieve recommended levels of physical activity if they were to substitute at least one (in adults) or two (in younger than 18) short motorised trip by walking. This change would increase in 405,694 men [95%CI 394,742-416,619] and 321,303 women [95%CI 311,989-331,012] the number of people in Catalonia who would achieve recommended daily levels of physical activity through walking as a means of transport. In both men and women, the association of making short motorised trips increases with decreasing age (OR=3.01, [2.13-4.50] in 4-11 aged boys; OR=6.04[3.91-9.31] in girls), increases with decreasing size of municipality (OR=4.32[3.71-5.05]; OR=6.49[5.34-7.89], men and women, respectively, residing in the smallest municipalities) and is associated with living with 2 or more other people only among women (OR=1.71[1.44-2.04]).
Conclusion: This study shows the potential of daily trips on foot as a source of physical activity when combating current levels of sedentarism.

PRENATAL EXPOSURE TO PM2.5 AND ITS RELATIONSHIP WITH LOW BIRTH WEIGHT IN THE INMA-GIPUZKOA COHORT.

Background and Aims: Research has shown that prenatal exposure to air pollutants may have a detrimental effect on foetal development. Weight at birth is the most commonly used anthropometric variable for assessing foetal growth. The objective of this study was to assess the role of exposure to 2.5 µm particulates ($PM_{2.5}$) in the first trimester of pregnancy considering the birth weight of children of the INMA-Gipuzkoa cohort (Spain) (www.proyectoinma.org).
Methods: Growth charts for both sexes were constructed from the data of children born between 2006 and 2008 in Gipuzkoa (N=21,629). The estimation of percentiles was carried out using the Least Mean Square (LMS) method for smoothing and Small for Gestational Age (SGA) babies among INMA children were identified. Data on exposure to $PM_{2.5}$ were obtained from 3 DIGITEL high volume samplers and two stations in the air quality network of Basque Government (Spain).Assignment to a level of exposure was made for those women who lived in the city less than 500 metres from one of the sites where measurements had been taken. They were assigned an average value for $PM_{2.5}$ for week 12 of their pregnancy. Two multivariate regression models were build using birth weight and SGA as the dependent variables, while exposure was introduced as a continuous and dichotomous variable (>20 $\mu g/m^3$).
Results: Out of the 601 births in INMA, 64 (10%) were identified as SGA. The average level of exposure to $PM_{2.5}$ at week 12 of pregnancy was 17.56 $\mu g/m^3$ (range: 8.3-35.4 $\mu g/m^3$). Results showed a statistically significant relationship between exposure and SGA ($OR_{PM2.5}$ =1.007; p=0.036, unadjusted OR>20 =2.537; p=0.008 and OR>20 adjusted=1.11; p=0.038).
Conclusions: We observed a positive relationship between the prenatal levels of exposure to $PM_{2.5}$ during the embryonic stage of pregnancy and an increased risk of low weight at birth in terms of SGA.

PUBLIC HEALTH RISK ASSESSMENT ASSOCIATED WITH HEAVY METAL AND ARSENIC EXPOSURE NEAR AN ABANDONED MINE (KIRKI, GREECE)

Christos Nikolaidis, *Democritus University of Thrace, Greece*
Moysis Orfanidis, *Democritus University of Thrace, Greece*
Stratos Mylonas, *Democritus University of Thrace, Greece*
Theodore Constantinidis, *Democritus University of Thrace, Greece*

Background and Aims: The "Agios Philippos" lead-zinc mine in the Kirki region (NE Greece) is now closed but its legacy of heavy metal contaminated land remains at the site (Loupasakis and Konstantopoulou 2009, Nikolaidis *et al.* 2010). A risk assessment approach was elaborated in order to address the potential adverse health effects associated with lead, cadmium, zinc and arsenic exposure.
Methods: Soil samples from the proximity of the mine were collected and analyzed using standard procedures (Chen *et al.* 2006). Risk assessment guidelines developed by US EPA were employed in order to assess exposures related to i) inhalation of dust particles, ii) dermal absorption of trace elements adhered to the skin and iii) soil ingestion (US EPA 1997). The average daily dose (ADD) was calculated taking into account both the carcinogenic and non-carcinogenic risk. The reference dose (RfD) for each element was used to yield a hazard quotient (HQ) of non-carcinogenic effects. The hazard index (HI) was then generated by summing up all individual HQs. A slope factor (SF) was used to calculate the carcinogenic risk (CR) for arsenic (IRIS 2009).
Results: The majority (69.2%) of samples approximating the source of heavy metal contamination produced an increased toxicological risk for arsenic and lead. The overall hazard index near the mine portal exceeded the accepted value (HI• 1) by 4.3-fold. An unacceptable carcinogenic risk for arsenic (CR> 1 x10^{-5}) was evident near the contamination source, which gradually faded out with distance from the mine.
Conclusions: These findings indicate that heavy metal contamination in the "Agios Philippos" mine poses a significant risk to the exposed population (Kirki, NE Greece). These exposures have to be carefully evaluated at the biological level and validated by appropriate epidemiological methods before any further conclusions can be made.

EFFECTS OF PRENATAL AIR POLLUTION EXPOSURE ON CHILDHOOD BLOOD PRESSURE AND CAROTID INTIMA-MEDIA THICKNESS

Carrie V. Breton, ScD,[1] ,Talat S. Islam, MD,[1] Wendy J. Mack, PhD,[1,2], Xinhui Wang, MS,[1] Lora Whitfield-Maxwell, RN,[2] Howard N. Hodis, MD,[1,2] Nino Künzli MD,[3,4] Ed Avol, MS[1]

1. *University of Southern California, Dept of Preventive Medicine, Los Angeles, California*
2. *University of Southern California, Atherosclerosis Research Unit, Los Angeles, California*
3. *Swiss Tropical and Public Health Institute, Basel, Switzerland*
4. *University of Basel, Basel, Switzerland*

Background and Aims: Air pollution exposure is a risk factor for atherosclerosis in adults but whether this association exists at a younger age remains unclear. We hypothesized that prenatal and lifetime exposures to air pollutants would be associated with increased blood pressure and carotid intima-media thickness (CIMT) in children.

Methods: We investigated these hypotheses in a subset of 568 children from the Children's Health study on whom we measured blood pressure and right common carotid IMT and calculated prenatal and lifetime air pollution exposures. Average pollutant concentrations for each trimester and total lifetime exposure were computed using a weighted average of calendar month averages based on central site monitoring data and residential history. Caline dispersion model estimates of $PM_{2.5}$ and NO_x based on traffic data within 5 km of each residence were calculated. Linear regression models were used in all analyses.

Results: Prenatal exposures to NO_2, $PM_{2.5}$, and CO were associated with increased childhood systolic blood pressure (SBP) in univariate analyses. After adjustment for sex, age, ethnicity, BMI percentile, income, town, and parental history of high blood pressure and high cholesterol, only prenatal exposures to NO_2 (β= 0.09 mm Hg per 1ppb, p= 0.06) and PM_{10} (β =0.05 mm Hg per 1 $\mu g/m^3$, p=0.06) during the third trimester remained marginal predictors of childhood SBP. Second trimester exposure to elemental carbon (EC) was significantly associated with a 0.01 mm increased CIMT (p=0.04) per $\mu g/m^3$ change in a smaller subset of children with EC data (n=403). However, this association was reduced by half after adjustment for covariates. None of the lifetime exposures and Caline-derived estimates were associated with childhood SBP or CIMT.

Conclusions: Prenatal exposure to air pollutants may have deleterious effects on childhood cardiovascular risk factors.

SHORT-TERM EXPOSURE TO AMBIENT AIR POLLUTION AND BLOOD PRESSURE IN THE FRAMINGHAM HEART STUDY

Joshua I Rosenbloom, *Beth Israel Deaconess Medical Center, USA*
Elissa H Wilker, *Beth Israel Deaconess Medical Center, USA*
Gary F Mitchell, *Cardiovascular Engineering, Inc. USA*
Brent Coull, *Harvard University, USA*
Naomi A Hamberg, *Boston University, USA*

Petros Koutrakis, *Harvard University, USA*
Joseph A Vita, *Boston University, USA*
Murray A Mittleman, *Beth Israel Deaconess Medical Center, USA*
Daniel E Levy, *National Heart Lung and Blood Institute, USA*

Background and Aims: The association between exposure to ambient particulate matter (PM) air pollution and blood pressure (BP) is uncertain. We investigated the association between short-term average levels of PM2.5 and black carbon (BC) and BP in the Framingham Heart Study (FHS) Offspring cohort, hypothesizing that higher short-term exposure would be associated with higher BP.
Methods: In a repeated measures prospective cohort study, systolic (SBP) and diastolic (DBP) BP and clinical and demographic information were obtained at the FHS Offspring Exams 7 (1998-2001; 1966 eligible participants [n]) and 8 (2005-2008; n=1604). PM2.5 (mean daily level 9.9 $\mu g/m^3$) and BC (mean 0.84 $\mu g/m^3$) concentrations were measured at a central monitoring site near downtown Boston, Mass. Subjects living beyond 40 km from the monitor were excluded. We assessed the association between 1, 2, 3, 5, 7, 14, 21, and 28-day moving averages (MAs) of the pollutants' concentrations and the BP outcomes. We used a linear mixed effects model with a random intercept for each subject to analyze the overall association between pollution exposure and BP measurements, adjusting for age, sex, body mass index, use of lipid-lowering and antihypertensive medications, diabetes, cardiovascular disease, smoking , season, apparent temperature, and date.
Results: A 1 $\mu g/m^3$ higher 7 day MAs of PM2.5 was associated with a 0.010 (p=0.92) lower SBP and 0.078 (p=0.17) lower DBP. For BC, a 1 $\mu g/m^3$ higher 7 day MA was associated with a 0.23 (p=0.86) lower SBP and a 0.98 (p=0.18) lower DBP. Results for other MAs were similar.
Conclusions: In this cohort of largely suburban community-dwelling middle-aged-to-elderly white adults, there was no association between short-term exposure to PM2.5 or BC and BP. Future analyses will incorporate additional FHS exams and more precise exposure assessments, as well as assess the association between chronic exposure to traffic related pollutants and BP.

THE PILOT STUDY OF HEARING LOSS IN JUNIOR HIGH SCHOOL STUDENTS USE MP3 PLAYER

Chang, Shu-Ju, *Department of Industrial Management & Enterprise Information, Aletheia University, Taipei, Taiwan*

Wei, Chieh-Yu, *Institute of Labor Relationship, Chinese Culture University, Taipei, Taiwan*

Wang, Chang-Yu *Department of Industrial Management & Enterprise Information, Aletheia University, Taipei, Taiwan*

Background: Along with the technical progress, MP3 (MPEG-1 Audio Layer III) is modern person indispensable electronic product. Many studies showed that the the most noise source of recreational activities was MP3 for teenagers. Fligor et al. indicated that MP3 sound pressure levels measured volume control setting ranged from 91 to 121 dB(A) and peak sound pressure levels exceeded 130 dB(A) in 2004. It's very easy to damage the structure of ear. The study discussed that junior high school students used MP3 whether or not and it influenced hearing seriousness and relationship.

Methods: The subjects were 101 grade seven students in north Taiwan. Using MP3 were exposed subjects and disusing MP3 were non-exposed subjects. The degree of hearing loss measured was interview questionnaire which assisted pure-tone audiometry.

Results: In both groups, their left and right ears had poorer hearing thresholds at low frequency. There was a dip in 6k Hz which is included noise hearing loss primarily. And the hearing thresholds of non-exposed group were worse than exposed group in right ears. The possible reason was that the non-exposed group were used to watch TV in entertainment activities 3.03 times than exposed group. The volume of TV also affects the hearing. In blood pressure, two groups didn't have significant difference but exposed group who systolic and diastolic blood pressure were higher than non-exposed group. Noise exposed made blood pressure rising indeed and raised probability to get hypertension.

Conclusions: The volume don't surpass 60% in the loudest volume by using MP3 and continuous listening time don't exceed 60 minutes. To avoid teenagers have early hearing loss.

RISK-BENEFIT ANALYSIS: NUTRITIONAL AND ENVIRONMENTAL SAFETY OF FISH CONSUMPTION

Shirra Freeman, *Harvard School of Public Health, USA and University of Haifa, Israel*
James Hammitt, *University of Toulouse, France and Harvard School of Public Health, USA*

Background and Aims: Research reveals associations between fish consumption and long-chain polyunsaturated fatty acid (n-3PUFA) intake, exposure to environmental contaminants and health outcomes including developmental, coronary heart disease (CHD) and cancer (IOM, 2007; Mozaffarian and Rimm, 2006; Willett, 2005). There is also evidence of public confusion about risks and benefits inherent in consuming fish, raising concerns about food safety communication. (WHO, 2009; McManus et. al., 2009). The aims of this study are to: (1)demonstrate the influence of fish consumption choice on exposures to risks and benefits; and (2)quantify associated health and socio-economic outcomes.

Methods: A risk-benefit framework is applied to the association between CHD and low-dose, chronic exposure to methyl mercury (MeHg) and n-3PUFAs resulting from fish consumption. Ecological exposure assessment is conducted with reference to species and quantity consumed and whether fish are farmed or wild. A baseline consumption profile and exposure factors are constructed for the US population. Five consumption/exposure scenarios are elaborated and input into a dose-response synthesis to assess associated changes in CHD. The Value of a Statistical Life Year (VSLY) method is used to analyse the socio-economic implications of the dose-response results.

Results: The distribution of fish species within the consumption portfolio is the main determinant of exposure factors. Significant improvements are achievable with minor adjustments in consumption patterns. The dose-response synthesis supports assertions that for CHD outcomes, n-3PUFAs and MeHg are, respectively, the main sources of benefits and risk. The simulations point to associations between lower relative risk of CHD death and consumption profiles featuring lower MeHg/ higher n-3PUFAs species.

Conclusions: This risk-benefit framework is effective for analyzing and communicating food safety information and is applicable to multiple attributes and health associations. Incorporating socio-economic analysis translates health information for a wider audience.

LINKAGE OF THE NATIONAL HEALTH INTERVIEW SURVEY TO CLIMATE INDICATORS: A RESOURCE FOR UNDERSTANDING THE IMPACT OF CHANGE

Jennifer Parker, *National Center for Health Statistics, USA*
Suril Mehta, *U.S. Environmental Protection Agency, USA*
Raghuram Murtugudde, *University of Maryland, USA*
Amir Sapkota, *University of Maryland, USA*

Background and Aims: Although there is growing literature describing acute health effects of extreme climate events, such as heat waves, less is known about the effects of climate changes on chronic conditions. Appropriate measures that reflect long term climate changes that can be linked to health outcome data are unknown. This study describes potential climate indictors for linkage to the U.S. National Health Interview Survey (NHIS).
Methods: 2006-2008 NHIS data for adults were linked to county-level climate data from National Climatic Data Center. Health measures examined included: fair/ poor health, heart disease, hypertension, and asthma. Using 1977-1987 as the baseline, the 99th and 1st percentiles of maximum and minimum temperatures for each county and month (about 300 values) were used to define thresholds of excessively hot and cold days. Indicators were created for each county by summing the number of days in the prior 5 years that exceeded thresholds and identifying the 90th percentile of days; approximately 75% of NHIS respondents lived in counties with complete data for the prior 5 years. Odds ratios (AOR) of associations between indicators and health measures were adjusted for race/ethnicity, age, region, and urbanization.
Results: Respondents in areas with a relatively large number of hot days over the prior 5 years may experience more adverse health outcomes, including hypertension, heart disease, and fair/poor health. Furthermore, living in areas with a large number of hot spring days was associated with significant increases in hay fever (AOR=1.24 (95% CI 1.04, 1.48)) and asthma emergency department visits (AOR=1.68 (CI 1.08, 2.62)). Cold days were not associated with these outcomes.
Conclusions: People in unusually hot areas may experience more adverse health conditions, although mechanisms are not understood. Developing appropriate indicators of extreme climate conditions will increase our ability to monitor potential impacts of climate change on health.

SOURCE IDENTIFICATION AND APPORTIONMENT OF PARTICULATE MATTER IN ACCRA, GHANA

Background and objective

Cities in the developing world are growing rapidly, particularly in sub-Saharan Africa, with corresponding increases in economic activity and traffic. Little is known about air pollution sources and their relative contributions to air pollution in African cities. The objective of this study is to identify sources of ambient particulate matter (PM) in Accra, Ghana and to characterize the contribution of each source.

Methods

We collected 48-hour $PM_{2.5}$ (aerodynamic diameter less than 2.5 μm) and PM_{10} (aerodynamic diameter less than 10 μm) samples at 11 residential or roadside sites in four neighborhoods of Accra between November 2006 and August 2008. Elemental composition of PM was assessed by performing X-ray fluorescence (XRF). We developed an extended factor analysis method that accounts for spatial and temporal correlation of data and for site-specific covariates. We applied this method to the elemental concentration data for source identification and apportionment.

Results

XRF results show that crustal elements (Al, Si, Fe, Ca, Mg), sea salt elements (Na, Cl), K and S had the highest concentrations at various sites. Source apportionment results indicate that crustal material, road dust, combustion, and sea salt are the four main sources contributing to the observed concentrations in Accra. Crustal material was found to be the most important contributor at each site, followed by combustion. The sea salt factor was seen at each site, with the highest contribution at the site closest to the coast.

Conclusion

Crustal material, road dust, combustion, and sea salt are primary source contributors to PM in urban Accra.

LYMPHOHEMOPIETIC NEOPLASMS AND DIOXIN EXPOSURE IN THE SEVESO COHORT 30 YEARS AFTER THE ACCIDENT (1977-2006)

Angela Cecilia Pesatori, *Department of Occupational and Environmental Health, Università degli Studi di Milano, and Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy*
Dario Consonni, *Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy*
Raquel Carace, *Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy*
Raffaella Sindaco, *Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy*
Pier Alberto Bertazzi, *Department of Occupational and Environmental Health, Università degli Studi di Milano, and Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milan, Italy*

Background and Aims: The 1976 Seveso, accident caused the contamination of a large inhabited area by 2,3,7,8-tetrachlorodibenzodioxin (TCDD). Three zones with decreasing soil TCDD levels were delimited: A (highest), B (high) and R (low). Persons ever living in the contaminated zones and in a surrounding non-contaminated area were followed-up, blind of their exposure status, to evaluate long-term health consequences. The main finding of the mortality (1976-2001) and cancer incidence study (1977-1991) was an increase in lymphatic and hematopoietic cancers in the most polluted zones (A and B). We report preliminary results of the extension of the follow-up to 30 years after the accident for lymphoemopietic cancers.
Methods: Incident cancer cases were ascertained through the hospital discharge registration system of the Lombardy region, where over 95% of the cohort was still resident in 1986. For each case all relevant medical records were reviewed. Relative risks (RR) and 95% Confidence Intervals (CI) were estimated with Poisson regression techniques controlling for age, gender and calendar period using the surrounding non contaminated area as reference.
Results: The incidence of all lymphohemopietic cancers was slightly increased in zone A (6 cases, RR =1.2; 95%CI 0.5-2.7) and showed a 50% excess in zone B (47 cases; RR=1.5; 95%CI 1.1-2.0). Non-Hodgkin's Lymphomas were modestly increased in zone B, whereas the RR for all leukemias was 2.0 (95%CI 1.2-3.4). 5 cases were lymphatic leukaemia and yielded a RR of 1.6 (0.6-4.1); 10 cases of myeloid leukaemia showed a RR of 2.1 (95%CI 1.04-4.15). All lymphatic leukaemias occurred after 20 years since the accident (RR=4.0; 95%CI 1.4-11.6) whereas myeloid leukaemia did not show a consistent pattern across different categories of time since the accident.
Conclusions: The extension of the follow-up confirms an increased risk for lymphatic and hemopoietic cancers, particularly leukemia, in the Seveso population.

PREVALENCE OF CIGARETTE SMOKING AND ENVIRONMENTAL TOBACCO SMOKE (ETS) VS URINARY COTININE IN A SPANISH COHORT OF PREGNANT WOMEN

Background and aims: To estimate the prevalence of smoking during pregnancy and establish the cut-off point for urinary cotinina (UC) that differentiates smokers from non-smokers, as well as assessing exposure to ETS.
Methods: A total of 2,263 women from the INMA cohort (www.proyectoinma.org) recruited between 2003 and 2008 were included in the study. Data concerning smoking was collected using a questionnaire, and UC was measured by immunoassay in week 32 of pregnancy. Validity was assessed and the area under the ROC curve was calculated. Factors associated with tobacco smoking and misclassification (nondisclosure) were analysed using logistic regression.
Results Fifty-five per cent of women reported having smoked at some point in their life, 32% smoked at the beginning of their pregnancy, 20% at week 12 and 18.5% at week 32. A cut-off value of 50 ng/ml UC was found to have 95.7% sensitivity and 95.2% of specificity, while the positive and negative predictive values were 81.6 and 99.0% respectively and the area under the ROC curve was 98.6% (89.2-99.0%). There were 18 cases of false negative results and 90 false positives, while the numbers of true positive and true negative cases were 400 and 1,755, respectively. Smoking status and nondisclosure were associated with: women age<24 years old, social class IV, a low level of education and being European. The median of UC in smokers was 1,744 ng/ml. A linear correlation was found between UC and tobacco smoking ($p<0.001$), while among non-smoking women with UC <50ng/ml, UC was linearly correlated with the number of sources of exposure to ETS ($p< 0.05$). **Conclusions**: In week 32 of pregnancy, 18.5% of women reported that they were smoking and a further 3.9% probably smoked, or nonsdisclosure. We propose 50 ng/ml as a cut-off point for UC among pregnant women. UC was significantly associated with ETS.

ASSOCIATIONS BETWEEN ARIES AIR POLLUTION MEASUREMENTS AND ACUTE PRIMARY CARE VISITS FOR RESPIRATORY ILLNESSES—TEN-YEAR TIME SERIES

Amber H. Sinclair, *Kaiser Permanente-Georgia, USA*
Dennis Tolsma, *Kaiser Permanente-Georgia, USA*

Background and Aims: Previous 53-month analyses found several statistically significant air pollutants for acute childhood asthma primary care visits. Air pollution and primary care visit data are now available for 10 years. This analysis examines the effects of particulate matter and its components and gases on acute primary care visits for asthma and upper and lower respiratory infection (URI and LRI) over 116 months beginning 8/1/98. Presented results will cover 120 months.
Methods: Data sources are daily acute respiratory visits from a nonprofit managed care organization and air pollution measures from a centrally-located air monitoring site, both in Atlanta, GA, USA. Acute visits are appointments made on the same day the visit was completed. Pollutants included in this analysis are: $PM_{2.5}$, PM_{10}, Coarse PM, OC, EC, $PM_{2.5}$ water-soluble (ws) metals, coarse ws metals; $PM_{2.5}$ Zn, ws Cu, ws Fe, and ws Mn; and coarse PM ws Cu, ws Fe, and ws Mn. Poisson GLM was employed to determine the relationships between lagged pollutants (0-2, 3-5, and 6-8 day moving averages) and acute visits.
Results: Most pollutants produced insignificant results for each respiratory outcome. Significant findings included: PM10 (lag 3-5) and EC (lag 6-8) with acute childhood asthma visits (RR=1.024 and 1.018, respectively), and $PM_{2.5}$ ws metals (lag 3-5) and $PM_{2.5}$ ws Fe (lag 3-5) for LRI (RR=1.033 and 1.039, respectively). There were no significant findings for adult asthma and URI.
Conclusions: This is one of the longest times series analyses for examining the relationships between primary care outcomes and ambient air pollutants. As with our 53-month analysis, EC and PM_{10} are significant for childhood asthma. Additionally, presented results will compare ten-year results for two-pollutant, VOCs, and other models to 53-month results.

VARIATION OF NO_2 and NO_x CONCENTRATIONS AND NO_2 and NO_x LAND USE REGRESSION (LUR) MODELS IN 37 STUDY AREAS IN EUROPE

Matthias Birk, *Helmholtz Zentrum München, Germany*
Josef Cyrys, *Helmholtz Zentrum München, Germany*
Joachim Heinrich, *Helmholtz Zentrum München, Germany*
Marloes Eeftens, *Institute for Risk Assessment Sciences (IRAS), Utrecht*
Rob Beelen, *Institute for Risk Assessment Sciences (IRAS), Utrecht*
Gerard Hoek, *Institute for Risk Assessment Sciences (IRAS), Utrecht*
Dorothea Sugiri, *IUF - Leibniz Research Institute for Environmental Medicine, Germany*
Ursula Krämer, *IUF - Leibniz Research Institute for Environmental Medicine, Germany*
Marta Cirach, *CREAL - Center of Research in Enviromental Epidemiology, Spain*
on behalf of the ESCAPE WP2 group

Background and Aims: NO_2 and NO_x are important pollutants because they have been used extensively as a marker for several air pollutants in motor vehicle exhaust. Within ESCAPE, measurements of NO_2 and NO are made to develop land use regression (LUR) models. The comparison between and within study areas concerning the measured NO_2 and NO_x variation and the results of LUR modelling will be presented.
Methods: In the framework of ESCAPE, annual mean NO_2 and NO_x were estimated in 37 study areas across Europe between in 2008-2010. In each study area the concentrations were measured at 40-80 monitoring sites. The measurements were conducted for two weeks per site in three different seasons, using Ogawa badges. The calculated annual means were regressed against several GIS data. Here we present the results for 6 selected study areas: Barcelona, Catalunya, Dutch-Belgian, Ruhr, Munich-Augsburg, and Erfurt.
Results: Between and within all study areas significant variation was found for NO_2 and NO_x concentrations. In study areas in southern Europe the highest median levels and ranges (10-90th percentile) were observed (NO_2: 55 (34-82) µg/m³, NO_x: 90 (48-158) µg/m³). In densely populated areas in Central Europe smaller median levels and ranges were observed (NO_2: around 30 (20-45) µg/m³, NO_x: 45 (30-90) µg/m³). A small city in a less densely populated area (Erfurt, Germany) showed lower median and ranges (NO_2: 18 (12-30) µg/m³, NO_x: 26 (17-48) µg/m³). Land use regression models were developed which explained a large fraction of the measured variance of NO_2 (R^2 between 0.71-0.89) and NO_x (R^2 between 0.69-0.88). All LUR models include variables which cover road traffic as substantial predictor variables.
Conclusions: There was a substantial spatial variation in annual mean NO_2 and NO_x between and within all study areas. LUR models were developed which explained a large fraction of variability, with road traffic being the most important predictor.

GREEN CITIES AND HEALTH: A QUESTION OF SCALE?

Elizabeth A. Richardson, *School of GeoSciences, University of Edinburgh, Edinburgh, UK*
Richard Mitchell, *Public Health and Health Policy Section, University of Glasgow, Glasgow, UK*
Terry Hartig, *Department of Psychology, Uppsala University, Gävle, Sweden*
Sjerp de Vries, *Alterra, Department of Landscape and Spatial Planning, Wageningen University and Research Centre, Wageningen, The Netherlands*
Thomas Astell-Burt, *Social and Public Health Sciences Unit, Medical Research Council, Glasgow, UK*
Howard Frumkin, *School of Public Health, University of Washington, Seattle, USA*

Background and Aims: Cities are expanding and accommodating an increasing proportion of the world's population. It is important to identify features of urban form that promote the health of city dwellers. Access to green space has been associated with health benefits at both individual and neighbourhood levels, but no studies have tested this association at the scale of entire cities. We investigated whether a relationship between green space coverage and selected mortality rates exists at the city level in the USA.

Methods: An ecological cross-sectional study. A detailed land use dataset was used to quantify green space for the largest US cities (n = 49, combined population 142 million). Linear regression models were used to examine the association between city-level 'greenness' and city-level standardised rates of mortality from heart disease, diabetes, lung cancer, motor vehicle fatalities, and all causes, after adjustment for confounders.

Results: There was no association between greenness and mortality from heart disease, diabetes, lung cancer, or automobile accidents. Mortality from all causes was significantly higher in greener cities.

Conclusions: While considerable evidence suggests that access to green space yields health benefits, if we green our cities without attention to the form the green spaces take, and the form of contact with it, there may be no benefit to population health. In the USA, greener cities tend also to be more sprawling cities, with higher car dependency. Any benefits that the green space might offer seem easily eclipsed by these other hazardous exposures and the lifestyles they engender.

DISTINGUISHING THE POSSIBLE INDEPENDENT HEALTH EFFECTS OF EXPOSURE TO AMBIENT NITROGEN DIOXIDE FROM THOSE OF PARTICULATE MATTER AND OTHER FACTORS

Mills, Inga *PhD student: St George's, University of London*

Background: It has been suggested that the epidemiological associations between ambient concentrations of nitrogen dioxide (NO_2) and health outcomes might not be due to NO_2 *per se* but to other air pollutants, mainly fine particulate matter (PM), within the urban mixture of air pollutants. Furthermore, the heterogeneity in those estimates has added to the uncertainties regarding a possible independent effect for NO_2.
Aim: To assess systematically ecological time-series studies on NO_2, which simultaneously incorporated concentrations of PM in two- or multi-pollutant statistical models, to identify adverse health effects that are independent from those of PM and other factors, and, if so, to suggest concentration-response functions for NO_2 for use in health impact assessments.
Methods: A Microsoft Access relational database is being constructed by assembling data from the literature; the Air Pollution Epidemiology Database (APED) (managed by St George's); and, a range of other sources. The database will include quantitative estimates pertaining to NO_2 and PM: all relevant two-/multi-pollutant model, seasonal model and lagged model results reported in the literature; data on possible confounders and effect modifiers, i.e. various study-level characteristics; Pearson correlations among the concentrations of pollutants. Analyses will use meta-analytical techniques, including meta-regression. Exploratory analyses will test for and investigate sources of heterogeneity and effect-modification. Tests for evidence of publication bias will also be conducted.
(Preliminary) Results: Work to date has focused on constructing the database. Data extracted from APED (for time-series studies published up to the year 2006 (2007 for studies conducted in Asia)) have been interrogated: 185 papers are available for 11 categories of health outcomes linked to NO_2. Of the 185 studies, 70 examined associations between NO_2 and health (hospital admissions; mortality; GP consultations; emergency room visits; GP house calls) using two-/multi-pollutant statistical models, with mortality and hospital admissions being the most common endpoints examined. The corresponding 336 estimates were produced largely from studies conducted in Europe, the USA and Canada using mainly 1-hour and 24-hour measures of exposure to NO_2. Less than 25% of the estimates from two-/multi-pollutant analyses are based on studies using a multi-city design. The final database will include time-series studies published up to May 2009.
Conclusions: Investigating heterogeneity in NO_2-effect estimates by way of systematic review is not common place in air pollution epidemiology. It is hoped that the final results will add to the evidence on whether there is an independent effect of NO_2.

CADMIUM AND ARSENIC EXPOSURE FACTORS IN A POPULATION LIVING ON POLLUTED SOILS, CASSIOPÉE STUDY, AVEYRON, FRANCE, 2008

Cécile DURAND, Regional office of the French institute for public health surveillance (Cire) Midi-Pyrénées, Toulouse, France
Nicolas SAUTHIER, Cire Midi-Pyrénées, Toulouse, France
Valérie SCHWOEBEL'Cire Midi-Pyrénées, Toulouse, France
Frédéric DOR, French institute for public health surveillance (InVS), Saint-Maurice, France

Background and Aims:
The town of Viviez (south-west of France) experienced 150 years of industrial activity generating atmospheric emissions until 1987 and substantial soil pollution, in particular by cadmium and arsenic. A public health assessment was carried out in order to estimate the health impact of this pollution and to formulate recommendations. This assessment included an exposure study with the objective of identifying exposure factors that increase the cadmium and arsenic body burden.

Methods:
Adult residents of Viviez and Montbazens (an unexposed town) who did not have occupational exposure to pollutants were included. Urinary cadmium and arsenic were analyzed by multivariate regression taking into account individual factors (age, smoking…) and environmental factors. Statistical methods for analysis of censored data were used in order to take into account concentrations below detection limit.

Results:
In Viviez, 21.6% of adults exceeded 1 µg of cadmium/g.creatinine and 5% exceeded 2 µg/g.creatinine against 4% and 0% in Montbazens. After adjustment for individual factors, the geometric means of urinary cadmium and arsenic were higher in Viviez than in Montbazens. Contrary to Montbazens, some environmental factors in Viviez were associated with urinary cadmium (length of residence, consumption of local fruit and vegetables and animal products), and with urinary arsenic (recent consumption of local poultry, consumption of local well and spring water, low frequency of mopping the floor, frequency of gardening).

Conclusions:
Differences in mean concentrations between the exposed and the unexposed town and exposure factors associated with cadmium and arsenic body burden suggest an environmental exposure of Viviez population. Residents could be presently exposed by local food ingestion and by inhalation or ingestion of polluted dust and soils. They could also have been exposed in the past by inhalation of atmospheric emissions. Recommendations based on these results will be made to limit further exposure.

ANALYSIS OF CHARACTERISTICS AND SOURCES OF PM10-BOUND PAHs IN TIANJIN City

Xiao Ding, *State Environmental Protection Key Laboratory of Urban Ambient Air Particulate Matter Pollution and Control, College of Environmental Science and Engineering, Nankai University, China*
Zhipeng Bai, *State Environmental Protection Key Laboratory of Urban Ambient Air Particulate Matter Pollution and Control, College of Environmental Science and Engineering, Nankai University, China*

Background and Aims: Polycyclic aromatic hydrocarbons (PAHs) are a series of certain compounds, many of which have proven to be mutagenic and/or carcinogenic. This study elucidates the temporal and spatial distribution of PM_{10}-bound PAHs in Tianjin, as well as their possible sources and healthy impacts, to provide a baseline reference on exposure assessment, health risk, and pollution controlling in such a densely populated city.
Methods: Atmospheric PM_{10} samples were collected at 8 sampling sites in Tianjin City every six-day from September 2009 to August 2010. The mass concentrations of 16 PAHs loaded in PM_{10} samples were measured by GC-MS method. PAHs ratios, PCA and PMF methods were applied for source identification.
Results: The results shows that the total mass concentrations of PM_{10}-bound PAHs ranged from 10.91 ng m^{-3} to 1988.81 ng m^{-3}, while the average concentration was 41.91 ng m^{-3} in spring, 24.56 ng m^{-3} in summer, 129.78 ng m^{-3} in autumn and 355.32 ng m^{-3} in winter. Vehicle exhaust was recognized to be a most significant PAHs contributor in both summer and winter, while and the contribution of coal combustion increased in winter.
Conclusions: The total mass concentrations of PM_{10}-bound PAHs varied temporally and spatially at a remarkable extent, with a higher concentration in winter and a lower one in summer, while concentration was the highest in industrial area. With more complex molecular structures, PAHs species with four and more rings composed most of the PAHs concentrations, namely, four-rings in winter and five and six-rings in summer. Coal combustion, vehicle exhaust and steel industry emission were identified to be three major sources of PM_{10}-bound PAHs, however, in summer there may existed more other sources such as biomass combustion and refinery.

CHILDHOOD ASTHMA AND AIR POLLUTION: DO FINDINGS VARY BY WARM AND COLD SEASONS?

Amber H. Sinclair, *Kaiser Permanente-Georgia, USA*
Dennis Tolsma, *Kaiser Permanente-Georgia, USA*

Background and Aims: Ambient air pollution has been associated with asthma outcomes in children in time series analyses that control for season. In this study, we examine the effects of air pollution on acute outpatient visits for childhood asthma separately for warm and cold months to assess whether the associations vary by season.
Methods: Data sources are daily acute respiratory visits from a nonprofit managed care organization and air pollution measures from a centrally-located air monitoring site, both in Atlanta, GA, USA. Acute visits are appointments made on the same day the visit was completed. Pollutants included in this analysis are: $PM_{2.5}$, PM_{10}, Coarse PM, OC, EC, $PM_{2.5}$ water-soluble (ws) metals, coarse ws metals; $PM_{2.5}$ Zn, ws Cu, ws Fe, and ws Mn; and coarse PM ws Cu, ws Fe, and ws Mn. Poisson GLM was employed to determine the relationships between lagged pollutants (0 -2, 3-5, and 6-8 day moving averages) and acute visits. The warm season months were defined as April through October, while cold season was November through March.
Results: For the warm season, we found one significant positive association for a 3-day moving average lag: OC (lag 3-5). For single day lags, we also found significant positive associations for PM_{10} (lag 4), OC (lag 4), and $PM_{2.5}$ (lag 4). For the cold season, there were no significant positive associations, but two significant negative findings both for lag 0: OC and $PM_{2.5}$. Compared to the overall 116-month findings that controlled for season, PM_{10} (lag 4) was significant in both analyses.
Conclusions: These findings show seasonal variation in associations between childhood asthma and ambient air pollution. More pollutants are significant in the warm season, with positive effects. Separate models for warm and cold months may be more informative in some cases than controlling for season. Presented findings will include additional pollutants for a 120-month time period.

GENETIC SUSCEPTIBILITY TO ARSENIC EXPOSURE AND PREVALENT SKIN LESIONS IN BANGLADESH

Maria Argos, Mohammed Kibriya
The University of Chicago, USA

Yu Chen
New York University, USA

Faruque Parvez, Vesna Slavkovich, Joseph Graziano
Columbia University, USA

Habibul Ahsan
The University of Chicago, USA

ABSTRACT
Background and Aims: Elevated concentrations of arsenic in groundwater pose a public health threat to millions of people worldwide. While arsenic is an established human carcinogen, a mode of action has yet to be determined for arsenic carcinogenesis. However, the oxidative stress and DNA repair pathways have been implicated in arsenic toxicity and have been hypothesized to underlie arsenic carcinogenesis.
Methods: Utilizing cross-sectional data from the 2000-2002 survey of the Health Effects of Arsenic Longitudinal Study (HEALS) for 610 prevalent arsenical skin lesion cases and 1,079 randomly selected controls, we evaluated the associations of single nucleotide polymorphisms (SNPs) in genes encoding antioxidant enzymes and DNA repair enzymes on skin lesion prevalence based on logistic regression and Hierarchical Bayes modeling. We also evaluated potential SNP-SNP interactions as well as SNP-environment and higher-order interactions in determining skin lesion prevalence through a multi-analytic approach by MDR, CART, and logistic regression models.
Results: There were no statistically significant associations between individual SNPs and skin lesion prevalence. However, there was marginal evidence that skin lesion prevalence was increased among individuals who carried 4 or more risk alleles compared to individuals carrying 0-2 risk alleles in antioxidant enzyme SNPs. Additionally, there was a significant departure from additivity for the risk allele score and primary methylation index (i.e., ratio of MMA to inorganic arsenic) on skin lesion prevalence. Additionally, we observed a significant inverse association of total fruit and vegetable consumption with skin lesion prevalence and, there was a significant interaction on the additive scale between fruit and vegetable intact with the polymorphism in ERCC5 in relation to skin lesion prevalence.
Conclusions: The results of this study provide evidence of genetic and gene-environment effects in relation to arsenic-related skin lesion prevalence.

THE UNIQUE PHARMACOKINETIC CHARACETERISTICS OF BISPHENOL A IN AMNIOTIC FLUID: THE IMPLICATION OF FETAL EXPOSURE

Chensheng (Alex) Lu, *Harvard School of Public Health, USA.*
Andrea Edlow, *Brigham and Women's Hospital, USA.*
Nicole Smith, *Brigham and Women's Hospital, USA.*
Mei Chen, *Harvard School of Public Health, USA.*
Thomas McElrath, *Brigham and Women's Hospital, USA.*

Background and Aims: Bisphenol A (BPA) is an estrogenic compound widely used in polycarbonate plastics and many household products. The placental β-glucuronidase may deconjugate BPA into its "free" active form, which has estrogenic, endocrine-disrupting properties. There are few data regarding BPA levels in the fetal compartment, and even sparser data regarding conjugated versus free BPA fractions. The effects of prolonged exposure of the fetus to the active form of BPA are unknown. Thus, we sought to quantify levels of conjugated and free BPA in second trimester amniotic fluid specimens to better define the role of the placenta in fetal exposure.
Methods: Liquid chromatography/mass spectrometry was used to measure BPA concentrations in 20 prospectively collected second trimester amniotic fluid specimens. Concentrations were quantified using stable-isotope BPA. The total and free BPA were measured by direct analysis of samples with and without overnight enzymatic hydrolysis, respectively. The conjugated BPA concentrations were obtained by subtracting free BPA levels from the total BPA measurements.
Results: Total BPA was detected in 17/20 samples, with levels ranging from non-detect to 0.75 ng/mL, with a median concentration of 0.44 ng/mL. Three samples contained no BPA, and 7 samples contained only conjugated BPA. Free BPA was detected in 10/20 samples, and levels ranged from non-detectable to 0.43 ng/mL, with a median concentration of 0.26 ng/mL. For those 10 amniotic fluid specimens that contained free BPA, it represented an average of 82% of the total BPA level.
Discussion: Free BPA was detected in the fetal compartment in 50% of amniotic fluid specimens, and its concentration comprised 82% of total BPA levels. Because BPA is quickly conjugated in the adult liver once absorbed, our data suggest that BPA may be deconjugated in the placenta by β -glucuronidase, which leads to increasing potential fetal exposure to the active form, or free BPA.

INTEGRATED ENVIRONMENTAL HEALTH IMPACT ASSESSMENT BASED ON PERSONAL EXPOSURE TO PM2.5

Background and Aims: When drafting regulations for enhancing environmental quality or public health, it is useful to assess their health effects in advance as policies might have interrelated but opposing effects. Currently, in integrated impact assessments of air pollutants the estimation of health effects is based on concentration response functions that are applied to outdoor air concentration. In contrast, this study aims to assess the health effects of exposure to PM2.5 using modelled personal exposure.
Methods: Personal exposure to fine particles as time-weighted concentration in different micro-environments was derived for various policy measures (e.g. increased insulation and simultaneously decreased emissions) using the tooL for Air pollution exposure Modelling and Assessment (LAMA). Based on this personal exposure, health effects, DALYs and damage costs were estimated.
To derive health effects, concentration response functions were scaled and converted into exposure response functions based on the relationship between background concentrations and personal exposure experienced indoors from outdoor sources.
Results: Results show that the mean exposure due to insulation of residential buildings increases: For insulation scenarios for the years 2020, 2030 and 2050 about 10 to 500 thousand DALYs are caused due to accumulation of PM from indoor and outdoor sources in residential dwellings in the EU30 (corresponding to about 800 to 40,000 million EUR_{2010}). However, due to a simultaneous decrease in the outdoor air concentration the total impact of the modelled measure ranges from -20 thousand to 100 thousand DALYs. When only considering outdoor air sources 100 to 300 thousand DALYs can be avoided due to the measure.
Conclusions: Personal exposure modelling as a basis for integrated environmental health impact assessment provides a means of better assessing mitigation measures with direct effects on exposure. However, there remains the need for further enhancement of the input data and assumptions, including the exposure response functions

Romain Meeusen, *Vrije Universiteit Brussel, Belgium*

Background and Aims: Commuting by bike has a clear health enhancing effect. Moreover, regular exercise is known to improve brain plasticity, which results in enhanced cognition and memory performance. Animal research has clearly shown that exercise upregulates Brain-Derived Neurotrophic Factor (BDNF – a neurotrophine) enhancing brain plasticity. Studies in humans found an increase in serum BDNF concentration in response to an acute bout of exercise. Emerging evidence suggests that exposure to air pollution is increased during commuting. Furthermore, enhanced exposure to particulate matter (PM) air pollution is linked to negative neurological effects, such as neuroinflammation and cognitive decline. We carried-out a cross-over experiment to examine the acute effect of exercise on serum BDNF and the potential effect-modification by exposure to traffic-related air pollution.
Methods: 38 non-asthmatic volunteers (mean age: 43, 26% women) performed two cycling trials, one near a major traffic road (mean UFP concentration: 28867 particles/cm^3) and one in an air-filtered room (mean UFP concentration: 496 particles/cm^3). The heart rate during cycling and cycling duration were similar for both trials. Serum BDNF concentrations were measured before and 30 minutes after each cycling trial.
Results: As expected, exercise significantly increased serum BDNF concentration after cycling in the air-filtered room (+14.4%; p=0.02). In contrast, serum BDNF concentration did not increase after cycling near the major traffic road (+0.5%; p=0.94).
Conclusions: Although active commuting is considered to be beneficial for health, this health enhancing effect could be negatively influenced by exercising in an environment with high concentrations of PM. Whether this effect is also present with chronic exercise and chronic exposure must be further elucidated.

ADOLESCENT NEIGHBORHOOD ENVIRONMENT AND HYPERTENSION IN YOUNG ADULTHOOD

Shakira F Suglia, *Boston University, USA*
Ana Diez-Roux, *University of Michigan, USA*
Renee Boynton-Jarrett, *Boston University USA*
Megan Sandel, *Boston University USA*
Jonathan Levy, *Boston University, USA*

Background and Aims: Associations between features of the built environment and hypertension have been noted among adult populations. However the relationship between neighborhood built environment in adolescence and hypertension in young adulthood has not been studied.
Methods: We examined the relationship between adolescent neighborhood environment (landscape diversity, street connectivity and access to pay and public recreational facilities) and elevated blood pressure in young adulthood, and whether gender modified this association in the National Longitudinal Study of Adolescent Health. Neighborhood environment during adolescence (Wave 1 1995-1996, mean age 15.5, n=12627) and young adulthood (Wave 3 2001-2002) was assessed using a geographic information system. The presence/absence of having received a diagnosis of elevated blood pressure was assessed by self-report (Wave 3). Generalized estimating equation models were adjusted for individual level sociodemographic factors and neighborhood level median household income.
Results: An interquartile range increase in landscape diversity was associated with lower odds of reporting a diagnosis of elevated blood pressure (OR 0.92 95%CI 0.8, 1.0). This association did not vary significantly by gender, though there was evidence that and increase in access to public facilities was associated with lower of odds of reporting a diagnosis of elevated blood pressure among females.
Conclusions: Our findings suggest that adolescent neighborhood environment may affect the development of hypertension. Further studies should examine the potential mechanisms through which the built environment could affect the development of hypertension.

EXPOSURE ASSESSMENT AND SOURCE CHARACTERIZATION OF LEAD IN LATINO CHILDREN IN SAN DIEGO, CALIFORNIA

Kathryn Dowling, *Iniciativa EQUIPS, Madrid, España*
Vanessa Galaviz, *University of Washington, Seattle, USA*
Veronica Miranda, *University of Kentucky, Lexington, USA*
Ming Ji, *San Diego State University, California, USA*
Paul English, *California Department of Public Health, Sacramento, USA*

Background and Aims: Lead poisoning is an insidious problem to which Latino children may experience additional exposure related to their cultural practices. The current cross-sectional exposure assessment study evaluated environmental (housepaint, dust, soil and water) and cultural factors (family acculturation, child behavior and exposure to potentially lead-contaminated Mexican products) plus socioeconomic status and heath care access.
Methods: This 2006 study was conducted in 15 census tracts in southern downtown San Diego, California. Parents/guardians of 166 Latino children (aged 12 - 71 months) from 128 households participated. Environmental samples and child blood samples were analyzed for lead and a questionnaire, including photos, was administered. Lead exposure due to contaminated candy was estimated based on California Department of Public Health analyses.
Results: The 68% participation rate was quite respectable for this underserved group (77% spoke Spanish at home and 80% of respondents identified as Mexican). Blood lead measurements on 89% of the child participants indicated a 2 µg/dL median value, with 9% at or above 5 µg/dL. Mexican candy consumption (1 to 6 g/day) was the only important cultural exposure reported. Close to 90% of analyzed candy had undetectable lead levels (< 0.05 µg/g), which IEUBK modeling indicated are unlikely to represent daily child intakes of more than 0.1 µg lead/day in the most conservative scenario. SAS Generalized Estimating Equations modeling indicated elevated blood lead levels related to child age and gender, candy consumption, soil lead levels and child private health insurance coverage.
Conclusions: This work served an exploratory purpose, providing both a solid methodologic basis for future work and hypothesis generation. More work is necessary to evaluate the extent to which both environmental and cultural components are driving lead exposure.The study's culturally-appropriate in-home phlebotomy approach proved so successful that its implementation to reach the most underserved Latino children merits consideration.

APPLYING ALTERNATIVE EXPOSURE METRICS IN A MULTIPOLLUTANT EPIDEMIOLOGICAL STUDY

Stefanie Sarnat, *Emory University, Atlanta, Georgia, USA*
Jeremy Sarnat, *Emory University, Atlanta, Georgia, USA*
James Mulholland, *Georgia Institute of Technology, Atlanta, Georgia, USA*

Background and Aims: Epidemiological studies of air pollution have traditionally relied upon surrogates of personal exposures, such as ambient concentration measurements from central-site monitoring stations. This study examines the spatial and temporal variations of alternative measured and modeled exposure metrics for multiple pollutants (i.e., particulate matter, elemental carbon, sulfates, nitrogen oxides, carbon monoxide and ozone), developed and applied within an epidemiological study in a large US metropolitan area.
Methods: Several tiers of exposure metrics for ambient traffic-related and regional pollutants were used for predicting health impacts of ambient air quality and population exposures on daily ZIP code level emergency department (ED) visits in Atlanta, GA for the period 1999-2002. The approaches included central site or interpolated monitoring data, regional pollution levels based on measurements or models (CMAQ) and local scale (AERMOD) air quality models, hybrid models, statistically blended modeling and measurement data, concentrations adjusted by home infiltration rates based on LBL algorithms utilizing information on housing stock and meteorology, and the population human exposure (SHEDS and APEX) model predictions.
Results: The various exposure metrics were compared in their ability to characterize the spatial and temporal variations of multiple ambient air pollutants across the study area. These metrics were then used to examine associations between ambient air pollution and acute morbidity. The pollutant–specific relative risks (RRs) obtained from epidemiological analyses of the alternative exposure metrics were compared to those obtained from using a conventional approach (i.e., central site data alone). Both pollutant and metric dependent differences were found suggesting a complex exposure prediction error structure among the pollutants studied.
Conclusions: Our results suggest the need for case-specific enhancements for future exposure assessments in conjunction with different types of individual or multipollutant air pollution epidemiologic study designs.

THE ROLE OF ENVIRONMENTAL POLLUTANTS IN THE CAUSATION OF BIRTH DEFECTS IN CALI, COLOMBIA: DEVELOPMENT OF A RESEARCH STRATEGY WITH AN INTERDISCIPLINARY APPROACH

Fabian Mendez, *Universidad del Valle, Colombia*

Background and Aims: In Cali, Colombia, clusters of very rare congenital defects were reported at a hospital-based registry and subsequent evaluation demonstrated a 5 to 10 fold prevalence increase of other birth defects including vascular disruption defects (VDD) and neural tube defects (NTD). An inadequately managed municipal landfill site and a polluted river with different sources of contamination were hypothesized as potential environmental sources of teratogens. Our aim is to provide a framework and strategy for assessing concerns about the role of environmental pollutants in causing birth defects in a locality.
Methods: A multidisciplinary team designed and implemented a comprehensive study aimed to describe social and environmental conditions of the area, and to determine risk factors of birth defects.
Results: The steps for developing such integrated approach are presented, including the definition of common gaps of knowledge inside the research team. Key questions arising during study implementation are: How better integrating methodological issues? How constructing a pathway model for research? How defining a risk communication strategy? What analytical tools are fundamental?
Conclusions: We support the notion that synergistic efforts from different disciplines are required to better understand causes and also to help making decisions

Using Statistical, Technological, and Participatory Methods to Identify Environmental and Health Disparities in California

Galatea King, California Environmental Health Tracking Program, U.S.A.
Michelle Wong, California Environmental Health Tracking Program, U.S.A.
Natalie Collins, California Environmental Health Tracking Program, U.S.A.
Eric Roberts, California Environmental Health Tracking Program, U.S.A.
Paul English, California Environmental Health Tracking Program, U.S.A.
Craig Wolff, California Environmental Health Tracking Program, U.S.A.

Background and Aims: Low-income and communities of color often bear the disproportionate burden of environmental hazards and poor health outcomes. The mission of the California Environmental Health Tracking Program (CEHTP) is to provide data and develop tools to identify environmental and health inequities, examine trends over space and time, and generate hypotheses about relationships between environmental hazards and health outcomes.
Methods: To accomplish the mission, CEHTP utilizes advanced statistical, technological, and participatory methods. Hierarchical Bayesian methods are employed to calculate rate estimates where data are sparse. Hazard and health data are displayed in dynamic web maps, allowing users to pan and zoom across the state. Participatory processes are used to engage stakeholders to provide input on tools development, validate data, and disseminate data. Stakeholders include community groups, governmental and non-governmental organizations, planners, and researchers.
Results: Using these innovative methods, CEHTP identifies and examines critical environmental hazards and health disparities that exist in California. For example, pesticide exposure and pre-term birth are of concern to many communities throughout California, especially low-income communities and communities of color. The CEHTP Pesticide Web Mapping Tool displays agricultural pesticide use at the community level for the entire state. A non-governmental partner organization has used the tool to identify and outreach to communities most vulnerable to pesticide exposure. CEHTP also created a web mapping tool that displays modeled pre-term birth data. This has enabled community-based partners to see spatial patterns of pre-term birth that vary significantly by census tract and follow patterns of poverty.
Conclusions: CEHTP's efforts have contributed to the identification and characterization of environmental hazards and health disparities in California, a critical function of public health programs. CEHTP must continue to utilize statistical, technological, and participatory methods to support a variety of stakeholders in their efforts to reduce environmental and health disparities in communities.

ETHYLENE OXIDE HEMOGLOBIN ADDUCTS AND BIRTH WEIGHT. THE NEWGENERIS EUROPEAN STUDY

Silvia Agramunt, Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain

Background and aims: A general exposure to ethylene oxide in the population originates from endogenously produced ethylene, metabolised to ethylene oxide. Cigarette smoke is also a source of exposure and give rise to elevated ethylene oxide hemoglobin adduct levels. There is limited epidemiologic evidence that exposure to ethylene oxide may be associated with an increased risk of spontaneous abortions and preterm births. We determined whether ethylene oxide hemoglobin adducts measured in cord blood are associated with birth weight.
Methods: Singleton births (n=1069) from Greece, Norway, Spain, Denmark and the United Kingdom were included in the study. Cord blood adducts were determined by the "adduct FIRE procedure" using liquid chromatography–tandem mass spectrometry (LC–MS/MS).
Results: A significant association between ethylene oxide hemoglobin adducts and self-reported maternal smoking status during pregnancy was observed, with higher levels among newborns born by smokers (22.8 (3.8-120.7) vs. non-smokers 8.8 (2.8-40.5) pmol/g Hb, median (min-max); $p<0.001$). In the full study population, in which 152 smokers were included, a 10 pmol/g Hb increase in hemoglobin adducts from ethylene oxide were associated with a significant decrease in birth weight (adjusted □: 30 grams; S.E.: 10, $p=0.002$). The difference in mean birth weight for infants in the highest quartile compared to those in the lowest quartile was -68 grams (SE: -37; $p=0.07$, n=1069), while the difference in infants of non-smokers was -17 grams (SE: -39, $p=0.7$, n=917). Similar decreases in birth weight were observed when maternal age, pre-pregnancy BMI, gender, parity and season of birth were included as additional covariates but associations were non-significant.
Conclusions: These results indicate that reduced birth weight and ethylene oxide hemoglobin adduct levels are associated. The association was not significant when the study population was restricted to self-reported non-smokers. Further results on other birth outcomes will be presented.

Optimizing the use of on-street car parking system as a passive control of air pollution exposure in street canyons by large eddy simulation

John Gallagher, *Trinity College Dublin Ireland*
Laurence W Gill, *Trinity College Dublin Ireland*
Aonghus McNabola, *Trinity College Dublin Ireland*

Background and Aims: An investigation was carried out to establish the effectiveness of parked cars in urban street canyons as passive controls on pedestrian pollutant exposure. A numerical model of a generic street canyon was developed using a large eddy simulation (LES) model to compare personal exposure on the footpath with and without the presence of parked cars.
Methods: Three configurations of car parking systems were investigated (parallel, perpendicular and 45_parking) in addition to the influence of wind speed, wind direction and car parking occupancy. A tracer gas (CO_2) was used as a representative pollutant from vehicular sources within the street canyon models. The results indicated that parked cars may act as a temporary baffle plate between traffic emissions and pedestrians on the footpath.
Results: The results indicated that parked cars may act as a temporary baffle plate between traffic emissions and pedestrians on the footpath. Reductions in exposure of up to 35% and 49% were attained on the leeward and windward footpaths in perpendicular wind conditions, with parallel winds allowing up to 33% pollutant reduction on both footpaths for parallel parking. The perpendicular and 45_car parking configurations investigated proved less successful as passive controls on air pollution exposure and an increase in pollutant concentration occurred in some models. An investigation of parking space occupancy rates was carried out for parallel parked cars. The fraction of parked cars influenced the level of reduction of pollutants on the footpaths with steady reductions in perpendicular winds, yet reductions were only evident for occupancy rates greater than approximately 45% in parallel wind conditions. One negative impact associated with the parked cars study was the increase of pollutant levels on the roadway as the parked cars acted as a baffle wall, which trapped pollutants in the road.
Conclusions: The paper underlines the potential of on-street car parking for reducing the personal exposure of pollutants by pedestrians and the optimum parking layout to achieve maximum health protection.

Blood lead levels in children and adolescents in Torreón, Mexico, 1999 - 2009: an age, period, and cohort analysis

Background and Aims: Torreón, a large city in Northern Mexico, is home to the 4th largest lead smelter in the world. Previous studies indicate that children in Torreón are exposed to high levels of lead, but these studies used selected samples and did not track study participants over time. In 1999, officials in Torreón established a biomonitoring program for blood lead levels (BLLs) based on a census of children and adolescents in the communities surrounding the smelter. We describe age, period and cohort trends in BLLs in Torreón from 1999 to 2009 using data from the community biomonitoring program.
Methods: BLLs were available in 45,702 children and adolescents between January 1, 1999 and October 1, 2009. 31,383 (68.7%) participants had at least one additional measurement. We examined trends in BLL by calendar year and age using mixed models for longitudinal data.
Results: BLLs decreased from 1999 (median 18.5 μg/dL; 5th and 95th percentiles 6.4 – 48.5) to 2009 (median 4.5 μg/dL; 5th and 95th percentiles 1.9 – 11.3). The percentages of children and adolescents with a BLL above 10 μg/dL were 89.1% in 1999 and 18.0% in 2009. BLLs peaked at around age one (median 9.6 μg/dL; 5th and 95th percentiles 2.7 – 32.1) and decreased thereafter. Boys had higher BLLs compared to girls (medians 8.5 vs. 7.8 μg/dL, respectively), and there was a sex by age interaction in BLLs (after the initial peak at early ages, BLLs in girls decreased faster than in boys).
Conclusions: BLLs in Torreón's children and adolescents have decreased markedly from 1999 to 2009, due in part to environmental remediation efforts. In spite of these changes, BLLs in children and adolescents in Torreón are still high compared to other Mexican and US areas.

A RISK ASSESSMENT OF CHILDHOOD LEUKAEMIA AND NATURAL RADIOACTIVITY IN FRANCE

Olivier Laurent*, Laboratoire d'Epidémiologie, Institut de Radioprotection et de Sûreté Nucléaire
Jacqueline Clavel, Equipe Epidémiologie Environnementale des Cancers, Institut National de la Santé et de la Recherche Médicale
Dominique Laurier, Laboratoire d'Epidémiologie, Institut de Radioprotection et de Sûreté Nucléaire

Background and Aims: Natural radioactivity (NR) is an ubiquitous phenomena and exhibits large geographical variations. Current risk models for radiation-induced leukaemia prediction, which are mainly issued from the epidemiological study of Hiroshima and Nagasaki A-bomb survivors, imply that levels of NR could induce some leukaemia cases. In the framework of an epidemiological research project designed to study the link between childhood leukaemia and NR, we conducted a risk assessment of the proportion of leukaemia cases that could be attributable to NR in France.
Methods : National rates of childhood leukaemia over period 1990-2004 were provided by the French registry of childhood malignancies. Mean doses to the red bone marrow that children would receive from radon, cosmic and terrestrial gamma rays in France were estimated. Risk models proposed by the United Scientific Committee for the Effects of Atomic Radiation and by the US National Research Council to predict radiation-induced leukaemia cases were applied.
Results : Overall, 6,784 leukaemia cases were registered over the study period. A mean annual dose of 1.25 milliSieverts was estimated for the sum of radon, cosmic and terrestrial gamma rays. The proportion of leukaemia cases that could be attributed to these dose components vary from a few percents to several tenths, according to the risk model used, the age group and the hypotheses for transposition from A-bomb survivors to French children (additive or multiplicative risk transfer).
Conclusions : These estimates are issued from a risk assessment approach that rely on many assumptions and hypotheses. They should be interpreted cautiously, as an indication for the magnitude of the expected risk related to NR. Variability and uncertainty analyses will focus on alternate dose scenarios, as well as statistical uncertainty. Refined estimates will allow appreciating the capacity of an ongoing epidemiological study to detect a leukaemia risk related to NR in French children.

WATER CONTAMINATION BY POLYCHLORINATED BIPHENYLS IN ARMENIA

Artak Khachatryan, *Waste Research Center, Yerevan, Republic of Armenia*

Background and Aims: To reveal the state of environmental pollution by such Persistent Organic Pollutants as Polychlorinated Biphenyls (PCBs) in the surface water basins of the Republic of Armenia the following categories of water basins were selected:
1. Rivers Hrazdan, Vorotan, at which there are hydroelectric power plants
2. Rivers Debet and Voghchi, at which there are industrial enterprises;
3. Lake Sevan and Arpa river, at which no industrial enterprises or hydroelectric power plants are functioning.
Methods: Samples of water were analyzed by means of gas-liquid chromatography.
Results: Determination of PCBs in samples taken from water reservoirs of the 3rd category demonstrated that PCBs were detected in the range of 0.07-0.93mkg/l.
In Sevan – Hrazdan ecosystem the highest level of determination in bottom sediment made 1.193 mcg/kg, in periphyton the residues reached 1.505 mcg/g. In macrophytes PCBs content amounted to 2.119 mcg/g, while in the organism of craw-fish – 1.347 mcg/g.
In samples of water taken from rivers belonging to the 1st category the content of PCBs was 2-fold higher than in water samples from reservoirs of the 3rd category. In these samples PCB residues ranged from 0.44 mcg/l to 2.93 mcg/l.
Conclusions: Study of water samples taken from the rivers, in the water collection area of which there are enterprises having potential to contaminate the environment by PCBs (category 2), revealed that from the point of view of PCB-induced contamination these samples were in an intermediate state. Residues of PCBs made from 0.44 to 1.68 mcg/l. Average PCB content in these samples was 0.68-1.33 mcg/l.
Open water basins studied for PCBs were contaminated by these substances, signifying that the environment of Armenia is contaminated by PCBs and power engineering system is the main source of PCB-related contamination in Armenia.

PERSONAL EXPOSURE TO ULTRAFINE PARTICLES; BLACK CARBON AND $PM_{2.5}$ IN DIFFERENT MICROENVIRONMENTS

Josef Cyrys, Helmholtz Zentrum München, Institute of Epidemiology II, Germany, University of Augsburg, Germany
Mike Pitz, Helmholtz Zentrum München, Institute of Epidemiology II, Germany, University of Augsburg, Germany
Jianwei Gu, Helmholtz Zentrum München, Institute of Epidemiology II, Germany, University of Augsburg, Germany
Susanne Breitner, Helmholtz Zentrum München, Institute of Epidemiology II, Germany
Alexandra Schneider, Helmholtz Zentrum München, Institute of Epidemiology II, Germany

Veronika Fensterer, Ludwig-Maximilans-University Munich, Germany
Helmut Küchenhoff, Ludwig-Maximilans-University Munich, Germany
Annette Peters, Helmholtz Zentrum München, Institute of Epidemiology II, Germany

Background and Aims: Exposure assessment studies have shown that air pollution measured by fixed monitors at residential locations may not adequately represent individual exposures, especially for times spent away from home. In the framework of an ongoing study combining individual and central monitoring site measurements we characterize personal exposures in specific micro-environments to particulate air pollutants from different sources.
Methods: During a three weeks period in February 2011, exposure data were collected by a single researcher equipped with personal monitors for continuous measurements of particle number concentration (PNC), black smoke (BS) and $PM_{2.5}$. As pedestrian or passenger in public transportation he was taking the same route including major roads, urban background and industrial areas every day. His position was recorded by a GPS device.
Results: The overall average personal exposure to each pollutant was higher than the corresponding ambient levels (39 vs. 27 μgm^{-3} $PM_{2.5}$, 4.1 vs. 2.8 μgm^{-3} for BS and 21375 vs. 12497 cm^{-3} for PNC). Whereas personal exposure to $PM_{2.5}$ during his walks along busy streets and in a residential area was very similar (41.5 vs. 41.1 μgm^{-3}), there were very pronounced differences regarding PNC or BS (35656 vs. 15369 cm^{-3} or 5.7 vs. 3.3 μgm^{-3}, respectively). Times spent in the bus highly contributed to elevated personal BS levels. As the measurements are planned for winter, spring and summer weather conditions, the study is still ongoing. At the conference results for all three periods will be shown.
Conclusions: The obtained results provide insight into the potential air pollution levels to which people could be exposed and will be used in planned analyses in addition to data from the fixed monitoring station in order to get more reliable estimates concerning people's total exposure to UFP, BS and $PM_{2.5}$, especially when being in traffic or in a near-road environment.

COMPARISON OF ACUTE NEUROLOGICAL EFFECTS OF UFP EXPOSURE DURING EXERCISE AND REST

Background and Aims: Long term exposure to air pollution, such as particulate matter, is associated to negative neurological effects, including neuroinflammation and cognitive decline. Regular exercise stimulates brain health and plasticity. Brain-Derived Neurotrophic Factor (BDNF), a neurotrophine, is suggested to play a key role in this process. However, recent evidence suggests that exposure to air pollution during exercise is about 4 times higher compared to rest, due to higher ventilation.
The first aim is to find out if a short exposure to a high concentration of ultrafine particles (UFP) during rest or exercise induces acute neurological effects. Effects are investigated by gene expression analysis of IL1• , IL1• , TNF• , IL6, COX-2 (inflammatory cytokines and mediators), NRF (transcription factor activated by oxidative stress), BDNF. The second aim is to investigate if there is a difference in effect size between UFP exposure during rest and exercise.
Methods: 24 male, Wistar rats were divided into 4 groups and each group (n=6) was exposed for 1.5 hours to 1 of 4 exposure scenarios. The four exposure scenarios included: peak UFP exposure during exercise, peak UFP exposure during rest, ambient air exposure during exercise, and ambient air exposure during rest. The miniCAST sootgenerator was used to create a peak UFP concentration of 10^7particles/cm^3 into an exposure chamber containing a treadmill. UFP concentration was monitored (DMS50) in the exposure chamber. Blood, hippocampus, bulbus olfactorius and frontal cortex were collected 24 hours after exposure. Hippocampal BDNF was analyzed by ELISA. All tissues were analyzed for gene expression by Q-PCR.
Results (preliminary) and conclusions: Hippocampal BDNF is not significantly increased (p=0.16) 24 hours after exercise (n=4) compared to rest (n=4), during ambient air exposure. Analysis of RNA quantity and integrity shows that the RNA meets the requirements that are needed for further gene expression analysis.

CARDIOVASCULAR HOSPITAL ADMISSIONS IN RELATION TO AIRCRAFT NOISE, ROAD NOISE AND AIR POLLUTION IN WEST LONDON

Anna Hansell, *Imperial College London, UK*
Marta Blangiardo, *Imperial College London, UK*
Lea Fortunato, *Imperial College London, UK*

Heathrow Study Team, Small Area Health Statistics Unit, Imperial College London, UK

Background: There is increasing evidence that environmental noise exposure has a range of impacts on cardiovascular disease.
Methods: A small area study was conducted covering 12 local government districts in west London partly or wholly within the 2003 L_{day} 50 dBA Heathrow aircraft noise contour over the time period 2001-2005. Exposure variables were 2001 values for (i) aircraft noise for daytime $L_{eq,16hr}$ and nighttime L_{night}, (ii) daytime road traffic noise $L_{eq,16hr}$ (Rd16) from maps produced to comply with the European Noise Directive 2002/49/EC and (iii) modelled annual average concentrations of NO_2 and PM_{10}. These were examined in relation to hospital admissions for cardiovascular disease for people living in the study area. Census output areas (COAs), which comprise 250 people on average in the UK, were chosen as the unit of analysis. A Bayesian disease mapping model was constructed using a log-linear model for the risk for each COA and accounting for spatial residuals using a conditionally autoregressive structure and a hierarchical structure for unstructured residuals. Results were adjusted for ethnicity structure of the area and deprivation (Carstairs index). Tests for linear and quadratic trends across categories were conducted using the median value of each noise or air pollution category.
Results: There were 2,616,448 million people resident in the study area in 2001 and 180,738 cardiovascular hospital admissions in 2001-5, giving approximately 4 person admissions per COA per year of study. Correlation coefficients were low between road traffic and aircraft noise (r=0.018 for Rd16 and aircraft $L_{eq,16}$) but moderate between road noise and NO_2 (r=0.432). NO_2 and PM_{10} were highly correlated (r=0.952). The correlation between daytime and night aircraft noise was 0.88. Analytic analyses have been completed and results are currently being evaluated.
Conclusions: This study is expected to influence policy planning for high volume airports in urban areas.

HEALTH-PROMOTING EFFECTS OF VISITS TO GREEN SPACE – CASE STUDIES IN KUALA LUMPUR AND KUCHING, MALAYSIA

Nor Akmar Abdul Aziz, *University of Copenhagen, Denmark.*
Cecil C. Konijnendijk, *University of Copenhagen, Denmark.*
Ulrika Stigsdotter, *University of Copenhagen, Denmark.*
Kjell Nilsson , *University of Copenhagen, Denmark.*

Background and Aims: Major Malaysian cities such as Kuala Lumpur (Peninsular Malaysia) and Kuching (Sarawak) have been experiencing rapid development. The importance of green spaces as a contributor to the better quality of a resident's life has been recognized, though data on the use of green spaces and resulting benefits are still lacking. This paper presents results from a comparative study on the use of green spaces and visitor preferences for five selected parks located in Kuala Lumpur and Kuching. The study comprised, among others, a survey which conducted among residents living within two kilometre radius from the park boundaries.
Methods: A part of the survey focused on health promoting aspects of urban green spaces. Questions related to self-reported health status were proposed, which enabled a comparison between visitors and non-visitors to the nearby park. Moreover, respondents were also asked about the activities that they would recommend their close friends or family members should they experience stress or anxiety.
Results: A total of 1692 respondents answered the questionnaire. Result shown that most of the people who spend time visiting the neighbouring park claimed that they are in good health, while a larger share of people who do not spend time visiting the park reported that they are in conversely poor health condition. Respondents who live within 300m from the park reported that they are in better health condition than that of respondents who live far away. Most of respondents suggested that their close friends and family members go for vacation or involve themselves in sports/outdoor activities should they experience stress or anxiety.
Conclusions: This research claimed most people healthier because they visit green spaces frequently and these results had drawn attention to the importance of green spaces to human health, confirming the findings of studies from other parts of the world. Hence, decision makers and green space managers should consider and incorporate this health promoting role of green spaces in their activities.

ARSENIC EXPOSURE AND BLOOD INFLAMMATORY MARKERS OF CARDIOVASCULAR DISEASE

Yu Chen, New York University School of Medicine, USA
Muhammad Kibriya, Farzana Jasmine, University of Chicago, USA
Mengling Liu, New York University School of Medicine, USA
Vesna Slavkovich, Columbia University, USA
Tariqul Islam, Columbia University and University of Chicago Research Office in Bangladesh, Bangladesh
Faruque Parvez, Columbia University
Habibul Ahsan, University of Chicago, USA

Background: Arsenic exposure from drinking water has been related to elevated risks of an array of cardiovascular disease, including hypertension, ischemic heart disease, and carotid atherosclerosis. Although mechanistic studies have suggested that arsenic promotes inflammatory activity and lead to endothelial dysfunction, epidemiologic studies that evaluate the associations of arsenic exposure with biomarkers for inflammation and endothelial dysfunction relevant to CVD are needed.
Methods: We assessed the relationship between arsenic exposure, measured in both well water samples and urinary samples, and an arrays of makers for inflammation and endothelial dysfunction, including tumor necrosis factor-α (TNF-α), interleukin-6 (IL-6), soluble intracellular adhesion molecule-1 (sICAM-1), and soluble vascular cell adhesion molecule-1 (sVCAM-1), in serum samples collected from 669 participants aged 30 and above randomly selected from the Health Effects of Arsenic Longitudinal Study (HEALS), a population-based study in Araihazar, Bangladesh. Serum levels of markers were analyzed using xMap™ technology, with commercially available high-sensitivity kits from Linco/Millipore Research. Linear regression was conducted to evaluate association between arsenic exposure and each of the markers.
Results/Conclusions: Ongoing data analyses suggest that arsenic exposure is positively related to levels of several markers for oxidative stress and inflammation relevant to CVD. This is the first large study on arsenic exposure and markers of vascular inflammation and endothelial dysfunction in cardiovascular disease (CVD), and the findings may suggest possible mechanisms by which arsenic may lead to CVD.

PARTICULATE AIR POLLUTION EXPOSURE AND C-REACTIVE PROTEIN DURING EARLY PREGNANCY

Pei-Chen Lee, *University of Pittsburgh, USA*
Evelyn O. Talbott, *University of Pittsburgh, USA*
James M. Roberts, *University of Pittsburgh, USA*
Janet M. Catov, *University of Pittsburgh, USA*
Ravi K. Sharma, *University of Pittsburgh, USA*
Beate Ritz, *University of California at Los Angeles, USA*

Background and Aims: It is not well understood how air pollution leads to adverse pregnancy outcomes. One pathway may be through C-reactive protein, a biomarker of systemic inflammation that has been reported to increase the risk of preterm delivery. We examined whether air pollution influences serum concentrations of C-reactive protein in early pregnancy.
Methods: We studied 1696 pregnant women in Allegheny County, PA, from 1997 through 2001. C-reactive protein concentrations were assayed in blood collected before the 22nd week of gestation. We estimated levels of particles of less than 10 µm (PM_{10}) and less than 2.5 µm diameter ($PM_{2.5}$), carbon monoxide, nitrogen dioxide, sulfur dioxide, and ozone at the maternal ZIP code using Kriging interpolation for measurements obtained from ambient stations. Employing logistic regression we evaluated associations between air pollution and high C-reactive protein concentrations (• 8 ng/ml).
Results: Among non-smokers, observed 9.2 µg/m^3 increase in PM_{10} (averaged over 28 days prior to the blood sample) was associated with an odds ratios of 1.41 for high C-reactive protein concentrations (95% confidence interval = 0.99 – 2.00). Similarly, a 4.6 µg/m^3 increase in $PM_{2.5}$ was associated with an odds ratio of 1.47 (1.05 – 2.06). The odds ratio was 1.49 (0.75 – 2.96) per 7.9 ppb increase in ozone during summer. We saw no associations in smokers or for other air pollutants, and no evidence for effect-measure modification by obesity.
Conclusions: PM_{10}, $PM_{2.5}$, and ozone exposures were associated with increased C-reactive protein concentrations in early pregnancy, suggesting that these air pollutants contribute to inflammation and thereby possibly to adverse pregnancy outcomes.

AIR POLLUTION AND MOLECULAR MARKERS OF ASTHMA AMONG UTEP COHORT SIBLING PAIRS

Esther Erdei, *University of New Mexico*
Orrin Myers, *University of New Mexico*
Cassandra Garner, *University of New Mexico*
Alma Ruiz-Payan, *University of Texas—El Paso*
Kirsten A. White, *University of New Mexico*
M. Berwick, *University of New Mexico*
M. Amaya, *University of Texas—El Paso*
N. Pingitore, *University of Texas—El Paso*

Background and Aims: The Sibling Pair Asthma (SPA) study is a joint effort between the University of Texas at El Paso and the University of New Mexico Health Sciences Center funded by NIEHS. We investigated the impact of air quality on asthma prevalence among Mexican-American children.
Methods: Households from an ongoing cohort study with at least one asthmatic child and a non-asthmatic sibling were invited to participate in this study (N=104 children from 51 households). Participants of this study were 98% Mexican- Americans. Blood samples were collected using a mobile van among community residents. Serum total IgE was obtained and categorized as high (>89 IU/ml) or low concentration. Quantification of 10 serum cytokines important in asthmatic inflammation was carried out using xMAP bead-based technology and Luminex 100™ detection system. Daily concentrations of NO_2, O_3, SO_2, $PM_{2.5}$, and PM_{10} from USEPA air quality archives were used to calculate 1-7 day lagged concentrations. Chronic spatial gradients in pollution levels were created using traffic intensity, elevation, and distance to major point sources to predict NO_2 concentrations.
Results: Higher IgE levels were associated with coughing (60.8% vs. 35.9%, p=0.01) and with the number of respiratory symptoms (2.4±2.1 vs.1.6 ± 2.0, p=0.036). IgE was correlated with 7-day average 8-hr maximum ozone (rho =0.34 p=0.01). IL-4 was correlated with average one-day lagged ozone (rho=0.34 p=0.01) and two-day lagged ozone (rho=0.29 p=0.03). The effect of NO_2 exposure on increased IL-5 cytokine production was stronger among asthmatic children than in their non-asthmatic siblings. Increased serum IL-8 concentrations were associated with increased $PM_{2.5}$ exposures among non-asthmatic children, but not among asthmatics with high IgE. The chronic spatial exposure gradient was not associated with cytokine production.
Conclusions: Air pollutants had different effects on serum immune markers among sensitive asthmatic children compared to their healthy sibling pairs.

EXAMINING THE MORTALITY EFFECTS OF THE IRISH NATIONAL SMOKING BAN

Sericea Stallings-Smith, *Brunel University, West London, UK*
Ariana Zeka, *Brunel University, West London, UK*
Pat Goodman, *Dublin Institute of Technology, Dublin, Ireland*
Luke Clancy, *TobaccoFree Research Institute, Dublin, Ireland*

Background and Aims: Secondhand smoke causes disease and death in those exposed, with cardiovascular and respiratory problems as the most likely outcomes. The purpose of this study was to examine the mortality effects of the Irish national smoking ban of 2004.
Methods: Irish mortality data for years 2000-2007 were analysed for smoking ban effects following policy implementation in 2004. Population estimates for the years 2002 and 2006 were obtained from Irish census data and used to calculate death rates in adults (ages 18+) for each of the study years. Smoking-related causes of death were assessed by determining the absolute difference between the average death rates for pre-ban (2000-2003) versus post-ban (2004-2007) years. Analyses were conducted with SAS version 9.2 and Microsoft Office Excel 2007.
Results: These preliminary analyses indicated that when compared to pre-ban death rates, 5.63/10,000 (95% confidence interval [CI] = 0.98; 10.27) cardiovascular deaths were prevented for each year post-ban. On average, this was a 20% reduction in cardiovascular mortality. Additionally, 3.44/10,000 (95% CI = -0.19; 7.08) respiratory deaths were prevented, representing an average 22% reduction when compared to pre-ban years. This was roughly equivalent to 2,900 lives saved each post-ban year (with as few as 252 or as many as 5,560 lives saved). Further and more rigorous analyses are ongoing.
Conclusions: A decrease in smoking-related mortality was detected following the implementation of the Irish national smoking ban, indicating that comprehensive smoking ban policies can play a significant role in reducing mortality from cardiovascular and respiratory causes.

SENTIERI project: mortality study of residents in Italian polluted sites – IPS

Roberta Pirastu, *Sapienza Università di Roma, Italy*
Francesco Mitis, *WHO – ECEH, Rome, Italy*
Ivano Iavarone, *Istituto Superiore di Sanità, Italy*
Roberto Pasetto, *Istituto Superiore di Sanità, Italy*
Pietro Comba, *Istituto Superiore di Sanità, Italy*
Marco Martuzzi, *WHO – ECEH, Rome, Italy*

Background and Aims: Soil contamination occurs in approximately 250,000 sites in the European Environment Agency member countries. In Italy several thousands qualify for remediation and 57 are defined as "of national concern" on the basis of documented contamination. SENTIERI project, funded by the Ministry of Health, aims at describing the health status of population resident in Italian polluted sites – IPS.
Methods: Forty-four IPSs were selected for mortality analysis. IPSs were classified in terms of presence of environmental exposure as documented in Ministerial Decrees, namely: chemical industry/petrochemical plants&refineries/harbour area/asbestos or other mineral fibers/steel plants/thermoelectric power plants/mines or quarries/landfills/incinerators. In eah IPS, for the period 1995-2002, for 63 causes of death, for both genders were calculated: i) Italy 2001 mortality rates (x 100,000) ii),standardised mortality ratios, crude and adjusted for deprivation, regional reference
Results: In 1995-2002 Italian mortality rate for all causes is 1340 (100,000/year) for males and 828 for females. The rate is higher than the regional one respectively in 27 IPSs for males and 24 for females. For all tumors the national rate is 410 for males and 210 for females, the rate is higher than the regional one in 28 IPSs for males and 21 IPSs for females. Adjusting for deprivation, in all IPSs combined, around 10,000 and 4,000 excess deaths over the regional expected values are observed respectively for all causes and for all tumors.
Conclusions: The study shows that Italian IPSs contribute substantially to the environmental burden of disease confirming findings from previous investigations. Health impacts are heterogeneous, and several questions arise in the interpretation, for example regarding mixtures of exposures, residual confounding, occupational vs environmental effects. However, findings do provide an overall picture of the health profile of residents, and indications on priority action on mitigation and remediation of contaminated sites.

EXPOSURE ASSESSMENT OF FORMALDEHYDE FROM BABY CARE PRODUCTS

Kunning Zhu, Robert Miller, Jed Waldman, Hahn Lu, Kazukiyo Kumagai, *California Department of Public Health, United States*

Background and Aims: Formaldehyde-releasers are widely used as preservatives in water-containing cosmetics (baby care products/toiletries). It was observed that these compounds very rapidly release formaldehyde when dissolved in aqueous /polar solvents. Formaldehyde is a well-known sensitizer in children and allergy to this chemical is a more widely recognized problem in recent years[2]. In some children, small amounts of formaldehyde can trigger and maintain an eczematoid-type dermatitis, headache, or symptoms of asthma[3].
This study aims to conduct a survey to measure the free formaldehyde content in baby care products and assess exposure to formaldehyde during the usage of these products.
Methods: Extraction method is developed in our lab to extract free formaldehyde from a variety of matrixes such as water solution and baby wipe cotton. We also evaluated analytical methods to determine free formaldehyde levels in the presence of the formaldehyde releasers. We acquired products labelled with formaldehyde releasers, according to CDPH's cosmetics database. To assess exposure, we locate baby care products in a small chamber simulating real environment, and measure the formaldehyde concentrations in the air and in the solution.
Results: From the pilot test of six baby bath products, we found the free formaldehyde amount was about 0.3% of the product (weight percentage). The formaldehyde released in the sample air was in the range of 18~1700 μg/m^3.
Conclusions: Previous study reported that 23 out of 28 baby bath products tested contained formaldehyde at levels ranging from 54 to 610 parts per million[4]. Our pilot findings confirmed the presence of free formaldehyde in the products. We also found the formaldehyde released in the air during use of baby bath products, which may cause potential inhalation exposure.

IMPACT ESTIMATION OF THE EYJAFJALLAJÖKULL ERUPTION ON THE GROUND LEVEL OF PM_{10} IN AUGSBURG, GERMANY

Mike Pitz, Helmholtz Zentrum München, Institute of Epidemiology II, Germany, University of Augsburg, Germany
Annette Peters, Helmholtz Zentrum München, Institute of Epidemiology II, Germany
Jianwei Gu, Helmholtz Zentrum München, Institute of Epidemiology II, Germany, University of Augsburg, Germany
Jens Soentgen, University of Augsburg, Germany
Josef Cyrys, Helmholtz Zentrum München, Institute of Epidemiology II, Germany, University of Augsburg, Germany

Background and Aims: On April 14, 2010 the Icelandic volcano Eyjafjallajökull erupted and its ash cloud was transported by wind directly towards Central Europe. On April 19 and 20 exceedences of the daily PM_{10} threshold value were reported at nearly all monitoring stations in Munich and Augsburg, two cities located around 2500 km apart from the Icelandic volcano. In this study we applied positive matrix factorization (PMF) method using particle size distribution (PSD) data in the range from 3 nm to 10 µm for the identification of the Eyjafjallajökull ash plume and estimation of its contribution to PM_{10} levels in Augsburg, Germany.
Methods: A Twin Differential Mobility Particle Sizer system combined with an Aerodynamic Particle Sizer was used to measure PSD. We used the receptor model PMF 3.0 from the U.S. Environmental Protection Agency to identify and quantify PSD factors.
Results: A PMF factor associated with long range transported dust rose from background concentration to high levels simultaneously with the arrival of the volcanic ash plume in the planetary boundary layer. We used this factor for estimation of the Eyjafjallajökull ash plume contribution to ambient PM_{10} measured on ground level in Augsburg. From April 17 to 22, 2010 this factor contributed on average 31.6% (12.3 µg m^{-3}) to ambient PM_{10}. The maximal contribution of this factor to PM_{10} level in Augsburg was 70% (37 µg m^{-3}) which was observed at 20:00 on April 19, 2010.
Conclusions: The PMF method could be used for identification and quantification of natural source impact on PM threshold exceedences. Without further evidence from toxicological studies and following the knowledge about the ash plume components we assume that the volcanic plume contributed to the overall exposure of the population and therefore in principal may have had minor effects on exacerbation of respiratory and cardiovascular symptoms.

MEASURING THE LUNG FUNCTION CONTINUOUSLY AND UNOBTRUSIVELY

Ville-Pekka Seppä, *Tampere University of Technology, Finland*
Jari Hyttinen, *Tampere University of Technology, Finland*
Jari Viik, *Tampere University of Technology, Finland*

Background and Aims: The conventional pulmonary function tests (PFTs) require respiratory maneuvers like forced maximal expiration, and only give snap shot information of the lung function. Our aim is to devise methodology for continuous unobtrusive assessment of the lung function using a wearable impedance pneumography (IP) system.
Methods: IP is based on the knowledge that the electrical impedance of the thorax is proportional to the lung volume. Thus, variation in the lung volume can be assessed by placing two or more measurement electrodes on the surface of the body to measure the impedance variations. Furthermore, the obtained signal can be used to produce diagnostic tidal breathing flow-volume loops. The shape of these loops change in a characteristic way when an airway obstruction occurs or is relieved (Beydon et al. 2011).
Results: We have conducted multiple measurements on healthy subjects and patients with obstructive airway diseases, assessing the agreement between the IP and a direct mouth airflow measurement. Thanks to our research on electrode locations and signal processing techniques, we have been able to produce highly accurate pulmonary flow-volume loops regardless of the subject body posture or presence of an obstructive airway disease. We also have produced a wearable cell phone size 24h IP recording device.
Conclusions: IP is accurate enough to produce diagnostic pulmonary flow-volume loops. It does not require any direct connection with the airways nor any proactivity from the measurement subject, unlike the conventional PFTs. This potentially enables continuous, long-term estimation of changes in lung function due to external agents and obstructive diseases like asthma. In combination with personal exposure monitors, IP could be used to assess the immediate real-time effects of air pollution on the lung function. This would be especially beneficial for preschool children and infants with whom the conventional PFTs cannot be used at all.

EXPOSURE TO BISPHENOL A DURING PREGNANCY AND MATERNAL AND NEONATAL THYROID HORMONE LEVELS

Jonathan Chevrier, *Center for Environmental Research and Children's Health (CERCH), School of Public Health, University of California, Berkeley, United States*
Kim G. Harley, *Center for Environmental Research and Children's Health (CERCH), School of Public Health, University of California, Berkeley, United States*
Asa Bradman, *Center for Environmental Research and Children's Health (CERCH), School of Public Health, University of California, Berkeley, United States*
Antonia M. Calafat, *Center for Environmental Research and Children's Health (CERCH), School of Public Health, University of California, Berkeley, United States*
Xiaoyun Ye, *Centers for Disease Control and Prevention, United States*
Brenda Eskenazi, *Centers for Disease Control and Prevention, United States*

Background and Aims: Bisphenol A (BPA) is widely used in the manufacture of polycarbonate bottles, food packaging, can linings, and dental sealants. High detection frequencies in numerous environmental and human specimens indicate that BPA is a widespread contaminant. Animal and *in vitro* studies suggest that BPA may disrupt thyroid hormone (TH) but little human data are available, particularly in pregnant women and neonates. Normal thyroid function during these critical developmental periods is essential for normal brain development. Our aim was thus to determine whether maternal exposure to BPA is related to thyroid hormone levels in pregnant women and neonates.
Methods: We measured BPA in urine samples collected during the first and second half of pregnancy in women participating in the Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS). Pregnant women who were >=18 years, <20 weeks gestation, English or Spanish speaking, and qualified for Medicaid (health insurance for low-income families) were eligible for participation in the study. Free thyroxine (T4), total T4 and thyroid-stimulating hormone (TSH) was measured in 339 maternal serum samples obtained at ~27 weeks' gestation. Neonatal TSH levels were abstracted from medical records (n=371).
Results: The median BPA urinary concentration was lower in CHAMACOS women (1.1 µg/L) than in the general U.S. population (2.8 µg/L). Preliminary analyses suggest that every 10-fold increase in maternal BPA urinary concentration in the second, but not the first, half of pregnancy was associated with a 0.5 µg/dL decrease in total T4 (95%CI=-1.0, -0.1) after controlling for confounders. Associations were stronger when BPA was measured closer in time to total T4. BPA urinary concentrations were not associated with maternal free T4 or TSH, or with neonatal TSH.
Conclusion: Maternal exposure to BPA was inversely associated with total T4 during pregnancy. Findings may have implications for fetal brain development.

WORKING WITH NON-HEALTH SECTORS: A REVIEW OF EXPERIENCES WITH ECONOMIC APPROACHES TO PROMOTE CYCLING AND WALKING: THE HEALTH ECONOMIC ASSESSMENT TOOL (HEAT)

Francesca Racioppi, *WHO Regional Office for Europe, European Centre for Environment and Health, Rome, Italy*
Sonja Kahlmeier, Thomas Götschi, *Physical Activity and Health Unit, Institute of Social and Preventive Medicine, University of Zurich, Switzerland*
Nick Cavill, Charlie Foster, Paul Kelly, *British Heart Foundation Health Promotion Research Group, Department of Public Health, University of Oxford, England*
Max Herry, *Herry Consult, Austria, Vienna*
Harry Rutter, *National Obesity Observatory England, United Kingdom*

Background and Aims: Walking and cycling are increasingly recognized as effective forms of physical activity, an important public health priority. Urban and transport planning are more influential for mobility behaviour than "classic" health promotion approaches. Therefore, the challenge is to reach out to these sectors to support interventions that promote walking and cycling. Economic appraisals are an established practice for transport projects but rarely take health effects into account. The WHO therefore coordinated an international project to develop a Health Economic Assessment Tool (HEAT) for cycling and walking.
Methods: Reviews of economic valuations of cycling or walking and of the epidemiologic literature were carried out to identify approaches and relative risk estimates for the health effects. International multi-disciplinary consensus meetings addressed methodological issues for the development of HEAT cycling and walking.
Results: HEAT is a transparent, robust, conservative and practice-oriented tool estimating the value from reduced mortality due to physical activity from cycling or walking, i.e.: if x people cycle (or walk) y distance on most days, what is the economic value of reduced mortality? For regular commuter cycling, the relative risk from a large study was used (RR 0.72, 95% CI 0.57-0.91). For regular walking, an aggregate risk for all-cause mortality of 0.77 (CI 0.63-0.95) has been calculated. HEAT cycling has been applied in several countries. E.g in Austria, it showed that the current bike modal share of 5% leads to 412 averted deaths per year, equating an economic value of over 400 mio. EUR. In Portland, USA, investments of over 40mio. EUR over 20 years lead to quintupling of cycling, with health benefits equating about 14 mio EUR per year. Results from the first applications of HEAT walking from Parnu/Estonia, Kuopio/Finland and Brighton-and-Hove/UK will also be presented.
Conclusions: The HEAT tools have shown to be effective in fostering the integration of health effects into economic transport appraisals.

Background and Aims: Valid biomarkers that link environmental exposures to the pathogenesis of human disease can enhance health risk assessment and contribute to effective new disease prevention policies in environmental and occupational settings. This presentation concerns results of a large scale evaluation of changes in gene expression in relation to body burdens of PCBs (polychlorinated biphenyl ethers) using microarrays, combined with a primary validation through high-throughput TLDA in a NIEHS project to SKD.
Methods: The microarray results of global gene expression in peripheral blood for individuals with varying levels of PCBs, and in PBMC cells (*in vitro*) with Slovak human median equivalence concentrations of PCBs were analyzed by GeneSpring GX 10.0. The Ingenuity Pathway Analysis retrieved the top biofunctions, networks, and major molecules to establish these signature biomarkers relative to disease and developmental processes occurring after exposure to these chemicals. The high-throughput qRT-PCR by TLDA studies were done on ABI platform. Data analysis was done through DataAssist™ and StatMiner®.
Results: The potential signature biomarkers **(RRAD, MYC, CD3, CYP1A2, PON1, CYP2D6, ARNT, BCL2, LEPR, LPR12, ENTPD3, ITGB1, NPPB,** and **TRAP1**) identified in the PCB-exposed population and in *in vitro* studies, involved relevant biological pathway signatures leading to major abnormalities and disorders in the PCB-exposed population (viz., Cardiovascular, Developmental Disorders, Neurobehavioral, Cancer). The analyses of global expression on validating the genes have indicated that the subjects are grouped into different clusters (high and low PCB exposure groups) depending upon the quantitative expression of the candidate genes. These gave a hint that these gene fingerprints could lead to identification of groups at risk through specific pathways based upon the PCB exposure.
Conclusion: Upon validation, this high-throughput biomarker-based method will be capable of identifying high-risk individuals with specificity & selectivity, through therapeutically relevant genomic classifiers, as a measure of biological responses to environmental stressors.

Comentario [IH1]: did you look at multiple samples from the same person? if not, then 'changes in' does not appear to be the correct description of what you did.

SHORT-TERM EFFECT OF FINE PARTICULATE MATTER ($PM_{2.5}$) AND OZONE ON DAILY MORTALITY IN LISBON, PORTUGAL

Pedro Garrett Lopes, *Climate Change Impacts, Adaptation & Mitigation Research Group (CCIAM), Faculty of Sciences, University of Lisbon, Portugal*
Elsa Casimiro, *Climate Change Impacts, Adaptation & Mitigation Research Group (CCIAM), Faculty of Sciences, University of Lisbon, Portugal - INFOTOX Environmental Risk Consultants, Lisbon, Portugal*

Keywords: Ozone, Fine Particulate Matter, Acute Effects, Generalized Additive Modeling, Lisbon
Aim: Determine the exposure-response relationships of ambient ozone and fine particulate matter ($PM_{2.5}$) concentrations on daily mortality in Lisbon.
Abstract: Urban ambient air pollution exposures continue to be a global public health concern. Although air quality targets are often exceeded in Lisbon, the largest city in Portugal, there is currently no study that has assessed the quantitative impact of these pollutants on daily mortality.
In this study we conduct a time series analysis using generalized additive modeling to determine the exposure-response effect from ambient ozone (O_3) and fine particulate matter ($PM_{2.5}$) concentrations on daily mortality in Lisbon. The dataset used was limited to the Lisbon municipality and for the period 2004-2006.
For $PM_{2.5}$ exposures, we found that the relative risk for cardiovascular mortality in the population group ≥ 65 years is 2.39% (95%CI: 1.29%, 3.50%) for each 10µg/m^3 increase. A statistically significant cause-effect relationship for $PM_{2.5}$ and mortality was not observed in other population groups.
We also report O_3 exposures to be associated with an increase of 1.11% (95% C.I. (0.58, 1.64)) for all-cause mortality in the population group ≥ 65 years and an increase of 0.96% (95% C.I. (0.56, 1.35)) for the general population. When analyzing by cause of death, our results showed a stronger association between O_3 exposure and cardiovascular mortality.

Real-time Monitoring of Formaldehyde Concentrations in the Built Environment

Stacy Doore, *University of Maine, USA*
Clint Eaton, *University of Maine, USA*
John C. Whittier, *University of Maine, USA*
Paul Smitherman, University of Maine, USA
Delia, Massey, *University of Maine, USA*

Background and Aims: Volatile organic compounds (VOCs) are a major concern in indoor air quality investigations and formaldehyde , in particular, is the subject of considerable environmental health and monitoring research[1,2, 3]. New regulatory standards are focused on reducing formaldehyde levels in both residential settings and building materials manufacturing. In order to develop new tools to meet lower national thresholds [4], there is need for research on the design, implementation and testing of a wireless formaldehyde monitoring systems. The objectives of this research are to 1) compare the performance of commercially available sensors within the network architecture, 2) identify fine scale spatio-temporal patterns in formaldehyde emissions, and 3) provide improved information integration models for the assessment of environmental and personal exposure events.
Methods: (Arial, 8pt, bold) The formaldehyde monitoring system consists of wireless sensor nodes, a base station, a Sensor Observation Service (SOS), a database system, and a web-based user interface. Sensor nodes collect data and then pass it to the Sensor Observation Service (SOS) that provides a web-based user interface to enable users to view the latest sensor readings and historical analysis results.
Results: (Arial, 8pt, bold) Although the full results of this prototype system will not be available until current testing is completed this spring, anticipated issues this research will be able to address include: efficient and effective wireless communication configurations, comparison of data storage and processing methods, representation of conceptual model that can adequately capture both personal exposure and general area exposures, and ensuring effective user interface design.
Conclusions: (Arial, 8pt, bold) Applications of this research will benefit manufacturing industry and wood composite researchers as they move towards producing materials with lower formaldehyde emissions as well as the environmental epidemiology community looking for new tools and methods for collecting and analyzing the longitudinal impact of formaldehyde exposure at lower levels.

ABSTRACT

Background and Aims: Several reports indicate that drinking water arsenic (WAs) and manganese (WMn) areassociated with children's intellectual function. Very little is known, however, about possible associations with other neurological outcomes such as motor function.
Methods: We investigated the associations of WAs and WMn with motor function in 304 children in Bangladesh, aged 8-11 years. In addition to water, we measured arsenic and manganese concentrations in blood, urine and toenails. We assessed motor function with the Bruininks-Oseretsky Test (BOT-2), which can be summarized with a total score of overall motor proficiency (TMC) or in four subscales: fine manual control (FMC), manual coordination (MC), body coordination (BC) and strength and agility (SA).
Results: Log transformed blood As (BAs) was associated with decreases in TMC (ß=-3.65, p<0.01), FMC (ß=-1.70, p<0.05) and BC (ß= -1.61, p<0.01), with adjustment for gender, school attendance, head circumference, mother's intelligence, plasma ferritin, blood Mn, Pb, and Se. Other measures of As exposure (water As, urinary As, and toenail As) demonstrated similar associations. We also have observed a strong positive association between square transformed blood selenium (BSe) and motor function, another novel finding. A significant association between BSe and TMC (ß=3.54, p<0.005), FMC (ß=1.55, p<0.005) and MC (ß=1.57, p<0.005) was found in the unadjusted models; the relationship between BSe and MC remained significant in the full model. Mn exposure was not associated with motor function.
Conclusion: Our research demonstrates an adverse association of As exposure and a protective association of Se on motor function in children.

EXPOSURE ASSESSMENT OF CONSTITUENTS OF AIR POLLUTION: A POOLED ANALYSIS OF NINE VALIDATION STUDIES

Marianthi-Anna Kioumourtzoglou, *Dept. of Environmental Health, Harvard School of Public Health*
Donna Spiegelman, *Dept. of Biostatistics and Epidemiology, Harvard School of Public Health*
Biling Hong, *Dept. of Epidemiology, Harvard School of Public Health*
Francine Laden, *Dept. of Environmental Health and Epidemiology, Harvard School of Public Health*
Ronald Williams, *Human Exposure and Atmospheric Sciences Division, EPA*
Helen Suh, *Dept. of Environmental Health, Harvard School of Public Health; Public Health Division, NORC at the University of Chicago*

Background and Aims: Exposure error has long been a concern in chronic air pollution health effect studies, which generally assess exposures using measures of ambient concentrations. This study develops statistical methods to adjust for bias due to measurement error based on regression calibration de-attenuation factors, using monthly averages of personal fine particulate ($PM_{2.5}$) exposures and ambient concentrations, and assesses to what extent these factors vary by city and season.
Methods: Personal and ambient $PM_{2.5}$ data were compiled from validation studies performed in eight US cities (one in 1995, seven between 1998-2002) and one in the Netherlands (2004-2005), with 416 participants in total. Corresponding elemental carbon (EC) levels were also obtained from five of these studies (n=208). Personal measurements were assumed as the 'gold standard'. Linear mixed effects models were employed to estimate the association between monthly-averaged ambient and corresponding personal exposures. City-specific effects were estimated, adjusting for season. The homogeneity of effects between cities was assessed and the pooled effects were estimated using random effects models.
Results: Monthly-averaged personal and ambient concentrations were significantly correlated, with Spearman correlation coefficients of 0.43 for $PM_{2.5}$ and 0.56 for EC, adjusted for city and season. Significant heterogeneity was observed between cities, with city-specific, personal-ambient $PM_{2.5}$ slopes ranging between 0.32-1.64. Random effects meta-analysis yielded a de-attenuation factor of 0.59 (0.38, 0.80). For monthly EC, significant personal-ambient slopes were observed only in three cities, with slopes ranging between 0.39-0.89. The pooled de-attenuation factor for EC was 0.46 (0.12, 0.79).
Conclusions: Exposure measurement error of this magnitude is likely to lead to appreciable bias in estimates of the effect of chronic PM exposure on human health. These de-attenuation factors will be used to develop a regression calibration model to adjust for bias due to measurement error in studies of chronic PM health effects.

IMPACT OF AN IMPROVED BIOMASS STOVE (PATSARI) INTERVENTION ON CHILDREN´S HEALTH

Astrid Schilmann, *Instituto Nacional de Salud Pública, México*
Karina Ramírez-Sedeño, *Instituto Nacional de Salud Pública, México*
Horacio Riojas-Rodríguez, *Instituto Nacional de Salud Pública, México*
Isabelle Romieu, *International Agency for Research on Cancer, France*
Rogelio Pérez-Padilla, *Instituto Nacional de Enfermedades Respiratorias "Dr. Ismael Cosío", México*

Background and Aims: In México, about 27 million people use wood as primary source of energy. One approach to decrease the health burden related to indoor air pollution has been implementation of improved wood-burning chimney stoves. The aim of this study is to assess the impact of the introduction of Patsari stoves on the respiratory health of younger than 4 years of age children in highlands Michoacán.
Methods: Households (n=668) in six rural communities in a fuel wood using region were selected and randomized to receive an improved stove (Patsari) early on or keep their traditional wood fire until the end of the follow up including 10 monthly visits. During each home visit, a questionnaire was applied to the mother asking for a two week recall of signs and symptoms of the index child and the field worker observed and measured signs and symptoms. Longitudinal data was analyzed using population averaged modified Poisson regression.
Results: More than half of the children were younger than 24 months of age. No severe cases of acute respiratory infections (ARI) were detected and only a few moderate cases of ARI were observed by field workers. During follow up, adherence to the intervention was low (50%) and an analysis according to the reported stove use was performed. The younger than 24 months of age children of mothers who reported using the Patsari stove most of the time compared to those using the open fire had a slightly lower risk of respiratory symptoms (nasal secretion RR=0.90, 95%CI 0.74, 1.09; wheezing and/or breathing difficulty RR=0.80, 95%CI 0.36, 1.77) adjusting for relevant confounders.
Conclusions: The intention to treat analysis showed no impact of the improved stove intervention on children respiratory outcomes, but considering the stove use reported by the children mothers' a small effect was observed.

NON-HODGKIN LYMPHOMA (NHL) LINKAGE WITH RESIDENCE NEAR HEAVY ROADS - A CASE STUDY FROM HAIFA BAY, ISRAEL

Shlomit Paz, *University of Haifa, Israel*
Shai Linn, *University of Haifa and Rambam Medical Center, Israel*
Boris Portnov, *University of Haifa, Israel*
Micha Barchana, *Ministry of Health, Israel*

Background and Aims: Some of the risk factors for Non-Hodgkin Lymphoma (NHL) are related to environmental exposure and occupations. However, studies into a possible linkage between NHL and residence near heavy traffic roads are lacking.
NHL rates of Israeli Jews are among the highest in the world while the highest NHL rate within Israel is in Haifa Metropolis. The study analyzed the possible linkage between NHL morbidity and residence near heavy traffic roads among the Jewish population in the Haifa Metropolitan Area.
Methods: Addresses of 1436 patients (94.5% of all cases, 1995-2004) were geocoded. Only patients residing in the metropolis at least 10 years prior to the diagnosis were included (gender, age). The density values were interpolated by the Inverse Distance Weighted (IDW) method. The number of NHL patients was calculated for buffer zones, extending by a 50-meter increment from a main road. By dividing the actual number of NHL patients (male/female) in each buffer zone by the value of the "density coefficient", we obtained the "density adjusted" number of patients in each zone. Testing for the statistical significance of the differences across buffer zones was performed using a non-parametric Chi-square test.
Results: The road distances for each NHL patient ranged from 0 to 700m, with the median distance of 56.5m. About half of the NHL' patients appear to live in a distance of less than 50m from a main road. The analysis indicates steady decline in the "density adjusted" numbers of patients as a function of increasing road distances ($P<0.01$). Differences between genders / age groups or socioeconomic levels were not found.
Conclusions: The much higher occurrence of NHL in areas near main roads may be indicative of disease risks. Future studies may compare the relative contribution of residence near traffic to other factors such as industrial air pollution.

PUBLIC HEALTH IMPORTANCE OF AIR POLLUTION AS TRIGGER OF MYOCARDIAL INFARCTION: A COMPARATIVE RISK ASSESSMENT

Tim Nawrot, *Hasselt University, Belgium; Leuven University (KULeuven), Belgium*
Laura Perez, *Tropical and Public Health Institute, and University of Basel, Switzerland,*
Nino Künzli, *Tropical and Public Health Institute, and University of Basel, Switzerland*
Elke Munters, *Hasselt University, Belgium*
Benoit Nemery, *Leuven University (KULeuven), Belgium*

Background and Aims: Acute myocardial infarction is triggered by various factors, such as physical exertion, stressful events, heavy meals, or increases in air pollution. However, the importance and relevance of each trigger are uncertain. We compared triggers of myocardial infarction at an individual and population level.
Methods: We searched PubMed and the Web of Science citation databases to identify studies of triggers of non-fatal myocardial infarction to calculate population attributable fractions (PAF). When feasible, we did a meta-regression
analysis for studies of the same trigger.
Results: Of the epidemiologic studies reviewed, 36 provided sufficient details to be considered. In the studied populations, the exposure prevalence for triggers in the relevant control time window ranged from 0・04% for cocaine use to 100% for air pollution. The reported odds ratios (OR) ranged from 1.05 to 23.7. Ranking triggers from the highest to the lowest OR resulted in the following order: use of cocaine, heavy meal, smoking of marijuana, negative emotions, physical exertion, positive emotions, anger, sexual activity, traffi c exposure, respiratory infections, coffee consumption, air pollution (based on a difference of 30 µg/m3 in particulate matter with a diameter <10 µm [PM10]). Taking into account the OR and the prevalences of exposure, the highest PAF was estimated for traffi c exposure (7.4%), followed by physical exertion (6.2%), alcohol (5.0%), coff ee (5.0%), a difference of 30 µg/m3 in PM10 (4.8%), negative emotions (3.9%), anger (3.1%), heavy meal (2.7%), positive emotions (2.4%), sexual activity (2.2%), cocaine use (0.9%), marijuana smoking (0.8%) and respiratory infections (0.6%).
Conclusions: In view of both the magnitude of the risk and the prevalence in the population, air pollution is an
important trigger of myocardial infarction, it is of similar magnitude (PAF 5–7%) as other well accepted triggers such as physical exertion, alcohol, and coff ee. Our work shows that ever-present small risks might have considerable public health relevance.

RELIABILITY OF MEASUREMENTS OF ANOGENITAL DISTANCE AND PENIS WIDTH IN BOYS AND ANOGENITAL DISTANCE IN GIRLS. MOTHER-CHILD COHORT IN CRETE (RHEA STUDY)

Eleni Papadopoulou, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain and University Pompeu Fabra, Barcelona, Spain*
Marina Vafeiadi, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain and University Pompeu Fabra, Barcelona, Spain*
Xavier Basagaña, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Leda Chatzi, *Department of Social Medicine, Medical School, University of Crete, Heraklion, Greece*
Antonis Koutis, *Department of Social Medicine, Medical School, University of Crete, Heraklion, Greece*
Martine Vrijheid, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Manolis Kogevinas, *Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain and National School of Public Health, Athens, Greece*

Background and aims: In animal studies, different measurements of anogenital distance are indicators of *in-utero* exposure to androgens and chemicals with anti-androgen effect, though limited data exist for humans. There is little empirical evidence on the reliability of these measurements. We estimated the reliability of anogenital distance measurements in boys and girls.
Methods: The study included thirty 2-year-old children (13 boys and 17 girls) whose mothers participated in the Rhea study, Crete. Two experienced examiners performed 10 blind repeated measurements each (total 730 measurements for each examiner). Anogenital distance (AGD- from anus to upper penis), anoscrotal distance (ASD- from anus to scrotum) and penis width (PW) were measured in boys; anoclitoral (ACD-from anus to clitoris) and anofourchetal distance (AFD-from anus to fourchete) in girls. Ratios of anogenital distances divided by body weight were calculated. Mixed effect models were used to estimate the between-children, between- and within-examiner variance, as well as the reliability coefficient for each distance and ratio.
Results: In boys, mean (±SD) AGD, ASD and PW was 82(±6)mm, 44(±7)mm and 13(±1)mm, respectively. In girls mean (±SD) ACD and AFD was 49(±7)mm and 24(±4)mm, respectively. Mean differences between examiners varied from 0 to 4mm. Reliability coefficients for AGD, ASD, ACD and AFD ranged from 0.89 to 0.91 and were higher than for PW (0.75). Differences between children were the main source of variation for all anogenital distance measures. For AFD between examiner variation was also high (22%). Measurement variation for PW, within the same child and the same examiner was higher than for other measures (25%). Ratios by weight were stable and their main source of variation was the between-children variance.
Conclusions: Anogenital distance measurements and weight-ratios are highly reliable measures if conducted by experienced examiners and they are not affected by between- or within- examiner variation.

ARE SILICOSIS AND SILICA-RELATED ILLNESSES BECOMING DISEASES WITH ETHNIC DISPARITIES?

David F Goldsmith, *George Washington University, Washington DC, USA*

BACKGROUND: In the U.S. and other industrial nations, the risk of silicosis mortality has declined. That is a function of improved practices in many dusty industries, including health surveillance, improved capture of silica dusts, use of wet methods, and regulation. However, this decline masks concerns about the burden of silica related diseases impacting minority ethnic groups in the U.S.

CURRENT SILICA DISEASE RISKS: African-American silicosis risks have been described by studies from the Michigan Silicosis Registry. Michigan silicosis risks have been 7 X more common among African-Americans than whites. That has been a function of black workers taking the dustiest jobs, including working as sand blasters after WW II. In the past decade, skilled and unskilled construction workers have tended to be recent immigrants from Latin America. The most serious problem was the finding of acute silicosis cases arising among Mexican men sandblasting near Midland-Odessa TX in the early1990s. Current construction practices can include very dusty cement sawing without using wet methods, and evidence has pointed to cases of silicosis arising from dry cement cutting. Uranium mining was a common occupation among the Navajo Indians and white miners in the southwestern U.S. Navajo workers have elevated risks for both silicosis and other pulmonary diseases, including lung cancer . The lung cancer excesses among Navajo men is more remarkable because they smoke much less than the general population of the U.S.

FUTURE SILICOSIS RISKS: Silicosis mortality risk is declining, but it remains a concern that the residual risk falls on the backs and lungs of minority workers. This means health leaders must educate workers about effective ways to prevent inhalation of silica. Furthermore, we need to expand our definition of silica-related illnesses to include scleroderma, rheumatoid arthritis, kidney disease, TB, as well as lung and other cancers.

CONCLUSION: The OEM communities must continue to pressure for improvements to reduce silica dust exposures. These efforts must include international programs so that developing countries and their workers will see effective prevention policies for silica-related diseases. Health advocates must continue to warn minority workers in the U.S. of the dangers of unprotected silica exposure.

RELATIONSHIP BETWEEN CADMIUM AND METALLOTHIONEINS IN BREAST TUMOUR PATIENTS

Loreta Strumylaite, *Institute for Biomedical Research, Medical Academy, Lithuanian University of Health Sciences, Lithuania*
Dale Baranauskiene, *Institute for Biomedical Research, Medical Academy, Lithuanian University of Health Sciences, Lithuania*
Rima Kregzdyte, *Institute for Biomedical Research, Medical Academy, Lithuanian University of Health Sciences, Lithuania*
Olegas Abdrachmanovas, *Institute for Biomedical Research, Medical Academy, Lithuanian University of Health Sciences, Lithuania*
Algirdas Bogusevicius, *Department of Surgery, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania*

Background and Aims: There is evidence that cadmium (Cd) may be related to breast cancer. Metallothioneins (MTs) are metal binding proteins that play an important role in eliminating toxic metals from the organism. The aim of the study was to assess relationship between Cd and MTs level in biological media of cancer and benign breast tumour patients.
Methods: Cd and MTs were determined in breast tissue and blood of 57 breast cancer and 51 benign tumour patients (controls). Two samples of breast tissue from each patient, i.e. tumour and healthy tissue were taken for the analysis. Cd was measured by atomic absorption spectrometry (Perkin-Elmer, Zeeman 3030), MTs were determined by spectrophotometry.
Results: Cancer patients had greater content of Cd and MTs in breast tumour tissue compare to healthy breast tissue (53.4 ng/g 95% CI 42.2–64.6 and 5.2 µg/g, 95% CI 3.6-6.7 vs. 20.1 ng/g 95% CI 14.4-25.9 and 1.7 µg/g 95% CI 1.2-2.3, respectively, $p<0.001$). In controls, there was no difference between Cd level, but MTs content was greater in tumour than in healthy breast tissue ($p<0.05$). Cd in blood of cancer patients did not differ from that in controls. However, there was significant difference between MTs level in blood of cancer patients and controls (3.0 µg/ml 95% CI 2.8-3.3 and 2.5 µg/ml 95% CI 2.2-2.7, $p<0.05$). In cancer patients, blood Cd levels and Cd in healthy and tumour tissue correlated significantly with MTs in healthy and tumour breast tissue with exception correlation between Cd and MTs in breast tumour tissue that was suggestive ($p=0.08$).
Conclusions: Cadmium and metallothioneins levels are greater in breast cancer than that in healthy breast tissue. Significant correlation is defined in breast cancer patients between cadmium and metallothioneins in breast tissue and blood.

HEALTH IMPACTS OF CLIMATE CHANGE IN CASCAIS, PORTUGAL

Elsa Casimiro, *INFOTOX – Environmental Risk Consultants, Lisbon Portugal - Climate Climate Change Impacts, Adaptation and Mitigation Unit , Faculdade de Ciências da Universidade de Lisboa, Portugal.*
Sofia Almeida, *Climate Climate Change Impacts, Adaptation and Mitigation Unit , Faculdade de Ciências da Universidade de Lisboa, Portugal.*
Ana Gomes, *Environmental Risk Consultants, Lisbon Portugal - Climate Climate Change Impacts, Adaptation and Mitigation Unit , Faculdade de Ciências da Universidade de Lisboa, Portugal.*

In this study we present the potential health impacts of climate change in the Cascais municipality, Portugal. Current and future health impacts associated with heatstress and vector borne diseases are presented.
Heatstress impacts were assessed based on the local temperature and daily mortality relationship that was determined using Generalized Estimating Equations (GEE) modelling. The risk of transmission of vectorborne diseases was assessed based on biological temperature thresholds for disease transmission. For the future impact assessment we used daily climate data indicative of the period of 2020-2047 and 2070-2097 for IPCC SRES scenarios. The latter datasets were developed specifically for this study region by downscaling global climate scenarios.
Heatstress impacts: Our results show that increases of 1^{o}C in the maximum temperature above the threshold of 30^{o}C results in a 4.7% increase risk of mortality. Since all the future climate scenarios used in this study indicate significant increases in days with maximum temperatures above this threshold, we concluded that the risk of dying from heatstress will increase in the future.
Vector-borne disease Impacts: Diseases endemic to Cascais such as leishmaniasis and Mediterranean spotted fever were studied as well as those currently not endemic to the region such as malaria, dengue, West Nile fever, yellow fever, Chikungunya fever and murine typhus. Climate change may change the disease transmission risks of these diseases throughout the year. There is also a real risk that transmission risks of diseases currently not endemic will increase significantly under current as well as future climates if infected vectors are introduced to the region. It is therefore urgent that vector surveillance systems be developed and implemented in Cascais.

THE IMPACT OF TRAFFIC AIR POLLUTION ON CHRONIC LUNG REJECTION AND MORTALITY AFTER LUNG TRANSPLANTATION

Bart M Vanaudenaerde, *Leuven University (KULeuven), Belgium*

Background and Aims: Approximately half of all lung transplant patients suffer from Bronchiolitis Obliterans Syndrome (BOS), the clinical correlate of chronic rejection, within five years after transplantation. This prevalence is much higher than for other solid organ transplantations, possibly due to the lung's direct contact with the environment. We assessed the association of residential proximity to major roads with BOS and mortality in a cohort of lung transplant patients.
Methods: We calculated hazard ratios for BOS and mortality in relation to residential proximity to major roads, adjusting for relevant covariables, in 288 lung transplantations at the Leuven University Hospital between 1997 and 2009 and with follow-up until August 2009. Inflammatory parameters in plasma and bronchoalveolar lavage (BAL) were assessed in 207 patients.
Results: During follow-up 117 (41%) patients developed BOS and 61 (21%) died. Patients whose residence was within 171m of a major road (lowest tertile) were 2.06 (95% CI 1.39-3.05) times more likely to develop BOS and 2.20 (1.25-3.86) times more likely to die than those living farther away. The adjusted hazard rates (HR) of BOS and mortality were 0.57 and 0.72 for each tenfold increase in distance from major roads. Proximity to a major road was inversely associated with plasma CRP levels and neutrophil percentage and interleukin-6 concentration in BAL.
Conclusions: Living close to a major road represents a substantial risk of developing BOS and premature dying after lung transplantation. Overall, traffic-related air pollution appears to constitute a serious risk of BOS and mortality after lung transplantation.

SELF-REPORTED SUN EXPOSURE BEHAVIOUR AND SKIN REDNESS

Triguero-Mas, Margarita, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Dadvand, Payam, *Centre for Research in Environmental Epidemiology (CREAL), Spain*
Nieuwenhuijsen, Mark J, *Centre for Research in Environmental Epidemiology (CREAL), Spain*

Background and Aims: Previous studies have shown that up to one-fourth of annual personal UVR exposure amongst European population can occur during sun holidays. Skin redness during sun holidays has been linked to higher risk of skin cancers. The study aim was to study sun exposure behaviour patterns during sun holidays and their effects on redness from received UVR.
Methods: A semi-experimental study was conducted with twenty sun worshipping Spanish volunteers taking part in a one-week holiday in Canary Islands (Spain) during March 2010. They were asked to fill in a personal diary every thirty minutes about their location, clothing and sunscreen application. Their redness was objectively measured twice a day by a UV-Optimizer (Chromo-light Co.).
Results: The median age of participants was 33 years with 70% of participants being female. Amongst study subjects, 30% had skin type II, 45%, III and 25%, IV. Median of days with sunscreen application was 3.5 (range 0 and 7 days). The median of number of sunscreen application during the high-risk hours (two hours around solar noon) was 0.7 times a day that was higher amongst women ($p=0.012$). On average, the study subjects exposed their arms for 95% of the days. The last day arms redness was correlated with the redness before exposure (Spearman correlation coefficient (rho) of 0.54 and $p=0.013$), number of days with clothes leaving arm exposed ($rho=0.49$ and $p=0.029$) and was inversely associated with number of sunscreen applications during high-risk hours ($rho=-0.49$ and $p=0.029$). However, it was neither correlated with number of hours out during whole day ($p=0.144$) nor during high-risk hours ($p=0.465$).
Conclusions: Skin redness during sun holidays is associated with redness before exposure, number of days with arm exposed and inversely associated with sunscreen use. Further work will include construction of models to explain redness after sun exposure.

AIR POLLUTION AND BLOOD PRESSURE IN BEIJING, CHINA

Background: Particulate Matter (PM) air pollution is critical in Beijing, China, due to very high population density, rapid increase in the number of vehicles, and limited control of industrial emissions. PM effects on blood pressure (BP) have been investigated as a mechanism mediating cardiovascular risks, but results have been inconsistent.
Methods: The Beijing Truck Driver Air Pollution Study (BTDAS) was conducted shortly before the Beijing 2008 Olympic Games (June 15-July 27, 2008) and included 60 truck drivers and 60 office workers in Beijing. $PM_{2.5}$ measured during work hours using portable small-sized monitors and post-work BP measurements were obtained on two different days, separated by 1-2 weeks. We used ambient PM_{10} data averaged for the 5 days before the study from 27 monitoring stations operating in Beijing. Mixed-effect regression models were used to examine associations of exposures (occupational group, personal $PM_{2.5}$, or ambient PM_{10}) with BP controlling for age, gender, BMI, day of the week, smoking, pack-years and cigarette/day, work hours/week, tea, alcohol, and outdoor temperature.
Results: Mean personal $PM_{2.5}$ was 94.6 $\mu g/m^3$ (SD=64.9) in office workers and 126.8 (SD=68.8) in truck drivers ($p<0.001$). Systolic (SBP), Diastolic (DBP) and mean (MAP) BP was not different between the two groups ($p>0.14$). Also, personal $PM_{2.5}$ during work hours was not associated with BP. In all subjects combined, a 10 $\mu g/m^3$ increase in 5-day ambient PM_{10} was associated with BP increments equal to 0.63 (95%CI 0.09-1.16), 0.50 (95%CI 0.06-0.95), and 0.55 (95%CI 0.13-0.96) mmHg for SBP, DBP, and MAP, respectively.
Conclusions: Our study shows a delayed effect of ambient PM_{10} on BP. The absence of associations with the exposure group and with personal $PM_{2.5}$ measured during work hours indicates that the PM_{10} effects are related to the background levels of particulate pollution in Beijing, rather than to traffic exposure.

OXIDIZED-LDL AND CARBON LOAD OF LUNG MACROPHAGES

Lotte Jacobs, *Leuven University (KULeuven), Belgium*
Jan Emmerechts, *Leuven University (KULeuven), Belgium*
Marc Hoylaerts, *Leuven University (KULeuven), Belgium*
Chantal Mathieu, *Leuven University (KULeuven), Belgium*
Peter Hoet, *Leuven University (KULeuven), Belgium*
Benoit Nemery, *Leuven University (KULeuven), Belgium*
Tim Nawrot, *Hasselt University, & Leuven University, Belgium*

Background and Aims: Epidemiologic studies indirectly suggest that air pollution accelerates atherosclerosis. We hypothesized that individual exposure to particulate matter (PM) derived from fossil fuel would correlate with plasma concentrations of oxidized low-density lipoprotein (LDL), taken as a marker of atherosclerosis. We tested this hypothesis in a susceptible population of patients with diabetes.
Methods: In a cross-sectional study of non-smoking adult outpatients with diabetes we assessed individual chronic exposure to PM by measuring the area occupied by carbon in airway macrophages, collected by sputum induction and by determining the distance from the patient's residence to a major road, through geocoding. These exposure indices were regressed against plasma concentrations of oxidized LDL, von Willebrand factor and plasminogen activator inhibitor 1 (PAI-1)..
Results: We could assess the carbon load of airway macrophages in 79 subjects (58 percent). Each doubling in the distance of residence from major roads was associated with a 0.027 µm² decrease (95 % confidence interval (CI): -0.048 to -0.0051) in the carbon load of airway macrophages. Independently from other covariates, we found that each increase of 0.25 μm^2 [interquartile range (IQR)] in carbon load was associated with an increase of 7.1 U/L (95% CI: 1.5 to 12.7) in plasma oxidized LDL. Each doubling in distance of residence from major roads was associated with a decrease of -3.1 U/L (95% CI: -5.3 to -0.93) in oxidized LDL.
Conclusions: The observed positive association, in a susceptible group of the general population, between plasma oxidized LDL levels and either the carbon load of airway macrophages or the proximity of the subject's residence to busy roads is compatible with a proatherogenic effect of traffic air pollution.

ARE AMERICAN CONSUMERS READY FOR FOOD NANOTECHNOLOGY?

William K. Hallman, *Rutgers University, USA*
Cara L. Cuite, *Rutgers University, USA*
Dietram A. Schuefele, *University of Wisconsin – Madison, USA*

Background and Aims: Nanoscale materials have been used for decades and already appear in more than 1000 consumer products. Within the agriculture and food sectors, the adoption of nanoscale technologies is expected to have significant impacts on farmers and food. The current research was designed to examine the American public's perceptions of food-based nanotechnology, and to determine the parameters of public acceptance.
Methods: Data were collected by an Internet survey research firm during the month of April, 2010. A nationally representative sample of 1210 American adults enrolled in the company's existing online panel responded to the 20-minute survey (66% completion rate).
Results: Consistent with earlier surveys, reported familiarity with nanotechnology was very low. Initial levels [REV11]of acceptance of nanotechnology were also very low. For example, on an 11 point scale, where 0 represented "strongly disagree" and 10 was "strongly agree," the mean rating for "I would eat foods labeled as containing nanotechnology" was 2.5, and 74% of respondents gave the statement a rating of 4 or lower. However, the survey findings also indicate that a number of features of the product significantly affect Americans' expressed level of approval of nanotechnology in food products. These include: the specific product benefits (food safety and health benefits were the highest ranked), the congruence between product type and benefit type (health benefits were preferred in healthy foods rather than the same benefits in less healthy foods), the specific nanotech materials used (plant-based nanotechnology was preferred), and where the nanotech materials are located (nanotech packaging is preferred over having nanomaterials in the product or applied to the outside of the food).
Conclusions: The findings indicate that while overall acceptance of nanotech foods may be low, certain applications of nanotechnology to food products are seen as more acceptable than others.

DOT OR NOT — IS IT WORTH THE EFFORT IN THE MANAGEMENT OF TUBERCULOSIS

Eldrian Basson, *Epidemiologist, South African Military Health Services, Kimberley, Northern Cape, South Africa*

Background: Prevention and control of TB necessitate a public health infrastructure that includes a well trained labor force.
Southern Africa contribute approximately 280 000 cases every year in Africa. Almost half of these come from South Africa.
A complication of tuberculosis has been the emergence of multi-drug resistant strains. Patients require prolonged chemotherapy with expensive medication which will at best cure only half.
In 1996 a new control programme based on DOTS were implemented.
The DOTS program was extended to include the treatment of MDR-TB. Resource limitations mean that DOTS-Plus may lead to the diversion of resources from DOTS programs and a decrease in overall standards of care.
An open-label, randomized study failed to show a lasting advantage for directly observed TB therapy over self-administered therapy.
Method: During a study conducted from 01 April 2008 to 30 September 2009, in the geographic area of Kimberley, Northern Cape, 86 pulmonary TB patients where evaluated to compile this hypothesis.
Results: By week 12, the rate of bacteriological success was 89% in the DOT group and 84% in the self-administration group - a difference insufficient to prove the superiority of DOT. At 24 weeks the success rates remained similar between the groups (80% and 73%).
Vast amounts of time, energy and money are spend on the promotion of DOT - the question remains, can't this resources be better utilized in an already overburdened health system.
Study results points to the fact that more energy should be spend on aftercare and relapse prevention. The present challenge is not the tuberculosis bacteria perse, but the under and overuse of medication.
Conclusion: Even with adequate financing, critical deficiencies in human resources will impede progress in Africa. Political commitment is required to support the overall structural and financial changes needed to improve the availability, distribution and motivation of competent health workers.

MATERNAL SERUM COTININE AS A SURROGATE MARKER OF EARLY CHILDHOOD EXPOSURE TO CIGARETTE SMOKE

Libby Morimoto, *University of California, Berkeley, School of Public Health*
Catherine Metayer, *University of California, Berkeley, School of Public Health*
Anand Chokkalingam, *University of California, Berkeley, School of Public Health*
Todd Whitehead, *University of California, Berkeley, School of Public Health*
Joanne Colt, *National Cancer Institute, Division of Cancer Epidemiology and Genetics*
Mary Ward, *National Cancer Institute, Division of Cancer Epidemiology and Genetics*
Patricia Buffler, *University of California, Berkeley, School of Public Health*

Background and Aims: Obtaining valid measures of past exposures is a challenge in population-based case-control studies. When bio-specimens are collected at study enrollment, measured levels may not reflect actual exposure levels at the sensitive period of development, particularly biomarkers with short half lives in the body. Studies of childhood diseases are further constrained when the collection of bio-specimens from child controls is not feasible. The possibility of using maternal bio-specimens to estimate early childhood exposures is, therefore, a provocative one, although not without significant methodologic considerations.
Methods: To evaluate the use of maternal sera with respect to a child's past exposure to tobacco smoke, we measured serum cotinine levels from a subset of 163 mothers of childhood leukemia cases (0-7 years of age) and matched controls enrolled in the California Childhood Leukemia Study (CCLS). Recorded information on demographic characteristics, lifestyle, and environmental exposures, as well as levels of nicotine in household dust samples was available for all subjects. Using multivariable linear regression, we evaluated the relationship between nicotine in household dust samples (ng/g) and maternal serum cotinine (ng/mL), as well as the modifying effects of various epidemiologic factors and sampling characteristics.
Results: Not surprisingly, the strongest predictor of maternal serum cotinine was current maternal smoking ($p<0.001$). When analyses were limited to current non-smokers, household dust nicotine was statistically significantly related to maternal serum cotinine ($p<0.001$). There was evidence that this relationship was modified by the interval between blood collection and dust collection ($p=0.04$); paternal smoking ($p=0.01$); and to a lesser extent maternal height ($p=0.07$) and household income ($p=0.09$).
Conclusions: Although further exploration of these data is warranted to fully characterize the potential use of maternal serum cotinine to estimate early childhood exposures to tobacco smoke, preliminary results suggest that maternal biomarkers are a useful complement to self-reports and environmental sampling.

BEDBUG, MICE AND RAT COMPLAINTS AND PESTICIDE USE AMONG WASHINGTON DC RESIDENTS BY NEIGHBORHOOD: GIS ANALYSIS

Kristin Rury, *George Washington University, Washington DC, USA*

David F. Goldsmith, *George Washington University, Washington DC, USA*

Introduction: There are public health concerns about urban pests such as bedbugs, mice and rats. In 2008, GWU's Environmental and Occupational Health Department surveyed 789 Washington DC residents in order to elicit attitudes towards residential pests and pesticides. Participants needed to be DC residents, >18 years, with valid IDs. Responses to questions relating to bedbugs, treatments for bedbugs, mice, rats and treatments for mice and rats were analyzed by city wards in order to map the responses. This is the largest survey of pests and pesticide uses in any urban area, and we expected lower income wards 7 and 8 to have the most pest complaints and the most use of pesticide products.
Methods: Ward-specific results were compared to all responses for DC as a whole using the non-parametric Wilcoxon signed-rank test. Significant differences ($p<0.05$) were then displayed using Geographic Information Systems (GIS) to highlight findings for selected pest complaints and pesticide uses between individual wards and all of Washington DC.
Results: DC Ward 1 reported significantly ($p<0.05$) more bedbug problems than the city as a whole. Ward 1 reported significantly higher use of mattress powder/dust than DC. However, Ward 4 reported more bedbug treatments by pest control officials than DC as a whole. Wards 4, 5 and 8 reported significantly more frequent mice problems than DC as a whole, more frequent use of glue, sticky, and snap traps (both by the respondents themselves or someone in their home). Ward 1 also reported significantly more frequent rat problems than DC as a whole. Findings do not suggest that lower income Wards 7 and 8 in DC have the most pest problems/complaints.
Conclusion: Based on our survey, bedbug treatment and residential educational efforts should focus on Ward 1. Mice and rat intervention and educational efforts should focus on Wards 4, 5 and 8. After treatment and educational efforts are completed, DC residents should be resurveyed to test effectiveness.

DOES AIR POLLUTION TRIGGER INFANT MORTALITY IN WESTERN EUROPE? A CASE-CROSSOVER STUDY.

HansScheers, *Leuven University (KULeuven), Belgium*
Samuel Mwalili, *Leuven University (KULeuven), Belgium*
Christel Faes, *Hasselt University, Belgium*
Benoit Nemery, *Leuven University (KULeuven), Belgium*
Tim Nawrot, *Hasselt University, & Leuven University, Belgium*

Background and Aims: Numerous studies show associations between fine particulate air pollutants (PM10) and mortality in adults. We investigated short-term effects of elevated PM10 levels on infant mortality in Flanders, Belgium, and studied whether the European Union (EU) limit value protects infants from the air pollution trigger.
Methods: In a case-crossover analysis, we estimated the risk of dying from non-traumatic causes before the age of one year in relation with outdoor PM10 concentrations on the day of death. We matched control days on temperature in order to exclude confounding by variations in daily temperature.
Results: During the study period (1998-2006), PM10 concentration averaged 31.9 µg/m³ (SD 13.8). In the entire study population (N=2382), the risk of death increased by 4% (95% CI: 0-8%, P=0.045) for a 10 µg/m³ increase in daily mean PM10. However, this association was only significant for late neonates (2-4 weeks of age, N=372) in whom the risk of death increased by 11% (1-22%, P=0.028) per 10 µg/m³ increase in PM10. In this age class, infants were 1.74 (1.18-2.58, P=0.006) times more likely to die on days with a mean PM10 above the EU limit value of 50 µg/m³ than on days below this cut-off.
Conclusions: Even in an affluent region in Western Europe, where infant mortality is low, days with higher particulate air pollution are associated with an increased risk of infant mortality. Assuming causality, the current EU limit value for PM10, which may be exceeded on 35 days per year, does not prevent PM10 from triggering mortality in late neonates.

AMBIENT TEMPERATURE AND BIOMARKERS OF HEART FAILURE: A REPEATED MEASURES ANALYSIS

Elissa Wilker, *Beth Israel Deaconess Medical Center & Harvard School of Public Health, USA*
Gloria Yeh, *Beth Israel Deaconess Medical Center, USA*
Gregory Wellenius, *Brown University,USA*
Roger Davis, *Beth Israel Deaconess Medical Center, USA*
Russell Phillips, *Beth Israel Deaconess Medical Center, USA*
Murray Mittleman, *Beth Israel Deaconess Medical Center & Harvard School of Public Health, USA*

Background and Aims: Extreme temperatures have been associated with increases in hospitalization and death from cardiovascular disease, and individuals with heart failure (HF) may be particularly vulnerable. We investigated associations between outdoor temperature (0-4 day moving averages) in the Boston area and biomarkers of inflammation and myocyte injury in a repeated-measures study of individuals with stable HF. We hypothesized that extreme temperatures would be associated with adverse effects, and that humidity would exacerbate these associations in the warm season.
Methods: We analyzed data from a completed clinical trial of 100 patients with HF randomized to 12 weeks of tai-chi classes or HF education control supplementing usual care. B-natriuritic peptide (BNP), C-reactive protein, and tumor necrosis factor-alpha were measured at 3 timepoints (baseline, 6 and 12 weeks). Endothelin-1 was measured at baseline and 12 weeks. We used mixed-effects models to evaluate associations with temperature**.** Models were adjusted for randomization arm, medical history and socioeconomic factors, weekday, and seasonality. We examined associations across all seasons and separately for the warm and cold seasons. Models of temperature and relative humidity were compared to models of apparent temperature, a marker of perceived temperature.
Results: The 100 participants provided 285 observations from 2005-2009. Significant associations were observed only with BNP levels. A 5 °C change in the 3-day moving averages of ambient and apparent temperature were associated with 12.4% (95% Confidence Interval (CI): (1.6,24.3)) and 13.5% (95% CI: 3.6, 24.3) higher BNP. Larger estimates were observed in the warm season (March – August). Apparent temperature was a more significant correlate of BNP than temperature and humidity together. Adjustment for ambient pollution did not substantially alter these associations.
Conclusions: We observed positive associations between temperature and BNP, a marker of HF severity. The magnitude and strength of these associations was greater in the warm season.

REPETITIVE ELEMENT METHYLATION EXTENT IS ASSOCIATED WITH INFANT GROWTH AND DEVELOPMENTALLY RELATED GENE METHYLATION

James Padbury, *Women and Infants Hospital, Providence, RI ,USA*
Carmen Marsit, *Department of Pathology and Laboratory Medicine, Brown University, Providence, RI,USA*

Background and Aims: Fetal programming describes the theory linking environmental conditions during embryonic and fetal development with risk of diseases later in life. Environmental insults in-utero may lead to changes in epigenetic mechanisms, resulting in deleterious changes to overall placental function. In this study, we aimed to examine the impact of birthweight percentile on repetitive element methylation in placental tissue, and to determine if repetitive element methylation could be an indicator for changes in methylation of specific CpG loci.
Methods: Placental tissues were obtained from patients delivering at Women and Infants Hospital in Providence, RI. Birthweight percentile and levels of LINE1 and AluYb8 methylation were determined for 380 subjects; methylation profiling was performed using the Illumina Infinium27 Methylation BeadArray on 184 subjects. We used multiple linear regression to investigate the association between birthweight percentile and repetitive element methylation, and used model-based methods, such as gene set enrichment analysis, to test the association between repetitive element methylation and individual CpG loci methylation levels.
Results: Birthweight percentile was a significant predictor of both LINE1 and AluYb8 methylation levels, with maternal smoking during pregnancy predicting only AluYb8 methylation levels. Increasing levels of AluYb8 were associated with increasing average class methylation of individual CpGs found in polycomb group target sites. Developmentally related transcription factor binding sites and important cellular processes pathways were over-represented for differentially methylated loci associated with both LINE1 and AluYb8.
Conclusions: AluYb8 methylation status may be a biomarker for individual CpG loci changes occurring in polycomb group target sites, and for specific changes occurring in developmental pathways. It may therefore be a potential biomarker for epigenetic changes occurring during development.

RETROSPECTIVE SPATIOTEMPORAL AIR POLLUTION EXPOSURE ASSESSMENT FOR A NATIONAL CANADIAN LUNG CANCER CASE-CONTROL STUDY

Perry W. Hystad, University of British Columbia
Paul A. Demers, Cancer Care Ontario
Michael Brauer, University of British Columbia

Background and Aims: Few epidemiological studies have used residential histories to conducted long-term retrospective exposure assessments of ambient air pollution, and even fewer have incorporating local exposures from vehicle or industrial sources. We conduct such an assessment for a Canadian national lung cancer case-control study of 8,353 individuals using self-reported residential histories from 1970 to study entry (1994-1998).
Methods: Annual ambient pollution concentrations were derived from fixed site monitors within 50km's of residential postal codes. For postal codes located farther than 50km's from a monitor, national spatial pollutant surfaces, created from recent satellite-based (for PM2.5 and NO2) and dispersion models (for O3), were calibrated with historical fixed site monitoring data to estimate annual ambient concentrations. Random effect models were developed from co-located PM10/PM2.5 and TSP monitors, along with geographic variables, to estimate PM10 and PM2.5 exposures back to 1970. In addition, proximity to highways and major roads, incorporating a temporal weighting factor based on Canadian mobile emission estimates, were calculated to assess vehicle emission exposures. A comprehensive inventory of approximately 16,000 geocoded industrial emissions sources from 1970 to study entry, representing fifty standard industrial classifications, was used to estimate exposure to industrial emissions.
Results: In total, 130,143 (65%) exposure-years occurred in urban areas and 70,755 (35%) in rural areas. No significant difference (p=0.43) was present for completeness of self-reported residential histories by case and control status. Mean (SD) exposures were PM2.5 15.7(3.3)ug/m3, NO2 16.7(9.3)ppb and O3 22.4(3.9)ppb. Study participants lived on average 3.8 years within 300m of a highway and 1.7 years within 1km of a major industrial source.
Conclusions: A spatiotemporal modeling approach was used to estimate air pollution exposures for a national Canadian lung cancer case-control study. Incorporating residential mobility was important for accurate exposure assessment.

MULTIMETAL EXPOSURE IN ADOLESCENTS FROM A SMELTER COMMUNITY IN NORTHERN MEXICO

Background and Aims: The city of Torreon Coahuila, located in north central Mexico, is home to the largest Pb-Zn-Ag smelter complex in Latin America. The smelter has caused high concentrations of Pb in blood (PbB) in city residents. We examined environmental exposure to eight metals in adolescents in Torreon using exposure biomarkers.
Methods: Cross-sectional study conducted in 512 adolescents (age 12-15 years) who were under epidemiological surveillance due to environmental exposure to Pb and other metals. We measured PbB using atomic absorption spectrometry and the urinary concentrations of As, Cd, Mo, Sb, Tl, W, and U using ICP-MS.
Results: The median PbB (range) was 3.97 µg/dL (0.97 - 21.92). For urine metals, the medians (range; both in µg/L) were 40.8 for As (1.6 - 667.8), 0.24 for Cd (0.0 - 3.49), 73.15 for Mo (2.63 - 508.04), 0.13 for Sb (0.0 - 0.96), 0.33 for Tl (0.0 - 1.52), 0.16 for W (0.0 - 2.62), and 0.04 for U (0.0 - 1.74). The following metals were correlated: PbB and urine Cd; urine As and U; and urine Sb with PbB, urine Cd and As.
Conclusions: Children in Torreon showed a complex pattern of metal exposure. Urine uranium levels were high compared to the general US population. Uranium may have been introduced by re-suspension or dissolution of soil, but also by release of uranium from mining and milling activities, or by burning coal.

PRENATAL EXPOSURE TO OUTDOOR AIR POLLUTION IN RELATION TO RESPIRATORY HEALTH, ECZEMA AND OTITIS EARLY IN LIFE

Background and Aims: Prenatal exposure to air pollution may effect respiratory health and increase the susceptibility towards infections during early childhood. We assessed the relationship between maternal exposure to traffic-related air pollution and respiratory health, eczema and otitis in infants from four areas within the Spanish INMA (Environment and Childhood) study.
Methods: Temporally-adjusted land-use regression models were developed to predict pregnancy exposures to outdoor NO_2 and benzene for 2,173 women. Information on chest infections (bronchitis, bronchiolitis and pneumonia), wheezing, eczema and otitis was obtained by questionnaire at 1-1.5 years old. Associations between air pollutants exposure and health outcomes were assessed with log-binomial regression models, controlled for potential confounders. Because of heterogeneity, the association between air pollution and otitis was assessed by area. Sensitivity analyses were performed for non-movers and for women who spent more time at home during pregnancy.
Results: Mean (sd) exposure during pregnancy was 28.85 (11.25) $\mu g/m^3$ for NO_2 and 1.56 (0.93) $\mu g/m^3$ for benzene. Adjusted relative risks (RR) associated with an increase of 10$\mu g/m^3$ in NO_2 exposure were 1.06 (95% CI=1.00-1.14) for chest infections, 1.01 (95% CI= 0.92-1.11) for eczema, and 1.05 (95% CI=0.99-1.13) for wheezing. NO_2 exposure was significantly associated with otitis in three out of the four areas, with RRs ranging between 1.23 and 1.31. An increase of 1 $\mu g/m^3$ in benzene exposure was associated with a RR of 1.07 (95% CI=0.99-1.16) for chest infections, 1.03 (95% CI= 0.93-1.14) for eczema, and 1.05 (95% CI=0.98-1.12) for wheezing. All the RRs were higher among the subset of infants whose mothers spent more time at home during pregnancy.
Conclusions: There is some indication that prenatal exposure to traffic-related air pollution may contribute to the development of respiratory effects and otitis in early life. To what extent these associations are influenced by postnatal exposures need to be elucidated.

A COUPLE OF SQUIRTS A DAY KEEPS THE DOCTOR AWAY. A CLUSTER RANDOMIZED CONTROLLED TRIAL OF ALCOHOL-BASED HANDRUBS FOR PREVENTION OF INFECTIOUS DISEASE IN CHILDREN

Juan C. Correa, *División de Salud Comunitaria, Fundación Santa Fe de Bogotá, Colombia*
Diana Pinto, *Fedesarrollo. Departamento de Epidemiología Clínica y Bioestadística, Pontificia Universidad Javeriana, Colombia*
Lucas Salas, *División de Salud Comunitaria, Fundación Santa Fe de Bogotá, Colombia*
Juan Camacho, *División de Salud Comunitaria, Fundación Santa Fe de Bogotá, Colombia*
Martín Rondón, *Departamento de Epidemiología Clínica y Bioestadística, Pontificia Universidad Javeriana, Colombia*
Juliana Quintero, *Centro de Estudios e Investigaciones en Salud, Fundación Santa Fe de Bogotá, Colombia*

Background and Aims: This first cluster randomized controlled trial in a developing country setting sought to investigate if the use of alcohol-based handrub (ABH) reduced the incidence of acute diarrhoea (ADD) and respiratory infection (ARI) in children under five years. Handwashing with soap and water is known to be effective to prevent these illnesses, but alternatives are needed for settings where it is impractical.
Methods: The trial was performed in childcare centres with limited tap water availability located in six Colombian towns. Participants were randomly assigned to use ABH as a complement to handwashing (intervention arm: 21 centres/794 children); or to continue previous handwashing practices (control arm: 21 centres/933 children). Cases were identified through teacher-reported signs and symptoms of illness. Adverse events were monitored. Hazard ratios were obtained using Cox proportional hazards multivariate regression shared frailty models.
Results: Child-days of surveillance totalled 336,038. Attrition rate was 14%. For both diseases the hazard ratio did not differ during the first trimester of the trial. However, after this period the hazard ratios favour the intervention arm. The respective estimated risk of ADD for the second and third trimesters among children in the intervention group was 55% and 44% of the risk in the control group ($p<0.001$). The respective estimated risk of ARI for trimesters two and three among children in the intervention group was 80% and 69% of the risk in the control group ($p<0.001$). No adverse events occurred.
Conclusions: Alcohol-based handrub gels effectively prevent acute diarrhoea and respiratory infection and are safe. These results corroborate the findings of studies done in more affluent societies. National public health policies for prevention of these diseases should consider use of gels. Further research about the cost-effectiveness of ways to facilitate long-term behaviour change and technology adoption in diverse cultural contexts is needed.

LONG-TERM EXPOSURE TO TRAFFIC PARTICLES AND REPEATED MEASURES OF ATHEROSCLEROTIC PROGRESSION

Elissa Wilker, *Beth Israel Deaconess Medical Center & Harvard School of Public Health, USA*
Brent Coull, *Harvard School of Public Health, USA*
Alexandros Gryparis, *University of Crete, Greece*
Pantel Vokonas, *VA Boston Healthcare System and Department of Medicine, USA*
Joel Schwartz, *Harvard School of Public Health, USA*
David Sparrow, *VA Boston Healthcare System and Department of Medicine, USA*

Background and Aims: Recent evidence suggests that long-term chronic exposure to ambient pollution may contribute to atherosclerotic progression, but evidence from human studies is limited. We investigated the association between long-term exposure to traffic particles and carotid intima media thickness (CIMT), a marker of atherosclerotic burden, with a repeated measures analysis of men residing in the Boston area.
Methods: We estimated individual-level exposure to traffic particles (black carbon) at home addresses for 1 year prior to the baseline using a validated spatio-temporal model. Predictions are based on meteorological factors, as well as measures of land use at a given location. We examined the association between CIMT and log-transformed black carbon using a mixed effects model with random subject intercepts and covariates including medical history, indicators of socioeconomic position and seasonality.
Results: A total of 380 participants provided a baseline visit between 2004 and 2008. There were 2 and 3 follow up visits on 340 (90%) and 260 (68%) study participants. The mean ± SD age and CIMT at baseline were 75.9 ± 6.4 and 0.99 ± 0.18, respectively. CIMT was log-transformed to improve the normality of the distribution. In our analyses, an interdecile difference (equivalent to 0.48 $\mu g/m^3$) of log-transformed black carbon at baseline was associated with a 5.6% (95% CI: 1.2 – 10.1) higher CIMT. A penalized spline for black carbon showed deviation from linearity on the log scale, particularly at higher black carbon exposures, which were associated with higher CIMT.
Conclusions: Long-term exposures to traffic particles are associated with longitudinal measures of CIMT in a community-dwelling population of older men. This study provides further evidence for the potential role of long-term exposure to particles in advancing atherosclerosis and we observed detectable differences in effect size across a range of low levels of exposure.

SOCIAL INEQUALITY AND ITS ENVIRONMENTAL HEALTH CONSEQUENCES AMONG 9-10 YEAR OLD CHILDREN

Tamás Rudnai, National Institute of Environmental Health, Budapest, Hungary
Mihály J. Varró, National Institute of Environmental Health, Budapest, Hungary
Annamária Mácsik, National Institute of Environmental Health, Budapest, Hungary
Eszter Tüske-Szabó, National Institute of Environmental Health, Budapest, Hungary
Renáta Szentmihályi, National Institute of Environmental Health, Budapest, Hungary
Péter Rudnai, National Institute of Environmental Health, Budapest, Hungary

Background and Aims: Socio-economic status (SES) determines the people's potentials and the most essential environmental related health effects from the moment of fertilization until death. During the data analysis of the Hungarian country-wide respiratory survey we often met the determining role of social inequalities in both the level of environmental exposure and the health status of the children. The poster presents some of these "dose-response" relationships using a complex SES variable.

Methods: Source of the analysed data was the database of the country-wide survey on the children's respiratory health (OGYELF) covering all children attending 3rd grade classes with at least 10 pupils. The parents-completed questionnaires containing questions on the presence of respiratory and allergic symptoms and their possible risk factors, including socio-economic status, were sent back from 2,160 schools (79.2%) out of the 2,726 ones approached. Altogether 62,711 questionnaires (76.4% of the ones sent to these schools) were evaluated. A complex SES variable was constructed from 4 questions (low level of the mother's education, one-parent family, regular state benefit and self-rated low level of subsistence). Associations were analysed by multivariate logistic regression using STATA/SE 10.0.

Results: Several environmental risk factors showed significant dose-response relationships with SES which are, even in themselves, significant risk factors of the studied respiratory symptoms (e.g. heating with coal or wood-fired stoves or with gas cooker, crowdedness, environmental tobacco smoke, smoking during pregnancy, waste dump site near the home). Out of the studied health outcomes the prevalence of both chronic bronchitic and asthmatic symptoms showed significant dose-response relationships with the disadvantageous socio-economic status, while the prevalence of allergic symptoms showed opposite tendency.

Conclusions: Besides decreasing the harmful effects of environmental risk factors, reduction of social inequalities is inevitable in order to improve the health status of the population.

INCREASED MITOCHONDRIAL DNA-CONTENT ATTRIBUTABLE TO CADMIUM EXPOSURE AMONG ELDERLY

Nicky Pieters, *Hasselt University, Belgium*
Elke Munters, *Hasselt University, Belgium*
Karen Smeets, *Hasselt University, Belgium*
Valerie Pennemans, *Hasselt University, Belgium*
Harry Dewitte, General practice, Genk, Beligum
Joris Penders, *Hasselt University, Belgium*
Emmy Van Kerkhove, Hasselt University, Belgium
Jaco Vangronsveld, *Hasselt University, Belgium*
Ann Cuypers, *Hasselt University, Belgium*
Tim Nawrot, *Hasselt University, Belgium*

Background and Aims: Many lines of evidence suggest that mitochondria and oxidative DNA damage have a central role in ageing-related diseases and carcinogenesis. Cadmium is linked to increase cancer incidence but cadmium is not mutagenic by itself. Here we show, in a cross-sectional study of 143 elderly, a link between mitochondrial DNA (mtDNA) content, oxidative DNA damage (8-deoxyhydroxyguanosine) and urinary cadmium which is a biomarker of lifetime exposure.
Methods: In a case-crossover analysis, we estimated the risk of dying from non-traumatic causes before the age of one year in relation with outdoor PM10 concentrations on the day of death. We matched control days on temperature in order to exclude confounding by variations in daily temperature.
Results: We found that each doubling in urinary cadmium concentration was independently associated with a +0.10 (95% CI: 0.03 to 0.19;) increase in the ratio of mtDNA/nDNA content (COX-1, 3212/3319) and 8-deoxy-hydroxyguanosine increased substantially [+11.2% (0.85 to 22.2%; p=0.03)].
Conclusions: The observed association of an increased mtDNA/nDNA ratio in relation to urinary cadmium provides mechanistic plausibility to the hypothesis that carcinogenic metals like cadmium induce ageing related pathways.

ASSOCIATION BETWEEN LEAD EXPOSURE AND CARDIOVASCULAR RISK FACTORS IN AN ABORIGINAL POPULATION OF CANADA (JAMES BAY, QUEBEC)

Beatriz Valera, *Axe santé des populations et environnementaleCentre de recherche du CHUQ, Canada*
Éric Dewailly, *Axe santé des populations et environnementale Centre de recherche du CHUQ, Canada*
Paul Poirier, *Quebec Heart and Lung Institute, Laval Hospital Research Centre, Canada*

Background and aims: Lead exposure among Cree living in the eastern coast of the James Bay (Quebec) is related to hunting with lead shots and consumption of wildfowl and game. Exposure to lead has been associated with reduced heart rate variability (HRV) and increased blood pressure (BP), which are known cardiovascular risk factors. Low HRV is associated with sudden death while BP is a risk factor for ischemic heart diseases (IHD) and stroke. We aimed to assess the impact of lead on BP and HRV among Cree adults considering potential confounding factors.
Methods: Data were collected among 397 adults ≥ 18 years old living in three communities of the James Bay. Blood lead level was used as biomarker of recent exposure. BP was measured according to the WHO guidelines while HRV was derived from a 2-hour Holter monitoring. The relationship between lead and BP and HRV was studied using simple and multiple linear regressions in order to adjust for confounders (age, sex, fasting glucose, obesity, cholesterol, smoking, physical activity, antihypertensive/antiarrhythmic treatment, n-3 fatty acids, selenium and mercury levels).
Results: Mean age was 40±15 years and the sample was composed of 165 women and 232 men. Geometric mean of blood lead concentration was 0.12 μmol/L (95%CI: 0.11-0.13 μmol/L). Lead was negatively associated with HRV parameters such as low frequency (LF) (β= -0.22, p< 0.0001) and high frequency (HF) (β= -0.24, p= 0.0001) but these associations did not remained statistically significant after adjusting for confounders. In contrast, lead was positively associated with systolic blood pressure (SBP) (β= 2.66, p= 0.009) and diastolic blood pressure (DBP) (β= 1.77, p= 0.014) after adjusting for confounders.
Conclusion: Recent lead exposure seems to be associated with increased SBP and DBP among Cree of the James Bay.

INDIVIDUAL ACTIVITY CHANGE IN RESPONSE TO POOR AIR QUALITY

Ellen M. Wells, *Case Western Reserve University, Cleveland, United States*
Dorr G. Dearborn, *Case Western Reserve University, Cleveland, United States*
Leila W. Jackson, *Case Western Reserve University, Cleveland, United States*

Background and Aims: In the United States, several public health initiatives inform the general public about potential hazards of outdoor air pollution. Using National Health and Nutrition Examination Survey (NHANES) data, our aim was to evaluate the prevalence and characteristics of individuals who changed activities due to poor air quality.
Methods: This cross-sectional analysis included 5867 participants 16 years and older in NHANES 2007-2008 who were asked whether they changed activities in the past 12 months due to "bad" air quality. Descriptive statistics and logistic regression models including age, gender, race/ethnicity, smoking status, self-reported physical activity, and self-reported respiratory (asthma, emphysema, or chronic bronchitis) or cardiovascular (congestive heart failure, coronary heart disease, angina, heart attack, or stroke) conditions were evaluated using appropriate survey sample weights. Education, socioeconomic status, and body mass index were also considered.
Results: N=709 participants (12.3%, 95% confidence interval (CI): 10.4, 14.3) reported changing behavior in the past 12 months due to poor air quality. Based on an adjusted logistic model, older participants (≥ 45 years) and women were significantly more likely to change their activities. However, younger participants (<25 years), those reporting less physical activity, and smokers were significantly less likely to change their activities. Those with any respiratory condition (adjusted OR: 2.65, 95% CI: 2.01, 3.48) were also more likely to have changed activities. There was no association between those with any cardiovascular condition and activity change. Among those who changed activities, the most frequent change was spending less time outdoors (66.6%), whereas the least frequent was using public transportation (1.2%).
Conclusions: We present evidence that some individuals, including those with respiratory disease, reported changing activities in response to poor air quality. Public health initiatives should continue efforts to reach a broader population, particularly those with cardiovascular conditions.

SERUM AND FOLLICULAR FLUID CONCENTRATIONS OF POLYBROMINATED DIPHENYL ETHERS (PBDEs) AND *IN-VITRO* FERTILIZATION (IVF) OUTCOME

Paula I. Johnson, *University of Michigan School of Public Health, USA*
Larisa Altshul, *Harvard School of Public Health, USA; Environmental Health and Engineering, USA*
Daniel W. Cramer, *Brigham and Women's Hospital, USA*
Stacey A. Missmer, *Brigham and Women's Hospital, USA*
Russ Hauser, *Harvard School of Public Health, USA*
John D. Meeker, *University of Michigan School of Public Health, USA*

Background and Aims: Human exposure to polybrominated diphenyl ethers (PBDEs) is widespread and body burdens in North Americans are particularly high. There is evidence of reproductive effects of PBDEs in animals, but human studies are limited. Our objective was to investigate the use of serum and follicular fluid as biomarkers of exposure to PBDEs and to explore the relationship between PBDE exposure and early pregnancy loss.
Methods: We measured PBDEs in serum and follicular fluid from 65 women undergoing *in-vitro* fertilization (IVF). Logistic regression models were used to estimate the odds of failed implantation associated with higher levels of PBDEs among the women in the study.
Results: There were moderate Spearman correlations between serum and follicular fluid concentrations of BDE 28, 47, 100 and 154 (r=0.36-0.51, all p-values<0.004), but BDE 99 and 153 were not correlated between the two matrices (r<0.2, all p-values>0.2). Women with detectable concentrations of BDE153 (39% had detectable levels) in follicular fluid had elevated odds of failed implantation compared with women who had non-detectable concentrations (adjusted OR=10.0; 95%CI: 1.9 to 52; p=0.006; adjusted by age and BMI). There was also evidence for a dose-response trend when the women were divided into equal groups (adjusted OR for non-detect, medium, and high BDE 153 groups =1.0 [reference], 6.7, and 18.7, respectively; p-value for trend =0.008).
Conclusions: PBDE exposure may be associated with failed embryo implantation, but this association may be congener specific. Serum PBDE concentrations may not be a good indicator of the more biologically relevant follicular fluid concentrations when studying early pregnancy loss in women undergoing IVF. However, our ability to determine relationships between serum and follicular fluid PBDEs may be hindered by low detection rates.

EFFECTS OF RADON EXPOSURE AND SMOKING ON LUNG CANCER RISK: RESULTS OF A EUROPEAN COMBINED ANALYSIS AMONG URANIUM MINERS

Dominique Laurier, *Institut de radioprotection et de Sûreté Nucléaire (IRSN),France*
Maria Schnelzer, *Federal Office for Radiation Protection (BfS), Germany*
Ladislav Tomasek, *National Radiation Protection Institute (SURO), Czech Republic*
Estelle Rage, *Institut de radioprotection et de Sûreté Nucléaire (IRSN),France*
Michaela Kreuzer, *Federal Office for Radiation Protection (BfS), Germany*
Klervi Leuraud, *Institut de radioprotection et de Sûreté Nucléaire (IRSN),France*

Background and aims: Three case-control studies nested in the French, German and Czech cohorts of uranium miners were conducted in the frame of the Alpha-Risk European research project. These studies aimed at investigating the combined effects of radon and smoking on lung cancer risk. A pooled analysis of individual data of the three studies is presented.
Methods: The pooled data set includes 1476 cases and 3389 matched controls. Cumulated radon exposure during employment was obtained from measurements or a job exposure matrix. Smoking habits were determined from medical archives and questionnaires. Analysis was performed by conditional logistic regression using a linear excess relative risk model.
Results: Smoking status was established for 1046 cases and 2492 controls. Ninety four percent of cases and 76% of controls were ex- or current smokers. Mean five-year lagged cumulated radon exposure was 335 Working Level Months (WLM) for cases and 211 WLM for controls. The excess relative risk per 100 WLM adjusted for smoking was 0.79 (95% confidence-interval: 0.44-1.41). Lung cancer excess relative risk was higher among non-smokers than among smokers and the results suggest a sub-multiplicative interaction between smoking and radon exposure on lung cancer mortality risk.
Conclusions: This collaborative study is the largest uranium miner case-control study on lung cancer with smoking information in Europe. It confirms the persistence of radon effect on lung cancer risk when smoking is taken into account. The results are consistent with a sub-multiplicative interaction between radon and smoking and even among never smokers, the lung cancer risk is significantly associated with radon.

COMPARISON OF METHODS FOR ESTIMATING PERSONAL BLACK CARBON EXPOSURES IN URBAN SETTINGS

Jing Cai, *Lamont-Doherty Earth Observatory of Columbia University, USA; East China University of Science and Technology, China*
Beizhan Yan, *Lamont-Doherty Earth Observatory of Columbia University, USA*

Kyung-Hwa Jung, *Columbia University College of Physicians and Surgeons, USA*
James Ross, *Lamont-Doherty Earth Observatory of Columbia University, USA*
Nathan Rollins, *Lamont-Doherty Earth Observatory of Columbia University, USA*
Cosette Olivo, *Mailman School of Public Health at Columbia University, USA*
Benedicta B. Obeng, *Mailman School of Public Health at Columbia University, USA*
Fareeha Hafeez, *Mailman School of Public Health at Columbia University, USA*
Rachel L. Miller, *Columbia University College of Physicians and Surgeons, USA*
Steven N. Chillrud, *Lamont-Doherty Earth Observatory of Columbia University, USA*

Background and Aims: Epidemiological studies have demonstrated that black carbon (BC) exposures are associated with adverse health effects. To date, studies have primarily conducted exposure assessment based on fixed-site monitoring, or a single integrated 24-48 hr personal sample. This paper uses repeat personal BC measurements to explore the difference in distribution of personal BC exposure in a cohort of 9-10 years old urban children to fixed-site BC monitoring data.
Method: Personal sampling (PS) for each subject comprised carrying a microaethalometer (Magee Sci), for 5 weekday and 1 weekend 24hr periods, spread over a 3-4 weeks. Fixed-site BC sampling (FS) employed a rack mount Aethalometer® with the inlet located outside of a 5th floor window in Washington Heights, NYC. Here we start with comparing descriptive statistics and univariate correlations for 24 hr average data for P and F.
Results: Linear regressions between PS (as y) and FS (as x) on 24hr average displayed large variability in correlation, slope and intercept for 27 subjects that had 4 or more valid data for BC_P and BC_F. 9/27 subjects show poor correlation (R^2: 0.02~0.38, N≥4) and 8/27 subjects show moderate correlation (R^2: 0.51~0.69, N≥5) with FS. However, 10 of the subjects displayed high correlation between P and F (R^2: 0.72~0.94, N≥4) but displayed variable slopes (-19 to 1.0) and intercepts (near zero to ~38,000 ng/m^3).
Preliminary Conclusion: Based on our study, ~1/3 subjects' BC personal exposure could not be predicted by central site sampling, probably due to personal activities leading to BC exposures different from that of the fixed-site; Roughly, 1/3 subjects' personal measurements highly correlate with fixed-site data, though the relationships vary as a function of the subject, consistent with spatial variability in ambient BC. Time activity recall diaries and GPS data are being investigated to see if they support these preliminary conclusions.

DETERMINANTS OF INDOOR AND OUTDOOR LEVELS OF NO_2 IN A COHORT OF 4-YEARS-OLD CHILDREN

Background and Aims: Home outdoor NO_2 has been used as a marker of personal exposure to traffic-related air pollution. However, recent studies suggest that exposure to indoor NO_2 may be a risk factor in itself for respiratory health and neurodevelopment. We aimed at assessing the relationship between indoor and outdoor NO_2 levels and their determinants in a subset of the INMA birth cohort of Sabadell, Spain.
Methods: Indoor and outdoor NO_2 levels were measured with passive samplers during two measurement campaigns of one week (1^{st} campaign in fall/winter, 2^{nd} campaign in summer) at home addresses of 96 children. Characteristics of the home surroundings (street configuration, building density, and traffic-related variables) were obtained by the field workers and by Geographic Information Systems (GIS). Information on sources of NO_2 indoor levels (gas appliances, tobacco smoke) and additional variables (e.g.use of extractor fan, air conditioning) were obtained through questionnaires in each campaign.
Results: Mean levels of outdoor NO_2 were 36.7 $\mu g/m^3$ in fall/winter and 34 $\mu g/m^3$ in summer, while mean levels of indoor NO_2 were 22.8 $\mu g/m^3$ in fall/winter and 26 $\mu g/m^3$ in summer. The correlation between indoor and outdoor levels was lower in fall/winter (r=0.35) than in summer (r=0.51). The main determinants of outdoor NO_2 were the street configuration (continuous buildings on both sides vs. other configurations) and traffic-related GIS variables. Indoor NO_2 levels were influenced by tobacco smoke, time using gas cooking, time opening windows to ventilate, house age, and an interaction between outdoor NO_2 levels and use of air conditioning.
Conclusions: The influence of traffic-related NO_2 pollution on indoor levels is higher in summer than in fall/winter, probably due to differences in ventilation patterns. Gas cooking and tobacco smoke are the main indoor sources of NO_2, whereas ventilation, use of air conditioning, and house age are additional determinants.

EXPRESSION OF PROTEIN HSP-70 IN HUMAN LYMPHOCYTES INDUCED BY NITRATE AND LEAD ACETATE.

ABSTRACT

The effects of lead are involved almost the entire cellular environment, inorganic lead compounds as well as some non-essential metals for cell homeostasis may alter directly or indirectly the immune system due to its sensitive response to the presence of these and therefor exert immunosuppressive action. This response to the presence of the exhibition serves as a biomarker of contaminant through the expression of heat shock proteins (Hsp) and Hsp-70. **Objective:** The purpose of this study was to determine the amount of heat shock protein Hsp-70 expressed in human lymphocytes of de blood of healthy people, at be subject to concentration of acetate and nitrate of lead smaller to 10 µg/dl. **Materials and Methods:** The tissue was obtained through venous puncture of healthy volunteers. The lymphocytes were isolated by Ficoll–Paque gradient, experimental lots were subject to stress with a concentration of acetate and lead nitrate by 2.5, 5.0, 7.5, 10 µg/dl during 3 hours at 37 ^{0}C, like positive control to the expression of Hsp 70 protein was used two samples, a with concentration of 100 µg/dl under the same conditions and other positive control by heat at 42 ^{0}C during 3 hours, after of stress period the lymphocytes leave them in recovery with culture medium during 3 hours at 37 ^{0}C without the stressor agent. The cell protein extract were separated by SDS-PAGE, detected by immunoblotting and the quantification were done by densitometry. **Results:** The protein Hsp-70 was expressed in each different concentration of acetate and nitrate lead. **Conclusions:** It was found that the concentration used of acetate and nitrate of lead are biomarker of cellular stress to the lymphocytes expressing by increase in the expression of heat shock protein Hsp-70. **References:**Bozhkov A, Padalko V, DlubovskayaV and Menzianova N. Resistance to Heavy Metal Toxicity in Organisms under Chronic Exposure. Indian Journal of Experimental Biology2010;48:679–696.

PERSISTENT ORGANIC POLLUTANTS AND OVERWEIGHT AT AGE 6.5 YEARS; DO SEX OR HIGH-FAT INTAKES OF THE CHILD MATTER?

Background and Aims: Recent experimental evidence suggests prenatal exposure to endocrine-disrupting chemicals may increase postnatal obesity risk, and that these effects may vary by sex or be enhanced when animals are postnatally placed on a high-fat diet. Little is known about these associations in humans. We explored whether prenatal exposure to organochlorine compounds (OC) (PCBs, DDE, DDT) is associated with overweight at age 6.5 years and whether children's sex or fat intakes modify these associations.
Methods: We studied 344 children from a Spanish birth cohort established in 1997/98. OC concentrations were measured in cord blood. Overweight at 6.5 years was defined as a BMI z-score • the 85th percentile of the WHO reference. Using a food frequency questionnaire of children's diet in the past year, a high-fat intake was defined as above median fat intakes as a percentage of energy. We estimated relative risks using generalized linear models.
Results: Third tertile PCBs exposure was found to be associated with overweight in girls (RR^{a}=2.13, 95%CI=0.99, 2.57), but not clearly in boys (RR^{a}=1.43, 95%CI=0.82, 2.38; p-interaction=0.04). Children with higher-fat intakes had an increased risk of overweight related to third tertile PCBs exposure (RR^{a}=1.95, 95%CI=1.00, 3.82), but the interaction was not statistically significant (p-interaction=0.63). Second tertile DDE exposure was associated with overweight (RR^{a}=1.67, 95%CI=1.10, 2.55), with a somewhat stronger association in girls than boys (p-interaction=0.20). No effect modification by fat intake was observed for DDE (p-interaction=0.93). Second tertile DDT exposure was associated with overweight only in boys (RR^{a}=1.96, 95%CI=1.06, 3.62; p-interaction=0.25) and among children with higher-fat intakes (RR=2.31, 95%CI=1.16, 4.58; p-interaction=0.20). For none of the OC, linear dose-response relationships were observed.
Conclusions: Though no clear evidence was found for a dose-response relationship, prenatal PCBs, DDE and DDT concentrations might increase the risk of overweight at 6.5 years in a sex-specific and diet-dependent way.

TOENAIL ARSENIC CONCENTRATIONS AMONG RESIDENTS OF A COAL MINING AREA OF THE APPALACHIAN MOUNTAINS OF THE UNITED STATES: A PILOT STUDY.

Claudia Hopenhayn, *University of Kentucky, United States*
Nancy Johnson, *University of Kentucky, United States*
Brent Shelton, *University of Kentucky, United States*
Jason Unrine, *University of Kentucky, United States*
Jay Christian, *University of Kentucky, United States*
Thomas Tucker, *University of Kentucky, United States*

Background and Aims: Arsenic is an established lung carcinogen. Lung cancer rates in the Appalachian region of Kentucky are about twice the national rates in the U.S.A. The high rates of smoking in the area do not explain all the elevation in lung cancer risk. This area is also characterized by extensive coal mining activity. This pilot study explored a comparison of toenail arsenic concentrations in Appalachian Kentucky and another distant region of the state.
Methods: Toenail samples were collected for a population-based case-control study in Kentucky. A sub-group of the samples were selected and analyzed for trace elements, based on location of the study participants, who were included if they lived in the East Kentucky Coal counties in Appalachian Kentucky, or in the largest urban center of Jefferson County. For the assessment of population-based exposure, only the controls of the original study were included. Total elemental analyses were performed using inductively-coupled plasma- mass spectrometry. There were a considerable number of samples with arsenic concentrations below the method detection limit, due in part to inadequate sample mass. Therefore, a reverse Kaplan-Meier method was used for the statistical analysis of the left-censored data.
Results: A total of 88 toenail samples from Appalachian Kentucky and 155 from Jefferson County were analyzed for arsenic concentrations. The reverse Kaplan-Meier estimation indicated that the arsenic concentrations in the Appalachian counties were significantly higher than in Jefferson (75^{th} and 90^{th} percentiles were 0.13 vs. 0.03 and 0.29 vs. 0.04 ug/g, respectively).
Conclusions: The results of this study suggest that residents of the selected Appalachian Kentucky counties with high coal mining activity have higher exposure to arsenic than those in an urban, non-coal mining region of the same state. However, further studies are needed to elucidate the source of the arsenic exposure.

IMPORTANCE OF CAREFUL DISEASE PHENOTYPING IN STUDIES ON DEVELOPMENT OF ASTHMA AND ALLERGIES

the GABRIELA study group

Background and Aims: The protection from childhood allergies and atopic sensitisation by farming environments has been shown in numerous studies. Reports on the 'farm-effect' on wheeze and asthma have been less consistent. We aimed to determine whether protection conferred by exposure to farming was different for various wheeze phenotypes and whether this protection was independent of atopic sensitisation.

Methods: The GABRIEL Advanced Studies are cross-sectional multi-phase surveys on exposure to farming environments and its effect on asthma and allergic disease among 79,888 children at age 6 to 12. Detailed data on wheeze, exposure to farming environments, and total and specific immunoglobulin E were collected from a stratified random sample of 8,023 children. A further stratified random sample of 895 children was invited for lung function including bronchodilator response and exhaled nitric oxide measurements. We used adjusted weighted stratified regression analyses to assess effects of farming exposure.

Results: We were able to confirm the protective farm-effect on prevalence of childhood atopy and showed also an influence on the degree of atopy. For atopic subjects, no further farm-effect on the prevalence of current wheeze was seen but an effect on exhaled nitric oxide and lung function. Exposure to farming led to decreased prevalence of transient early wheeze and among non-atopic children to decreased prevalence of current wheeze.

Conclusions: Exposure to farming environments may affect distinct mechanisms during the development of atopic sensitisation and wheeze. Besides the known effect on atopy, farming affects prevalence of current wheeze among non-atopic subjects, suggesting mechanisms independent of atopic sensitisation. Phenotypic heterogeneity may explain the previously less consistent reports of the farm-effect on wheeze.

LEAD CONCENTRATION IN FORAGE, FODDER, WATER AND BOVINE MILK IN SAN IGNACIO.

Lead is widespread in the environment by a variety of exposure routes allow toxic heavy metals like lead to enter the food chain of farm livestock animals. Samples were taken during the fall, winter, spring and summer season in the region of San Ignacio located in the state of Zacatecas in Mexico were in the middle of agricultural fields is located a metal recycler facility. **Objective:** Samples of forage, fodder, water and bovine milk used to cattle feeding were taken in order to determine the lead concentration.
Materials and Methods: Samples were processed and prepared to be analyzed with Atomic Absorption Spectrometry, determinations were performed by triplicate obtained by of pool of the three sample of each season, that it was taken by each one having a relative error < 1% for all them.
Results: From fodder and forage samples it was found that in average the lead concentration is 4.16 µg/g, being the summer season where lead levels reach its maximum values. From water samples the mean lead concentration was 0.218 mg/L, the winter season where water reaches its larger concentration level. The average of cow´s milk concentration lead is 0.033 mg/L, being the winter season where lead levels reach its maximum values 0.0545 mg/L, during spring the level of lead reaches the lowest concentration 0.0179 mg/L. For the milk-forage correlation values it was (p= .430) and for the correlation milk-water was (p= 0.874).
Conclusions: The average lead concentration is below the limits defined by the European Union, the average lead concentration water samples was 22 times higher to levels recommended by the Mexican Norm, and the average lead concentration cow´s milk is above the limits defined by the European Union, Australian, FAO. The lead concentration in cow´s milk probably is due to the water lead concentration. Therefore, lead concentration in the water and bovine´s milk is a potential source contamination to the community habitants.

THE ASSOCIATION BETWEEN BLOOD LEAD AND BLOOD PRESSURE VARIES BY RACE AND DEPRESSIVE SYMPTOMS

Margaret Hicken, *University of Michigan, Department of Epidemiology, USA*
Gilbert Gee, *University of California Los Angeles, Department of Community Health Sciences, USA*
Howard Hu, *University of Michigan, Department of Environmental Health Sciences, USA*

Background and Aims: Previous work has documented that US Blacks exhibit a stronger positive association between blood lead (BL) and blood pressure (BP) than Whites. The reason for this disparity is unclear, but might be due to effect modification. We examine psychological factors as a potential modifier.
Methods: With data from the National Health and Nutrition Examination Survey 2005-2008, we use race-by-lead interactions with linear regression to estimate Black-White differences in the associations between BL and BP, adjusting for age, hypertension risk factors, and SES. To account for any differences in lead effect due to disparities in lead level, we employ Oaxaca-Blinder decomposition techniques. To examine the role of mood, as reflected by depressive symptoms (DS), we employ race-by-DS-by-lead interactions. We calculate BL-BP associations for each race-DS group. All analyses are stratified by gender.
Results: Black men show a 2.4mmHg (se=1.0, $p<0.05$) increase in systolic BP (SBP) for each doubling of BL while White men show no increase. Women show similar disparity patterns. Decomposition analyses indicate that Black-White disparities in mean BL levels do not explain the greater BL effect shown by Blacks compared to Whites. Black men with high DS experience an 8.0mmHg increase in SBP with each doubling of BL (se=3.4, $p<0.05$) while those with low DS show no association (b=1.0, se=0.7). Black women with high DS experience a 3.8mmHg increase in SBP (se=1.6, $p<0.05$) while those with low DS show no association. Whites show no association in either DS group.
Conclusions: Our analyses suggest a mechanism for the stronger relationship between BL and BP among Blacks than Whites observed in prior studies. The BL-SBP association appears limited to those Blacks who report high DS. Our results suggest that mood, a psychological factor potentially related to psychosocial stress, may enhance susceptibility to the harmful health effects of environmental hazards experienced by socially disadvantaged populations.

CONCENTRATION OF DIOXINS (PCDD/F) AND PCBS IN FISH FROM THE TYNE RIVER ESTUARY, UK, WITH DIETARY INTAKE ESTIMATES

Tanja Pless-Mulloli, *Institute of Health and Society, Newcastle University, UK*
Lindsay Bramwell, *Institute of Health and Society, Newcastle University, UK*
David Mortimer, *Food Standards Agency, London, UK*
Alwyn Fernandes, *Food and Environment Research Agency, York, UK*
Phil Hartley, *Newcastle City Council, UK*
Martin Rose, *Food and Environment Research Agency, York, UK*

Background and Aims: The River Tyne estuary is located in a densely populated conurbation of one million people with long standing but now largely historic industrial heritage resulting in significant contamination along the shores. Contemporary discharges are from some upstream industries and raw sewage during storm events. Angling takes place on the Tyne estuary and caught fish is consumed in part by deprived populations for whom it may represent a regular part of the diet. Building on work carried out by the UK Food Standards Agency, we aimed to investigate for the first time PCDD/Fs and PCBs in a range of wild fish species and sample types from an estuarine river and to estimate potential risk to consumers.

Methods: We determined the concentrations of contaminants in different fish species and sample types. We collected a minimum of two kg each of Codling (G*adus morhua*) n=8, Whiting (*Merlangius merlangus*) n=22, Flounder (*Platichthys flesus*) n=19 and Eel (A*nguilla anguilla*) (Jan to June 09) n=14. Laboratory analysis was carried out by the Food and Environment Research Agency.

Results: Concentrations varied many-fold with, for example, sums of WHO TEQ (upper) in ng/kg: composites of whiting 0.15, flounder: 0.28, eel: 3.71, cod: 0.17, cod liver: 51.5. Whiting and cod had marginally higher concentrations of PCDD/F and PCBs than previous UK studies, eel concentrations were within the range of earlier studies.

Conclusions: Based on the FSA recommendation for a daily intake of <2pg WHO-TEQ/kg bodyweight for girls and women of reproductive age and < 8pg WHO-TEQ/kg bodyweight for males showed that girls and women of reproductive age should be advised not to consume Tyne eel more than once a week and all persons should be recommended to consume Tyne cod liver only very occasionally.

MODELING EXPOSURES TO THE OXIDATIVE POTENTIAL OF AMBIENT PARTICULATE MATTER IN LONDON

Jeff D. Yanosky, *Department of Public Health Sciences, Pennsylvania State University College of Medicine, Hershey, Pennsylvania, USA*
Cathryn C. Tonne, *Department of Social and Environmental Health Research, London School of Hygiene &Tropical Medicine, London, UK; MRC-HPA Centre for Environment and Health, School of Biomedical & Health Sciences, King's College London, London, UK*
Sean D. Beevers, *MRC-HPA Centre for Environment and Health, School of Biomedical & Health Sciences, King's College London, London, UK*
Paul Wilkinson, *Department of Social and Environmental Health Research, London School of Hygiene &Tropical Medicine, London, UK*
Frank J. Kelly, *MRC-HPA Centre for Environment and Health, School of Biomedical & Health Sciences, King's College London, London, UK*

Background and Aims: Differences in the toxicity of ambient particulate matter (PM) due to varying particle composition across locations may contribute to variability in results from air pollution epidemiologic studies. Though most studies have used PM mass concentration as the exposure metric, one which accounts for particle toxicity due to varying particle composition as well as PM mass may better elucidate whether PM from specific sources is responsible for observed health effects.
Methods: The oxidative potential (OP) of PM <10 um (PM_{10}) was measured as the rate of depletion of the antioxidant reduced glutathione (GSH) in a model of human respiratory tract lining fluid. Using a database of GSH OP measures collected in greater London from 2002-2006, we developed and validated a predictive spatio-temporal model of the weekly GSH OP of PM_{10} that included geographic predictors. Predicted levels of OP were then used in combination with those of weekly PM mass to estimate exposure to PM_{10} weighted by its OP.
Results: Using cross-validation, brake and tire wear emissions of PM_{10} from traffic within 50 m and tailpipe emissions of nitrogen oxides from heavy-goods vehicles within 100 m were important predictors of GSH OP levels. Predictive accuracy of the models was high for PM_{10} (cross-validation R^2=0.83) but only moderate for GSH OP (cross-validation R^2=0.47) when comparing weekly levels; however, the GSH OP model predicted spatial trends well (spatial cross-validation R^2=0.80).
Conclusions: Results suggest that PM_{10} emitted from traffic sources, specifically brake and tire wear, has a higher OP than that from other sources, and that this effect is very local, occurring within 50-100 m.

Background and aims: Perfluorooctanesulfonate (PFOS) and perfluorooctanoate (PFOA) are man-made, widespread persistent organic pollutants. Although they have been related to deleterious effects towards fetal growth in animals, the evidence on human effects is scarce (1, 2).
Anogenital distance (AGD) is an anthropometric measurement that has been taken to the newborns, and it is widely known as a marker of exposure to hormonal disrupters for animals. AGD would be a sensitive quantitative marker of disruptors exposure and could eventually be used as a risk factor measurement for endocrine-related dysfunctions (such as sterility) (3). The hypothesis of this study is that PFOS/PFOA could act as hormone disruptors and therefore lead to a modified AGD.

Methods: 10 newborns with the lowest AGD mean (33.63±2.16mm) and the 10 newborns with the highest AGD mean (50.64±3.89mm) went through analysis of levels of PFOS/PFOA. Moreover, this preliminary study provided the opportunity to validate an automatic method for PFOS analysis, which consists on liquid chromatography associated with masses spectrometry.

Results: The mean levels were 2059 (±1567) ng/ml for PFOS and 914 (±3449) ng/ml for PFOA. When AGD was divided into lowest and highest categories, the lowest AGD group had higher levels (ng/ml) of PFOS (2517, 95% CI 1332 - 3702, versus 1600, 95% CI 594 - 2607, p 0.19). Unconsistent results were find for PFOA analysis (115±45.3ng/ml for the lowest versus 1802±5008ng/ml for the highest AGD mean group, p=ns).

Conclusions: These preliminary results suggest that PFOS levels could be associated to anogenital distance. Levels of PFOS/PFOA were comparable to those obtained in previous studies. The inconsistent findings for PFOS and PFOA in relation to AGD could be due to different mechanisms of action, as observed for other hormone related endpoints. Future analyses will be presented at the conference, evaluating a larger sample of 200 children participating in NewGeneris-Spain and will allow us evaluate the association of AGD with PFOS/PFOA.

Background and aims: Maternal consumption of omega 3 polyunsaturated fatty acid can to act as an adjuvant in the immune system and have effects on the neonatal inflammatory response**.** We conducted the present study to investigate the effect of prenatal docosahexaenoic acid (DHA) supplementation on respiratory symptoms and to identify the main prenatal environmental risk factors for these symptoms in infants.
Methods: We included 784 infants whose mothers were randomly assigned to receive daily supplement of 400 mg of DHA or placebo from week 18-22 of pregnancy until childbirth. During pregnancy we collect information on sociodemographics characteristics, past health history, maternal stress and environmental exposures. Also, we collected blood samples to determine maternal specific IgE levels in plasma. Child respiratory symptoms information was collected using a recall questionnaire at 1, 3, 6, 9, 12 and 18 months of age. Poisson regression models were used to identify the main prenatal risk factors for respiratory symptoms.
Results: The occurrence of respiratory symptoms did not differ significantly between groups; however, the occurrence of a combined measure of some symptoms was lower in the DHA group. We observed that the higher risk of respiratory symptoms were for the children whose mothers were randomly assigned to receive placebo. The main risks factors were use pesticides in home (OR= 1.18; 95%IC 1.08, 1.29) gender male (OR= 1.09; 95% CI 1.01, 1.18) and maternal atopy (OR= 1.03 95%CI 0.95, 1.12).
Conclusions: DHA supplementation during pregnancy decreased the occurrence of respiratory symptoms in infants and this study strengthens the evidence that the family history and prenatal environmental exposure in early stages of life increase the risk of respiratory symptoms in childhood.

US TODDLERS EXPOSURE TO PBDE FLAME RETARDANTS: ASSOCIATIONS WITH HOUSE DUST, HAND WIPES, AND SOCIAL/ECONOMIC VARIABLES

Heather M. Stapleton, Sarah Eagle, Andreas Sjödin, Thomas F. Webster

Background and Aims

Polybrominated diphenyl ethers (PBDEs) are persistent and bioaccumulative flame retardants associated with adverse effects on thyroid regulation and neurodevelopment. Little is known about children's exposure and body burdens. The objectives of this study were to determine if PBDE body burdens were associated with the following: house dust and/or PBDE residues on hand wipes collected from the children; gender, age, race, and education level of the parents.

Methods

Blood samples, hand wipes and house dust were collected from children 12-36 months old residing in central North Carolina between 2009-2010. A short questionnaire was administered which collected information on the child's physical and behavioral characteristics, breast feeding, and the parents race and education levels.

Results

PBDEs were detected in every serum sample and the most abundant congeners were those associated with the PentaBDE mixture. Concentrations ranged from 5.2-745 ng/g lipid with a geometric mean value of 46.7 ng/g lipid. PBDE levels were significantly higher ($p < 0.05$) in the oldest age group (>24 months) relative to the youngest (~12-18 months). PBDE concentrations were significantly higher in African Americans relative to Caucasians; lower PBDE levels were observed with higher maternal education levels. Significant correlations were observed between the serum BDE47 levels and BDE47 measured on hand wipes ($r = 0.60$; $p<0.0001$) and BDE47 levels in house dust ($r=0.40$; $p<0.001$). No associations were observed between PBDE levels and duration of breast feeding as an infant.

Conclusions

These data suggest that children's exposure to PBDEs from house dust appears to be the leading exposure pathway in toddlers, and not diet or breast milk exposure. Minorities and families with lower educational levels are also at higher risk to exposure to this class of contaminants.

PM2.5 CHEMICAL CONSTITUENTS AND MORTALITY IN 49 U.S. COMMUNITIES FROM 2001 TO 2005

Background and Aims: Short-term exposure to ambient particulate matter less than 2.5 µm in aerodynamic diameter (PM2.5) is consistently associated with adverse health outcomes in population studies. The PM2.5 mass represents a chemically diverse mixture of pollutants and there is limited evidence on the health effects of PM2.5 constituents.
Methods: We conducted a national multi-site time series analysis to examine the association between daily non-accidental mortality (≥ 65 years of age) and ambient levels of seven major PM2.5 chemical constituents: sulfate, elemental carbon (EC), nitrate, organic carbon (OC), silicon, sodium ion, and ammonium ion. Average lag-specific relative rates of death associated with each constituent were estimated using a two-stage Bayesian hierarchical model to combine evidence across 49 U.S. communities from 2001-2005.
Results: In a single pollutant model controlling for weather and seasonality, an interquartile range (IQR) increase in 2-day lagged EC levels (0.46 µg/m3) was associated with a 0.41% [95% posterior interval (PI), 0.06–0.76%] increase in the relative rate of death. An IQR increase in 1-day lagged OC levels (2.47 µg/m3) was associated with a 0.64% (95% PI, 0.14–1.15%) increase in the relative rate of death.
Conclusions: These findings suggest that ambient levels of EC and OC were positively associated with all-cause mortality for the elderly population. However, further investigations are needed to elucidate the joint effects of the PM2.5 constituents and their sources.

This is abstract does not necessarily reflect the policies of the U.S. Environmental Protection Agency.

AIRWAY AND CIRCULATORY PRO-INFLAMMATORY EFFECTS OBSERVED IN HEALTHY VOLUNTEERS AFTER AMBIENT AIR POLLUTION EXPOSURE: RAPTES HEALTH EFFECT ASSESSMENT

Gerard Hoek, *Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, the Netherlands*
Nicole Janssen, *National Institute for Public Health and the Environment (RIVM), Bilthoven, the Netherlands*

Background and aims: Despite the large amount of data available on the adverse health effects of ambient particulate matter (PM) there is limited information on the influence of which PM characteristics mainly drive these effects. The aim of RAPTES (Risk of Airborne Particles: Toxicological-Epidemiological hybrid Study) is to investigate which PM characteristics contribute to effects on the respiratory and circulatory system.
Methods: Thirty healthy volunteers were exposed to ambient air pollution at five different sites in the Netherlands: two traffic sites, an underground train station, a farm, and an urban background site. Sampling took place on 30 days from March-October 2009. Each subject visited at least 3 sites and was exposed for 5h per visit. Air pollution was characterized during this 5h-period, including measurements of PM_{10} and $PM_{2.5}$ mass and elemental composition, particle number concentration (PNC), PM oxidative potential (OP) and PM_{10} endotoxin content. Pro-inflammatory parameters were measured before and at 2h and 18h post-exposure, including cytokines and differential cell counts in nasal lavage (NAL) and blood.
Results: PM_{10} endotoxin content was associated with elevated NAL cytokine levels. Two hours post-exposure, we observed a significant increase over baseline in IL-6 and IL-8 (3.2% and 1.5% per endotoxin unit respectively), as well as 18h post-exposure (1.7% IL-6). PM_{10}, $PM_{2.5}$ mass concentration, PNC and OP were not associated with NAL cytokine levels. Furthermore, no changes in NAL differential cell counts were observed after ambient PM exposure. In blood, PM characteristics were not associated with IL-6 (IL-8 not measured). A significant increase (15%) of leukocytes was observed 2h post-exposure followed by a significant decrease 18h post-exposure (10%). This was predominately characterized by an increase in neutrophils, especially in relation to PM_{10} and $PM_{2.5}$ mass, organic and elemental carbon.
Conclusions: Increased expression of pro-inflammatory airway and circulatory markers was observed in healthy volunteers after five-hour exposure to ambient air pollution. These effects were particularly associated with endotoxin and organic carbon.

THE ATTRIBUTABLE COSTS OF US OCCUPATIONAL LEAD POISONING

Ronnie Levin, *Harvard School of Public Health*
Joel Schwartz, *Harvard School of Public Health*

Background: Occupational standards for lead in the US have not been changed for decades, during which the knowledge about lead's health effects has grown substantially, and new health outcomes and lower exposures associated with those outcomes are a general pattern.

Objective: We estimated the health and economic benefits that would accrue from a reduction in occupational lead levels in the United States.

Methods: We reviewed the literature on both occupational and general population studies of the effects of lead, and found substantial evidence for multiple health endpoints. We took data from the cost of illness literature to estimate avoided costs by reducing these effects and estimated the benefits that might be expected. To estimate exposure, we used US government data on the number of workers exposed; this is likely to be a significant underestimate of actual exposures.

Results: Payer and private medical costs alone are estimated at $40 million (09US$) per year, and total direct and indirect costs are estimated at $117-142 million (09US$) per year for the 11,000 or so workers with occupational lead exposures. This does not include increased mortality, a valuation of all health effects associated with lead exposures and quality of life decrements.

Conclusions: Reducing allowable lead limits would result in benefits of approximately $10,000 per worker per year, suggesting that cost effective reductions are likely to be possible. Given underreporting of actual exposures and the omission of important health effects, this is likely a significant underestimate of the true benefits of reducing occupational lead exposures in the US.

SAVING LIFE THROUGH TEACHING FIRST AID SKILLS AND RULES OF THE ROAD

Almaz Sultashev, *Kyrgyz State Medical Academy, Bishkek, Kyrgyz Republic*

Background and Aims: Prevention of accidents is one of the most important socio-economic problems for the development of the country, the life and health of people. In traffic accidents knowledge and skills on giving first aid is critical for saving the life and health of individuals. This study was carried out within the project "Saving life through teaching first aid skills and rules of the road" of the European Commission in partnership with the Dutch Red Cross. The aim of the study was to assess educational activities on road safety and first aid skills in traffic accidents.
Methods: Statistical data and reports on accomplished road safety projects in the country were reviewed. 500 respondents from 7 regions were surveyed on first aid giving in traffic accidents.
Results: Traffic accidents were found to be steadily increasing and associated with a high level of mortality and injury. Review of activities in various projects on road traffic safety showed that they are directed primarily at reducing the number of traffic accidents through promoting road safety measures. 7 training centres on first aid skills and road safety rules have been established to provide training to the population on a regular basis using modern educational methods.
Conclusions: The campaign on raising the first aid and road safety awareness covered a considerable number of young people (13,000 persons). State authorities and NGOs were involved in the project. The investigation of opinions of the population showed high efficiency of the educational methods and strategies used. 88% of respondents gave correct answers about first aid and road safety rules that should be observed for personal safety and the safety of people near you.

DO METEOROLOGICAL CONDITIONS PLAY A ROLE IN OCCURENCE OF PREECLAMPSIA ?

TC. Tran,
A. Boumendil, *UVSQ UPRES EA 2506, Versailles, FRANCE*
P.Rozenberg , *Obstetrics Dpt - Poissy-St-Germain Hospital, FRANCE*
P.Aegerter, *UVSQ UPRES EA 2506, Versailles, FRANCE*

Background: Preeclampsia is a major obstetric complication and a leading cause of morbidity and death among mothers and infants. Previous attempt to study influence of meteorological parameters on occurrence of preeclampsia yielded contradictory results, with some studies evidencing correlations with temperature or humidity.
Objective: To determine the influence of meteorological conditions near date of conception on the occurrence of preeclampsia .**Methods:** Maternal, obstetrical and neonatal data on all pregnancies occurring in the French department of Yvelines were prospectively recorded between January 2007 and June 2010. Daily temperature, humidity, rainfall and sunlight intensity were provided by the French meteorological agency (Meteo France) then averaged near the Estimated Date of Conception (EDC): ten days around the EDC, ten days and thirty days after the EDC. Associations between occurrence of preeclampsia in singleton pregnancies and meteorological parameters were investigated with Poisson regression models adjusted on maternal age; past history of preterm birth and caesarean section; previous pregnancy; gender of child ; urban/rural profile of place of living.
Results: Preeclampsia occurred in 353 of the 46339 singleton pregnancies recorded during the study period (0.8%). The incidence of preeclampsia was not different according to month of conception. Furthermore, no meteorological parameters seemed to influence occurrence of preeclampsia, whatever the timing considered. At last, place of living (urban vs rural) did not influence the risk of preeclampsia.
Conclusion: In our cohort study - adequately powered to detect OR as small as 1.5 – there was no evidence of any influence of temperature, humidity, rainfall nor sunlight intensity near the EDC on the risk of preeclampsia. However, incidence of preeclampsia was lower than incidences generally measured in other studies (from 1.8 to 7%). In order to understand the association between meteorological conditions and adverse events in pregnancies, outcomes and measures of meteorological factors must be more accurately defined.

REVIEW OF METHODS AND APPROACHES USED TO EVALUATE HEALTH INTERVENTIONS IN NATURAL ENVIRONMENTS: A CONTRIBUTION TO THE DEVELOPING GREEN SPACE AND HEALTH EVIDENCE BASE

Aileen Marshall Brown, *University of Highlands and Islands, UK*
Lucy Johnston, *University of Highlands and Islands, UK*

Background and aims: The University of Highlands and Islands led a UK initiative, the "Outdoors and Health Network" (OHN) funded by the UK's Economic and Social Research Council and Medical Research Councils in 2009/10. An emergent finding from the network was an identified gap in the critical review of the research approaches taken in evaluating health interventions in natural environments. The review aimed to provide recommendations for strengthening the research methods used to evaluate health interventions in the natural environment. Whilst the links between health and natural environments have been well documented, the most effective ways in which environments can be used to improve health remains largely elusive. By scrutinising intervention evaluations, the ways the natural environment can be utilised for health improvement will be clearer. More importantly the green space and health knowledge base will become more transparent and its current limitations and potential better understood.
Methods: A search strategy and inclusion criteria were developed. Data from each of the included evaluation reports was extracted into a pre-determined template, framed around five key review questions.
Results: Forty evaluations were reviewed. The review findings illustrate how current evaluation methods and approaches can be strengthened. Health interventions and natural environments are both complex and dynamic. The results suggest that evaluation methods are currently not complex and dynamic enough to capture and interpret the processes and outcomes relevant to health interventions in the outdoors.
Conclusions: Given the limitations of some methods and weaknesses in application within this area of enquiry, the review concludes that the developing knowledge base from evaluations of interventions is problematic, under-developed and under-utilised. The evidence base for green space and health could be strengthened by more effective use of mixed methods by multi-disciplinary teams; increased use of existing evidence, increased coordination of evaluation input and enhanced guidance and training.

VOLATILE ORGANIC COMPOUNDS AIR CONCENTRATIONS AND RESPIRATORY SYMPTOMS IN MEXICAN INFANTS FROM MOTHERS WHOSE PARTICIPATED IN A RANDOMIZED CLINICAL TRIAL DURING PREGNANCY

Usha Ramakrishnan, *Rollins School of Public Health, Emory University, Atlanta, GA, USA*
Isabelle Romieu, *International Agency for Research on Cancer, Lyon, France*

Background and Aims: Early exposure to air pollution is crucial in the development of the immune response. Supplementation with omega-3 may be a protective factor for the development of allergic diseases. We realized the present analysis to determine the impact of air pollution on respiratory symptoms in infants and evaluate the interaction between supplementation with omega-3 fatty acids and air pollution exposure in this population.
Methods: We included 924 infants whose mothers were randomly assigned to receive daily supplement of 400 mg of DHA or placebo from week 18-22 of pregnancy until childbirth. During pregnancy we collected information on sociodemographics characteristics, past health history and environmental exposure. Also, we determine maternal specific IgE levels in plasma. Child respiratory symptoms information was collected using a recall questionnaire at 1, 3, 6, 9, 12 and 18 months of age. For environmental exposure, we conducted local monitoring of air pollution (NO_2 and Volatile Organic Compounds（BTX) in deferent city sites and the association between respiratory symptoms and air pollution exposure were analyzed using Poisson regression models.
Results: The occurrence of respiratory symptoms did not differ significantly between groups. However, the occurrence of a combined measure of some symptoms was lower in the DHA group. The heptane, hexane and xylene air concentrations were significantly related to respiratory symptoms (cough, nasal congestion and/or runny nose) ($p<0.05$). We did not observe a potential interaction between treatment groups and air pollution exposure.
Conclusions: Exposure to heptane, hexane and xylene (BTX) air concentrations in the general environment increase the respiratory symptoms in Mexican Infants.

ASSESSING LITTLELEAF LINDEN (*TILIA CORDATA)* AND NORWAY MAPLE (*ACER PLATANOIDES)* LEAVES AS MEDIA FOR MONITORING HEAVY METAL AIR POLLUTION IN WINDSOR, ONTARIO, CANADA

Alice Grgicak-Mannion, *Great Lakes Institute for Environmental Research, University of Windsor, Ontario, Canada*
Lindsay Miller, *Department of Civil and Environmental Engineering, University of Windsor, Windsor, Ontario, Canada*
Joel Gagnon, *Department of Earth and Environmental Sciences, University of Windsor, Ontario, Canada*
Hongcheng Zeng, *Great Lakes Institute for Environmental Research, University of Windsor, Windsor, Ontario, Canada*
Brian J. Fryer, *Great Lakes Institute for Environmental Research, University of Windsor, Ontario, Canada*

Background and Aims: Epidemiological studies have shown correlations between traffic-related and other air pollutants and medical conditions [1-3]. Health agencies routinely rely on a limited number of fixed active and passive monitoring devices to measure regional/local air quality over fixed times. Increasing the number of monitoring sites is beneficial yet cost prohibitive (equipment, personnel and analytical costs); novel monitoring strategies are required. We investigated Littleleaf Linden and Norway Maple leaves in Windsor, an industrial border city in southwestern Ontario, Canada, sharing the world's busiest trade route with industrial neighbour, Detroit, Michigan, U.S., as potential air quality monitors for heavy metals near roads with varying traffic/industrial sources.
Methods: Co-located trees were allocated using a geospatial random stratified approach: traffic counts, road type and a buffered distance of 200 m were the main selection criteria. Leaves were collected from these trees over eight two-week periods in 2010. Thirty-eight elements were analyzed using ICP-MS; 11, using ICP-OES. NIST standards were used for QA/QC. EDAX-SEM was used for forensic validation of particle composition of ICP-MS and ICP-OES analytics.
Results: At two expressway sites, Sr concentrations up to 2,000 ppm were observed. These leaves were placed under the EDAX-SEM; angular mineral fragments were found to contain K, Sr, Ca and Si. At three sites, concentrations of Pb up to 1.2ppm and Fe up to 350ppm were observed. Under the microscope, spherical, striated particles containing Pb, Fe, and Ni, potentially indicate a steel manufacturing source [4]. At the expressway and a residential area, concentrations of Ni up to 60ppm and Mo up to 30ppm were observed. Under the microscope, spherical particles indicated Mo, Ni and Co, potentially a localized mobile source.
Conclusions: In the pilot study, leaves from Littleleaf Linden and Norway Maple proved highly effective air quality monitors for heavy metals in Windsor, Ontario and effective media for elemental forensic analyses.

MAPPING ENVIRONMENTAL HAZARDS AND BLACK CARBON MEASUREMENTS IN AN IMMIGRANT COMMUNITY

Thu Quach, *Cancer Prevention Institute of California, USA*
Julie Von Behren, *Cancer Prevention Institute of California, USA*
My Tong, *Cancer Prevention Institute of California, USA*
Robert Gunier, *Cancer Prevention Institute of California, USA*
Andrew Hertz, *Cancer Prevention Institute of California, USA*
Scarlett Gomez, *Cancer Prevention Institute of California, USA*
Lisa Fu, *California Healthy Nail Salon Collaborative, USA*
Erika Garcia, *Cancer Prevention Institute of California, USA*
Peggy Reynolds, *Cancer Prevention Institute of California, USA*

Background and Aims: The Vietnamese population in the US is a rapidly growing immigrant group. This population shows increasing trends for many chronic health problems with increasing number of years in the US, which may be attributed in part to environmental stressors. The objective of this project is to use qualitative and quantitative methods to identify and characterize neighborhood-level environmental hazards for the Vietnamese population in California. Key to this work is the integrated participation and perspective of Vietnamese community members to identify and prioritize elements of their community that potentially impact their health.

Methods: Community members (N=35) from two counties in California were recruited and trained to conduct walking street audits of environmental hazards in neighborhoods where they live and work. Each street segment was approximately one city block long. Participants carried GPS devices, collected black carbon measurements using small real-time personal monitors, conducted five-minute car and truck counts and used Photovoice documentary methods.

Results: The walking audits were conducted on 144 street segments, of which 45% were in business areas and 55% in residential areas. The mean five-minute truck count was 2 (range: 0 -10) on business streets and 0.3 (range: 0-4) in residential areas. The median level of black carbon was 1.3 µg BC/m3 (range: 0-41). Observational audit survey data highlighted issues around litter and smoking, as well as traffic-related odors and noise. Qualitative data from Photovoice and written comments from auditors reflected concerns around neighborhood safety.

Conclusions: We successfully engaged community members in collecting qualitative and quantitative environmental data on their local neighborhoods. Comparisons between these community-collected snapshot data to governmental monitoring data for traffic and black carbon will help inform how well existing secondary data can capture perceived local environmental hazards and how the community-collected data can be used to enhance existing environmental measurement data.

Spatial patterns of personal exposure to particulate pollution in Accra neighborhoods

Raphael E Arku[a], Kathie L Dionisio[a,b], Zheng Zhou[a,b], Jose Vallarino[a], Allison F Hughes[e], John D Spengler[a], Samuel Agyei-Mensah[c,d], Majid Ezzati[f *]

[a]Department of Environmental Health, Harvard School of Public Health, Boston, MA 02115; [b]Department of Global Health and Population, Harvard School of Public Health, Boston, MA 02115; [c]Environmental Science Program, University of Ghana, Legon 25, Ghana; [d]Department of Geography and Resource Development, University of Ghana, Legon 25, Ghana; [e]Department of Physics, University of Ghana, Legon 25, Ghana; [f]MRC-HPA Center for Environment and Health, Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London W2 1PG, UK

Background and Aims

Spatial and temporal patterns of particulate matter (PM) pollution in cities of developing countries differ from those in high-income countries due to differences in sources. While recent studies have assessed the spatial patterns of PM pollution in developing country cities, little is known about personal exposure to PM and how it is affected by ambient concentration and time-location-activity budgets. Our aim was to characterize the spatial patterns of exposure to fine PM for students in four Accra neighborhoods.

Methods

We measured 24-hour integrated and continuous $PM_{2.5}$ exposure for 52 students in four neighborhoods of Accra. Exposure was measured by the subject wearing a backpack fitted with portable PM monitors and GPS units. We concurrently measured ambient $PM_{2.5}$ at fixed monitoring sites in the four neighborhoods. Questionnaires were used to collect additional information about kitchen characteristics, household fuel use and exposure behaviors.

Results

Mean personal 24-hr exposure concentration of the students was 94$\mu g/m^3$, ranging between 26 $\mu g/m^3$ and 283$\mu g/m^3$. Mean exposures by neighborhood were between 70 and 126$\mu g/m^3$. The correlation between average ambient concentrations and average personal exposure concentrations was 0.39.

Conclusion

School children's exposure to $PM_{2.5}$ in Accra neighborhoods is substantially higher than WHO Air Quality Guidelines. Epidemiological studies of air pollution health effects need to use exposure indicators that account for its spatial patterns.

ENVIRONMENTAL DISEASE DISPARITIES AMONG AMERICAN INDIANS

David F Goldsmith, *George Washington University, Washington DC, USA*
Bonnie S Hillsberg, *Center for Medicare & Medicaid Services, Baltimore, MD USA*

Background: American Indians, like many indigenous communities throughout the world, have patterns of excess disease compared to society as a whole. In the US, the overall mortality risk for Indians is 1.56 times that of whites. This evaluation will examine the role of environment plays in disease disparities among American Indians, and the funding to address them. There are clear-cut mortality differences that Native Americans have in contrast to white Americans: unintentional injuries; suicide; homicide; alcohol related causes, including fetal alcohol syndrome; chronic liver disease/cirrhosis; and diabetes.
Environmental components: Defining "environment" broadly, all of the excess causes of death listed above, except suicide, are linked strongly with dietary or personal environment. There has been success in reducing the environmental disparity gap in tuberculosis by improving clinical control of TB among all Indian communities from the 1970s to recent years. But it is clear with regard to diabetes and alcohol-related illnesses that community primary prevention efforts, including improving diets and access to healthy foods, and alcohol abuse prevention are essential to reducing the disparities we now see.
Medical costs: In general, costs for treating excess environmental diseases such as unintentional injuries; suicide; homicide; alcohol related causes; chronic liver disease/cirrhosis; and diabetes are borne by individuals, by the tribes and their judicial systems, the Indian Health Service, and the Center for Medicaid and Medicare Services. Politics plays a significant role in securing resources for both prevention and treatment.
Conclusions: Community-based prevention programs and obtaining sufficient treatment resources are keys to reducing the disparities in environmental diseases in American Indian country.

FUTURE ENVIRONMENTAL HEALTH ALONG THE LINES OF FOOD, WATER, ENERGY AND CLIMATE: AN INTEGRATED MODELLING APPROACH

Henk Hilderink, *PBL, the Netherlands*
Paul Lucas, *PBL, the Netherlands*

Background Aims: Health can be considered as one of the most important constituents of quality of life. In many of the global assessments, the health dimension was underrepresented. The health module of the Population& health model PHOENIX has been refined and further developed to be able to explore how future health will evolve. The main purpose of it is to describe future health status using of the concept of the health transition, given changes in socio-economic and environmental conditions. The main purpose of the health model is to describe the burden of disease by sex and age.
Methods: The methodology is a multi-state modeling approach which largely follows the approach as described in the World Health Report 2002 (WHO, 2002), the Disease Control Priorities Project (DCPP) (Cairncross and Valdmanis, 2006) in combination with that Global Burden of Disease methodology (Mathers and Loncar ,2005). The states distinguished in the model are exposure, disease states and death. The dynamic and integrated character of the proposed methodology is represented by the risk factor-attributable mortality and morbidity. This component is strongly connected with the socio-economic and environmental domain.
Results: The most relevant health risk factors and the associated diseases have been included, with a special focus on environmental risks. Food and hunger, Water supply and sanitation, climate change and malaria, energy supply and indoor / outdoor air pollution are amongst the risk factors included, covering already a substantial part of the health-related Millennium Development Goals (MDG).
Conclusions: Exploration of existing consistent socio-economic and environmental baseline scenario shows that many of the health-MDGs will not be attained, given current MDG-policy targets. Additional analyses also show that health loss can be substantially reduced by various health policy packages, especially in South Asia and Sub Saharan Africa.

THE EFFECT OF DISINFECTION BY-PRODUCTS, WATER SOURCE, AND TYPE OF DISINFECTION IN PREGNANCY LOSS IN MASSACHUSETTS

Zorimar Rivera-Núñez, *National Research Council, Washington DC*
J. Michael Wright, *National Center for Exposure Assessment, Office of Research and Development, US Environmental Protection Agency, Cincinnati, OH*

Background and Aims: Previous research suggests that exposure to different water sources, disinfection type (e.g., chlorinated surface water), and disinfection by-products (DBPs) may be associated with pregnancy loss. We assessed the potential risk of water source, disinfection type, and DBPs on pregnancy loss in Massachusetts.
Methods: We used birth and death certificate data on 510,264 pregnancies to examine this risk using 1998• 2004 data from 275 Massachusetts towns. Fetal loss was defined as losses after the 20th week of gestation, and was examined using logistic regression.
Results: Based on 2,488 pregnancy losses, preliminary unadjusted results indicate that mothers using public surface water systems had an increased risk of fetal loss (Odd Ratios (ORs) =1.37; 95% CI: 1.24,1.51) compared to mothers using ground water sources. Following adjustment for confounding by maternal risk factors (i.e., age, race, education, tobacco use), and disinfection type, this risk was attenuated (OR= 0.98; 95%CI: 0.85, 1.13). Compared to untreated water systems, mothers using chlorinated and chloraminated public water systems had an increased risk of fetal loss with ORs of1.15 (95%CI: 1.01, 1.33) and 1.36 (95% CI: 1.17, 1.58), respectively. ORs of 1.01 (95% CI: 0.85, 1.21) and 0.97 (95% CI: 0.79, 1.19) were found following adjustment for confounding by maternal risk factors and source water. No increased risk was found for the relationship between trihalomethanes (sum of chloroform, bromodichloromethane, dibromchloromethane, and bromoform) and fetal loss in any exposure category compared to the lowest (0 µg/L) category. Similarly, no increased risk was found for the relationship between haloacetic acids (sum of monochloroacetic acid, dichloroacetic acid, tricholoroacetic acid, bromoacetic acid, and dibromoacetic acid) and fetal loss in any exposure category compared to the lowest (0 µg/L) category.
Conclusions: Further analyses will include fetal loss data from 1996-1997 and will utilize other statistical approaches such as Poisson regression.

A Methodology to Estimate Canadians' Exposure to Tetrachloroethylene in Outdoor Air Using Industrial and Micro-Emitter Databases

Alejandro Cervantes-Larios, *University of British Columbia, Canada*
Perry Hystad, *University of British Columbia, Canada*
Eleanor Setton, *University of Victoria, Canada*
Brian Klinkenberg, *University of British Columbia, Canada*
Paul A. Demers, *Cancer Care Ontario, Canada*

Background and Aims: As part of Carex Canada, we developed a methodology for estimating tetrachloroethylene (PERC) concentrations in outdoor air at approximately 478,000 street block centroids in Canada. We combined five different databases in a Geographic Information System: PERC levels measured at National Air Pollution Surveillance (NAPS) monitors, large emitter data from the National Pollutant Release Inventory (NPRI), small emitter information from Environment Canada's Annual Report for Dry Cleaners (DC) and the Dunn & Bradstreet (D&B) commercial registry, and population information from Census Canada.
Methods: Concentration estimates were assigned to each of 478,000 block centroids in three steps: first, a background concentration (rural or urban) was derived using data from NAPS air monitors (n = 53); second, Screen3 (a dispersion model developed by the U.S. Environmental Protection Agency) was applied to known industrial and micro-emitters; third, concentrations derived from the dispersion model were added to the background value at those street blocks that fell within the model's distance of influence. Micro-emitter emission rates ranged from 0.01 to 0.7g/s and were approximated considering yearly amounts of PERC consumed and type of equipment used.
Results: Concentrations are very heterogeneous across Canada, (min=0.12 µg/m3, max=132 µg/m3, mean=1.12 µg/m3, std. dev= 3.62µg/m3). On average, Canadians live 11.3 kilometres (km) from a PERC emitter and 71 km from a NAPS monitor that measures PERC. However, almost 5.5 million people live within 500 meters of a known emitter and those are on average at 23 Km from a monitoring station. Our preliminary results suggest that approximately 15% of all street blocks in Canada, where 31% of the population live, have PERC concentrations 10 to 20 times higher than those reported by the NAPS network.
Conclusions: We describe a novel approach for calculating environmental exposure to PERC by incorporating spatial data sets of known emitters. Our findings confirm that utilizing only the measured concentrations from the NAPS network is insufficient and would likely underestimate population exposures.

LONG-TERM EXPOSURE TO AMBIENT AIR POLLUTION AND LUNG CANCER RISK IN CANADA

Perry W. Hystad, *University of British Columbia, Vancouver, Canada*
Paul A. Demers, *Cancer Care Ontario, Canada*
Kenneth C. Johnson, *Public Health Agency of Canada, Canada*
Michael Brauer, *University of British Columbia, Vancouver, Canada*

Background and Aims: Previous studies have identified air pollution exposure as a risk factor for lung cancer incidence. We examine lung cancer risk in Canada from exposure to long-term ambient air pollution.
Methods: We utilize the lung cancer component of the National Enhanced Cancer Surveillance System, which includes 3280 lung cancer cases, with histology, and 5073 population controls collected between 1994 and 1998 in eight Canadian provinces. Cases were identified by provincial cancer registries and sent a research questionnaire (61.7 % response rate for contacted lung cancer cases). Questionnaires collected information on family income, education, marital status, BMI, smoking history, second-hand smoke exposure, alcohol use, dietary history, physical activity, and lifetime occupational exposures and residential histories (geocoded to 6-digit postal codes). Population controls, with an age/sex distribution similar to that of all cancer cases, received the same questionnaire (67.4% response rate for contacted controls).
A spatiotemporal modeling approach was used to estimate individual's annual air pollution exposures from 1970 to 1994 for PM2.5, NO2, and O3. Residential postal codes within 50km's of fixed-site monitoring stations were assigned annual average concentrations. Postal codes located farther than 50km's from a monitoring station were assigned predicted annual concentrations from national spatial pollutant surfaces, created from recent satellite-based (PM2.5 and NO2) and dispersion models (O3), calibrated with historical fixed-site monitoring data.
Results: Odds ratios (95%CI) for lung cancer incidence associated with a 10-unit increase in PM2.5 (ug/m3), NO2 (ppb) and O3 (ppb) were 1.31 (1.00-1.72), 1.14 (1.04-1.26) and 0.84 (0.67-1.06), respectively, after adjustment for 17 individual and 4 geographical covariates. Differences in risk were also found by lung cancer histology.
Conclusions: Long-term exposure to PM2.5 and NO2 air pollution was associated with increased lung cancer risk in Canada.

FUTURE PROJECTIONS OF THE DISEASE BURDEN OF URBAN AIR POLLUTION

Henk Hilderink, *PBL, the Netherlands*
Frank De Leeuw, *RIVM, the Netherlands*
Jan Wijbe Hoekstra, *PBL, the Netherlands*

Background Aims:: Human health effects from exposure to outdoor air pollution, particularly ground level ozone and airborne particulate matter (PM), cause globally, 8% of lung cancer deaths, 5% of cardiopulmonary deaths and around 3% of respiratory infection deaths (Prüss-Üstü, A and C. Corvalán, 2009). These impacts can be expected to increase even further given increasing emissions, an ongoing urbanization and an ageing population.
Method: The Global Urban Air quality Model (GUAM) has been developed to estimate PM_{10} concentrations and their attributable effects on human health for the largest 3200 cities in the world. GUAM originates from the GMAPS model (World Bank, 2002) and links observed PM_{10} concentrations to a set of variables of economic activity, population, urbanization and meteorological information. The resulting concentrations lead to increased health effects of acute respiratory diseases, lung cancer, and cardiopulmonary diseases. These health impacts are derived using the global burden of disease methodology (Mathers and Loncar, 2005).
Results: Air pollution has been projected over the period 2000-2050 using a baseline scenario for emissions, population and urbanization. The concentrations will increase in many regions. The associated annual number of deaths will increase from 1 million in 2004 till 3.5 million in 2050 with the vast majority occurring in Asia. Next, uncertainty analyses have been performed to test the robustness of the methodology. These outcomes have been decomposed by changes in population, ageing, urbanization and emissions.
Conclusions: To a large extend increases in the future disease burden of air pollution are determined by trends that can not be influenced and relatively small fraction is due to increased emissions.

ESTIMATING THE EFFECTS OF LONG-TERM EXPOSURE TO AMBIENT PARTICULATE AIR POLLUTION ON BIOLOGICAL MARKERS OF CARDIOVASCULAR RISK IN A COHORT OF MIDLIFE WOMEN

Background and Aims: Several studies have reported associations between long-term exposure to fine particulate matter ($PM_{2.5}$ or particles less than 2.5 microns in diameter) and cardiovascular mortality. However, uncertainty remains about the biological mechanisms underlying the disease process. We examined the effect of $PM_{2.5}$ on serum markers of cardiovascular disease risk in a cohort of midlife women.
Methods: Midlife women enrolled at six sites in the multi-ethnic, longitudinal Study of Women's Health Across the Nation (SWAN) had repeated measurements of several cardiovascular markers, including LDL, HDL, C-reactive protein, fibrinogen, tissue-type plasminogen activator antigen (tPA-ag), plasminogen activator inhibitor Type 1 (PAI-1), and Factor VIIc. These data were merged with ambient exposure data over 5 consecutive annual visits (1999-2004) using $PM_{2.5}$ monitors located within 20 kilometers of the geocoded residence. Monitor measurements were averaged for the preceding year, 6 months, 1 month and 1 day prior to each blood draw visit.
Results: A total of 2,191 women (990 Caucasian, 598 African American, 241 Japanese, 193 Chinese, and 169 Hispanic) were eligible for analysis; mean age at the beginning of the study period was 49 years. The $PM_{2.5}$ annual average across the SWAN sites for all visits ranged from 12.1 to 20.8 mg/m^3. Our analysis examined the association between $PM_{2.5}$ and the blood markers using longitudinal linear mixed regression models, taking into account other air pollutants, temperature, body mass index, race/ethnicity, age, smoking, socioeconomic status, menopausal status, health history, and medication use. Preliminary results for the association of $PM_{2.5}$ with the cardiovascular markers will be presented.
Conclusions: This is the first study to use repeated measures to examine the longitudinal association between blood markers of cardiovascular disease risk and $PM_{2.5}$ in a multi-ethnic, longitudinal cohort of women going through the menopausal transition.

Florence Rouget, *INSERM U625, University of Rennes I, IRSET, France*
Sylvaine Cordier, *INSERM U625, University of Rennes I, IRSET, France*

Background and Aims: Some studies have shown that household pesticide use, indoor or outdoor, may entail significant exposure. Besides, some of these pesticides are suspected to be toxic for development. Our purpose was to determine whether household use of pesticides in early pregnancy was associated with impaired fetal growth of the babies.
Methods: A mother-child cohort (PELAGIE) was conducted in Brittany (France) and enrolled 3421 pregnant women before 19 gestational weeks between 2002 and 2006. Birth weight and head circumference were collected from maternity records. A questionnaire of self-reported household use of pesticides in early pregnancy was collected when the child reached 2 years for 44% of the cohort (n=1505). Scores of exposure to eight pesticide uses were built according to the user, frequency, type of products, and place of use, assuming that these differences in use corresponded to different exposure levels Adjusted means of fetal growth indicators were performed from multivariate linear models.
Results: A decrease in birth weight was observed with increasing score of exposure to pesticides used on outdoor plants (no use: mean=3387 g; score<median: mean=3351 g; score>median: mean=3278 g; p-trend=0.001). A decreased head circumference was observed with increasing score of exposure to insecticides used on paths and lawns (no use: mean=34.9 cm; score<median: mean=35.1 cm; score>median: mean=34.3 cm; p-trend=0.01), and to a lesser degree with increasing score of exposure to pesticides used to treat wood framework.
Conclusions: Our study observed a possible impact on fetal growth of household use of pesticides during pregnancy, in particular to treat plants. We proposed a scoring method to improve assessment of household pesticide exposure. This scoring method appears to be efficient, taking into account all details reported in the questionnaire, and allows to assess dose-response relationships.

FREQUENT USE OF HOUSEHOLD CLEANING SPRAYS AND DECREASES IN HEART RATE VARIABILITY IN SAPALDIA

Nino Künzli, *Swiss TPH, Basel, Switzerland*
Nicole Probst-Hensch, *Swiss TPH, Basel, Switzerland*
and SAPALDIA-Team

Background and Aims: Household cleaning products are an indoor source of exposure to volatile organic compounds and toxic air contaminants. We investigated if non-professional use of household cleaning and air freshening sprays, and scented products was associated with reduced heart rate variability in the Swiss Cohort Study on Air Pollution and Lung and Heart Diseases in Adults (SAPALDIA).
Methods: In a cross-sectional survey, 24-hour electrocardiograms were recorded in 580 randomly selected SAPALDIA participants • 50 years of age, who also reported cleaning activities in their homes. Of the 580 participants, 515 reported use of any household spray or scented product, and 65 did not report use to any product and were considered unexposed. Adjusted average percent changes in standard deviation of all normal-to-normal intervals in 24-hours (24-hr SDNN), total power (TP), low frequency (LF), and high frequency (HF) were estimated in association with frequency (< 1, 1-3, and 4-7 days/week, unexposed as reference) of using cleaning sprays, air freshening sprays, and scented products in separate multiple linear regression models after adjustment for potential confounders. Smoking status, markers of systemic inflammation, and presence of chronic airways disease were evaluated for effect modification.
Results: Statistically significant ($p<0.05$) decreases in 24-hr SDNN and TP were observed in association with frequent use of all products of interest. Relative to unexposed subjects, the strongest reductions in 24-hr SDNN (-12.2%, 95%CI: -20.6 – -2.0%) and TP (-28.8%, 95%CI: -45.7– -7.7%) were observed in subjects who used air freshening sprays 4-7 days/week. The inverse effects from using cleaning and air freshening sprays, and scented products on 24-SDNN, TP, LF, and HF were observed mainly in subjects present with chronic airways disease.
Conclusions: Chronic use of household cleaning spray products may affect autonomic dysfunction in older adults, and those with pre-existing pulmonary conditions may be more susceptible.

AIR POLLUTION EXPOSURE AND TELOMERE LENGTH IN HIGHLY EXPOSED SUBJECTS IN BEIJING, CHINA

Background and Aims. Shortened leukocyte telomere length (LTL) is a marker of cardiovascular risk that has been recently associated with long-term exposure to ambient particulate matter (PM). However, LTL is increased during acute inflammation, allowing for rapid proliferation of inflammatory cells. Whether short-term ambient PM exposure increases LTL has not been evaluated.

Methods. The Beijing Truck-Driver Air Pollution Study was conducted shortly before the 2008 Olympic Games (June 15-July 27, 2008) and included 60 truck drivers and 60 office workers. Personal $PM_{2.5}$ and Black Carbon (BC, a tracer of traffic particles) measured during work hours using portable monitors, and post-work blood samples were obtained on two different days separated by 1-2 weeks. Blood LTL was measured by real-time PCR and expressed in relative units. Ambient PM_{10} was averaged from 27 monitoring stations operating in Beijing. We have regressed log-transformed LTL over exposure variables (occupational group, personal $PM_{2.5}$, personal BC, or ambient PM_{10}) in mixed-effect models adjusted for age, gender, BMI, day of week, cigarettes/day, central heating, commuting time/day, outdoor temperature, and dew point.

Results. Mean personal $PM_{2.5}$ was 126.8 µg/m^3 (inter-quartile range[IQR]:73.9-160.5) in drivers and 94.6 µg/m^3 (IQR:48.5-126.6) in office workers (p<0.001). Covariate-adjusted LTL means were higher in drivers (0.87, 95%CI:0.74-1.03) relative to office workers (0.79, 95%CI:0.67-0.93; p=0.001). In all subjects combined, we estimated a 5.2% (95%CI:1.5-9.1, p=0.007) increase in LTL per an IQR increase in personal $PM_{2.5}$. LTL was also positively correlated with personal BC (+4.9%, 95%CI:1.2-8.8, p=0.01), and with average ambient PM_{10} on the study day (+7.7%, 95%CI:3.7-11.9, p=0.001) and over the two days before (+8.1%, 95%CI:3.1-13.3, p=0.002). Longer PM_{10} averages (e.g., 5-day) were not associated with LTL.

Conclusions. Our study showed that short-term exposure to ambient PM is associated with increased LTL. LTL may favor leukocyte proliferation and sustain the inflammatory mechanisms associated with PM health effects.

Word Count. 300

INDUSTRIAL EXPOSURES AT BIRTH ARE ASSOCIATED WITH REDUCED FORCED VITAL CAPACITY IN CHILDHOOD

Lucas Neas, *U.S. Environmental Protection Agency, NHEERL, USA*

Ann Williams, *U.S. Environmental Protection Agency, NHEERL, USA*
Luther Smith, *Alion, Inc. USA*

Background and Aims: Previous studies have focused on particulate air pollutant exposures , we examined the impact of other early life exposures on pulmonary function in childhood.
Methods: In Detroit and Dearborn, MI in 2007, we examined children aged 7 to 13 years in a clinical cohort (241 with asthma and 365 without asthma). We collected pulmonary function and exhaled nitric oxide measurements using standard ATS/ERS protocols. Using information on traffic and local point sources coupled with passive monitoring of nitrogen dioxide and petroleum-related volatile organic compounds (benzene, toluene, ethylbenzene, and xylenes), we developed land-use regression models to estimate the long-term, outdoor exposures of these children at their current residence and at their birth residence. Forced vital capacity (FVC) and other measures of pulmonary function were modelled as the natural logarithm adjusted for a random neighborhood effect; sex; race; the natural logarithms of weight, height and the interaction of height and sex; parental education; home ownership; and environmental tobacco smoke in the home.
Results: In this population, 43 percent of the children had different residences at birth. Based on their birth residence, a 100-ppt increment in modelled o-xylene was linearly associated with a 2.6 percent decrement in FVC (95% CI -4.7, -0.5) and this decrement was stronger among the 365 children without asthma (-3.2 percent, 95% CI -6.0, -0.5). Proximity to a specific industrial site was associated with a 2.2 percent decrement in FVC (95% CI -3.4, -0.1) for a 5 km increment. Other estimated petroleum-related compounds at birth residence showed similar associations, but weaker associations at their current residence.
Conclusions: Early life exposures as indexed by modelled outdoor concentrations of petroleum-related compounds for the residence at birth appear to be associated with persistent decrements in lung volumes.

Regular Breakfast and Blood Lead Levels among Preschool Children

Abstract

Background

Previous studies have shown that fasting increases lead absorption in the gastrointestinal tract of adults. Regular meals/snacks are recommended as a nutritional intervention for lead poisoning in children, but epidemiological evidence of links between fasting and blood lead levels (B-Pb) is rare. The purpose of this study was to examine the association between eating a regular breakfast and B-Pb among children using data from the China Jintan Child Cohort Study.

Methods

Parents completed a questionnaire regarding children's breakfast-eating habit (regular or not), demographics, and food frequency. Whole blood samples were collected from 1,344 children for the measurements of B-Pb and micronutrients (iron, copper, zinc, calcium, and magnesium). B-Pb and other measures were compared between children with and without regular breakfast. Linear regression modeling was used to evaluate the association between regular breakfast and log-transformed B-Pb. The association between regular breakfast and risk of lead poisoning (B-Pb≥10 μg/dL) was examined using logistic regression modeling.

Results

Median B-Pb among children who ate breakfast regularly and those who did not eat breakfast regularly were 6.1 μg/dL and 7.2 μg/dL, respectively. Eating breakfast was also associated with greater zinc blood levels. Adjusting for other relevant factors, the linear regression model revealed that eating breakfast regularly was significantly associated with lower B-Pb (*beta*=-0.10 units of log-transformed B-Pb compared with children who did not eat breakfast regularly, p=0.02).

Conclusion

The present study provides some initial human data supporting the notion that eating a regular breakfast might reduce B-Pb in young children. To our knowledge, this is the first human study exploring the association between breakfast frequency and B-Pb in young children.

ABSTRACT ISEE Barcelona 2011

Title: Respiratory health in firefighters

Background The aim of the present study w as to determine associations betw een respiratory health and exposure to smoke of fires.

Methods

The studies comprised 3 subsequent stages. First, all active firefighters of the municipal fire brigades of 3 provinces in the Netherlands were invited to fill in a web-based questionnaire. Second, a randomly chosen subset of 402 firefighters underwent spirometry and methacholine provocation, and blood samples were taken to assess atopy and serum pneumoproteins. Third, 51 exposed subjects of the second stage were enrolled in the third stage of the study when they were exposed to fire smoke and a blood sample could be obtained within 24 hours post-exposure. Sputum was induced within 5 days following exposure, and after at least 24 hours more spirometry and bronchial responsiveness testing was carried out and a second blood sample was taken. After three months a third blood sample was taken. In serum pneumoproteins and cytokines were assessed.

Results

Significant positive associations were found between exposure to fire smoke and respiratory health parameters (respiratory symptoms, bronchial hyperresponsiveness, serum pneumoproteins and cytokines) with and without adjustments for smoking, sex, atopy, age and main job exposure.

Conclusions

The results suggest that the risk of health consequences of exposure to fire smoke is underestimated in public and occupational health. From a practical point of view, reduction of exposure to fire smoke could be achieved relatively easy when first responders are instructed about these health consequences and how to reduce fire smoke exposure.

The Construction of Healthy Environments in Ceilândia, Brasilia, Brazil, 2011.

Ryckardo Rodrigues – *University of of Brasilia*
João Paulo Rodrigues – *University of of Brasilia*
Maria Madalena Torres– *Communitie of Ceilândia*

Background and Aims: Ceilândia is one of the most populated areas of Distrito Federal having around 350,000 residents. Originated from the Campaign for Eradication of Invasions (CEI), it was born during the process of the social space segregation plan that guided the construction of Brasilia, Brazil's capital. An important part of the over 60.000 workers who built Brasilia in the 60s were reallocated to Ceilândia, turning it into one of the largest slums (favelas) in Brazil in the 80s. Even in an inappropriate place, the organization and struggle of its population resulted in access to public policies such as sanitation, energy, telecommunications and, more recently, the creation of a new campus of the University of Brasilia. **Methods:** This study aims to understand and analyze social environmental risks which might compromise the quality of life of vulnerable population groups living in Ceilândia. Moreover, it is expected to contribute to the transformation of this reality through the proposal of sustainable actions involving social networks, the brazilian public health system (SUS) and other related sectors (environment, education, culture, work). The chosen methodology to cope with these objectives involved a mapping of the existing local organizations and actors which work in health promotion of the quality of life and construction of healthier environments. This mapping resulted in a database of the contacts and profiles of these groups that can be used to promote networking and strengthening of common projects. **Results and conclusions:** Thirteen sessions of Cinema Club were an important strategy to meet and discuss problematizing subjects with residents of the city related to the promotion of healthy environments. At the end were set priorities for the development of demonstration projects in partnership with society.

A SCREENING TOOL FOR CLIMATE CHANGE POPULATION VULNERABILITY ASSESSMENTS

Paul English, *California Department of Public Health, USA*
Max Richardson, *California Department of Public Health, USA*
Rachel Morello-Frosh, *University of California, Berkeley, USA*
Manuel Pastor, *University of Southern California, USA*
James Sadd, *Occidental College, USA*
Michael Jerrett, *University of California, Berkeley, USA*
William Jesdale, *University of California, Berkeley, USA*

Background and Aims: Conducting vulnerability assessments is one of the key tools for adaptation for climate change. Population vulnerability screening is needed to guide policy makers in planning efforts to address climate change impacts. California has proceeded in implementing cap and trade as a regulatory method to mitigate greenhouse gas (GHG) emissions. Decision-makers need to determine whether there are ways to target GHG mitigation schemes in ways that maximize community-level health benefits from co-pollutant reductions and minimize the likelihood that market-based approaches produce or exacerbate disparities in health benefits.

Methods: We utilized an existing environmental justice screening method and targeted it for two areas in California which are likely to experience climate change impacts, Fresno and Los Angeles counties. This method maps cumulative impacts and vulnerability to air pollution and models the locations of pollutant sources as well as vulnerable populations. We further adapted this method with metrics that are associated with adaptation capacity such as population sensitivities (e.g. , elderly living alone and senior housing), air conditioning ownership, green space, co-morbidities, and flood and wildfire risk.

Results: A cumulative climate change vulnerability score was computed for each census tract for the two counties. A separate score for the climate change vulnerability and environmental justice layers, and a combined score, was computed. The predictive power of the scores was validated by examining the sensitivity to emergency room and hospitalization data for heat-related illness.

Conclusions: We developed a geospatial mapping resource that identifies climate change vulnerable populations in two major metropolitan areas of California. This tool can be used by multiple stakeholders to identify locations of high cumulative exposures to environmental hazards and social vulnerability that may require targeted efforts to promote adaptation to climate change impacts, and increase the likelihood that mitigation strategies will yield maximum decreases in localized co-pollutants.

TRAFFIC RELATED AIR POLLUTION AND REGIONAL AIR QUALITY ARE ASSOCIATED WITH AUTISM

Heather E. Volk, *University of Southern California, USA*
Frederick Lurmann, *Sonoma Technology, Inc., USA*
Bryan Penfold, *Sonoma Technology, Inc., USA*
Irva Hertz-Picciotto, *University of California at Davis, USA*
Rob McConnell, *University of Southern California, USA*

Background and Aims: Autism is a developmental disorder with rising prevalence. Examination of regional pollutants has suggested the importance of air toxics in autism etiology, yet little research has examined local level air pollution exposure beyond measures of roadway proximity. In this study we investigate the relationship between traffic related air pollution (TRP), regional air quality, and autism.
Methods: This study analyzed data on 303 autism cases and 259 typically developing controls enrolled in the Childhood Autism Risks from Genetics and the Environment (CHARGE) Study. Autism diagnosis was confirmed from evaluations conducted at the M.I.N.D. Institute. The mother's address from the birth certificate and addresses from a residential history questionnaire were geo-coded and used to determine residential location for the first year of life and each trimester of pregnancy. TRP estimates were assigned to each location using the CALINE4 line-source air-quality dispersion model. Regional air pollutant measures were assigned using the EPA's Air Quality System data. Logistic regression models were fit comparing estimated first year pollutant levels for autism cases vs. typically developing controls.
Results: Cases were more likely to live at residences with the highest quartile of TRP exposure as compared to controls (OR 2.02, 95%CI 1.25-3.28). Measures of regional $PM_{2.5}$ and PM_{10} also increased autism risk (2.10, 1.18-3.76 per 8.8 $\mu g/m^3$ $PM_{2.5}$ and 2.15, 1.22-3.84 per 12.4 $\mu g/m^3$ PM_{10}). Results were relatively unchanged after including covariates.
Conclusions: Exposure to both regional and local air pollutants was associated with autism risk. Further examination of specific air pollution measures is needed to better understand this association.

SAFE NEIGHBORHOODS MAKE CHILDREN MOVE; RESULTS FROM THE SPATIAL PLANNING AND CHILDREN'S EXERCISE (SPACE) STUDY

Frank Pierik, *Expertise center Earth, Environmental and Life Sciences, TNO, The Netherlands*

Sanne de Vries, *Expertise center Lifestyle, TNO, The Netherlands*

Background and Aim: The effectiveness of urban planning interventions for physical activity (PA) levels and obesity is largely unknown. This study aimed to examine the effect of changes in the built environment on walking and cycling in children.
Methods: The population involved 448 children (aged 6- 12 years) in 2004 and 292 children in 2008 from five Dutch neighborhoods that were partially restructured between 2004 and 2008, and five control neighborhoods. In 2004 and 2008, walking and cycling behavior was assessed by a 7-day physical activity diary, and built environmental characteristics were assessed by neighborhood observation. Anthropometric values were also collected. Multilevel linear regression analyses were conducted to identify environmental determinants of children's walking and cycling behavior. Analyses were adjusted for age, sex, parental education level, and ethnicity.
Results: In 2004, children made on average 13.3 walking and 6.6 cycling trips per week for transportation; 3.6 walking and 1.5 cycling trips per week to school; and 0.7 walking trip per week for recreation. Cross-sectional analyses showed that in 2004 both commuting modes were positively associated with the frequency of pedestrian crossings and parallel parking spaces in the neighborhood. About 30% of the variance in walking and cycling for transportation could be explained by the number of recreation facilities in the neighborhood and the walking and cycling infrastructure of the neighborhood. Longitudinal analyses indicate that improving the traffic infrastructure (slower traffic, less traffic crossings) have a positive effect on PA in children.
Conclusions: Built environmental correlates of children's walking and cycling behavior differ by purpose and by commuting mode implying a behavior-specific approach for interventions. Physical activity in children may be improved by traffic safety measures.

IMPACT OF AN INDOOR COOK STOVE INTERVENTION ON MEASURES OF SYSTEMIC INFLAMMATION

Background and Aims: Approximately three billion people use inefficient and poorly-vented indoor cook stoves, which can result in high indoor air pollution concentrations. Few studies have evaluated the cardiovascular effects of indoor biomass burning. Evidence from ambient air pollution research suggests that systemic inflammation plays a central role in the biologic pathway linking air pollution exposure and cardiovascular disease.
Methods: We conducted a pilot-level cook stove intervention in 123 Nicaraguan households. Forty women provided finger-stick dried blood spot samples at baseline and one year following the improved cook stove introduction. We measured several markers of systemic inflammation in the dried blood spots. Additionally, we measured 48-hour indoor particulate matter ($PM_{2.5}$) concentrations in a subgroup before and after improved stove introduction.
Results: Approximately half of the population reported continued use of the traditional open fire (solely or in conjunction with the improved stove) during the follow-up year. A 68% reduction in $PM_{2.5}$ was observed among the entire sample with exposure data (n=34); a larger reduction (78%) was observed among those not reporting any open fire use in the follow-up year (n=16). Among participants adopting the improved stove (n=18), we observed a 36% mean reduction (95% confidence interval: 1-71%) in C-reactive protein from baseline to follow-up; less consistent associations were observed for other inflammatory markers. We generally observed larger reductions in inflammation among obese participants.
Conclusions: This study incorporated a novel method for measuring systemic inflammation in dried blood. Mixed use of traditional and improved stoves may have limited our ability to detect consistent reductions in inflammatory markers. Given the ubiquity of traditional cook stove use combined with increasing cardiovascular disease and obesity in developing countries, cook stove research should evaluate a broader range of health effects.

BLOOD LEAD LEVELS IN SCHOOLCHILDREN LIVING NEAR TO AN INDUSTRIAL ZONE IN CALI, COLOMBIA: THE SYNERGISTIC ROLE OF SOCIOECONOMIC CONDITION

Paola Andrea Filigrana, *Universidad del Valle- Grupo Epidemiología y Salud Poblacional, Colombia*
Fabián Méndez, *Universidad del Valle- Grupo Epidemiología y Salud Poblacional, Colombia*

Background and Aims: In developing countries, distribution of health effects associated to lead sources could be differential, in particular, because greater exposure and susceptibility occur among people with lower socioeconomic condition(SEC). Northern Cali-Colombia limits with a large industrial zone producing steel, batteries and metals. According to previous reports, high concentrations of airborne lead (1.77µg/m^3) may reach population living in the area. We determined blood lead levels (BLL) in schoolchildren 6-14 years old exposed to industrial sources of lead and to evaluate the synergistic role of SEC.
Methods: A cross-sectional study was conducted in an area exposed to industrial pollutants in northern Cali. A control area was also studied and children in two schools at corresponding study areas were selected. Venous samples (5 mL) were collected in heparinized, evacuated tubes to determine BLL by graphite furnace absorption spectrometry. Using regression models we assessed risk factors for high BLL, controlling for potential confounders and evaluating the potential effect modification of socioeconomic condition.
Results: We enrolled 350 schoolchildren, 44.5% living in the exposed area. Schoolchildren in this area had higher BLL (4.7±1.6 vs. 2.9±1.2) and prevalence of BLL • 5 µg/dl (44.2% vs. 8.2%, p:0.000) than those in control area. An independent association was found between exposure and BLL • 5 µg/dL (OR:16.3; CI95%:6.7-30.1), younger age (OR:2.1; CI95%:1.1-4.1), male gender (OR:;2.7 CI95%:1.4-5.3), lower socioeconomic condition (OR:2.5; CI95%:1.2-5.0), middle/low parent´s attained education (OR:2,3; CI95%:0.97-5.9) and black ethnicity (OR:4.7 IC95%: 1.8-14.9). Additionally, synergistic effects on greater risk of BLL were observed between low socioeconomic condition (P for interaction: 0.000).
Conclusions: Residence in an urban area exposed to industrial lead emissions is associated to higher levels of BLL. Socioeconomic conditions and male sex modify observed BLL, with a greater risk of exposure. Given that higher disease susceptibility is also expected among those children, health effects could be potentiated in these children.

Alain Le Tertre, *French Institute for Public Health Surveillance, France*
Camille Lecoffre, *French Institute for Public Health Surveillance, France*
Marie-Laure Bidondo, *French Institute for Public Health Surveillance, France*
Philippe Bretin, *French Institute for Public Health Surveillance, France*

Background and Aims: Children's exposure to lead has decreased in recent years, thanks to the ban of lead in gasoline. It remains however of public health concern because of evidence of cognitive effects even at low levels, without toxicity threshold. The last survey about lead burden was carried out in France 15 years ago. A national survey was conducted in 2008-2009 1/ to estimate the current prevalence of elevated blood lead level (BLL) among children aged 1 to 6 years, 2/ to determine the distribution of BLL by French region and 3/ to measure the contribution of various environmental sources of lead.
Methods: This cross-sectional survey included 3,255 children, recruited at hospital. A two-stage probability sample, stratified by hospital and French region was conducted. The data collected included blood samples, socio-demographic characteristics, environmental and parent's occupational exposure. We used small area estimation techniques based on empirical bayesian approach to derive specific mean on each region. Quantile regression models were used to quantify the association between BLL and environmental risk factors.
Results: The overall prevalence of elevated BLL was 0.11% (95%CI [0.02-0.21]): i.e. 5,333 children [784-9,882] in France. The BLL geometric mean was 15.1 • g/L (95%CI [14.7-15.5]). Levels were slightly higher in males.. A difference of 9 • g/L on geometric mean was observed between French regions. Factors significantly associated with BLL mean were leaded water supply pipes, tap water consumption, old housing with chipped paint or recent renovation, parent's occupational with lead exposure, child behaviour, passive smoking. The regression on 95th percentile of BLL (34.5 • g/L) has showed an association with chipped paint in old housing, passive smoking and child behaviour.
Conclusions: In the last 15 years, the prevalence of elevated BLL decreased from 2.1% (95%CI [1.6-2.6]) to 0.11% (95%CI [0.02-0.21]). This highlights a substantial decrease in exposure of children in France, as it occurs in adult population. The distribution of BLL was quite similar to that observed in US and in other European countries.

THE IMPACT OF RESIDENTIAL SOURCES OF LEAD ON BLOOD LEAD LEVELS OF YOUNG CHILDREN IN MONTRÉAL, QUÉBEC (CANADA)

Patrick Levallois, *Institut national de santé publique, Québec, Canada*
Julie Saint-Laurent, *Institut national de santé publique, Québec, Canada*
Denis Gauvin, *Institut national de santé publique, Québec, Canada*
Marilène Courteau, *Institut national de santé publique, Québec, Canada*

France Lemieux, *Health Canada, Ottawa, Ontario, Canada*
Patricia Rasmussen, *Health Canada, Ottawa, Ontario, Canada*
Monique D'Amour, *Health Canada, Ottawa, Ontario, Canada*

Background and Aims: Lead sources in the general environment have reduced dramatically but the importance of domestic sources in Canada remains unknown. This study evaluated the contribution of residential sources of lead to blood lead levels (BLLs) of young children.
Methods: We conducted a cross-sectional survey from September 2009 to March 2010. A total of 306 children aged 1-5 yrs, selected at random in old sectors of Montréal, participated in the study. Only participants who drank tapwater and had lived at least one year at the same residence were included. During home visits, the following environmental samples were collected: 5 kitchen tap water samples (1 liter after 5 minutes flushing and 4 liters after 30 minutes stagnation), 3 house dust floor and one windowsill samples. Paint content for lead was also evaluated by XRF. Parents answered questionnaires regarding dietary and general habits. A venous blood sample was drawn from the child. All laboratory analyses were done using established or slightly modified USEPA methods and included internal and external quality control. Multiple linear regression analyses of the log transformed BLL were used for statistical analysis.
Results: The geometric mean (GM) of BLLs was 0.065 µmol/dl (95% Confidence Intervals: 0.061-0.069). There was a positive relationship between BLLs and the arithmetic mean (AM) of lead concentrations in tapwater treated in tertiles or as a continous variable ($p < 0.05$). There was also a positive relationship with window dust with significant interaction with season and daycare at home ($p < 0.05$). The predictive model explained 22.2% (R^2) of the variation of BLLs. Both regression models were adjusted for co-variates and other residential exposures.
Conclusions: Despite low BLLs in young children living in old sectors of Montréal, tapwater and house dust are still responsible of some increase of BLL during fall and winter.

PERFLUORINATED COMPOUND LEVELS IN UMBILICAL CORD BLOOD AND CHILD BEHAVIOR AT 2 YEARS OF AGE

Pau-Chung Chen, *Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University Collage of Public Healt, Taipei, Taiwan*

Background and Aims: The perfluorinated compound (PFCs) is persistent organic pollutants with global distribution. Their adverse impact on neurobehavior had been reported in animal studies with high dose exposure. Yet, the evidence in human studies is inconclusive. The aim of this study was to explore the association between child behavior at the 2 years of age and the concentration of PFCs in umbilical cord blood plasma.
Methods: A prospective cohort study was conducted among 238 mother-infant pairs between 2004 and 2005 in northern Taiwan. Structured questionnaires were used to obtain demographic data including exposure history during pregnancy. Cord blood was collected for PFOA and PFOS analysis by using UPLC-MS/MS method. Children's behavior problems at 2 years of age were obtained through maternal reported Child Behavior Checklist/1.5-5. PFCs levels in cord blood plasma were $\log_{10}$ transformed to fit normal distribution. Multiple linear regression models were used to assess the effects of PFCs exposure on child behavior
Results: The average concentration of PFOA and PFOS levels in cord blood plasma were 2.48 ng/mL (standard deviation, SD: 2.53) and 6.90 ng/mL (SD: 2.53), respectively. We found no association between scores of Child Behavior Checklist and cord blood levels of PFOA or PFOS.
Conclusions: Our data suggest no significant associations between prenatal PFOA and PFOS in general population and child behavior problems at the age of 2. However, other developmental problems or effect of higher exposure could not be concluded.

Background and Aims: Particulate matter exposure has been associated with increased cardiovascular morbidity and mortality, and several studies showed that exposure to fine particles may influence vagal regulation of heart rhythm. We studied the effect of exposure to ultrafine particles (UFP) on heart rate variability (HRV) in subjects with ischemic heart disease.
Methods: Personal exposure to UFP (number concentration) was continuously monitored during 24-hr, in the warm and in the cold season, in 37 non-smokers individuals with ischemic heart disease. Simultaneously, a 24-hr ambulatory ECG was recorded to measure the standard deviation of normal-to-normal intervals (SDNN), a marker of overall HRV, and two HRV markers of vagal modulation, i.e. the percentage of intervals that vary more than 50 ms from the previous interval (pNN50) and the power in high frequency (HF). The associations between UFP exposure (lag0 and 1-hr to 4-hr moving averages, MA) and HRV indices were assessed with mixed effects models.
Results: A negative association was observed between UFP exposure and all investigated HRV indices only in subjects not taking beta-blockers. This effect was greater on pNN50, with a -6.2% decrease (95% confidence interval (CI) -8.6 to -3.7) and on SDNN with a -3.1% decrease (95%CI -4.9 to -1.2) for an interquartile increase in 1-hr average UFP ($13.59*10^3$ #/cm^3). The interaction with beta-blockers was significant for pNN50 ($p<0.001$) and SDNN ($p<0.002$), and marginally significant ($p=0.052$) for HF.
Conclusions: Our results suggest an acute effect of UFP on vagal tone modified by beta-blockers use, and confirm previous findings for fine particles (de Hartog et al 2009).

Background and Aims: Methylation changes in promoter regions of genes have been linked to gene expression changes and subsequent human disease. Heavy metals are known to trigger oxidative stress, changes in immune response, and inflammation throughout the body. DNA methylation is a potential pathway through which heavy metals exert their toxicity. We aimed to evaluate the association between exposure to arsenic, cadmium, mercury, manganese and lead and DNA methylation in nine different genes related to inflammation, immune response, and endothelial function in a population of environmentally exposed elderly men.
Methods: Our study population was 773 participants from the Normative Aging Study cohort in Boston, USA, with repeated visits between 1999 and 2009. Our associations of interest were explored in a minimum of 423 and a maximum of 611 participants depending on the availability of the exposure and outcome measurements. We measured the concentration of metals in toenails (in mcg/gr) while DNA methylation (in % of 5methyl cytosine) in promoter regions of the IL6, IFN-gamma, iNOS, ICAM, CRAT, OGG, TLR2, F3 and GCR genes was measured in blood leukocytes. The toenail metal concentrations were natural logarithm-transformed. We used multivariable linear mixed effects models to evaluate the associations of interest.
Results: Toenail arsenic and manganese concentrations were negatively associated with the iNOS gene methylation [b=-0.2, 95%CI: -0.3 to -0.1 for ten percent increase in toenail arsenic; b= -0.1, 95%CI: -0.1 to -0.01 for ten percent increase in toenail manganese). We did not find any statistically significant associations between the other metals and gene-specific methylation.
Conclusions: Both arsenic and manganese concentrations were associated with decreased iNOS methylation which can potentially lead to increased iNOS gene function and subsequent increased nitrogen oxide production, a process involved in inflammation. Our results indicate that heavy metal exposures may exert their effects through epigenetic mechanisms.

LUNG INFLAMMATION AMONG CHILDREN WITH ASTHMA EXPOSED TO INDUSTRIAL AND TRAFFIC POLLUTION

Nina A Dobbin, *Health Canada, Canada*
Amanda J Wheeler, *Health Canada, Canada*

Marie-France Valois, *McGill University, Canada*
Mark S Goldberg, *McGill University, Canada*

Background and Aims: Children with asthma are susceptible to the effects of ambient air pollution, including increased symptoms and lung inflammation. Industrial emissions are an important source of air pollution in many areas. Oil refinery emissions are of particular concern as they comprise a complex mixture of organic and inorganic pollutants. We examined associations between fractional exhaled nitric oxide (FeNO), an indicator of airway inflammation, and exposure to oil refinery and traffic emissions on the health of children with asthma in Montreal, Canada.
Methods: We recruited 69 children (age 8-13 years) with a physician diagnosis of asthma from schools and an asthma clinic. Subjects participated in the panel study for 10 consecutive days between October 2009 and April 2010. We measured personal exposures to sulphur dioxide (SO_2) using Ogawa passive samplers (Ogawa & Company, Pompano Beach, FL, USA) and fine particulate matter ($PM_{2.5}$) using Harvard Personal Environmental Monitors (HPEM, BGI, MA, USA) and continuously using the personal DataRAM (pDR-1200, MIE Inc, Bedford, MA). Filters were also analyzed for metals associated with oil refinery emissions. We recorded online FeNO daily using the NIOX MINO monitor (Aerocrine, Solna, Sweden) and collected participants' reports on health, medication use, and activities. Linear mixed-effects regression models with autoregressive correlation structure were used to estimate the association between FeNO and pollutant exposure.
Results: The geometric mean of FeNO was 20.9 ppb (geometric standard deviation: 2.2). Mean (SD) personal exposure to $PM_{2.5}$ was 9.5 (13.4) $\mu g/m^3$, while for SO_2 it was 0.81 (3.21) ppb. Preliminary models indicate that an increase of 10 $\mu g/m^3$ in previous 8-hour personal exposure to $PM_{2.5}$ was associated with a 1% (95% CI: 0.1-2.0%) increase in FeNO, adjusted for corticosteroid use, age and sex.
Conclusions: Preliminary results indicate an association between personal exposures to $PM_{2.5}$ and increased airway inflammation in children with asthma.

USE OF REMOTE SENSING ESTIMATES OF NO2 AND PM2.5 EXPOSURE IN A STUDY OF HOSPITAL AND EMERGENCY ROOM VISITS IN ONTARIO, CANADA

Nina A Dobbin, *Health Canada, Canada*
Andrew Davidson, *Carleton University, Canada*
Sabit Cakmark, *Health Canada, Canada*
Liu Sun, *Health Canada, Canada*
Randall Martin, *Dalhousie University, Canada*
Aaron van Donkelaar, *Dalhousie University, Canada*
Lok Lamsal, *Dalhousie University, Canada*
Markey Johnson, *Health Canada, Canada*

Background and Aims: Remote sensing (RS) offers an alternative to ground based air pollution monitoring that provides broad, cost-effective coverage. However, the use of RS estimates in epidemiological studies has not been thoroughly studied, especially for acute health effects. We examine the use of RS to estimate exposure in a case-crossover study of acute myocardial infarction (MI) and asthma hospital visits in Ontario, Canada.

Methods: Daily estimates of NO_2 and $PM_{2.5}$ levels were developed by combining retrievals from the OMI, MODIS and MISR instruments with daily profiles from a chemical transport model for the summer of 2005 (June-September). For comparison, ground-based measurements were obtained from Environment Canada's National Air Pollution Surveillance (NAPS) network. Hospitalization and emergency room visit data, including individual level data on main cause of admission/visit (ICD-10 code), age, sex, and three-digit postal code of home residence, were obtained from databases maintained by the Canadian Institutes for Health Research. Individual exposure was estimated by linkage of residential postal code centroid to the RS estimate (at approximately 10 km resolution) and the nearest NAPS station within 40km. We will use a case-crossover analysis with full-stratum bidirectional control selection as well as a sensitivity analysis with two-week bidirectional control selection to examine the acute health effects of air pollution exposure as estimated by both RS and ground-based methods.

Results: There were 7,562 hospitalizations for MI and 26,962 emergency room visits for asthma in Ontario in the summer of 2005. Preliminary analyses show RS estimates were available for $PM_{2.5}$ on 36% of days and for NO_2 on 24% of days over this time period. RS estimates of $PM_{2.5}$ were highly correlated with daily-average ground-based NAPS measurements ($r=0.73$), while daily NO_2 measurements were moderately correlated ($r=0.48$).

Conclusions: RS estimates of $PM_{2.5}$ and NO_2 are well correlated with ground-based measurements and offer a promising alternative for estimating exposure in a study of acute health effects.

DERMAL TRANSMISSION OF BISPHENOL A IN HUMANS FROM THERMAL RECEIPT PAPER

Annette M Hormann, *University of Missouri, United States*
Julia A Taylor, *University of Missouri, United States*
Susan C Nagel, *University of Missouri, United States*
Fredrick S vom Saal, *University of Missouri, United States*

Background and Aims: Bisphenol A (BPA) is a known endocrine disrupting chemical that can be found in > 90 % of Americans. BPA exposure is often from sources of polycarbonate water bottles, dental sealants and canned food products. Pharmacokinetic data in humans do not account for all of the circulating BPA levels that are present. Recent reports suggest that dermal absorption of BPA through contacting thermal paper could be contributing to circulating BPA levels in people. We hypothesized that a single handling of thermal receipt paper leads to trans-dermal exposure to BPA and that there will be measurable amounts in blood and urine.
Methods: Our specific objectives are to 1) examine the amount of BPA in thermal receipt paper, 2) evaluate how much is transferred onto the skin and 3) determine whether human dermal exposures to BPA lead to an increase in serum and urine BPA. BPA (unconjugated and conjugated) will be measured in serum of 25 males and 25 female volunteers before and one hour after touching receipt paper.
Results: The preliminary findings suggest that thermal receipt paper is coated with milligram amounts of free BPA in a 2-inch sample strip. Observations made after touching a receipt for a mere 10 seconds concluded that the skin adsorbed BPA. Additionally, exposure increases with length of time. There appears to be a direct relationship based on the time held and amount an individual is exposed.
Conclusions: Our preliminary findings show that there could be significant trans-dermal exposure to BPA that might escape rapid first pass metabolism. Leaching of BPA from receipts should be researched further because BPA is a ubiquitous endocrine disrupting chemical that can pass through the skin. We expect that results from this study will show that dermal exposure is a major pathway of human exposure, especially for cashiers.

EXPOSURE ASSESSMENT OF SPECIFIC CHEMICAL COMPONENTS AT STREET, URBAN AND REGIONAL SITES IN FOUR EUROPEAN LOCATIONS OF THE ESCAPE STUDY

Aleksandra Jedynska, *TNO, The Netherlands Applied Research Organization, Utrecht, The Netherlands*
Ingeborg Kooter, *TNO, The Netherlands Applied Research Organization, Utrecht, The Netherlands*
Gerard Hoek, *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands*
Josef Cyrys, *Helmholtz Centre for Environmental Research, Munich, Germany*
Christian Madsen, *Norwegian Institute of Public Health, Oslo, Norway*
Mark Nieuwenhuijsen, *Environmental Epidemiology Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Audrey de Nazelle, *Environmental Epidemiology Center for Research in Environmental Epidemiology (CREAL), Barcelona, Spain*
Bert Brunekreef, *Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands*

Background/Aim: The ESCAPE study is a large EU-funded study on long-term health effects of outdoor air pollution. In 21 European locations the study adds air pollution exposure assessment to health data available from European cohort studies. The goal of the present study was assessment of PM2.5 specific components and oxidative potential in four European locations to test hypotheses about the effect of these components on health.
Methods: In four ESCAPE locations (The Netherlands, Oslo, Barcelona, Munich/Augsburg): (nitro/oxy-)PAH, hopanes/steranes, levoglucosan, EC/OC and oxidative potential were measured. This is in addition to NOx, PM2.5 and PM10 mass and reflectance, and metals measured at all ESCAPE locations. Three two-week average samples were taken at 20–40 street, urban and regional background sites in each study area. A T60A20 filter was used for the GC/MS measurement of (nitro/oxy-)PAH and hopanes/steranes. A quartz filter was used for thermal-optical EC/OC determination, GC/MS levoglucosan analysis and DTT assay. For each site the annual average was calculated using continuous measurements at one background site as a reference.
Results: We will present an analysis of the temporal and spatial variability of concentrations including the correlation with 'standard' components (PM2.5, soot, NO_2) for four study areas. The Dutch results showed that for most components the concentrations at the street locations were highest. However, levoglucosan has comparable concentrations in street and regional background locations. Spatial correlations between components were investigated. PAH's sum correlates high with levoglucosan (r=0.85) and moderate but significant with PM2,5 (r=0.721). Hopanes/steranes sum correlates moderately with soot (r=0.694), NOx (r=0.656) and EC (r=0.635).
Conclusions: The results of chemical composition show different correlations between measured components. It indicates that the chemical components may also have other sources than motorized traffic, including wood combustion. This could potentially help to correlate the health effects to specific components and/or their origin.

ARSENIC EXPOSURE AND DNA METHYLATION WITHIN REPETITIVE ELEMENTS IN ELDERLY MEN

Pantel Vokonas, *VA Normative Aging Study, Veterans Affairs Boston Healthcare System and Department of Medicine, Boston University School of Medicine, Boston, MA, USA*
Joel Schwartz, *Departments of Environmental Health and Epidemiology, Harvard School of Public Health, Boston, MA, USA*

Background and Aims: Arsenic (As) exposure has been linked to epigenetic modifications such as DNA methylation in *in vitro* and animal studies. This association has also being explored in highly exposed human populations, but studies among populations environmentally exposed to low As levels are lacking. We aimed to evaluate the association between As exposure and DNA methylation changes in repetitive elements in a population of community-dwelling elderly men. We also explored the possibility of effect modification by plasma folate, cobalamine (B12), and pyridoxine (B6).
Methods: We measured toenail As levels by inductively coupled plasma mass spectrometry and DNA methylation in Alu and Long Interspersed Nucleotide Element-1 (LINE-1) repetitive elements by quantitative polymerase chain reaction-pyrosequencing of blood leukocytes. The study population was 581 participants from the Normative Aging Study in Boston, USA, with 434, 140, and 7 of them having 1, 2 and 3 visits, respectively, between 1999-2002 and 2006-2007. We used mixed effects models and included interaction terms to assess potential effect modification by plasma folate, B12, and B6.
Results: There was a trend of increasing Alu and decreasing LINE-1 DNA methylation as arsenic exposure increased. In subjects with plasma folate below the median (less than 14.1 ng/ml), As was positively associated with Alu DNA methylation (b=0.08; 95%CI, 0.03 to 0.13 for one interquartile range [0.06 mcg/g] increase in As) while a negative association was observed in subjects with plasma folate above the median
(b=-0.08; 95%CI, -0.17 to 0.01).
Conclusions: In our study, the association between As exposure and DNA methylation in Alu repetitive elements varied by folate level, a factor that participates in one-carbon metabolism. This suggests a potential role for nutritional factors in As toxicity.

ASSOCIATION BETWEEN PARTICULATE MATTER(PM), O3 AND NOX AND EMERGENCY ROOM(ER) VISITS AND HOSPITAL ADMISSION FOR RESPIRATORY AND CARDIOVASCULAR DISEASES IN CALI-COLOMBIA

Paola Filigrana, *Universidad del Valle-Grupo Epidemiologìa y Salud Poblacional, Colombia*
Liliana Jiménez, *Universidad del Valle-Grupo Epidemiologìa y Salud Poblacional, Colombia*
Nathalie Abrahams, *Universidad del Valle-Grupo Epidemiologìa y Salud Poblacional, Colombia*
Daniel Cuartas, *Universidad del Valle-Grupo Epidemiologìa y Salud Poblacional, Colombia*
Fabián Méndez, *Universidad del Valle-Grupo Epidemiologìa y Salud Poblacional, Colombia*

Background and Aims: Studies have found a higher risk of respiratory and cardiovascular morbidity associated with PM exposure. Cali is the third largest city in Colombia, showing a rapid urban growth and multiple sources of air pollutants. Despite this, little is known about air quality and health effects in this developing country. We assess the association between short-term variations in PM10, O3, NOx and ER visits, hospital admissions and mortality for respiratory(RD) and cardiovascular diseases(CVD) in Cali-Colombia.
Methods: We developed an ecological time series study between 03/2010-06/2011. Daily concentrations of PM10, NOx, 8-h average of O3, and daily measures of meteorological variables were obtained from Air Quality Monitoring System. Records of hospital admissions and ER visits for RD and CVD were collected directly from health care institutions. Admissions were summarized into daily counts and diagnostics were based on ICD-10. Using a Generalized Additive Model with natural splines, we determined the association between daily counts of ER visits, hospital admissions and daily pollution levels.
Results: The daily average concentration of PM10 was 29.1 $\mu g/m^3$ (4.9-55.9); NOx, 0.02 ppm (0.001–0.05); and the maximum 8-h average O3, 0.02 ppm (0.008–0.05). We observed a daily average of 12 ECV and 132,8 RD admissions. The maximum admission for ECV and RD per day was 28 and 246, respectively. ECV diseases accounted for about 6% of total respiratory and cardiovascular disease admissions, while RD admissions were more than 90%. After controlling for potential confounders, we found a potential association between daily variation in PM10, O3 and NOx and ECV, RD admissions.
Conclusions: Although not showing high levels of air pollution on air, the results suggest an association between daily variations in the concentration of air pollutants and respiratory and cardiovascular health, mainly by increasing hospital admissions and ER visits.

AIR QUALITY IMPACT ON RESPIRATORY MORTALITY RISK IN SÃO PAULO

Luiz Pereira [1], Jezabel Azevedo[1]

[1] Environmental Epidemiology Laboratory, Medicine Faculty, São Paulo University

Introduction

Sao Paulo is one of most populous cities in the world. Air pollution caused by automobile traffic, coupled with industrial features in a subtropical climate create special atmospheric conditions that have a particular impact on population health.

Objective

This study aimed to evaluate the impact of the air quality and meteorological conditions on respiratory mortality (RM).

Methodology

This paper follows the design of ecological time series study using as dependent variable, the RM causes, by the government registers (CID 10ª Revison) and independent variables: the daily pollutants concentration and air temperature (AT) and average relative humidity (RH), from 2004 to 2006. Poisson Regression with generalized linear models was used to treat the variables.

Results

RM were shown to be directly related to the pollutants CO (1 day lag, 0.0190, $p<0.05$), NO_2 (5 days lag, 0.0006, $p<0.0131$) and O_3 (1 day lag, 0.0005, $p<0.05$; 3 days lag, 0.0004, $p<0.05$) and AT (minimum) (2 days lag, 0,0063, $p<0.05$) and inversely with RH (-0.0020, $p<0.05$). The Poisson Regression Analysis (PRA) showed O_3 (3 days lag) 0.0004, $p<0.0448$, that means 2% (95% CI, 0.004; 3.94) increase in the mortality.

Conclusion

The respiratory diseases for the period studied appear to be directly related to temperature and some pollutants. This indicates that when temperature and pollutants increases the number of cases so increases. The decrease in temperature is commonly coupled with the arrival of cold fronts in the region under study. With the arrival of cold fronts occurs increasing cloudiness followed by rain. The RH is an important element in human comfort in a subtropical climate and the precipitation in the removal of most tropospheric pollutants. Therefore, mortality from respiratory disease decreases when the relative humidity increases and the risk of death increases with increasing pollutants concentration.

Key words: Air pollution, Respiratory Mortality, Sâo Paulo

MAPPING THE COMFORT ZONE ACROSS THE UNITED STATES

Barnett, Adrian Gerard, *Queensland University of Technology, Australia*
Soares Magalhães, Ricardo Jorge, *University of Queensland, Australia*

Background and Aims: The risk of death increases on both cold and hot days. The "comfort zone" is the range of moderate temperatures where the risk of death is lowest. The comfort zone has previously been defined using the indoor temperatures at which people feel comfortable. We aimed to define empirical comfort zones by finding the cold and hot temperature thresholds beyond which the risk of death increases.
Methods: We estimated the comfort zone in 97 US cities for 14 years (1987–2000). We assumed a U-shaped association between daily mean temperature and risk of death in each city by using a linear spline with movable cold and hot thresholds. We controlled for dew point temperature and season. A Bayesian geostatistical model was used to map the thresholds and comfort zone over the contiguous US.
Results: The average cold threshold was a surprisingly low 34 °F, the average hot threshold was 74 °F, giving an average comfort zone width of 40 °F. The cold threshold was lowest in Wisconsin and Michigan, and highest in Florida. The hot threshold was lowest in Maine and Washington, and highest in Florida. The comfort zone was widest in South Dakota and its neighbouring states (over 60 °F), and was narrowest in California and Florida (under 15 °F). There was little difference by age group, with the under 65 year age group having an average comfort zone width only 2.5 °F wider than the over 74 year age group.
Conclusions: The comfort zone is highly variable across the United States, with cold climate states coping with the widest ranges in temperature. The warmest states had the narrowest comfort zones suggesting that populations in these areas will struggle most with the increase in extreme temperatures expected under global warming.

COMMUNITY EXPOSURES TO INDUSTRIAL POLLUTION AND WASTE: ETHICS DISCUSSION

Steve Wing, *University of North Carolina, United States*
Wael Al-Delaimy, *University of California, San Diego, United States*

Background and aims: Epidemiologic studies in communities with residential exposure to hazardous pollutants from industrial production or waste facilities can be affected by many ethical, legal, and social issues. In this presentation, and as part of the ISEE Ethics and Philosophy Committee contribution, we consider ethical issues associated with research on community exposures to industrial pollution and waste and facilitate discussion with session participants.
Methods: We use information on past problems in studies of community exposures to identify problems that are relevant to recent and on-going research. Analysis of past problems will be used to promote examination of ethical, legal and social challenges in research presented at this ISEE meeting.
Results: Residents in communities with sources of industrial pollution may be distrustful of researchers associated with the government agencies that regulate and permit polluting facilities, hampering recruitment. Industry officials may be distrustful of research that could find evidence of harm for which industry could be held responsible, which may lead them to try to prevent access to data on releases or alter releases during times that measurements are being made. Additionally, industries may directly or indirectly attempt to obstruct research or intimidate community members or researchers. Other methodological challenges in conducting research in these situations include the absence of measurements needed to address research questions of most interest, such as whether community residents have been exposed to particular pollutants and whether those exposures have been a cause of disease. Epidemiologists trained to write for scientific journals may be expected to present study findings and limitations without reliance on technical jargon and in an adversarial context. Confidentiality of both individuals and neighborhoods may be compromised by legal proceedings.
Conclusions: Analysis of these issues could be helpful for improving the design, interpretation and communication of epidemiologic studies.

APPLYING A MULTI-SITE APPROACH TO ESTIMATING RELATIVE RISKS TO HEALTH ASSOCIATED WITH AIR POLLUTION EXPOSURE AT CITY LEVEL: A CASE STUDY IN MELBOURNE

Sarunya Sujaritpong, *Australian National University, Australia*
Keith Dear, *Australian National University, Australia*
Martin Cope, *The Centre for Australian Weather and Climate Research, Australia*
Sean Walsh, *Environmental Protection Authority Victoria, Australia*

Background and Aims: In time series studies of the health effects of ambient air exposure, multi-site approaches designed to overcome limitations of single-city and meta-analysis studies have increasingly gained popularity. Past studies applying such approaches have mainly estimated pooled relative health risks at national level. We used this approach to obtain a more reliable pooled relative health risk at city level. This can be achieved through an integrated technique to provide information on spatial meteorological and air quality gradients across a city.
Methods: Daily concentration fields of common air pollutants and meteorological variables at 3-km spacing in the area around Melbourne, a large city in Australia, for the period 1999-2008 were simulated by The Air Pollution Model - Chemistry Transport Model. The gridded data were subsequently blended with observations and then assigned to statistical local areas (SLAs) on the basis of distance and population density. In each SLA, log-linear Poisson models with smooth functions adjusting for potential confounders were used to estimate relative risks of air pollution on cardiovascular and respiratory mortality and morbidity. Hierarchical models further combined the relative risk estimates to derive overall values.
Results: Preliminary findings suggested increases in air pollution exposure attributable to increases in risk rates of most of the health outcomes examined, similar to results found in previous studies undertaken in Australia. Compared to previous single-city studies in which air pollution concentrations and weather variables were averaged uniformly across a city and a city was treated as a single location, the multi-site approach potentially provided better statistical power.
Conclusions: As long as estimating location-specific health risks remains necessary for policy and planning development, applying the multi-site approach at the city level has potential to improve statistical power and increase opportunities for exploring heterogeneity in health outcomes.

CONTRIBUTIONS ON THE SPACE PLANNING OF THE NESTINGS OF THE AGRARIAN REFORMATION AND THE ORGANIZATION OF THE HOUSING

Valéria Andrade Bertolini, *Universidade de Brasilia, Brasil*
Fernando Ferreira Carneiro, *Universidade de Brasilia, Brasil*

Background and Aims: This work has intention to present contributions on the space planning of the nestings of the Agrarian Reformation and the organization of the housing. Due to diversity of existing situations in all the country, one is about the reality of the DF.
Methods: One consists two-piece: first with the presentation of the state of the art and the theoretical reflections on the subject and,second with the practical aggravations of the reality of the Federal District and some contributions on the organization of the housing.
Results: In the planning of a nesting, the productive aspects and the use of existing natural resources are considered to define the forms and models of division.
Conclusions: However, in the nestings of the MST, one searchs to think the space in "sistemic" way, or either, the life in the center it project. Between the employed strategies they meet the stimulaton to the conviviality and the social participation and new forms to relate production and exploitation of the natural resources.

THE ASSOCIATION BETWEEN EXPOSURE TO PARTICULATE AIR POLLUTANTS FROM FIRECRACKERS AND OUTPATIENT VISITS FOR CARDIOVASCULAR AND RESPIRATORY DISEASES

Ming-Yie Liu, *Department of Environmental and Occupational Health, Medical College, and Sustainable Research Center, National Cheng Kung University, Tainan, Taiwan*

Chun-Yuh Yang, *Faculty of Public Health, Kaohsiung Medical University, Kaohsiung, Taiwan*

Chih-Ching Chang, *Department of Environmental and Occupational Health, Medical College, , and Sustainable Research Center, National Cheng Kung University, Tainan, Taiwan*

Background and aims: Fireworks are used worldwide for the celebrations. In Taiwan, the largest firework is held at a southern Taiwan township, and thousand pounds of firecrackers are fired in the township during the Lantern Festival. The aim of this study was to investigate the impact of exposure to particulate firework pollutants on the occurrence of outpatient visits for cardiovascular and respiratory diseases.

Methods: This study applied case-crossover study design to investigate the association between exposure to particulate firework pollutants emitted from the firecrackers and the outpatient visits for cardiovascular and respiratory disease. The information on outpatient visits were abstracted from National Health Insurance database. Environment exposure data were secured from the Taiwan Environmental Protection Agency.

Results: The results indicate that the concentrations of air pollutants were high on the evening of Lantern Festival, when most of the firecrackers were fired. It was increased on the first, second, and third day following the Festival. Firecracker particulate exposure (per 10 • g/m^3 increase) was significantly associated with outpatients visits for cardiovascular diseases (OR 1.41, 95% CI 1.37-1.45), hypertension (OR 1.47, 1.43-1.52), ischemic heart Disease (OR 1.25, 1.14-1.37), respiratory diseases (OR 1.42, 1.40-1.44), upper respiratory infection (OR 1.42, 1.40-1.43), asthma (OR 1.42, 1.31-1.55), COPD (OR 1.54, 1.50-1.58), and pneumonia/bronchiolitis (OR 1.54, 1.50 -1.58).

Conclusions: The results indicate that air pollutants emitted from firecrackers increase the risk of outpatient visits for cardiovascular and respiratory diseases. Prevention measures are needed to reduce the adverse health effect incurred by particulate firework pollutant exposure.

Land use regression application to predict the PM_{10} in São Paulo, Brazil

Mateus Habermann, *Faculdade de Medicina da Universidade de São Paulo, Brazil*
Nelson Gouveia, *Faculdade de Medicina da Universidade de São Paulo, Brazil*
Rogerio Prado, *Faculdade de Medicina da Universidade de São Paulo, Brazil*

Background and Aims: land use regression is a method able to predict air pollution concentrations in a specifically location, combining variables related to the concentration and dispersion of pollutants that can influence the exposure. Therefore we aimed to construct a land use regression model to predict the environmental concentration of PM_{10} in São Paulo, Brazil.
Methods: The study was based on the 2007 average of PM_{10} measured in monitoring stations in São Paulo, southeast Brazil. We used GIS applications to obtain geographic, demographic, roads and land use data to compose the regression model of the monitoring locations vicinity in buffers from 250 to 1.000 meters. First we calculated linear regression between each independent variables and PM_{10}. We selected most robust variables ($p \leq 0.2$) without collinearity to compose the multivariate linear regression. The final model was used to predict particulate matter in the city and mapping using interpolation method.
Results: The municipality has 12 PM_{10} monitoring stations, but in 2007 only 09 stations had sufficient valid measurements to construct the model. The annual average of PM_{10} was 40.1 $\mu g/m^3$ (±4.6 $\mu g/m^3$). For each location we obtained 113 independent variables. Four variables remained in the multiple regression model. The final model explained 63.8% of the MP_{10} variance with only one predictor variable, which was the average of mild traffic until 250 m from the monitoring stations. The model was applied in a grid of points 1 x 1 km and interpolation to mapping the dispersion of PM_{10} in the city.
Conclusions: This method is fast and easy to develop and may be used to predict air pollution in epidemiological studies in São Paulo when there is no available data from measurements. However, the results must be interpreted with caution because the model was based on measurements of only nine monitoring stations.

ARSENIC METABOLITES IN HUMAN URINE AFTER INGESTION OF SASHIMI TSUNA FISH

Akihisa Hata, *Chiba Institute of Science, Japan*

Kenzo Yamanaka, *Nihon University, Japan*

Yuko Yamano, *Showa University, Japan*

Yoko Endo, *Japan Labour Health and Welfare Organization, Japan*

Fujitani Noboru, *Chiba Institute of Science, Japan*

Endo Ginji, *Osaka City University, Japan*

Background and Aims: The consumption of seafood including tuna is increasing in the world. Seafood contains large amounts of various arsenic compounds but the risk from seafood ingestion is not clear. After the development of arsenic speciation analysis of seafood, we examined sashimi-grade tuna fish ingestion experiment using volunteers.

Methods: Arsenic content of tuna was measured after bead-beating treatment and 50% methanol extraction. Four volunteers ingested 300 g of sashimi-grade tuna fish, after refraining from eating seafood for 5 days. Arsenic metabolites in urine were monitored over 5-day period after the ingestion. Speciation analysis of arsenic in tuna and urine was performed by high-performance liquid chromatography and inductively coupled plasma mass spectrometry (HPLC-ICP-MS).

Results: Total arsenic (T-As) concentration of the tuna was 8.6 mgAs/kg. The compounds detected were arsenobetain (AsBe) and two unidentified arsenic compounds, but dimethylarsinic acid (DMA), monomethylarsonic acid, trimethylarsine oxide, arsenocholine, and inorganic arsenics (iAs) were not detected in 50% methanol extract. In 2.6 mg of arsenic ingested, 1.4 mg (54%) was AsBe and 0.4 mg (16%) of arsenic was insoluble arsenic. Approximately 40% of the ingested T-As was excreted in the urine during 5 days of the observation. The major urinary arsenics were AsBe and DMA, and the excreted total amounts were 948 ± 201 μg and 94 ± 38 μg, respectively. Approximately 70% of the ingested AsBe was excreted into the urine. Urinary AsBe excretion rate reached to 66.5 μg/h at 4 h after ingestion and that of DMA was 1.47 μg/h at 9 h.

Conclusion: Tuna, one of the most popular seafood, contains not only AsBe but also at least two kinds of soluble organic arsenic compounds and 16% of insoluble arsenic. Since neither DMA nor iAs detected in tuna, urinary DMA may be produced metabolically from unidentified arsenics or insoluble arsenic compounds.

THE CAUSAL ROLE OF AIRBORNE NANOPARTICLE ACTIVATED ONCOGENE EXPRESSION IN THE PROGRESSION OF LUNG ADENOCARCINOMA

Chih-Ching Chang, *Department of Environmental and Occupational Health, Medical College, and Sustainable Research Center, National Cheng Kung University, Tainan, Taiwan*

Li Pi-I, *Department of Family Medicine, Chi-Mei Medical Center, Tainan, Taiwan*

Lin Yi-Tsz, *Department of Environmental and Occupational Health, Medical College, National Cheng Kung University, Tainan, Taiwan*

Background and aims: Studies have suggested that exposure to nanoparticles is associated with the increased respiratory morbidity and mortality. Our epidemiological study has shown that exposure to traffic air pollution is associated with the risk of lung cancer. Oncogene activation and enhanced cell proliferation plays an important role in tumor initiation and progression. In the study, we aimed to explore whether c-Met oncogene activation is involved in the cell proliferation of lung adenocarcinoma following nanoparticle exposure.

Methods: Ultrafine carbon black (ufCB; 14 nm in diameter) was applied as a representative airborne nanoparticle. Cell proliferation assay with the use of pharmacological inhibitors were used to delineate the pathways involved in nanoparticle-induced tumor cell proliferation. Western blotting for c-Met oncogene phosphorylation, Met kinase activity assay and immunofluorescence staining were carried out to provide the mechanistic evidence for the involvement of c-Met signaling in ufCB-induced lung adenocarcinoma cell proliferation.

Results: The results demonstrate that ufCB at 50 • g/mL and 100 • g/mL induced dose- and time-dependent increases in the proliferation of lung adenocarcinoma cells. Met kinase inhibitor SU11274 and ERK1/2 inhibitor PD98059 significantly reduced cell proliferation incurred by ufCB exposure. Western blotting demonstrated that ufCB exposure triggered the phosphorylation of c-Met and ERK1/2. In accordance, ufCB significantly increased Met kinase activity. Moreover, SU11274 successfully suppressed ufCB-induced ERK1/2 phosphorylation, indicating that c-Met oncogene activation is responsible for the phosphorylation of ERK1/2 and cell proliferation.

Conclusion: The present results demonstrate that c-Met oncogene signaling plays an important role in nanoparticle-induced proliferation of lung adenocarcinoma cells. This has great implication on the role of airborne nanoparticle exposure in promoting tumor progression.

Estimation of the burden of home injury due to housing conditions in Europe

Michael Keall, *University of Otago, New Zealand*
David Ormandy, *University of Warwick, UK*
Michael Baker, *University of Otago, New Zealand*

Background and Aims: The authors recently undertook a study for the World Health Organisation estimating the European burden of injuries occurring in the home that can be attributed to remediable structural hazards in the house. In Europe, almost 110,000 people die each year as a result of a home/leisure injury and an estimated 32,000,000 are hospitalised. The 2003-2005 home/leisure fatal injury rate is 22 per 100,000 people Europe-wide, which is more than twice the rate of road fatalities
Methods: We undertook a review of existing literature on studies that have estimated injury risk associated with features of the home. Using data on the burden of home injury in the WHO European Region, we estimated the impact of two modifiable features of housing on injury incidence, deaths, and disability adjusted life years (DALYs) from fire and falls.
Results: There were considerable limitations in the safety issues of housing that could be encompassed by this burden of disease estimate due to inadequate surveillance data on both injury and exposures to given housing conditions, and a paucity of adequate studies examining the relationship between housing conditions and injury occurrence. The two aspects of housing conditions we were able to examine were estimated to cause about 7,500 deaths and about 200,000 DALYs per year in the WHO European Region.
Conclusions: Despite limitations in surveillance data and evidence linking housing exposures and injury risk, our estimates of home injury burden imply that improving housing quality and the prevalence of the two safety features smoke detectors and window guards would significantly reduce home injury levels in Europe.

AN ALTERNATIVE SPATIAL ANALYSIS OF BREEDING SITES DISTRIBUTION TO SUPPORT CONTROL ACTIVITIES FOR DENGUE.

Daniel Elías Cuartas Arroyave, *Universidad del Valle, Colombia*
Genny Martinez, *Universidad del Valle, Colombia*
Yoseth Ariza, Municipal Health Secretary Cali, *Colombia*
Fabian Mendez, *Universidad del Valle, Colombia*

Background/aim Dengue is an urban re-emerging infectious disease. In Cali-Colombia the disease is endemic and during the last years it has shown and increasing trend to larger outbreaks and more severe dengue cases. Control programs carry out actions to reduce populations of *Aedes aegypti* mosquitoes by detecting areas with high indexes of infestation (i.e.; more than 5% of recipients with *Aedes* pupae or larvae) and, subsequently, eliminating positive breeding sites. However, evaluations have not been developed about the role of negative, but potential, breeding sites in the dynamic of transmission. The objective of this study was to evaluate the distribution of positive and potential breeding sites inside households and in peri-domiciliar spaces.
Methods A geographic information systems(GIS) was implemented at a high space scale for storing, processing and analyzing data by using geo-statistical techniques(Kriging). We determined the spatial relationship between positive and potential breeding sites distributions.
Results Only 56%(R-squared) of the spatial variability of positive breeding sites distribution was associated to variability of potential breeding sites. 15,2% of the study area comprises zones with a simultaneous presence of high potential-high positive breeding sites and 64,2% of the area presented low potential-low positive breeding sites. However, 20,6% of the area presented a differential distribution of these types of breeding sites (5,1% high potential-low positive and 15,5% low potential-high positive). Maps were built to identify areas showing this lack of agreement in the distribution.
Conclusion Our results suggest that focusing interventions in areas only presenting high infestation with positive breeding sites might fail because they do not take into account the variability in breeding sites from potential to positive. Elimination and education activities could be better implemented taking into account the distribution of potential breeding sites.

THE SENSITIVITY OF TIME-SERIES HEALTH EFFECT ESTIMATES TO FINE PARTICULATE MATTER (PM2.5) CHEMICAL COMPONENTS SAMPLING SCHEDULES

Sun-Young Kim, *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, USA*
Jennifer L. Peel, *Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, USA*
Michael P. Hannigan, *Department of Mechanical Engineering, University of Colorado, Boulder, USA*
Lianne Sheppard, *Department of Biostatistics, University of Washington, Seattle, USA*
Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, USA
Steven J. Dutton, *U.S. Environmental Protection Agency, RTP, NC, USA*
Maggie L. Clark, *Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, USA*
Sverre Vedal, *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, USA*

Background and Aims: The U.S. EPA Speciation Trends Network (STN) is a resource used to investigate the association between PM2.5 chemical components and health in time-series studies. However, the temporally-sparse sampling on every third or sixth day reduces the number of days available for analysis and may influence resulting associations and interpretations. The Denver Aerosol Sources and Health (DASH) study obtained daily speciated PM2.5 data over five years allowing us to examine the impact of less than daily monitoring data on health effect estimates.
Methods: We performed a time-series analysis using daily PM2.5 chemical component concentrations and daily hospitalization counts from 2003 through 2007. Three every third-day sets of time series data for component concentrations were created from daily data, imitating the STN monitoring schedule. A fourth scenario was created using DASH data limited to the actual valid sampling days reported at the closest STN monitor. Four PM2.5 chemical components, elemental and organic carbon, sulfate, and nitrate, measured in the DASH study were examined. Relative risks (RRs per interquartile range increases) of hospitalizations for PM2.5 components at day lags 0 to 3 were estimated for each of the four systematically-missing and for the complete time-series using the Generalized Additive Model. Estimated RRs were compared across sampling schedules.
Results: The estimated RRs often varied between limited and complete sampling schedules and between the four limited sampling schedules, depending on PM2.5 components and hospitalization diagnoses. For example, the association of asthma hospitalization and of nitrate at lag0 using complete time-series data (RR = 0.999; 95 % confidence interval (CI) = 0.998, 1.010; 0.86 $\mu g/m^3$ increase) was elevated and statistically significant in one of the every-third-day scenarios (RR = 1.024; 95 % CI=1.005, 1.043).
Conclusions: Estimated effects of PM2.5 components on hospitalization in time-series studies were sensitive to the completeness of daily sampling and the selection of sampling days.

Robert Wright, *Harvard School of Public Health, 665 Huntington Avenue, Boston, USA*
David C. Christiani, *Harvard School of Public Health, 665 Huntington Avenue, Boston, USA*

Background: Arsenic (As) can cross the placenta and is a suspected epigenetic toxicant.
Objectives: Investigate the effect of prenatal As exposure at *LINE-1, Alu, p16* and *p53* using data from a prospective birth cohort recruited in Bangladesh.
Methods: Women whose gestational age was ≤28 weeks were recruited. At enrollment, water samples were collected from the tubewell the participant identified as her primary source of drinking water and analyzed for As using inductively-coupled plasma mass spectrometry (ICP-MS). DNA was extracted from fresh whole umbilical cord blood (N=114). DNA methylation was quantified using pyrosequencing at *LINE-1, Alu,* and seven and four CpG positions in the promoter region of *p16* and *p53*, respectively.
Results: Infants were categorized as exposed (53.1%) or unexposed (46.9%) using maternal water As concentrations. General linear regression models were used to compare DNA methylation between exposed (As ≥ 1 µg/L) versus unexposed (As < 1 µg/L) infants. In adjusted models, DNA methylation in exposed infants was significantly higher at *LINE-1* (81.5% vs 80.6%, p-value=0.01) and at *p16* position 2 (3.1% vs 2.4%, p-value=0.009) position 5 (2.3% vs 1.9%, p-value=0.01) position 6 (1.4% vs 1.1%, p-value=0.02) and position 7 (2.6% vs 2.1%, p-value 0.02) compared to unexposed infants. No difference was observed at *Alu* or *p53.*
Conclusions: These results suggest that *in utero* exposure to As was associated with DNA hypermethylation in umbilical cord leukocytes at both global and loci specific markers. Additional studies are needed to confirm these results and determine whether changes in DNA methylation of umbilical cord leukocytes are associated with health outcomes.

INFLUENCE OF NETWORK DESIGN ON HEALTH EFFECT ESTIMATES FROM PREDICTED EXPOSURES

Sun-Young Kim, *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, USA*
Lianne Sheppard, *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, USA*
Department of Biostatistics, University of Washington, Seattle, USA
Adam A. Szpiro, *Department of Biostatistics, University of Washington, Seattle, USA*
Sverre Vedal , *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, USA*

Background and Aims: Estimated health effects for long-term air pollution exposure predictions vary across cities in cohort studies. This may be due to features of network designs. In this simulation study, we hypothesized that distributions of land use characteristics in networks affect health effect estimation and investigated the impact on estimates of relative risks (RRs) of cardiovascular event occurrences for PM2.5 exposures in 29 U.S. cities as a function of monitor and subject distributions.
Methods: We explored the impact of assumed distributions for a land use variable in hypothetical cities and then considered the existing distributions in 29 Women's Health Initiative (WHI) study cities. We chose a land use variable that is spatially rough and assumed it was associated with PM2.5. Given distributions of this variable in each city, PM2.5 exposures were simulated using underlying geostatistical models also incorporating spatial correlation at subject and monitoring locations. Then, we predicted PM2.5 at 1500 subject homes given PM2.5 exposures at 30 monitoring locations. Survival times to cardiovascular events of subjects were simulated using underlying models conditional on simulated exposures. RRs of cardiovascular event occurrences for true and predicted PM2.5 were estimated in Cox proportional hazard models. Finally, we assessed the relationship between standard deviation of the land use covariate and properties of RR estimates across cities.
Results: We found improved performance of health effect estimates with increasing standard deviations of our spatial covariate in hypothetical networks. As variability in the spatial covariate at monitoring locations increased, bias and variance decreased, and coverage approached 95 percent. This pattern was similar but less clear in WHI cities.
Conclusions: Our simulation study showed that network designs determining distributions of a land use characteristic associated with air pollution exposures affected performance of health effect estimates of predicted exposures.

PREDICTORS AND TEMPORAL VARIABILITY OF URINARY PARABEN CONCENTRATIONS IN MEN AND WOMEN BEFORE AND DURING PREGNANCY

Kristen Smith, *Harvard University School of Public Health, USA*
Antonia Calafat, *Centers for Disease Control and Prevention, USA*
Jennifer Ford, *Harvard University School of Public Health, USA*
Myra Keller, *Harvard University School of Public Health, USA*
Russ Hauser, *Harvard University School of Public Health and Massachusetts General Hospital, USA*

Background and Aims: Parabens are used as antimicrobial preservatives in personal care products, pharmaceuticals, and food products, and are considered endocrine disruptors. There is widespread paraben exposure among the US population. To our knowledge, no studies have investigated variability in urinary paraben concentrations among men and women, as well as during pregnancy. Our objective was to evaluate the temporal variability and predictors of paraben concentrations.
Methods: Using on-line solid phase extraction-high performance liquid chromatography-isotope dilution tandem mass spectrometry we measured urinary concentrations of methyl-(MP), propyl-(PP), and butyl-paraben (BP).
Results: Between 2005 to 2010, 2218 urine samples were collected from 575 patients from the Massachusetts General Hospital Fertility Center: 356 women (1724 samples) and 219 men (494 samples). Eighty-one women became pregnant during the follow-up period and provided a pre-pregnancy urine sample and one during each trimester. For all participants, median concentrations were 117µg/L (range: < 1-23200µg/L; detection frequency: 99.7%) for MP, 25.5µg/L (<0.2-2550µg/L; 96.5%) for PP, and 0.70µg/L (<0.2-595µg/L; 67.0%) for BP. Adjusting for specific gravity (SG), MP concentrations were 5.2 fold higher among women compared to men ($p<0.0001$), 3.2 fold higher among African Americans compared to Caucasians ($p<0.0001$), and 27% lower during pregnancy compared to the woman's pre-pregnancy samples ($p=0.001$). The correlation of SG-adjusted MP concentrations was stronger between trimesters 1 and 2 ($r=0.33$; $p=0.003$) and 2 and 3 ($r=0.42$; $p=0.0001$) compared to between 1 and 3 ($r=0.26$; $p=0.02$). The intraclass correlation coefficient (ICC) for SG-adjusted MP was 0.51 for men and 0.43 for women. Similar results were found for PP.
Conclusions: Urinary paraben concentrations were significantly higher among women, and among African Americans compared to Caucasians, while concentrations decreased in women while pregnant compared to their pre-pregnancy samples. Finally, ICCs were higher for men compared to women suggesting lower temporal variability among men than women.

COMPARING METHODS FOR CLASSIFYING 'DANGEROUS HEAT' IN HEAT HEALTH WARNING SYSTEMS

Kai Zhang, *School of Public Health, University of Michigan, Ann Arbor, MI USA*
Richard B. Rood, *College of Engineering, University of Michigan, Ann Arbor, MI USA*
George Michailidis, *Department of Statistics, University of Michigan, Ann Arbor, MI USA*

Joel D. Schwartz, *Department of Environmental Health, Harvard University, MA.USA*
Antonella Zanobetti, *Department of Environmental Health, Harvard University, MA.USA*
Kristie L. Ebi, *Stanford University, Palo Alto, CA, USA.*

Background and Aims: Heat waves have been linked to excess mortality and morbidity, and are projected to increase in frequency and intensity with a warming climate. Several proposed weather-related triggers for activating heat health warning system (HHWS) triggers exist, including simple temperature or heat index (HI) thresholds and the synoptic (air mass) approach. This study compares methods to trigger HHWS, and introduces a new flexible data-driven method that combines the air mass approach with a more transparent procedure.
Methods: A novel multi-level hybrid clustering method (HCM) was developed to identify extremely hot days. The number of levels subjects to users' demand. Two-level and three-level HCM as well as common indices, including spatial synoptic classification (SSC), 90th, 95th and 99th percentile minimum heat index (HI) methods lasting for at least two days, were calculated using a historical summer time (May 1st to September 30th) weather dataset in Detroit from 1976 to 2006.
Results: The HCM, SSC, and minimum heat index methods differed greatly. The 90th minimum HI tended to define more potentially dangerously hot days (405 days over 31 years) than SSC (355 days), two-level HCM (189 days), three-level HCM (69 days), 95th and 99th minimum HI (180 and 22 days). SSC tended to include the days with lower daily minimum temperature and dew point. The average minimum temperature and dew point of SSC-identified heat wave days were 2.6 and 5.3 ^{o}C lower compared to those days identified by other methods. The overlapping days between SSC and other methods were small or moderate, ranging from 21 to 151 days.
Conclusions: Our proposed clustering framework shows some advantages such as flexibility and relatively transparency compared to the current synoptic classification methods. It can be applied in HHWSs, epidemiological studies and public health interventions to protect vulnerable populations from extreme heat events.

LIGHTS OUT: IMPACT OF THE AUGUST 2003 POWER OUTAGE ON MORTALITY IN NEW YORK, NY

G. Brooke Anderson, *Yale University, USA*
Michelle L. Bell, *Yale University, USA*

Background and Aims: In the United States, energy use is increasing, which stresses the aging power grid, creating frequent possibilities for power outages. Energy infrastructure is critical for national security, and power outages could increase from global climate change because of increased demand for energy on hot days and more frequent extreme weather. However, little is known about how power outages affect human health, despite the potential of such information to improve emergency planning.
Methods: Here we investigate all-cause mortality in New York, NY, during the August 14-15, 2003, blackout. We modeled mortality in New York, NY, 1987-2005, using a generalized linear model and modeled daily mortality rates using a Poisson distribution with overdispersion, based on methods used to study health effects of air pollution, temperature, and heatwaves. We used an indicator to model the days of the blackout and controlled for time-varying factors including day of week, weather, and long-term and seasonal mortality trends.
Results: Mortality spiked for both accidental deaths (122.1% increase; 95% confidence interval: 27.6%,286.8%) and non-accidental deaths (25.3%; 11.7%,40.5%), resulting in approximately 90 excess deaths. Increased mortality did not result from deaths being advanced by a few days; rather, for the remainder of August 2003, mortality risk remained slightly elevated.
Conclusions: To our knowledge, this is the first investigation of the effects of a power blackout on non-accidental mortality. Understanding impacts of power outages on human health is important, given that increased energy demand and climate change are likely to strain power grids, and terrorist attacks on power grids remain a security concern.

ASSOCIATION BETWEEN SOLAR LIGHT EXPOSURE AND TOTAL MORTALITY AMONG RENAL TRANPLANT RECIPIENTS

Spencer-Hwang R, *Loma Linda University School of Public Health*
Soret S, Knutsen SF, *Loma Linda University School of Public Health*
Elder J, and Oda K, *Loma Linda University School of Public Health*

Background: Vitamin D deficiency is prevalent among renal transplant recipients (RTRs). Vitamin D may play a role in reducing inflammation and slowing disease progression. Solar light is an essential component in initiating events resulting in the active form of vitamin D within the human body. This study evaluated the association between solar light and survival among RTRs.
Methods: This retrospective cohort study included 38,102 subjects identified through the US Renal Data System (USRDS), included adult, RTRs, transplanted between 1997-2002, and living in the continental U.S.A. Solar radiation data was obtained from the National Solar Radiation Database (NSRDB). Annual average values based on monthly concentrations of solar radiation data for the year 2000, were interpolated to ZIP code centroids according to the residence of the RTR population. Cox Proportional Hazard models used to estimate effect of solar radiation (<3600 reference, 3600-<4000, 4000-<4400 and 4400+ Wh/m^2 categories) on risk of total mortality, while adjusting for confounders.
Results: The relative risk (RR) for total mortality among RTRs residing in areas with 3600- <4000 Wh/m^2 of solar radiation was 1.14 (95% CI, 1.01-1.28) in the multivariable adjusted model. For subjects residing in higher solar radiation areas with 4000 – <4400 Wh/m^2 and for areas equal to or greater than 4400 Wh/m^2 the RR for total mortality was 1.08 (95% CI, 0.95 - 1.24) and 1.03 (95%CI, 0.91 -1.16), respectively in the adjusted models. When excluding subjects with prevalent heart disease at time of transplant, the strongest association between solar radiation and total mortality was RR=1.21(95%CI, 1.05-1.39) and found for subjects within the lower solar radiation area of 3600-4000 Wh/m^2.
Conclusion: The findings indicate that for RTRs, living in areas with lower levels of solar radiation may negatively impact survival and increased solar light exposure may be warranted among RTRs in areas with less intense solar radiation.

EXPOSURE TO AMBIENT NITROGEN OXIDES AND RESPIRATORY DISEASES IN CHILDREN BELOW FIVE YEARS

Rakesh Ghosh, University of California, Davis, USA
Jesse Joad, University of California, Davis, USA
Miroslav Dostal, Institute of Experimental Medicine, Academy of Sciences of the Czech Republic, Czech Republic
Radim J. Sram, Institute of Experimental Medicine, Academy of Sciences of the Czech Republic, Czech Republic
Irva Hertz-Picciotto, University of California, Davis, USA

Background and Aims: Acute lower respiratory illness causes more deaths in children below five years than any other disease and recent studies suggest a possible link between air pollution and respiratory illnesses. In this study, we investigated the association between ambient NOx with increased episodes of bronchitis and croup.
Methods: This longitudinal study was conducted in Teplice and Prachatice districts of the Czech Republic, between 1994 and 2003. Children were followed-up from birth to four and half years of age. Data were compiled from medical records at delivery and at follow-up, and from self-administered questionnaires from the same two time points. Ambient monitoring data for NOx was used as exposure averaged over five periods ranging from three – 45 days prior to an episode. To quantify the association between exposure and outcome, while accounting for the correlation between repeated measures we conducted logistic regression analysis using generalized estimating equations. Selection of covariates was facilitated by using a directed acyclic graph.
Results: The adjusted rate ratio (RR) for bronchitis in children <two year old associated with inter-quartile range increase (approximately 35 $\mu g/m^3$) in the 30-day average NOx was 1.31 (95% CI: 1.07, 1.61) and the same for two to 4.5 year olds was 1.23 (95% CI: 1.01, 1.49). Interestingly, the association between bronchitis and NOx increased with child's age in the <two years group. The RR for bronchitis associated with 30-day average NOx exposure in children ≤3 months was 0.61 (95% CI: 0.35, 1.07), >3 to ≤6 months, 1.17 (95% CI: 0.77, 1.79), >6 to ≤12 months, 1.32 (95% CI: 1.02, 1.71) and >12 months, 1.48 (95% CI: 1.11, 1.97). The association between NOx and croup was slightly smaller than bronchitis.
Conclusions: The evidence, if causal, can be of serious public health concern because the current regulatory air standards are much higher than the levels demonstrated to be associated with increased rates of respiratory illnesses in preschool children in this study.

BRAIN CANCER AMONG AGRICULTURAL WORKERS FROM RIO DE JANEIRO, BRAZIL: A DEATH CERTIFICATE-BASED CASE-CONTROL STUDY

Adalberto Luiz Miranda Fº, *Escola Nacional de Saúde Pública / FIOCRUZ,Rio de Janeiro, Brasil*
Gina Torres Rego Monteiro, *Escola Nacional de Saúde Pública / FIOCRUZ, Rio de Janeiro, Brasil*
Armando Meyer, *Instituto de Estudos em Saúde Coletiva / UFRJ, Rio de Janeiro, Brasil*

Background: Several studies indicate that agricultural workers are at greater risk to develop some specific types of cancer, such as brain cancer. The underline hypothesis for such increased risk is the intense exposure to pesticides experienced by these workers.
Objectives: To estimate the magnitude of the association between brain cancer mortality and agricultural activities, as well as ethnicity, education, and place of residence.
Methods: In this death certificate-based case-control study, cases were defined as any resident of Rio de Janeiro State, 18 years or older, male, whose basic cause of death was registered as brain cancer. For each case, 2 controls were randomly chosen among any male individual, 18 years or older, whose basic cause of death was registered as any disease different from neoplasms and diseases of the Nervous System.
Results: Agricultural workers were at higher risk to die by brain cancer, when compared to non-agricultural workers (OR: 1.41; CI95%: 1.09-1.85). Adjustment by age, ethnicity, and residence, increased the magnitude of this risk (OR: 1.83; CI95%: 1.26-2.65). In addition, the brain cancer mortality risk was higher among those individuals of higher education, white, and residents of Nova Friburgo region.
Conclusions: In agreement with international evidences, the present study suggests an association between brain cancer mortality and agricultural activity in the State of Rio de Janeiro, Brazil. Our results reinforce the hypothesis that environmental exposures experienced by this group of workers may play a role in the development of type of cancer.

SOURCE APPORTIONMENT OF AIR POLLUTION IN AN URBAN AREA INFLUENCED BY LOCAL INDUSTRIES IN CALI, COLOMBIA

Nathalie Abrahams, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*
Paola Filigrana, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*
Fabián Méndez, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*

Background and aim: Cali is the third largest city of Colombia, and is located in the southwest of the country. The northern city limits with Yumbo, a town with a large industrial area that includes smelting factories and battery recycling and production. Previous measurements did by environmental authorities showed air concentration levels above standards limits for PM2.5 and lead. As part of a study designed to assess the impact of this industrial area in air quality and health of scholars in northern Cali, we estimated source apportionment to PM2.5 using Positive Matrix Factorization(PMF).
Methods: We collected 90 air samples for PM2.5 on Teflon filters and analyzed them for 57 elements by X-ray Fluorescence(XRF), organic carbon(OC) and elemental carbon(EC) by Termogravimetry, and ions by Ion chromatography. After selection of species by number of samples over detection limits, duplicates species, signal to noise ratio, PMF where modeled with 24 species, including lead, which we used as Yumbo industrial activities tracer as Colombia have green gasoline(lead-free).
Results: The largest component of pm2.5 was the carbonaceous fraction, accounting for 53-83% total mass. 3 factors profiles were identified and their contribution estimated. The principal factor was industrial emissions(53.7% contribution), identified by presence of Pb(91.4%) in its profile, and others heavy metal like Ni(47.62%) and Cd(63.82%). Second factor was mobile sources and associated dust(27.7% contribution), identified by the large presence of OC(72.59%), EC(8683%) and V(51.71%) for mobile; and Fe(25.68%), Ti(36.22%), Ca(48.43%) and Si(38.91%) for associated dust. Third factor was from industrial sources(18.6% contribution) unrelated to lead generating activities, and was identified by presence of Zn(91.49%) and Fe(44.67%).
Conclusions: Industrial activities in the municipality of Yumbo have an impact on air quality in the northern area of Cali and this should lead to joint actions for pollution control.

EXPOSURE ASSESSMENT AND HEALTH EFFECTS ASSOCIATED TO PESTICIDES BURIED NEAR AN URBAN COMMUNITY IN COLOMBIA

Jenny Ordoñez, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*
Ghislianne Echeverry, *Grupo de Investigación en Contaminación Ambiental por Metales Pesados y Plaguicidas-Universidad del Valle, Colombia*
Janeth Mosquera, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*
Olga Gómez, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*
Martha Páez, *Grupo de Investigación en Contaminación Ambiental por Metales Pesados y Plaguicidas-Universidad del Valle, Colombia*
Fabian Méndez, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*

Background/aims: Organophosphate and organochlorine pesticides have been associated with neurological and respiratory effects in agricultural communities, but few studies have been conducted in buried pesticides deposited close to human settlements. An urban neighborhood and a school with >1,500 children was settled in a former agricultural area of 44ha in Cartagena-Colombia. During construction, several containers with pesticides were found. Contaminated soils and containers were removed and confined to an area close by. Our objective was to evaluate exposure to and potential health effects of these buried pesticides on surrounding communities.
Methods: Concentrations of pesticides in soil and air were determined. A health risk assessment was done modeling soil concentrations found at the pesticides confined area. Respiratory diseases data was obtained, and tests for pulmonary and neurological function were applied in children(n=389) and adults(n=440) at the exposed and a control area. Levels of pesticides in serum and their metabolites in urine were determined in a subsample of children.
Results: Presence of DDT isomers and metabolites were found in one soil sample and chlorpyrifos was reported in one air sample. Risk modeling suggests risk inside the confined area by different routes of exposure. Although individuals at the exposed area reported more frequently severe dyspnea(children OR:2.97; IC95%:1.0-8.97) and wheezing (adults OR:2.10; IC95%:1.13-3.90) evidence of lung function effects was not demonstrated by spirometry. There were not differences in intellectual performance. Pesticides in blood serum were mostly below detection limits, and only significant levels of pp-DDE were found, although at concentrations similar to non-exposed populations.
Conclusions: A confined area with buried pesticides but not direct contact with population is a potential source of risk. However, no evidence of exposure to pesticides was found in this area. Increased reports of respiratory symptoms could be explained by increased risk perception or other environmental exposures in the area.

STUDY ON THE RELATIONSHIP BETWEEN THE APPARENT TEMPERATURE AND POPULATION MORTALITY IN BEIJING, CHINA

Xiaochuan Pan, *School of Public Health, Peking University, Beijing, China*

Jianyong Tong, *School of Public Health, Peking University, Beijing, China*

Chu Jiang, *Haidian Center for Disease Control and Prevention, Beijing, China*

Yanhui Shen, *Haidian Center for Disease Control and Prevention, Beijing, China*

Yumin Liu, *Beijing Center for Disease Control and Prevention, China*

Fan Shen, *Beijing Center for Disease Control and Prevention, China*

Background and Aims: The relationship between air temperature and population mortality were more and more concerned by the researchers in recent years. However, the association of the population mortality with ambient apparent temperature which integrated air temperature and relative humidity was scarcely studied in China. The aim of our study is to explore the potential relationship between the apparent temperature and daily population mortality in Beijing, China.

Methods: Time series study design. The cause-specific mortality data and the data of meteorology and the ambient pollutants in 2004-2008 were collected from local CDC of Beijing and the website of the related local authorities of Beijing, respectively. Generalized additive model (GAM) with poisson regression were used to analyze the association between the daily apparent temperature and the counts of all cause death, cause-specific death of Chronic Ischemic Heart Disease (CIHD), myocardial infarction, intracerebral hemorrhage (ICH) and cerebral infarction (CI) of the exposed population in Beijing respectively, after adjusting relative humidity, air pressure, wind speed, influenza, time trends, week day with cubic spline function, etc.

Results: The cumulative general relative risk (RR) of all cause death was 1.0046 (95% CI= 1.00807 • 1.00133) for 1°C increase of daily mean apparent temperature, the strongest effect was occurred by the lag one day. The RR values for circulatory diseases were 1.00511 • 95% CI 1.00121 • 1.00511 Ž per 1°C increase, stratified analysis of age group showed that the effect of apparent temperature was stronger to the aged above 75. A V-shaped or U-shaped curve was found for the relationship between the apparent temperature and cause-specific death of the exposed population.

Conclusion: The apparent temperature was positively associated with the population mortality, which the subpopulations aged above 75 yrs were the most susceptible to the change of apparent temperature.

EXPOSURE ASSESSMENT OF PHTHALATES IN CHINA USING GEOGRAPHIC INFORMATION SYSTEMS

Li Chen, *School of Public School, Fudan University, Shanghai. China*

Yan Zhao, *School of Public School, Fudan University, Shanghai. China*

Yunhui Zhang, *School of Public School, Fudan University, Shanghai. China*

Background: As one kind of environmental endocrine disruptors, phthalates are widely used as plasticizers in a number of day-life products, exerts both short-term and long-lasting effects on reproduction and development of organisms. With increasing data of phthalates exposure and their relationship with human diseases, there is an emerging need for a thorough exposure assessment of phthalates in China.

Methods: Geographic information system (GIS) was used to map phthalate levels and distributions in China based on published data of environmental phthalates exposure during the past twenty years. The total daily intake (TDI), inner absorbed level and blood lipid concentration of phthalates was calculated by different models to evaluate human body burden of phthalates in China.

Results: Phthalates exposure in Chinese environment varied in geographical patterns. Mean levels of phthalates in atmosphere ranged through 300 ng/m^3 in winter and 600 ng/m^3 in summer, while those levels in water were in range of 5-50 μg/L. Severer phthalates pollution were found in soil and food samples, with concentrations of up to 100 mg/g d.w. TDI of phthalates was 103.9mg/d for people residing in Pearl River Delta area, significantly higher than those residing in Yangtze River Delta area (6.8mg/d).

Conclusions: Phthalate are ubiquitous in China. Food is the main source of phthalate intake for humans. DEHP accounts for over 70% of phthalate body burden in humans. People residing in Pearl River Delta area have relatively higher body burden of phthalate than those in other areas, which suggests that decision-maker in China be considering the potential health effects of phthalates on humans, especially children and elders, in this area.

Key words: phthalate; exposure assessment; GIS; body burden; DEHP

ASSOCIATION BETWEEN AIR POLLUTION AND GLUTATHIONE S-TRANSFERASE (GST) P1 ON ASTHMA AND WHEEZING AMONG CHILDREN IN TAIWAN

AIR POLLUTION AND GSTP1ON ASTHMA AND WHEEZING IN CHILDREN

Bing-Fang Hwang, Department of Occupational Safety, College of Public Health,China Medical University, Taichung, Taiwan

Yungling Leo Lee,Institute of Preventive Medicine, College of Pubic Health, National Taiwan University, Taipei, Taiwan

Background and Aims: There are limited studies on the role of interaction between exposure to ambient air pollution and glutanthione-S-transferase (GST) P1 on the risk of asthma and wheezing among children, which provided suggestive, but inconclusive results. The present study was to assess the joint effect of air pollutants and *GSTP1* on the risk of asthma and wheezing in Taiwan Children Health Study

Methods: We conducted a nationwide cross-sectional study of 5,049 Taiwanese children in 2007. The studied determinants were three *GSTP1* Ile105Val (rs 1695) genotypes (Ile-Ile; Ile-Val and Val-Val) and expoure to abmient air pollutants.We used routine air-pollution monitoring data for sulphur dioxide (SO_2), nitrogen dioxides (NO_2), ozone (O_3), carbon monoxide (CO), and particles with an aerodynamic diameter of 2.5 μm or less ($PM_{2.5}$). The exposure parameters were calculated using community annual average concentration. The effect estimates were presented as odds ratios (ORs) per interquartile changes for NO_2, CO, SO_2, $PM_{2.5}$ and O_3.

Results: In a two-stage hierarchical model adjusting for confounding, the risk of asthma was decreased with $PM_{2.5}$ (adjusted odds ratio (OR) 0.60; 95% confidence interval (CI) 0.45, 0.82), and O_3 (OR 0.74; 95% CI 0.60, 0.90) among ile105 homozygotes, but not among those at least one val105 allele (interaction p value=0.001 and 0.03, respectively). A similar tendency of effect modification between $PM_{2.5}$ and O_3 and GSTP1 on the risk of wheezing was found.

Conclusions: Children who carried ile105 variant allele may be protected from the increased risk of asthma and wheezing of ambient air pollutants, especially in $PM_{2.5}$ and O_3.

IMPACT OF AIR POLLUTION AND PARKINSON'S DISEASE ON MORTALITY

Stephen Van Den Eeden, *Kaiser Permanente Northern California, USA*
Kathleen Albers, *Kaiser Permanente Northern California, USA*
Lorene Nelson, *Stanford University, USA*
Caroline Tanner, *Parkinson's Institute, USA*
Jun Shan, *Kaiser Permanente Northern California, USA*
Charles Quesenberry, *Kaiser Permanente Northern California, USA*

Background and Aims: Preliminary studies suggest that traffic or air pollution may increase the risk of Parkinson's disease (PD). We sought to examine how exposure to ambient air pollution and Parkinson's disease are associated with mortality.
Methods: Study subjects were participants in the Parkinsonism Epidemiology at Kaiser (PEAK) case-control study. Patients with PD (n=470) were diagnosed in 1994-1995 and matched to sex- and age-matched controls (n=498); both groups were followed annually for mortality. Residential location for each individual was geocoded at time of diagnosis (cases) or reference date (controls) and assigned the mean level of air pollutants in the year prior to this date based on ambient air pollution data geospatially interpolated from air quality monitoring data. A four-level variable was created based on case-control status and exposure (as above and below mean for the pollutant) and was analyzed using proportional hazard models to estimate the hazard ratio (HR) with the case-exposure classifications variable entered indicator variables and mortality (all-cause) as the outcome, while adjusting for age, sex, race/ethnicity, BMI and smoking.
Results: Compared to controls with low (below mean) exposure, the mortality HR for PD cases with low NO_2 exposure and with high NO_2 exposure were 1.34 (95% CI 0.93-1.95) and 1.58 (95% CI 1.12-2.22), respectively. For ozone exposure, mortality was significantly elevated for PD low exposure and PD high exposure groups (HR=1.64; 95% CI 1.17-2.31; and HR=1.78; 95% CI 1.25-2.53, respectively). PM_{10} exposure, mortality was similarly elevated for PD low exposure and high exposure groups (HR=1.29; 95% CI 0.92-1.80; and HR=1.28; 95% CI 0.92-1.78, respectively). There were no significant associations for controls above the median relative to controls below the median for any of these pollutants. No associations were observed for exposure to CO.
Conclusions: These data suggest that air pollution may have an adverse mortality effect among individuals with Parkinson's disease.

CADMIUM INDUCED RENAL TUBULAR DAMAGE AMONG RESIDENTS LIVING NEAR THE COPPER REFINERY PLANT IN KOREA.

Geun-Bae Kim, *National Institute of Environmental Research, Korea*
Chung-Hee Park, *National Institute of Environmental Research, Korea*
Chul-Ho Lee, *National Institute of Environmental Research, Korea*
Seung-Do Yu, *National Institute of Environmental Research, Korea*
Sang-Yong Eom, *College of Medicine, Chungbuk National University, Korea*
Heon Kim, *College of Medicine, Chungbuk National University, Korea*

Background/Aims: Cadmium (Cd) is the most potent nephrotoxic heavy metal, with a long biological half-life in human body. This study aimed to assess the effect of environmental Cd exposure on kidney dysfunction.
Methods: The study subjects composed of 687 individuals who reside within 4 km area from a copper refinery plant. We analyzed the concentrations of Cd in blood and urine, renal tubular damage markers [urinary • $_2$-microglobulin (• $_2$-MG), N-acetyl-• -D-glucosaminidase (NAG) activity, and total protein], and kidney function markers [blood urea nitrogen (BUN) and serum creatinine]. Renal dysfunction rates were estimated and compared according to the hematologic and urinary Cd level.
Results: The blood Cd ranged from 0.21 to 16.12 • g /L (geometric mean; 2.56 • g/L) and the urinary Cd, from 0.14 to 22.42 • g/g creatinine (geometric mean; 2.72 • g/g creatinine). The urinary NAG activity was significantly correlated with urinary cadmium level (r=0.103, p=0.021). As blood or urinary Cd level increased, the prevalence of renal tubular damage (defined as U-NAG > 11.5 U/g creatinine, or U-• $_2$-MG > 300 • g/g creatinine) increased in a dose-response way. The odds ratio (adjusted for age, gender, smoking status, history of diabetes and hypertension) for abnormality of U-NAG according to U-Cd level showed a linear increase, but for U-• $_2$-MG was not. The prevalence of abnormal serum creatinine level (defined as serum creatinie > 1.3 mg/dL) was significantly increased in subjects with moderately elevated blood cadmium level (B-Cd; 2.0 ~ 5.0 • g/L) (odds ratio; 9.60, 95% CI; 1.23-75.17). There were significant differences in the prevalence of renal tubular damage and in that of abnormal serum creatinine level between individuals whose blood Cd level was 2.00 • g/L or higher and those with blood Cd level lower than 2.00 • g/L.
Conclusion: These results suggest a possibility that Cd as low as 2.00 • g/L for blood or 2.00 • g/g creatinine for urine can cause renal tubular or glomerular damage.

Keywords : copper refinery plant, cadmium, renal tubular damage

SOURCES OF INDOOR AIRBORNE CD AND PB IN A COHORT OF PREGNANT WOMEN IN CALI, COLOMBIA

Nathalie Abrahams, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*
Diana Caicedo, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*
Fabian Méndez, *Grupo Epidemiología y Salud Poblacional-Universidad del Valle, Colombia*

Background and aim: As part of the exposure assessment to heavy metals in a cohort of pregnant women in Cali, we evaluated presence and levels of Cd and Pb in food, water and air. Previous exploratory evaluations have been made in food(fish and vegetables) and water(Cali River and water distribution net) showing presence in moderate levels. Although environmental measurements of pm2.5 and its elemental composition shown presence in air of these metals and industrial activities have been identified as the main source, little is known about sources in the indoor. Although air is not the main source for these heavy metals, some practices may increase exposure levels and therefore become an important exposure media. The aim of this research was to identify sources of Cd and Pb in the indoor and immediate neighborhood.
Methods: Based on blood levels of lead and cadmium measured in the first trimester of pregnancy, we selected 50 women with detectable levels of one or both metals. We visited their houses and collected information about practices that could increase exposure to PM2.5, Pb and Cd; developed a peri-domicile assessment, registered sources in the outdoor, and determined distance to industrial areas or other source o fair pollution. Teflon filters were analyzed by X-ray fluorescence(XRF) for Cd and Pb.
Results: Main practices found associated with increased PM2.5 exposure were everyday sweeping, use of curtains for dividing rooms, and opened windows during the day. Practices in the immediate neighborhood like recycling and outdoor burning were also found associated to presence of Pb(max:0.09,min:0.04ug/m3), we did not found Cd in these measurements.
Conclusions: Many of the practices increasing likelihood of exposure in this population are related to poverty. There is a need to develop a complete exposure assessment to identify sources contributions, exposure routes and pathways.

THE RATE OF BONE DEMINERALIZATION WITH AGE DEPENDS ON THE URINARY CADMIUM CONCENTRATION

Jong-Won Kang, *College of Medicine, Chungbuk National University, Korea*
Sang-Yong Eom, *College of Medicine, Chungbuk National University, Korea*
Heon Kim, *College of Medicine, Chungbuk National University, Korea*

Chul-Ho Lee, *National Institute of Environmental Research, Korea*
Seung-Do Yu, *National Institute of Environmental Research, Korea*

Purpose: Janghang Refinery which was built in 1936 and operated for 50 years had emitted great amount of pollutants including cadmium (Cd), a heavy metal which has been reported to be associated with decrease in bone mineral density (BMD). This study was aimed to evaluate the relationship between urinary cadmium concentration and decrement in bone mineral density in residents having lived in the vicinity of Janghang Refinery.
Materials and Methods: The study subjects included 450 males and 619 females who were living within 20 km from Janghang Refinery. Bone mineral density was measured with ultrasonic method at the calcaneus area. Urinary cadmium concentration was evaluated using an atomic absorption spectrophotometer and adjusted with urinary creatinine concentration. The correlation between urinary Cd level and BMD was statistically tested according to age group (<50 yrs, 50 – 59 yrs, 60 – 69 yrs, >70 yrs) and sex, and the decreasing rate of BMD as age was estimated according to urinary Cd level (< 2, 2 – 5, 5 – 10, > 10 • g/g creatinine).
Results: As the age increased, BMD decreased and urinary Cd concentration increased. Urinary Cd concentration was significantly correlated with BMD in young males aged less than 60 years, and in females aged less than 50 years after controlling effects of age and menopause using multiple regression models. Neither in males aged 60 years or more, nor in females aged 50 years or more, were those correlations found. BMD was more strongly correlated with age in females than in males and, it decreased more rapidly as the urine Cd increased in female subjects.
Conclusion: These results suggest that cadmium exposure increases the rate of bone demineralization, especially in women.

HEALTH OF POPULATIONS EXPOSED TO CONTAMINATED AREAS, AN EPIDEMIOLOGICAL SURVEILLANCE PROPOSAL FOR STANDARDIZED PERFORMANCE IN AREAS WITH CONTAMINATED SOIL AND WATER IN BRAZIL

Introduction: The world changes geographic characteristics of populations, associated with industrial actions, triggering an intense urbanization in this process, areas of environmental degradation and consequent contamination of the environment is increasing. In Brazil, several areas were identified. The state of Sao Paulo, more than 2.900 areas has been identified as contaminated soil. The Center for Epidemiological Surveillance of São Paulo State, structured practical handbook of Health Surveillance of Populations Exposed to Contaminated Soil with participation of various sectors, completed in a workshop that describes guidelines.
The manual was prepared by technical staff of the Division of Disease caused by environment, with employees and consultants.
This paper describes all the process and the present the Manual.
Objectives: The main objectives are:

1. Develop guidelines on epidemiological surveillance for action in promoting the health of populations exposed to areas contaminated
2. Promote surveillance actives to the population exposed to contaminated areas.

Methodology: The manual was prepared with discussion involving: Pan American Health Organization, Ministry of Health, institutions of the Department of Health of Brazil, Department of the Environment (CETESB) and especially regional and local health activities in the area with environmental health at the SP state. Discusses: Definitions used in the area; Legal Grounds - Epidemiological Surveillance of people exposed to soil contaminated; Structure Footsteps - Epidemiological Surveillance of people exposed to soil contaminated:
Step 1: Creation of the Technical Group
Step 2: Removal of contaminated areas
Step 3: Register of contaminated areas
Step 4: Initial investigation of population exposed to contaminated soil
Step 5: Epidemiological investigation
Step 6: Protocols for monitoring of population exposed to soil contaminated
Conclusion: Front vast number of people exposed to contaminated areas, it is necessary foundations for health promotion, which can be initiated through the use of tools for epidemiological surveillance.

INTERACTION BETWEEN AIR POLLUTION AND BMI OVER LUNG FUNCTION AND EXHALED NITRIC OXIDE IN A COHORT OF ADOLESCENTS OBESE IN MEXICO CITY

Leticia Hernández-Cadena, *Instituto Nacional de Salud Publica, Mexico*

Isabelle Romieu, *Section of Nutrition and Metabolism, IARC, Lyon France*

Background and Aim. Both, obesity and asthma are common conditions. Air pollution has been associated with decreased lung function and higher inflammation. The combined effect of weight loss and air pollution on lung function and inflammation had not been evaluated. We conducted a study to evaluate the effect of air pollution and weight-loss on lung function and airway inflammation in obese adolescents with and without asthma.
Methods: We studied a cohort of 121 asthmatic and 226 non-asthmatic adolescents with obesity, followed by 12 months average during a weight loss intervention program. Spirometric tests and measurements of FeNO were conducted each month during follow-up. Exposure was estimated from outdoor PM2.5, concentrations recorded by the Mexico City government at fixed-site central monitoring (RAMA). Data were analyzed using linear mixed effects models.
Results: PM2.5 concentrations ranged 4.6 to 56.8 • g/m3 during study period (mean=25.8 ug/m3). Mean BMI (kg/m^2) decreased from 30.2(SD=4.8) to 27.5 (SD=4.4) after 5 months of follow up average (2-22 months), 76 participants (22.4%) lost weight at 5% or more. At baseline, FeNO was higher among asthmatics than non asthmatics (41.7 vs 33.7 ppb, p<0.05); but not difference were observed for FEV1, FVC and FEF2575. Days with high exposure (PM2.5>25 • g/m3) were associated with 1.06 ppb increase in FeNO, and inversely associated with FEV1 (• =-73.7 ml, p= 0.004) and FVC (• =-125 ml, p=0.033). FEV1 and FVC increased when lost weight 79.9 (95% CI:23.0, 136.8)ml and 69.4 (95% CI:-19.2,0.158.0) ml respectively, and fef2575 increased 131.0(IC95%:12.9,149.2) ml. FeNO decreased by 15 % (6.2 ppb) significantly, p<.05). However the improvement in lung function was different on days with low and high pollution.
Conclusion: Weight reduction in obese adolescents is associated with improved lung function and reducing inflammation of the airways, this change might be altered by exposure to environmental pollutants.

Socioeconomic and Racial Disparities in Cumulative Phthalates Exposure Among U.S. Reproductive-Aged Women From NHANES

Ami R. Zota, *University of California, San Francisco, United States*
Tracey J. Woodruff, *University of California, San Francisco, United States*

Background and Aims: Prenatal phthalates exposure is associated with increased risk of adverse male reproductive outcomes. The National Academy of Sciences (NAS) recommends chemical risk assessments account for exposure to multiple phthalates affecting the same common adverse health outcome. However, few, if any studies have characterized cumulative burdens of environmental contaminants in potentially vulnerable populations or attempted to identify high-risk subpopulations. We used NAS recommendations to develop cumulative metrics for phthalates exposures among a representative sample of U.S. reproductive-aged women, and examine racial/ethnic and socioeconomic differences.
Methods: We analyzed urinary phthalate data in 2324 women (aged 15 to 44 years) from National Health and Nutritional Examination Survey, 2001-2008. We analyzed metabolites of di-n-butyl phthalate (DBP), diisobutyl phthalate (DIBP), butyl benzyl phthalate (BBP), and di(2-ethylhexyl) phthalate (DEHP) (all anti-androgens). We summed concentrations of 6 metabolites (∑phthalates). We also created a weighted phthalate score (∑phthalates_BMD) using theoretical benchmark dose (BMD) values provided by the NAS.
Results: Metabolites of BBP and DEHP generally decreased during the study period whereas DIBP metabolite significantly increased. African American women had higher ∑phthalates_BMD scores than their White or Mexican-American counterparts ($p = 0.04$) after controlling for education, income, age, and creatinine levels. Education was not a significant predictor but in models stratified by race, lower educational attainment was associated with higher ∑phthalates_BMD scores among African American women ($p=0.04$). Women with less than a high school education had approximately 20% higher ∑phthalates_BMD scores than those with more than high school education (least square geometric means (± standard error): 3.70 ± 1.09 versus 2.97 ± 1.07, respectively). Similar socio-demographic trends were observed for ∑phthalates.
Conclusions: African American women in the US, particularly those with less education, may be at increased risk of phthalate-induced health risks, and further research is warranted to identify drivers of environmental health disparities.

DEVELOPING A LAND USE REGRESSION MODEL FOR ULTRAFINE PARTICLE CONCENTRATIONS IN VANCOUVER, CANADA

Rebecca Abernethy, *University of British Columbia, Canada*
Michael Brauer, *University of British Columbia, Canada*
Ryan Allen, *Simon Fraser University, Canada*

Background and Aims: Epidemiologic studies have associated adverse health outcomes with exposure to traffic-related air pollutants, principally NO_2, at levels below those showing effects in controlled exposure studies. (1) This suggests the importance of related contaminants in the traffic exhaust mixture such as ultrafine particles (UFP) (<0.1µm in diameter). Presently, no routine monitoring for UFP exists in North America and little information is available regarding UFP spatial distribution.We measured particle number concentrations (PNC) in Vancouver to develop a land use regression (LUR) model for use in epidemiologic studies and to identify important factors influencing concentrations.
Methods: During a three-week sampling period in spring 2010, PNC were measured with portable condensation particle counters (CPC3007, TSI®, Shoreview, MN) for one hour at eighty locations previously used to characterize spatial variability in nitrogen oxides. PNC was measured continuously at four additional locations to assess temporal variation.
LUR modeling was conducted using geographic predictors, including: road length, vehicle density, intersection and bus stop density, land use type, fast food restaurant density, population density and elevation.
Results: The range of measured (one-hour median) PNC values was highly variable, 1500 - 105000 particles/cm^3, (mean [SD] = 18200 [15900] particles/cm^3). Pearson correlations of PNC with two-week average NO, NO_2 and NO_x concentrations at the same sites were 0.59, 0.61 and 0.65. A preliminary LUR model (R^2 = 0.44) for temporally-adjusted PNC included ln-distance to nearest major road, area of industrial land within a 750m radius and density of bus stops within 100m.
Conclusions: Measured PNC was highly correlated with measured nitrogen oxides. However, geographic predictors explained a smaller proportion of variability in PNC levels than found previously for nitrogen oxides, suggesting some common sources and additional unknown factors accounting for PNC spatial variability. (2) A subsequent UFP LUR model will incorporate wind speed and direction.

Background and Aims: Inhaling fine particles ($PM_{2.5}$), one component of air pollution, into the deep regions of the lung can induce oxidative stress and inflammation, and may contribute to onset of preterm labor. The aim of this research was to examine the relationship between $PM_{2.5}$ and adverse birth outcomes among 22 countries in the World Health Organization Global Survey on Maternal and Perinatal Health from 2004-2008.
Methods: Global $PM_{2.5}$ estimates from remote sensing data were developed to produce long-term average values (2001-2006). Clinics were geocoded, and $PM_{2.5}$ levels were generated in 50 kilometer radius circular buffers around each clinic. We used generalized estimating equations to determine the relationship between clinic-level $PM_{2.5}$ levels and preterm birth and low birthweight at the individual level, adjusting for seasonality and potential confounders at the individual, clinic and country levels. Region-specific and country-specific associations were also investigated.
Results: When looking across all countries and adjusting for seasonality, $PM_{2.5}$ was not associated with preterm birth or low birthweight. Higher $PM_{2.5}$ was associated with higher odds of low birthweight in African countries. In China, the country with the largest range of particulate levels, higher $PM_{2.5}$ was associated with higher odds of preterm birth and low birthweight, with some evidence of a threshold effect when comparing the fourth quartile to the first quartile of $PM_{2.5}$ (Odds Ratio [OR] = 1.79; 95% Confidence Interval [CI]: 0.97-3.31 and OR = 1.60; CI: 1.02-2.51 for preterm birth and low birthweight, respectively).
Conclusions: Looking at the relationship between fine particles and adverse birth outcomes across countries and within countries with a large range of particulate levels gives additional insight into the potential causal mechanisms between air pollution and adverse birth outcomes.

SINGLE NUCLEOTIDE POLYMORPHISMS IN METALLOTHIONEIN AND CHANGES IN HAIR MERCURY LEVELS

Yi Wang, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*
Jaclyn Goodrich, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*
Brenda W. Gillespie, *Department of Biostatistics, University of Michigan, Ann Arbor, USA*
Robert A. Werner, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA; Department of Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, USA*
Niladri Basu, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*
Alfred Franzblau, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*

Background and Aims: Mercury (Hg) is a potent neurotoxicant of concern to the general public. Recent studies suggested that several genes that mediates mercury metabolism are polymorphic in humans. We hypothesized that single nucleotide polymorphisms (SNPs) in metallothionein (MT) genes may underlie inter-individual differences in mercury metabolism.
Methods: Dental professionals (n=515) were recruited during the Michigan Dental Association (MDA) Annual Conventions in 2009 and 2010. Samples of hair and buccal swabs were collected. Self-administrated questionnaires were completed for demographic information and estimating daily dietary Hg intake from fish.
Results: The sample consisted of 244 dentists (47.4%), 269 non-dentists (52.2%), and 2 unidentified (0.4%) and was predominantly Caucasian (90.5%). The arithmetic mean mercury level in hair (0.51µg/g) was not significantly different from that (0.47µg/g) of the US general population (NHANES 1999-2000). The mean estimated daily methylmercury intake was 0.084 µg/kg/day ranging from 0 to 0.98 µg/kg/day with 25% exceeding the current US EPA Reference Dose (RfD) of 0.1 µg/kg/day. A statistically significant difference was found in mean hair Hg levels of subjects with MT1M 3'UTR (T>C; rs9936471) TT and TC genotypes. Multivariate linear regression analysis found those with TC genotype had higher hair Hg levels than those with TT genotype (n=15) after controlling for estimated daily methylmercury intake from fish. Similar higher hair Hg levels were found in subjects with MT1E 3'UTR (G>T; rs708274) GG genotype compared to those with GT and TT genotypes (n=51).
Conclusions: The findings suggested that MT gene polymorphisms may influence mercury metabolism.

A CASE-CONTROL STUDY ON THE IMPACTS OF HIGH AMBIENT TEMPERATURE ON THE INCIDENCE OF UROLITHIASIS AMONG OUTDOOR WORKERS IN GUANGZHOU, CHINA

Haiming Luo, *Queensland University of Technology, Australia*

Background and Aims: High temperature exposure impacts the prevalence of urolithiasis on people, especially on those who are exposed to high temperature at their workplaces in tropical and subtropical areas in developing countries. Many previous studies compared prevalence between subjects exposed to, and not exposed to, high temperatures using cross-sectional designs. In this study, we proposed a retrospective matched case-control study to identify potential predictors for urolithiasis occurrence among outdoor workers in Guangzhou, China

Methods: Health surveillance data of a shipbuilding company were collected from Guangdong Institute of Health Inspection, including kidney B-ultrasonography results□strong medical diagnosis evidence for urolithiasis□, electroncardiography results, blood pressure, departments of work, length of service, daily exposure time, gender and age for the period 2003-2010. We matched cases and controls at 1:4 with gender and age as criteria, and used Conditional Logistic Regression (Cox Regression Model) for identifying potential predictors, including B-ultrasonography results with departments of work, length of service, daily exposure time, electrocardiogaphy results and blood pressure results

Results: Of 950 workers in the shipbuilding company, 190 (20.00%) had presented with at least one episode of urolithiasis. Of these, 149 were among workers exposed to high temperature (30.66%) and 41 among the workers not exposed to high temperature (8.84%) (X^2=70.65, P<0.001). Length of service, departments of work, and daily exposure time were all identified as predictors for urolithiasis occurrence (OR_1=1.012, OR_2=0.233, OR_3=0.001, p<0.001), and length of service had the highest odd ratio of the three.

Conclusions: This study shows that length of service, departments of work, and daily exposure time represent risk factors for urolithiasis among outdoor workers in Guangzhou, China.

IN-VEHICLE POLLUTANT EXPOSURES AND ACUTE CARDIORESPIRATORY RESPONSE IN A COHORT OF HEALTHY AND ASTHMATIC CAR COMMUTERS IN THE ATLANTA COMMUTERS' EXPOSURE STUDY

Jeremy A. Sarnat, *Emory University, USA*
Roby Greenwald, *Emory University, USA*
Stefanie E. Sarnat, *Emory University, USA*
Priya Kewada, *Emory University, USA*
Fuyuen Yip, *Centers for Disease Control & Prevention, USA*
Tegan K. Boehmer, *Centers for Disease Control & Prevention, USA*
Michael H. Bergin, *Georgia Institute of Technology, USA*

Background and Aims: Previous findings show acute cardiorespiratory response associated with very short-term exposures to traffic pollutants (McCreanor et al, 2007). It is, thus, plausible that daily car commuters comprise a vulnerable sub-population, despite limited data examining exposures during realistic commutes and health response. We conducted the Atlanta Commuters Exposures (ACE) Study to address these research needs.
Methods: Twenty healthy and 20 asthmatic subjects participated in two, 2h scripted car commutes. We measured a range of pulmonary and cardiovascular biomarkers immediately pre- and post-commute and for 3h, each hour, post-commute. We sampled in-vehicle concentrations of size-resolved particulate matter mass and number, and organic and elemental species using a novel sampling manifold. Mixed effect regression models were used to examine differences between pre- and post-commute biomarker levels.
Results: Elevated concentrations of many pollutant concentrations existed during the commutes. We observed significant ($p < 0.0001$) increases in post-commute exhaled nitric oxide (eNO) indicative of pulmonary inflammation. During the 4 post-commute measurement periods, mean eNO levels ranged from 12-16% above corresponding pre-commute levels and were typically highest at the 1h post-commute measurement period. C-reactive protein (CRP) levels, indicative of systemic inflammation, were also elevated, although not significantly, at each of the post-commute periods. CRP levels were highest (15% higher than pre-commute levels) immediately after the commute ($p = 0.07$). Associations between pre- and post-commute lung function were negligible. For these analyses, results were not significantly different by disease status.
Conclusions: Preliminary ACE study results showed significant elevations in several biomarkers of acute pulmonary and systemic inflammation following a realistic morning commute. These results provide indication that sub-clinical changes, consistent with inflammation, may be occurring in our cohort. Results examining the role of specific particle chemical components, effects on additional endpoints and potential confounding by stress and noise will also be discussed.

THE EFFECT OF EXPOSURE TO AIR POLLUTANTS ON INSULIN RESISTANCE MODIFIED BY GENOTYPES OF *GSTM1* AND *NAT2* IN THE KOREAN ELDERLY ENVIRONMENTAL PANEL STUDY (KEEPS)

Jin Hee Kim, *Institute of Environmental Medicine, Seoul National University Medical Research Center, Republic of Korea*
Yun-Chul Hong, *Institute of Environmental Medicine, Seoul National University Medical Research Center; Department of Preventive Medicine, Seoul National University College of Medicine, Republic of Korea*

Background and Aims: Previous studies have found that air pollutants increase cardiovascular outcome and diabetes mellitus (DM) increases the impact of air pollutants on cardiovascular outcome. However, recently, a possibility that DM may be an outcome of air pollution exposures in addition to being an effect modifier for air pollution-associated cardiovascular disease was suggested. Moreover, *GSTM1* and *NAT2*, in relation with detoxification, have been known to affect air pollution-related outcomes. Therefore, in this study, we evaluated the effect of air pollutants on insulin resistance (IR) which is an underlying mechanism of DM and metabolic syndrome and the effect modification by *GSTM1* and *NAT2* genotypes in the Korean elderly.
Methods: We recruited 560 of aged persons more than 60-years old and obtained blood samples three times during five medical examinations between 2008 and 2010. All ambient air pollutant concentration data (PM_{10}, SO_2, O_3, NO_2, and CO) during the study period were obtained from the Korea National Institute of Environmental Research air quality monitoring system. We measured levels of insulin and glucose in serum in order to assess IR. In addition, the HOMA, an indirect index for the assessment of IR, was calculated using the formula as follows; insulin (• U/ml) × [glucose (mmol/l)/22.5]. We also measured urinary level of cotinine as an indicator of smoking amount.
Results: When we estimated the effect of PM_{10}, SO_2, O_3, NO_2, and CO on each insulin resistance index using linear mixed-effect model, PM_{10}, O_3, and NO_2 were found to be associated with increased insulin resistance indices in the elderly after being adjusted for age, sex, BMI, cotinine level, and outdoor temperature (PM_{10}-glucose, p=0.0002; PM_{10}-insulin, p=0.3308; PM_{10}-HOMA, p=0.0888; O_3-glucose, p<0.0001; O_3-insulin, p=0.1061; O_3-HOMA, p=0.0423; NO_2-glucose, p=0.0004; NO_2-insulin, p=0.0302; and NO_2-HOMA, p=0.0019). The positive relationships between air pollutants and insulin resistance indices were apparent only in subjects with *GSTM1* null and *NAT2* GG genotypes.
Conclusions: Our study results suggest that PM_{10}, O_3, and NO_2 affect insulin resistance in the elderly and those with *GSTM1* null and *NAT2* GG genotypes are susceptible to PM_{10}, O_3, and NO_2 in respect of insulin resistance.

TEMPERATURE MODIFICATION ON THE ASSOCIATION BETWEEN OZONE AND MORTALITY IN THE 3 MAJOR CITIES, SOUTH KOREA

Hyunjoo Bae, *Korea Environment Institute*

Jongsik Ha, *Korea Environment Institute*

Ho Kim, *Seoul National University*

YoungSeong Shin, *Korea Environment Institute*

Background and Aims: Patterns of air pollutions are driven by weather. Particularly, ozone is correlated with temperature. Along with this, both temperature and ozone are associated with human health. Several studies have been suggested that apparent ozone effects could be to heat or an interaction between temperature and ozone could be plausible. In this study, we examined whether temperature modifies the associations between ozone and mortality.
Methods: The data consisted of daily time series of death counts, weather variables, and air pollutants from January 1999 to December 2009 in Seoul, Busan, and Daegu. We used a poission regression model to fit a bivariate response surface in order to examine patterns of interaction of both ozone and temperature on mortality. To quantitatively estimate the ozone-mortality associations across different temperature levels, we separately fitted the stratification model.
Results: When temperature (lag 0) was high (above the threshold temperature), for a 10ppb increase in ozone concentration, the contributions of non-accidental deaths in all ages population were 1.13% (95% confidence interval [CI]: 0.45~1.80%), 1.88% (95% CI: 0.87~2.88%), and 4.51% (95% CI: 2.99~6.00%) in Seoul, Busan, and Daegu, respectively. When temperature (lag 0) was low (below the threshold temperature), for a 10ppb increase in ozone concentration, the contributions of non-accidental deaths in all ages population were 0.22% (95% CI: -0.25~0.69%), 1.15% (95% CI: 0.32~1.97%), and 0.68% (95% CI: -0.25~1.61%) in Seoul, Busan, and Daegu, respectively.
Conclusions: The results of this study show that temperature modified ozone-mortality associations. We recommend that public health strategies to minimize adverse health impact of heat and ozone should be considered within control and prevention of air pollution and weather-related health impacts.

AN APPLICATION OF A RISK SET CALIBRATION METHOD TO A STUDY OF AIR POLLUTION EFFECTS ON ALL CAUSE MORTALITY IN THE NURSES' HEALTH STUDY

Background and Aims: Chronic exposure to air pollution has been consistently associated with increased risk of all-cause mortality. The majority of these studies have relied on ambient exposure monitoring to assign individual exposure levels. However, the impact of measurement error has not been incorporated into the estimates of risk. Here, we adjust for exposure measurement error using validation data from 9 cities where ambient exposure has been compared to personal exposure.
Methods: 57,574 women from the Nurse's Health Study living in Northeastern and Midwestern metropolitan areas of the United States were followed from 2000-2006 for 3,776,360 person-months, during which time 3642 deaths occurred. GIS-based spatial smoothing models were used to predict monthly exposure to particulate matter less than 2.5 microns in diameter ($PM_{2.5}$) at each participant's residence. Data on risk factors, residence and health outcomes are updated biennially. Using validation data from 9 cities -- Baltimore, Boston, Steubenville, Atlanta, Los Angeles, Seattle, Research Triangle Park, Nashville and Utrecht, Netherlands -- from 432 subjects over 950 person-months, a risk set regression calibration method was utilized to correct relative risk (RR) estimates for measurement error by re-calibrating the measurement error model within each risk set observed in the main study by its counterpart in the validation study.
Results: After adjusting for age in months, calendar year, state of residence and season, the RR for all cause mortality for a 10 $\mu g/m^3$ increase in the 12-month moving average of $PM_{2.5}$ was 1.35 (95% CI: 1.09-1.68) ; after error correction it was 1.63 (95% CI: 0.95-2.80).
Conclusions: These measurement-error corrected results confirm and strengthen the evidence that chronic $PM_{2.5}$ exposure is associated with the risk of all-cause mortality. The effects of chronic exposure $PM_{2.5}$ are likely stronger than previously considered. These findings may have implications for the formulation of environmental policy.

INFLUENCE OF IN UTERO AND CHILDHOOD LEAD EXPOSURE ON BODY MASS INDEX AND WAIST CIRCUMFERENCE AT AGES 7-15 YR

Karen E. Peterson, *University of Michigan School of Public Health, United States*
Kat Weber, *University of Michigan School of Public Health, United States*
Brisa N. Sánchez, *University of Michigan School of Public Health, United States*
Myriam Afeiche, *University of Michigan School of Public Health, United States*
Adrienne Ettinger, *Yale University School of Public Health, United States*
Lourdes Schnaas, *Instituto de Perinatologia, México*
David Cantonwine, *University of Michigan School of Public Health, United States*
Adrianna Mercado-García, *Instituto Nacional de Salud Publica, México*
Mauricio Hernández-Avila, *Secretaria de Salud, Mexico*
Howard Hu, *University* of Michigan School of Public Health, United States
Martha M. Téllez-Rojo, *Instituto Nacional de Salud Publica, México*

Background and Aims. Lead exposure in pregnancy has been negatively associated with weight at birth and during preschool years, but little is known about longer term effects on physical growth. We examined the association of *in utero*, early childhood and concurrent lead exposure with indices of fat mass and distribution during pre- and adolescence.
Methods. Among 673 mother-child pairs (325 females, 348 males), we estimated the effect of prenatal and early life lead exposure on body mass index (BMI) and waist circumference using separate multivariable linear regression models stratified by sex, adjusting for potential confounders (current child age and maternal BMI and maternal years of education at baseline).
Results. Mean±SD lead exposure levels were: maternal patella, 11.5±12.1• g/g, and tibia, 9.7±10.0• g/g, bone lead; log_e-umbilical cord blood lead (• g/dL), 1.52±0.65; cumulative log_e-blood lead (• g/dL) from 1 to 4 years (6.52±1.86); log_e-current blood lead (• g/dL), 0.94±0.57. No measure of lead exposure was associated with BMI or waist circumference in boys or girls aged 7-15 yr. Mean child age (yr) was 10.2 ±2.5; mean BMI was 19.7±4.0 and waist circumference (cm) 68.5 ± 11.4; mean current maternal BMI was 28.4±5.0. Each one unit increment in maternal BMI was associated with a 0.2 higher BMI in children ($p<0.0001$), and was associated with a $\geq$0.4 cm larger waist circumference in boys and in girls ($p\leq 0.001$), adjusted for each lead measure and other covariates.
Conclusions. Lead exposure *in utero* and in childhood did not appear to influence indices of weight status or fat distribution in pre- and adolescent Mexico City boys and girls. Further research should consider more proximal behavioral and environmental determinants of BMI and waist circumference and examine the long term effects of early lead exposure on linear growth.

EFFECTIVENESS OF INFLUENZA VACCINE IN THE COMMUNITY-DWELLING ELDERLY

Tsui-Ming Chang, *China Medical University College of Public Health, Taiwan*

Fung-Chang Sung, *China Medical University College of Public Health, Taiwan*

Background and Aims: Influenza vaccines are reviewed each year, and often changed, in an effort to maintain their effectiveness against drifted influenza viruses. There is however no regular review of influenza vaccine effectiveness during, or at the end of, Taiwan's influenza seasons. The main purpose of this study was to estimate the effectiveness of influenza vaccination of the high risk and healthy elderly population lived in non-institutionalized.

Methods: The present cohort comprised subjects who vaccinated and unvaccinated were select from Taiwan's National Health Insurance Research Database. Over seven seasons 2000–6, data on age, sex , area and vaccination status were collected. We used a retrospective case control design in seven consecutive influenza seasons, and estimated influenza vaccine effectiveness (VE) for patients of elderly.

Results: The major measurement found that, after adjusting confounding factors, the vaccinated could reduce a rate of 36% to catch a common cold, 2% to infect influenza-like illness as well as 45% to have hospital admission for pneumonia or cardiac disease. In the reduced medical expenditure of influenza vaccination, we estimated the saved of it based on the risk difference between the vaccinated and unvaccinated.

Conclusion: We deducted the cost of purchasing vaccine, diagnosis fee of national health insurance, the influenza vaccination could reduce the medical expenditure of 2.35 billin dollars if the vaccinated rate was 80%.

MERCURY LEVELS IN URINE AND HAIR, PERIPHERAL NERVE FUNCTION AND SINGLE NUCLEOTIDE POLYMORPHISMS RELATED TO MERCURY METABOLISM

Yi Wang, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*
Jaclyn Goodrich, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*
Brenda W. Gillespie, *Department of Biostatistics, University of Michigan, Ann Arbor, USA*
Robert A. Werner, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA; Department of Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, USA*
Niladri Basu, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*
Alfred Franzblau, *Department of Environmental Health Sciences, University of Michigan, Ann Arbor, USA*

Background and Aims: Mercury (Hg) is a potent neurotoxicant. We investigated the impact of Hg exposure on peripheral nerve function. We also hypothesized that single nucleotide polymorphisms (SNPs) in genes coding glutathione-related proteins, selenoproteins and metallothioneins may modify the relationship of Hg exposure with changes in peripheral nerve function.
Methods: Dental professionals (n=515) were recruited in 2009 and 2010. Samples and measurements included: sensory nerve conduction measurements (onset latency, peak latency and amplitude) of the median, ulnar and sural nerves; buccal swabs for DNA; hair; and urine.
Results: The subjects included 244 dentists (47.4%), 269 non-dentists (52.2%; mostly dental hygienists and dental assistants), and 2 of unknown occupation (0.4%) All participants completed a questionnaire for demographics and factors related to elemental and methyl- Hg exposure. The mean Hg levels in urine (1.06µg/L) and hair (0.51µg/g) were not significantly different from the US general population (0.95 µg/L and 0.47µg/g, respectively) (NHANES 1999-2000, 2003-2004). In multivariate linear regression models adjusting for demographics, there was a consistent, though mostly not statistically significant, relationship of increased hair Hg levels with improved nerve function for all nerves measurements. A similar relationship was found between increased methylmercury exposure via fish consumption (as measured in daily intake of polyunsaturated fatty acid, eicosapentaenoic acid and docosahexaenoic acid) and improved nerve function. No consistent relationship was observed in covariate-adjusted urine Hg models predicting nerve function. Only 3 out of a total of 504 multivariate models that investigated effect modification of SNPs on the relationship of Hg biomarkers with nerve function had stable and statistically significant interaction terms.
Conclusions: Overall, there might be a beneficial effect of fish consumption on peripheral nerve function. There was little evidence of effect modification of the studied SNPs on the relationship of mercury exposure and biomarkers, respectively with peripheral nerve function given the possibility of false positives.

LEGIONELLA SPP. AND LEGIONELLOSIS IN NEW ZEALAND, 2005-2010: DISEASE EPIDEMIOLOGY AND ENVIRONMENTAL SURVEILLANCE

Frances Graham, *Geohealth laboratory, University of Canterbury; Ministry of Health, New Zealand*
Associate Professor Simon Kingham, *Geohealth laboratory, University of Canterbury, New Zealand*
Dr Paul White, *United Nations, India*

Background and Aims: Legionellosis, an infection caused by the bacterium *Legionella*, is a serious and sometimes fatal cause of community-acquired pneumonia worldwide. In New Zealand two of the most common agents are *L. pneumophila* and *L. longbeachae*. In the past six years, some regions have seen an increase in the number of isolates of *L. longbeachae* and in 2009 it accounted for about 40% of total laboratory confirmed cases – about the same proportion as *L pneumophilia*. This differs from observed patterns in other parts of the world where the predominant species responsible for illness is *L. pneumophila* serogroup 1.
Legionellosis became a notifiable disease in New Zealand in 1980 and since then over 1,400 cases have been laboratory confirmed. The aim of this research was to characterise the incidence rates and occurrence of different species using descriptive epidemiology of surveillance and disease notification data.
Methods: We analysed cases using disease anonymous notification and laboratory surveillance data. Key data fields collected include case demographics, clinical features, laboratory identification (including environmental isolates) of the causative agent and risk factors.
Results: In the five years (2005-2009), overall notification rate was 1.7 per 100,000 but the age-specific notification rate for people 70 years and older was 6.3 per 100,000 population compared with 1.7 per 100,000 in the 40 to 49 year age group – Incidence Rate Ratio 0.27 (95% Confidence limits 0.19 to 0.37, $p < 0.00001$).
Notifications increased considerably in 2010 with an annual rate of 4.6 per 100,000. The increased rate may be a result of changed laboratory testing, direct laboratory notifications, greater clinical awareness of the illness or a true increased incidence of the disease in New Zealand.
Conclusions: The higher rates of legionellosis observed in New Zealand, and high proportion of *L. longbeachae* cases compared with other temperate countries, may be related to environmental factors. This suggests a distinctive legionellosis epidemiology for New Zealand, worthy of further research.

SPATIO-TEMPORAL VARIATION IN TRIHALOMETHANES IN NEW SOUTH WALES.

Christine Cowie, *Woolcock Institute of medical Research, Sydney, Australia*

John R Beard, *Department of Ageing and Life Course, World Health Organisation, Geneva, Switzerland*

Background and Aims: We described the spatio-temporal variation of trihalomethanes in drinking water in New South Wales, Australia from 1996 to 2007.
Method: We conducted a descriptive analysis of the spatial and temporal trends and the influence of season and drought on the monthly concentration and speciation of trihalomethanes (THMs) using routinely sampled data from two metropolitan and 13 rural water utilities within New South Wales.
Results*:* Monthly total THM concentrations in the two metropolitan water utilities of Sydney/Illawarra (mean 66.8µg/L) and Hunter (mean 62.7µg/L) were similar compared to the considerable variation between rural water utilities (range in mean THM: 14.5-330.7µg/L). Higher THM concentrations were found in water supplies treated with chlorination compared to chloramination and in water supplies sourced from surface waters compared to ground water. Ground water was found to have a higher proportion of brominated THMs compared to surface water. Chloroform was the predominate THM in two-thirds of the rural water utilities. We found variation in the concentration and speciation of THM between seasons and between periods of drought or no drought. The total mean THM concentrations were higher in summer than winter in twelve of the fifteen utilities. During drought the concentrations of chloroform were found to have decreased while BDCM and DBCM increased in a large number of utilities.
Conclusion: There is considerable spatial and temporal variation in THMs amongst New South Wales water utilities and these variations are likely related to water source, treatment processes, catchments, drought and seasonal factors. Although we had no data on the levels of organic matter in the water supplies, the decrease in chloroform during drought may be due to the lack of organic matter entering the water supplies from decreased rain run-off and the increase in DBCM and BDCM may be due to increased salinity from the lowering of water supplies.

RISK DIFFERENCE ADDITIVITY IS AN INAPPROPRIATE TEST OF BIOLOGICAL INTERACTION FOR MANY COMBINATION EXPOSURES

Gregory J. Howard, *Dickinson College, United States*
Thomas F. Webster, *Boston University School of Public Health, United States*

Background and Aims: Epidemiologists and toxicologists are faced with similar problems in assessing interactions between exposures, yet they approach the question very differently. Epidemiologic analysis of interactions has been categorized into several "contexts" (statistical, biological, public health, and individual). While statistical "interactions" are said to carry no biological meaning, it is often asserted that additivity of the risk differences (RDA) is the fundamental criterion for causal inference about biological interactions. Here, we contrast the theoretical frameworks for interaction in these fields, elucidating the different cases in which risk difference additivity is or is not a biologically appropriate criterion.
Methods: We analyze a simple thought experiment that has been used in both fields to develop the definition of non-interaction, with nearly opposite interpretations. In epidemiology, the "sham combination" leads to a requirement that non-interactive dose-response curves be linear. In toxicology, the same thought experiment results in the model of "concentration addition" (CA), a definition of non-interaction generally accepted by toxicologists as appropriate for similarly-acting chemicals. We apply epidemiologic tools for interaction analysis to mathematical models of concentration-additive combination exposures in order to evaluate the usefulness of these tools.
Results: The RDA model is equivalent to CA only when dose-response curves are linear, an uncommon situation. Simple models demonstrate that concentration-additive combinations can result in strong synergy or antagonism in the epidemiologic framework at even the lowest exposure levels. For these types of combination exposures, RDA is an inappropriate tool for the assessment of biological interactivity. In addition, for combinations which act through non-similar pathways, RDA is appropriate only at low effect levels.
Conclusions: RDA is not a biologically appropriate test of interaction for many exposures of interest. We suggest more appropriate methods for analysis of concentration-additive epidemiologic data. The two fields can learn a great deal about interaction from each other.

AIR QUALITY INDEX AND INCREASED ACUTE MYOCARIDIAL INFARCT ADMISSION TO HOSPITAL IN MELBOURNE, AUSTRALIA

Margaret Loughnan *Monash University, Australia*
Neville Nicholls *Monash University Australia*
Nigel Tapper *Monash University Australia*

Background and Aims: The health effects of the air pollutants have been known for many years, as has the interaction effect between air pollution and climate with respect to human health. In Australia, air pollution levels are generally lower than those observed in the US and Europe. Recent work in Melbourne has indicated that ambient air pollution in these cities is making significant contributions to daily mortality and hospital admissions for cardiovascular and respiratory disease. The aim is to determine whether the observed pattern of increased acute myocardial admissions (AMI) in Melbourne can be explained by air pollution.
Method: A One-Way ANOVA and Pearson's correlation was used to examine the relationship between daily AMI admissions and daily maximum air quality index (AQI). Daily AQI was categorised into five groups. A CHAID decision tree was used to determine which environmental variables showed the strongest relationship with AMI admissions.
Results: The results of the correlation analysis suggested a weak correlations between air quality and meteorological variables and AMI admissions, although these relationships are significant at $p = 0.01$ level. Results of the ANOVA indicated AMI admissions are significantly different on days when AQI is rated as Fair or Poor. The relationship is present at day 0 and lags of 1-3 days. The strongest relationship is at day 0. AQI maximum was the single most important variable in explaining the AMI admissions rate in Melbourne.
Conclusions: In this study in Melbourne, patterns are consistent with urban air pollution and urban meteorology impacts on health described by others. Days with poorer air quality appear to be associated with increased numbers of AMI admissions.

ASSESSING CLIMATE CHANGE AND HEALTH: THE EFFECT OF WIND, CHRISTCHURCH, NEW ZEALAND

Frances Graham, *Geohealth laboratory, University of Canterbury; Ministry of Health, New Zealand*
Associate Professor Simon Kingham, *Geohealth laboratory, University of Canterbury, New Zealand*
Professor Glenn McGregor, *University of Auckland, New Zealand*

Background and Aims: There is now widespread acceptance that human activities are causing climate change. In New Zealand a possible outcome of this will be a greater incidence of extreme heat events such as an increase in westerly windflow particularly hot, dry and turbulent wind colloquially known in New Zealand as the nor'wester. For epidemiologists, exposure to abnormally high ambient temperatures brought about through climatic conditions such as the nor'wester could potentially induce heat related conditions.
Few studies have specifically examined the link between climatic wind and heat-associated adverse health outcomes (morbidity) yet wind is undoubtedly an important environmental factor. The aim of this research was to retrospectively examine and identify the impacts of heat and wind on heat induced illnesses (e.g. cardiac, respiratory, renal disease, diabetes) on data collected from 1990 to 2010 in Christchurch, New Zealand.
Methods: The analysis was based on data collected for hospital admission and meteorological variables including temperature, wind speed and wind direction.
Results: Analysis of data revealed nine wind variables significantly related to heated induced illnesses. Further results will be presented to determine whether when compared with corresponding variables calculated over the 1990-2010 period, whether only the northerly wind on the day of admission has estimated associations with effect sign and size.
Conclusions: Research looking at relations between (natural) variation in meteorological variables, especially temperature and health effects has been extensive, encompassing several decades. Yet no material understanding the health risks from specific events such as climatic winds has been produced before in New Zealand. Knowledge of vulnerability allows an informed approach to the development and evaluation of strategies to lessen those health risks.

AN INTERVENTION STUDY USING FREE-STANDING HEPA AIR FILTERS AND AIR CONDITIONERS PLACED IN BEDROOMS OF INNER CITY CHILDREN WITH ASTHMA

Stuart Batterman, *University of Michigan, USA*
Liuliu Du, *University of Michigan, USA*
Edith Parker, *University of Iowa, USA*
Christopher Godwin, *University of Michigan, USA*
Ashley O'Toole, *University of Michigan, USA*
Thomas Robins, *University of Michigan, USA*
Jie Zhou, , *University of Michigan, USA*
Bhramar Muhkerjee, *University of Michigan, USA*
Toby Lewis, *University of Michigan, USA*
Community Action Against Asthma Steering Committee, *Detroit, USA*

Background and aims: Airborne particulate matter (PM) is an asthma trigger and can aggravate respiratory and other health conditions. Environmental tobacco smoke (ETS), to which many children are exposed, is associated with increased frequency and severity of asthma attacks, prolonged duration of symptoms, and decreased lung function. Children in urban areas are especially exposed to indoor pollutants, which often dominate exposures. Air filters can substantially reduce PM exposures and, as suggested in several studies, asthma symptoms. Room filters are inexpensive and easily installed, but performance is affected by clean air delivery rates, air exchange rates (AERs), and other factors. This study evaluates the utility of filters and air conditioners (ACs), intended to reduce AERs and improve filter performance, on exposures and health of asthmatic children in Detroit, Michigan.

Methods: 126 households containing an asthmatic child were randomized into a control group, a group receiving a HEPA filter placed in the child's bedroom, or a group receiving a filter and an AC. Each participant received educational community health worker home visits. Information regarding home characteristics and occupant activities were collected using surveys and inspections. Parameters monitored each season over a year included PM, CO2, ETS, and filter use. Child health measures included pulmonary function, medication use and symptom frequency.

Results: When used, filters substantially reduced PM concentrations, producing 70% reductions as measured immediately after filter installation. However, participants decreased their use of the filters over time. When corrected for ETS and other co-factors, ACs provided a modest drop in PM concentrations, but concentrations sometimes increased. The ongoing analysis of health symptoms suggests diminished symptoms when filters were used.

Conclusions: Measures that capture actual exposures are needed, including continuous monitoring of filter use and pollutant levels, in order to avoid biases that dilute effects seen in air filter and other intervention studies.

THE HEALTH AND ECONOMIC THREATS OF GLOBAL FOOD RECALLS AND THE GROWING NATIONAL AND INTERNATIONAL EFFORTS TO ADVANCE FOOD SAFETY

Firdu Zawide, *Jimma University, Ethiopia*

Background and Aims: The global burden of food borne disease and its impact on trade and development is currently unknown. On the other hand, the global recalls of food is increasing, contributing to the risk of pathogens across national borders creating new challenges to food safety regulators. The study examines the public health and economic threats of global food recalls and efforts being made by national and international agencies to advance food safety.

Methods: Data collection from multiple sources on food recalls and review of selected national and international initiatives to advance food safety.

Results: Based on the number of recalls reported globally, there has been a substantial increase in the past years. *Salmonella* accounts for the majority cases of food borne illnesses followed by undeclared allergens, and intolerances, *E.coli, Listeria, Monocytogens* and *Clostridium botulism.* The main foods that were subject to recall were dairy products, seafood, poultry including eggs, fruits and vegetables, nuts and raw agricultural commodities. Greater number of recalls were reported by United States, Canada, Australia and a few European and Asian countries. Most of the recalled foods originated from China, Mexico, North America and a few Asian and African countries. Two major initiatives laid the foundation to strengthen the food safety system globally. These were the " Food Safety Modernization Act" passed by the U.S senate in January this year and the WHO resolution on "Advancing Food Safety" endorsed by member states in May last year.

Conclusions: There is a continued need for closer collaboration among stakeholders to support measures and interventions in the global implementation of the initiatives to advance and modernize food safety. The important roles WHO and FAO play in support of the Codex Alimentarious Commission and the participation of developing countries should be given active consideration.

THE EFFECTS OF HEAT WAVES ON MORTLAITY AND HOSPITALISATION IN SYDNEY, AUSTRALIA 1994-2009.

Bin Jalaludin, *Clinical Support Cluster (Western) – New South Wales Health, Australia*

Background and aims: Global warming is likely to bring not only warmer temperatures on average, but greater frequency of extreme weather events, including hot days. Understanding who is susceptible to these extreme events will be important in minimising their public health impact, including establishing targeted health programs to better protect the vulnerable We examined the association of heat waves in Sydney with daily mortality (1997-2007) and hospital admissions (1997-2010).
Methods: We categorized the Sydney Greater Metropolitan Region into five sub regional climate zones. We defined sub-regional heat waves as days where the daily apparent maximum temperature exceeded the monthly 95th percentile for the study period. We used a time-stratified case-crossover design with a conditional logistic regression model adjusted for flu epidemics, public holidays, and region. Odds ratios (OR) and 95% confidence intervals for cardiovascular and respiratory mortality and hospital admissions on heat wave compared with non heat wave days were estimated.
Results: Heat waves (lag 0) were associated with all cause mortality (OR=1.07; 95%CI: 1.05-1.10), all cardiovascular mortality (OR=1.07; 95%CI: 1.03-1.12), all respiratory mortality (OR=1.13; 95%CI: 1.03-1.23). As expected heat waves (lag0) were associated with hospital admissions for heat related injuries, dehydration, and fluid disorders. Heat waves (lag1) were also associated with hospital admissions for renal disease (OR=1.09; 95%CI: 1.05-1.12), mental and behavioural disorders (OR=1.03; 95%CI: 1.01-1.05), and diabetes (OR=1.06; 95%CI: 1.01-1.12).
Conclusions: Heat waves are associated with increases in mortality and hospital admissions.

EPIDEMIOLOGY IN METALLIC MERCURY POISONING AFTER ENVIRONMENTAL EXPOSURE: CASE - INSTITUTIONAL ACTION ON THE CITY WITH MORE THAN 100 EXPOSED IN BRAZIL

Introduction: Human exposure to toxic substances and metals occurs worldwide, with severe consequences to the environment and human health. Accidents caused by substances and goods in the local inadequate are common.
The Epidemiological Surveillance Center was originally notified of two children poisoned by mercury metallic.
Upon investigation it was found 113 people exposed in a county in the state of SP.
Objectives : • To describe the epidemiological research generated by the initial cases that ended with 113 exposed
• Describe the main inter-institutional actions that were essential to facilitate diagnosis, treatment and control of intoxication
Methodology : The investigation began with the investigation of two children under 5 years of exposure intoxicated and involved the whole family, several students, workers and nearby residents. All exposed underwent specific complementary tests.Measurements were carried out preventive information and guidance to the entire population of the municipality. It involved a lawsuit with several institutions related to the issue of health, environment and education.
Conclusion : The investigation culminated with the identification of 113 exposed, clinical management, development of a protocol for future monitoring of exposure and environmental control of homes, schools and region.

URINARY ARSENIC AS A BIOMARKER OF IN UTERO EXPOSURE VIA MATERNAL DRINKING WATER AND DIET: RESULTS FROM A US PREGNANCY COHORT

Diane Gilbert-Diamond, *Dartmouth Medical School, USA*
Kathryn Cottingham, *Dartmouth College, USA*
Joann Gruber, *Dartmouth College, USA*
Tracy Punshon, *Dartmouth College, USA*
Vicki Sayarath, *Dartmouth Medical School, USA*
Jay Gandolfi, *University of Arizona, USA*
Emily Baker, *Dartmouth Medical School, USA*
Brian Jackson, *Dartmouth College, USA*
Carol Folt, *Dartmouth College, USA*
Margaret Karagas, *Dartmouth Medical School, USA*

Background and Aims: Emerging data indicate that in addition to drinking water contamination, rice consumption may lead to substantial inorganic arsenic exposure (As). Here, we report urinary arsenic excretion in 193 pregnant women in a region of the United States with elevated well water arsenic concentrations.
Methods: We enlisted pregnant women who reported using a private water system at their home, through clinics in the state of New Hampshire. At a six-month prenatal visit, we collected and analyzed a urine sample and a three-day dietary record for water, fish/seafood, and rice and rice products. We also tested women's home tap water for As, which we combined with tap water consumption to estimate exposure through water.
Results: 15% of women were consuming drinking water above the current WHO standard (10 µg As/L). Rice intake averaged 11.73 g/d (range = 0-111.58 g/d (dry mass). The median total urinary arsenic concentration (sum of inorganic As, monomethylarsonic acid and dimethylarsinic acid) was 3.99 µg/L (range = 0.45-38.84 µg/L). After adjusting for age and urinary dilution using creatinine, both rice consumption (g/d) and arsenic exposure through water (µg/d) were significantly associated with natural log-transformed total urinary arsenic in general linear models (β = 0.0095, $P < 0.0001$; β = 0.0295, $P < 0.0001$, respectively). Arsenobetaine levels were lower than those observed in non-pregnant women in our state (0.8 µg/L) reflecting fish/seafood avoidance by pregnant women.
Conclusions: We estimate consuming 1.1 cups of cooked rice/d is associated with urinary arsenic concentrations comparable to 2 liters/d of 10 µg As/L water. Given the potential adverse health consequences of arsenic even at low levels, exposure through rice consumption may need to be considered when designing strategies for reducing arsenic exposure among US pregnant women.

PARACETAMOL USE IS ASSOCIATED WITH ASTHMA IN FARMING AND NON-FARMING CHILDREN

Jeroen Douwes, *Centre for Public Health Research, Massey University, New Zealand*
Monica Nowicki, *Centre for Public Health Research, Massey University, New Zealand*
Soo Cheng, *Centre for Public Health Research, Massey University, New Zealand*
Noemie Travier, *Centre for Public Health Research, Massey University, New Zealand*
Neil Pearce, *Centre for Public Health Research, Massey University, New Zealand, London School of Tropical Hygiene and Medicine*

Background and Aims: Paracetamol use has been associated with asthma in both children and adults. This has not been assessed in farmers' children who have a lower prevalence of asthma compared to children of the general population. We assessed the associations between antibiotic use and paracetamol use, and asthma, hayfever, eczema and atopy, in a population of farming and non-farming children.
Methods: In a cross-sectional questionnaire survey of 1,370 farming children and 588 non-farming children, aged 5-17 years we assessed asthma, hayfever and eczema as well as paracetamol use and antibiotioc use.
Results: After adjustment for potential confounders paracetamol use in the first 12 months was associated with wheeze ever (OR=1.77, 95% CI 1.22-2.58) and asthma ever (OR=1.82, 95% CI 1.19-2.77). Current paracetamol use (at least once a month) was also significantly associated with most asthma symptoms (wheeze in last 12 months OR=2.84, 95% CI 1.67-4.82; asthma ever OR=1.80, 95% CI 1.16-2.79; wheezing during exercise OR=2.97,95% CI 1.76-5.02; cough at night OR=1.98, 95% CI 1.21-3.26),and rhinitis symptoms (sneezing ever OR=1.62, 95% CI 1.06-2.47; sneezing in last 12 months OR=1.61, 95% CI 1.04-2.48; hay fever ever OR=1.83, 95% CI 1.18-2.84). Current paracetamol use (at least once a month) was also weakly associated with itchy rash in the last 12 months (OR=1.81, 95% CI 1.02-3.20) and eczema ever (OR=1.55, 95% CI 1.01-2.37). Use of antibiotics in the first 12 months was also significantly (and independently) associated with asthma and rhinitis, but not with eczema. No clear associations between atopy and paracetamol or antibiotics were found. However, stratified analyses showed strongest associations for children with non-atopic symptoms. No differences were found for farming and non-farming children.
Conclusions: Paracetamol and antibiotics are associated with asthma, and rhinitis (and to a lesser extent eczema), with the strongest associations in non-atopics.

EFFECTIVENESS OF INTERVENTIONS IN IMPROVING INDOOR AND OUTDOOR AIR QUALITY: PRELIMINARY RESULTS FROM A RANDOMIZED TRIAL OF WOODSMOKE AND ASTHMA

Erin Semmens, *University of Montana Center for Environmental Health Sciences, USA*
Curtis Noonan, *University of Montana Center for Environmental Health Sciences, USA*
Tony Ward, *University of Montana Center for Environmental Health Sciences, USA*
Emily Weiler, *University of Montana Center for Environmental Health Sciences, USA*
Johna Boulafentis, *Nez Perce Tribe Environmental Restoration Waste Management, USA*

Background and Aims: We are conducting a randomized trial to examine the impact of simple interventions on woodsmoke-derived $PM_{2.5}$ and symptoms in children with asthma. Pre- and post-intervention indoor and outdoor air sampling results from the Nez Perce reservation in Idaho and 2 western Montana communities are presented here.
Methods: Participating homes were randomized to receive a new EPA-certified woodstove, a stand-alone filtration unit or a filtration unit with a placebo filter. Indoor and outdoor sampling was conducted in 35 homes during the winters of 2008-11. Air sampling included pre- and post-intervention 48-hour continuous monitoring of $PM_{2.5}$ mass in the common area and outside the home using DustTrak aerosol monitors (TSI).
Results: Overall mean(SD) indoor pre- and post-intervention $PM_{2.5}$ concentrations were 46.8(40.4) and 27.9(21.6) $\mu g/m^3$, respectively. Homes receiving the active filter intervention demonstrated a significantly greater percent reduction in indoor $PM_{2.5}$ concentrations [60.0; 95% CI: 24.4, 95.7] relative to placebo homes, whereas homes receiving woodstoves saw only small, highly variable reductions [3.6; 95% CI: -30.4, 37.6]. Overall mean(SD) outdoor pre- and post-intervention $PM_{2.5}$ concentrations were 41.4(24.9) and 35.5(21.1) $\mu g/m^3$, respectively. Although modest reductions in mean outdoor $PM_{2.5}$ [4.9(24.6) $\mu g/m^3$] were observed post-intervention in woodstove homes, reductions did not vary significantly by intervention status.
Conclusions: Results from the first 3 study communities with pre- and post-intervention data indicate high effectiveness of active filtration units in improving indoor air quality. Further precision in estimates is anticipated with the addition of newly recruited homes in Montana and Alaska. Surprisingly, relative to placebo, the woodstove intervention had no significant overall impact on $PM_{2.5}$ concentrations measured outside the home. Future work will evaluate ambient and meteorological data and home characteristics in examining intervention effectiveness in improving outdoor air quality.

NONLINEAR ASSOCIATION OF DIURNAL TEMPERATURE RANGE WITH OXIDATIVE AND PHYSIOLOGIC STRESS MARKERS IN THE KOREAN ELDERLY ENVIRONMENTAL PANEL STUDY (KEEPS)

Youn-Hee Lim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, Republic of Korea*
Ho Kim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, Republic of Korea*
Jin Hee Kim, *Institute of Environmental Medicine, Seoul National University Medical Research Center, Republic of Korea*
Sang-Hyuk Bae, *Environmental Health Center, Seoul National University College of Medicine, Republic of Korea*
Yun-Chul Hong, *Institute of Environmental Medicine, Seoul National University Medical Research Center; Department of Preventive Medicine, Seoul National University College of Medicine, Republic of Korea*

Background and Aims: While diurnal temperature range (DTR) has been found to be a risk factor for mortality in a previous study with an assumption of linearity, some disease mortality, such as that associated with rheumatic heart disease (RHD), showed a threshold effect for DTR. To define the nonlinear relationship pathway between DTR and health effects, we investigated how physiologic and oxidative stress markers responded to DTR.
Methods: This study was part of the Korean Elderly Environmental Panel Study (KEEPS). Data was obtained from 569 participants who regularly attended a community elderly care center located in Seoul, Korea. The study was conducted a total of five times over a three years period beginning in August, 2008. We examined physiologic stress markers including heart rate variability (HRV) and indices such as mean heart rate, standard deviation of normal-to-normal (SDNN), normalized low frequency (LF) and high frequency (HF), and low/high frequency ratio (LF:HF). Urinary malondialdehyde (MDA) was evaluated as an oxidative stress marker. Effects of DTR below or above the median level were estimated using a generalized linear mixed model.
Results: Significant differences in effects of DTR above and below the median level indicated the presence of a threshold effect or a nonlinear association between DTR and HRV markers. Estimated effects for log-transformed SDNN were 0.211 (standard error [SE] 0.069, *P* =0.0021) below and -0.093 (SE 0.038, *P* =0.0129) above the median DTR. While the mean heart rate slope above median DTR was significant, slopes of normalized HF and LF:HF ratio below median DTR were statistically significant. In addition, log-transformed MDA showed a pattern similar to HRV indices.
Conclusions: The study demonstrated that physiologic and oxidative stress increased at low and high DTR with minimal stress levels around the median level of DTR indicating a physiologic comfort point.

Introduction: The Brazilian Health Ministry has proposed as a means of establishing priority areas for developing the program for monitoring of Populations Exposed to Atmospheric Contaminants - VIGIAR, an Instrument for Identifying Risk Municipalities - IIMR. This tool creates a ranking for the municipality, taking into account information on health and environment. This work is construction of IIMR for the state of São Paulo.
Methodology: To construct the ranking, we use the existing databases, which are built with municipal indicators, which were referred to the general data of the state of Sao Paulo, where:
Health information:- Rate of hospital admissions for respiratory diseases by the municipality and the state as a whole, its index is the ratio of these measures.
- Mortality rate from respiratory diseases by the municipality and the state as a whole, its index is the ratio of these measures.
Environmental information: Presence of stationary sources of emissions, represented by extractive industries or processing, which is an indicator score established from their number in each municipality. - Fleet vehicle by municipality and population, its index is a score established from the ratio: number of cars per population in the municipality- Biomass burning due to forest fires or the burning of agricultural waste, which indicator is the ratio between the number of foci per area of the municipality and the total area for the sate
For each indicator was established as a scoring category.
Results: The municipality with the highest rankings were located in the metropolitan areas of the state, showing that these priority areas for the establishment of activities VIGIAR.
Conclusion: Indices generated Contribute to the identification and development of public polices of air pollution.

ASSESSING THE RELATION BETWEEN MUSCULOSKELETAL DISEASE PREVALENCE AND PHYSICALLY DEMANDING WORK

Nina Zaitseva, *Federal Scientific Center for Medical and Preventive Health Risk Management Technologies, Russia*
Pavel Shur, *Federal Scientific Center for Medical and Preventive Health Risk Management Technologies, Russia*
Vitaly Kostarev, *Federal Scientific Center for Medical and Preventive Health Risk Management Technologies, Russia*
Alla Klimenko, *Federal Scientific Center for Medical and Preventive Health Risk Management Technologies, Russia*

Background and Aims: The study was designed to assess cause-effect relations between physically demanding work and musculoskeletal disease prevalence using epidemiological analysis.
Methods: The study group comprised 24 male press operators (an average age of 37.8 ± 1.9, length of service – more than 17 months). The control group comprised 62 male subjects (an average age of 39.2 ± 1.5, length of service - more than 18 months). The main criteria for the choice of control group were absence of the studied adverse factor, similarity in age and length of service. In 2009, prevalence levels for the study and control groups were estimated to be 250 ‰ and 81 ‰, respectively. In view of respectively high disease prevalence within the groups, we calculated odds ratio (OR) along with relative risk (RR).
Results: The epidemiological analysis findings are the following: OR is 3.8 (95% confidence interval (CI) is 1.04 – 14.78); RR is 3.10 (95% CI is 0.87 – 11.01); etiological fraction (EF) is 67.7%. OR values indicate a reliable cause-effect relation between physically demanding work and musculoskeletal disease prevalence whereas RR also indicates this relation but with a lower degree of reliability. Risk difference is 0.17 which corresponds to the population risk for musculoskeletal diseases in healthy study group subjects – 3 cases per year. This disease can be considered occupational since according to the classification proposed in the Guidelines for Occupational Risk Assessment adopted in Russia, etiological relation between musculoskeletal diseases and work is significantly high.
Conclusions: The application of epidemiological indicators including OR allowed identification of a reliable cause-effect relation between physically demanding work and musculoskeletal disease prevalence in press operators. OR-based methods have better statistical characteristics than those based on RR, especially when a disease is rather prevalent, and provide more reliable assessment of the relation between factors and health effects.

HEALTH IMPACTS OF THE HEBEI SPIRIT OIL SPILL ACCIDENT ON THE RESIDENTS OF TAEAN, SOUTH KOREA

Yongseung Shin, *Korea Environment Institute, South Korea*

Jinhee Jung, *Korea Environment Institute, South Korea*

Background and Aims: The Hebei Spirit oil spill accident occurred just off the coast of Taean province in South Korea on December 7, 2007. It is estimated that 12,547 Kl of crude oil was spilled into the sea near Taean national park. This study investigated health impacts of the oil spill accident in the targeted residents.

Methods: Questionnaire survey and chemical analysis were carried out in order to look for health impacts 1 to 2 years following the Hebei Spirit oil spill. Urine samples were collected from the residents and analyzed for metabolites of volatile organic compounds(VOCs) and polycyclic aromatic hydrocarbons(PAHs).

Results: Analysis of the oil-related metabolites in the urine samples showed that the concentration of VOCs metabolites drastically decreased as compared to the initial period following the oil spill. On the other hand, metabolites of PAHs showed a trend of gradual decline over time, though the levels were not noticeably different from the control group. The analysis for the environmental samples showed that no VOCs were detected, but PAHs were partly present in groundwater, soil, vegetables , and seafood samples. Questionnaire survey showed that approximately 75% of the residents were concerned about health impacts due to exposure to the oil pollutants and suffered from symptoms such as vertigo, headache, nausea, skin disorders (itch), abnormalities in eyesight, and respiratory malfunctions.

Conclusions: The present study showed that various physical symptoms observed among the residents are possibly associated with exposure to oil pollutants and most of the residents recognized such maladies are attributable to exposure to the oil pollutants. Therefore, long-term health impacts should be monitored by the exposure to residual oil pollutants in the oil spill environment.

PRENATAL MANGANESE EXPOSURE AND FETAL GROWTH IN LIMÓN, COSTA RICA: DATA FROM THE INFANTS' ENVIRONMENTAL HEALTH (ISA) STUDY

Ana María Mora, *Universidad Nacional, Costa Rica; University of California at Berkeley, United States*
Berna van Wendel de Joode, *Universidad Nacional, Costa Rica*
Leonel Córdoba, *Universidad Nacional, Costa Rica*
Juan Camilo Cano, *Universidad Nacional, Costa Rica*

Brenda Eskenazi, *University of California at Berkeley, United States*

Background and aims: Mancozeb is the most widely used pesticide in banana plantations in Costa Rica. Recent studies suggest that mancozeb use potentially exposes agricultural workers and their families to manganese (approximately 21% by weight of mancozeb). Our study aims to determine whether prenatal exposure to manganese from mancozeb applications is associated with fetal growth.

Methods: The study population includes the participants of the Infants' Environmental Health (ISA) Study, a birth cohort study of 450 mother-child pairs living in communities near banana plantations with large-scale production and pesticide use in Limón, Costa Rica. To assess prenatal exposure to manganese, maternal hair and blood manganese levels were measured during the first, second, and third trimester. Determinants of exposure including residential proximity to banana plantations, household members' pesticide use patterns, and housing quality were examined. Questionnaires have been administered to the women during the first, second, and third trimester and shortly after delivery to ascertain information on sociodemographic characteristics, lifestyle habits, and occupational history. Birth outcomes are being abstracted from the newborns' Official Cards of Health. Multiple linear regression models and G-computation estimators will be used to examine the association between prenatal manganese exposure and fetal growth.

Results: We have completed enrollment of 370 mother-child pairs. Blood and hair samples have been sent for analysis and approximately 100 women have delivered. Preliminary analysis of 26 hair samples collected during the first or second trimester showed a significant difference in mean hair manganese levels between pregnant women living less than 100 meters away from a banana plantation and women living more than 100 meters away (Student t-test, $p<0.05$). We will present the full results of the relationship between hair and blood manganese, birth weight, and gestational duration in approximately 250 children.

Conclusion: This early finding suggests that hair manganese levels could be associated with proximity to banana plantations, and consequently with mancozeb exposure. Full results of the analysis with fetal growth will be presented and discussed.

TRAFFIC NOISE HEALTH EFFECTS AND THE BENEFIT OF ACCESS TO QUIET SIDE

Theo Bodin, *Lund University, Lund, Sweden*
Maria Albin, *Lund University, Lund, Sweden*
Evy Öhrström, *University of Gothenburg, Sweden*
Jonas Björk, *Lund University Hospital, Lund, Sweden*
Jonas Ardö, *Lund University, Lund, Sweden*

Background and Aims: Annoyance due to community noise is a growing problem in the urbanized world. Noise reduction at the source is inadequate to tackle the negative trend and other approaches must be investigated, such as of residential spaces. An earlier study in Sweden showed that access to quiet side in one's dwelling had a positive effect on noise annoyance and well-being.(Ohrstrom, Skanberg et al. 2006) Our aim was to confirm whether these results withstood and also whether quietness in different spaces (such as bedroom, living room and balcony) were of similar or differential importance.
Methods: A survey regarding noise and health was carried out in Malmö, southern Sweden in 2007. 2612 individuals aged 18-80 years participated. (response rate 54%). We used geographic information systems to assess the average road and railway noise (LAeq,24h) at the participants' residential address. Data included geometries of roads, railways, buildings, elevation data, ground types and noise barriers.
Results: Sleeping and concentration problems were associated to traffic noise from road, rail and the two sources combined. No significant differences were found depending on the noise source. In a logistic regression model adjusted for age, sex and noise exposure, having one's bedroom facing a large road was associated to both sleeping and concentration problems, while bedroom facing a railway mainly seemed to be associated with concentration difficulties and had no significant association to sleeping problems. Having a balcony facing large road or rail was associated to concentration difficulties but not to sleeping problems. Access to at least one quiet space in one's dwelling was strongly associated to lesser concentration difficulties and sleeping problems.
Conclusions: Having access to quiet places in one´s dwelling was associated to less sleep and concentration-related problems. We could not conclude that bedroom location was more important than quietness in other rooms.

SOCIOECONOMIC STATUS AND ACUTE MYOCARDIAL INFARCT ADMISSIONS TO HOSPITAL IN MELBOURNE, AUSTRALIA

Margaret Loughnan *Monash University Australia*
Neville Nicholls *Monash University Australia*
Nigel Tapper *Monash University Australia*

Background and Aims: Explanatory studies of the relationship between area deprivation and health have highlighted urbanisation and inequality as an emerging theme. Socioeconomic influences on health have been reported at both the individual and area levels of analysis. Acute myocardial infarction (AMI) morbidity in Melbourne and socioeconomic status was mapped to demonstrate spatial associations within the data.
Methods: Age standardised rate ratios are calculated by determining the age specific rates for each age group, the expected and observed AMI were calculated. The observed AMI divided by the expected AMI provided a ratio of observed to expected AMI admissions controlling for differences in age structure. The standard Melbourne population was the baseline population. The measure of socioeconomic status used to examine health inequalities was the 2001 area-based Socio-Economic Index for Areas (SEIFA). AMI admissions to hospital were classified into SEIFA quintiles according to SEIFA value for place of residence. Each quintile contained approximately 668,000 adult persons. Quintile 1 includes the most disadvantaged areas and quintile 5 the least disadvantaged areas.
Results: The absolute and relative differences in AMI admissions to hospital for SEIFA quintiles 1-5 indicate that rates of AMI admissions are higher in the most disadvantaged areas in the western suburbs, the urban fringe and industrial areas. The rate ratio suggests there were twice as many AMI admissions in quintile 1 (most disadvantage) than in quintile 5 (least disadvantage).
Conclusions: The analysis indicates that socioeconomic inequality contributes to AMI admissions to hospital in Melbourne. Regional differences in AMI admissions were quantified and described. Spatial analysis was used to identify spatial clusters of AMI admissions in Melbourne metropolitan region. Quintile maps highlighted the differences in AMI admissions rates per quintile. AMI risk was presented in a spatial framework capable of informing policy and addressing disease prevention.

MULTIPLE METAL EXPOSURES IN ADOLESCENTS: ATTENTION-INDUCED STRESS, LEAD, ARSENIC AND CARDIAC VARIABILITY

Patrick J. Parsons, *New York Department of Health, Albany,USA*
Ellen K. Silbergeld, *Johns Hopkins Bloomberg School of Public Health, Baltimore, USA*

Background and Aims: Cardiovascular mortality and morbidity in adults increase at lead and arsenic concentrations well below most international occupational guidelines. The few published studies of lead and cardiovascular function in children produced weak and conflicting results. Few studies systematically address multiple metal effects on cardiac health. We studied the combined effects of lead and arsenic on heart rate variability (HRV), a key predictor of cardiovascular morbidity and mortality, in adolescents to determine if metal exposures were associated with early signs of cardiovascular problems.
Methods: We recorded seated electrocardiograms (ECG) from 512 adolescents, 12-15 years, participants in a lead-surveillance program since early childhood in Torreón, Coahuila, a northern Mexican industrial city. We measured blood lead and spot urine creatinine-corrected arsenic on the recording day. We recorded three 10-minute ECGs, first with subjects in resting condition, the second and third during the Continuous Performance Test (CPT), a sustained attention task requiring response to rarely presented target sequences in easy and difficult conditions designed to produce cognitive stress, in counterbalanced order. Fourier decomposition produced power spectra of beat-to-beat ECG intervals. We analyzed CPT performance and ECG power in standard frequency bands with mixed models accounting for repeated measures. We also present models combining earlier childhood lead levels with contemporary arsenic concentrations.
Results: Lead and arsenic independently depressed CPT attention (no significant interaction) with no effect size change under two stress levels. High frequency HRV (0.14-0.40 Hz), indicating parasympathetic autonomic nervous system (vagal) activity, decreased with increasing stress, but paradoxically increased with increasing arsenic concentration in all conditions.
Conclusions: Lead and arsenic additively combined to depress sustained attention in adolescents. Cognitive stress depressed cardiac-vagal tone while arsenic increased vagal tone. We further explore connections between multiple metal exposures, attention and autonomic nervous system activity associated with cardiac health.

TRAFFIC-RELATED EXPOSURES AND HEALTH OUTCOMES OF CHILDREN WITH ASTHMA LIVING BOTH NEAR AND FAR FROM HIGHWAYS

Stuart Batterman, *University of Michigan, USA*
Shi Li, *University of Michigan, USA*
Savitha Sangameswaran, *University of Michigan, USA*
Bhramar Muhkerjee, *University of Michigan, USA*
Andrew Ekstrom, *University of Michigan, USA*
Thomas Robins, *University of Michigan, USA*
Philip Hopke, *Clarkson University, USA*
Suresh Raja, *Clarkson University, USA*
Toby Lewis, *University of Michigan, USA*
Community Action Against Asthma Steering Committee, *Detroit, USA*

Background and aims: Proximity to major roads has been associated with respiratory disorders and other adverse health effects. However, the understanding of traffic-related exposures and the associated health impacts is incomplete. Concentrations can vary dramatically spatially and temporally, and a fine spatial scale is needed to resolve traffic-related pollutants such as PM, black carbon (BC), NOx, and VOCs. This paper describes results obtained in recent and ongoing exposure and epidemiological studies in Detroit, Michigan.
Methods: We first explore the use of Medicaid data to investigate associations of acute asthma outcomes among Detroit children and proximity to major roads using a population-matched case-control analysis over a three year period, conditional linear regression, and both linear and nonlinear relationships with distance. We then present the design and preliminary results from an ongoing case-control study in which children with asthma were selected on the basis of residential proximity to major highways in Detroit, and which utilized seasonal health measurements, e.g., spirometry, and a variety of exposure assessment approaches.
Results: In the Medicaid data, asthma events were associated with proximity to primary roads with an odds ratio of 0.97 (95% CI: 0.94, 0.99) for a 1 km increase in distance, implying that asthma events were less likely as the distance between the residence and a primary road increases. In the field study, air quality impacts associated with traffic were observed in both time series and spatial studies, e.g., BC levels were elevated at monitors very near highways during the rush hour period, as well as on transects obtained across major roads.
Conclusions: There is moderately strong evidence of elevated risk of asthma close to major roads, based on case-control study, though increments of traffic-associated pollutants measured near the roads were generally modest.

A PRELIMINARY EVALUATION OF ENVIRONMENTAL LIGHT POLLUTION, ANTHROPOMORPHIC CHARACTERISTICS, AND BEHAVIORAL FACTORS IN PREDICTING URINARY MELATONIN METABOLITE CONCENTRATIONS

Peggy Reynolds, *Cancer Prevention Institute of California & Stanford University School of Medicine, USA*
Susan Hurley, *Cancer Prevention Institute of California, USA*
David Nelson, *Cancer Prevention Institute of California, USA*
Erika Garcia, *Cancer Prevention Institute of California & University of California Berkeley, USA*
Robert Gunier, *Cancer Prevention Institute of California & University of California Berkeley, USA*
Andrew Hertz, *Cancer Prevention Institute of California, USA*

Background and Aims: There is growing evidence that light pollution may play a role in a variety of diseases, including cancer. For cancer, the primary mechanism postulated is that exposure to light-at-night (LAN) suppresses the production of melatonin, an endogenous hormone with oncostatic properties. Our objective was to evaluate whether exposures to LAN, as well as anthropomorphic and behavioral factors, predict levels of 6-sulfatoxymelatonin (6-SMT), the primary urinary metabolite of melatonin.
Methods: Participants consisted of 301 women who provided a 24-hour urine sample, completed a questionnaire, and resided in Northern California. Approximately half lived in urban/suburban regions and half in more rural areas. A geographic information system was used to assign outdoor LAN levels to participants' residences based on satellite imagery data maintained by the U.S. Defense Meterological Satellite Program. Indoor LAN exposures were estimated from survey responses regarding the use of bedroom lighting and sleep habits. Data on anthropomorphic and behavioral factors were garnered from survey questions. An ELISA was used to quantify 6-SMT concentrations in urine. Concentrations were creatinine adjusted and transformed to symmetrize the data prior to statistical analyses. Age-adjusted generalized linear models were used to assess significant predictors of 6-SMT.
Results: Outdoor LAN values varied between participant residences, with levels highest among those in urban/suburban areas and lowest among those in rural areas (p-value <0.001). Among younger women, 6-SMT levels did not vary with age, but among those $\geq$55 years, levels dropped significantly with increasing age ($p<0.005$). While there was some suggestion that lower 6-SMT levels were related to indoor and outdoor LAN exposures, higher levels of physical activity, and use of oral contraceptives, none of these relationships were statistically significant.
Conclusions: These preliminary analyses failed to identify any significant predictors of 6-SMT, beyond age. We are continuing to evaluate these relationships through more comprehensive modeling.

EVALUATION OF A HEAT VULNERABILITY INDEX ON ABNORMALLY HOT DAYS: AN APPLICATION OF ENVIRONMENTAL PUBLIC HEALTH TRACKING DATA

Kathleen Navarro, *School of Public Health, Division of Environmental Health Sciences, University of California, Berkeley, CA, USA*
John Balmes, *School of Public Health, Division of Environmental Health Sciences, University of California, Berkeley, CA, USA*

Background and Aims: Heat waves and extreme hot weather conditions have been associated with increased morbidity and mortality, but the risks are not evenly distributed throughout the population. Previously, a heat vulnerability index (HVI) was created that combined factors of socio-economic and environmental vulnerability, social isolation, air conditioning prevalence, and pre-existing health conditions to geographically locate populations with increased vulnerability to heat in metropolitan areas throughout the United States. Our study aims to determine whether the intra-urban spatial distribution of heat vulnerability, as characterized by the HVI, is consistent with increased rates of morbidity and mortality on abnormally hot days.

Methods: We defined abnormally hot days as days where the difference between the maximum temperature for that day and the 30-year normal warm season maximum temperature was in the 95th percentile for that weather station for all warm season days (May-September) for 2000-2007. We used Poisson generalized estimating equations to assess the interaction between the HVI and abnormally hot days on hospitalization and mortality counts by zip code, controlling for daily ozone levels and day of week in five states from the Environmental Public Health Tracking Network.

Results: The HVI was consistently associated with higher hospitalization and mortality rates, but abnormally hot days were not associated with increased morbidity or mortality after adjustment for the HVI. The interaction of HVI with abnormally hot days was not significant. Division of the HVI into three categories showed different trends from state to state, indicating potentially nonlinear relationships between the HVI and health outcomes.

Conclusions: Our results demonstrate that the HVI denotes increased health vulnerability that was independent of the measure of heat that we used. Further investigation of our heat measure compared to other heat measures and the HVI as a measure of vulnerability in other areas of the country is warranted.

HEATWAVES INCREASE THE RISK OF EMERGENCE HOSPITAL ADMISSIONS FOR RENAL DISEASES IN CHILDREN

Shilu Tong, *School of Public Health and Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia*
Xiao Yu Wang, *School of Public Health and Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia*
Adrian Gerard Barnett, *School of Public Health and Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia*
Xiaoming Shen, *Department of Developmental and Behavioral Pediatrics of Shanghai Children's Medical Center & Shanghai Key Laboratory of Children's Environmental Health, XinHua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

BACKGROUND: Heatwaves can cause significant health consequences such as increased mortality and morbidity. However, their impact on the children living in tropical/subtropical regions remains to be determined. This study aimed to examine the association between heatwaves and emergency hospital admissions (EHAs) for renal diseases in children (aged 0-14 years) in Brisbane, Australia.
METHODS: A local definition of heatwave was developed (• 37°C for two or more consecutive days). EHAs for renal diseases in children and environmental data were obtained for Brisbane city from 1996 and 2005. A time-stratified case-crossover design was used to compare risks for renal diseases between heatwave and non-heatwave periods.
RESULTS: There were 1,747 EHAs for renal diseases in children. Heatwaves exhibited a significant impact on EHAs for renal diseases in children after adjusting for confounders (odds ratio (OR): 2.7; 95% confidence interval (CI): 1.1-6.3). Heat effects on children's renal diseases appeared to be acute and gradually attenuated with lagged days (OR: 2.3 (95% CI: 0.9-6.3) for lag 1; 1.1 (95% CI: 0.4-3.6) for lag 2).
CONCLUSIONS: There were significant increases in EHAs for renal diseases in children during heatwaves in Brisbane, a subtropical city where people are well accustomed to warm weather. This finding may have significant implications for pediatric renal care.

Epidemiological study of health effect on stone workers of Hualien—Processing gemstone and nephrite had the highest risk

Hsiao-Yu Yang, Department of Occupational Medicine, Buddhist Tzu Chi General Hospital and University, Taiwan

Ruei-Hao Shie, Green Energy & Environmental Research Laboratories, Industrial Technology Research Institute, Taiwan

Pau-Chung Chen, Institute of Occupational Medicine and Industrial Hygiene, National Taiwan University College of Public Health, Taiwan

Background and aim: Hualien is the main place of stone industry in Taiwan. The stone workers had been long-term exposed to some ores that contain quartz or asbestos. However, most of them work in small and unregistered factories. The health effect on these workers is unknown. The objective of study was to assess the pulmonary fibrotic changes in stone workers and evaluate the hazard of different works in stone industry.

Methods: We had completed 47 walk-through surveys of stone processing workplaces between 2006 and 2009. The work environment, processing procedures, materials used in each procedure were recorded. We grouped workers into 8 types of works, including processing gemstone, processing nephrite, making stone embellishment, making vase, making urn, make small stone decoration, artistic carving, and construction material factory. Each type of work was treated as a similar exposure group. A cross-sectional survey was performed in stone workers and their family of Hualien in 2010. The profusion of chest radiogram was graded complied with ILO/ICRP standard. Those who had profusion 1/1 or greater with lung crackle were identified as cases of pulmonary interstitial fibrosis. To prevent confounding, subjects were excluded when they had history of tuberculosis or other occupations that may cause lung fibrosis. Multivariate logistic regression was used.

Results: 328 subjects were enrolled for analysis. Among them, 17 subjects was identified as cases and the prevalence was 5.2%. After adjusting the pack-years of smoking and age, processing gemstone had the highest risk (OR=3.85, p=0.02), followed by processing nephrite (OR=3.10, p=0.05). By using employment less than 10 years as the reference group, the odds ratio of process gemstone more than 20 years was 6.62 ($p<0.01$) and the odds ratio of processing nephrite more than 20 years was 4.79 ($p<0.01$).

Conclusions: Processing gemstone and nephrite had the highest risk in stone industry.

Background

Research needs on climate change and health can be categorized into (1) identifying exposure-response relationships between weather and climate parameters and health outcomes, taking into consideration confounding and effect modification by other factors associated with particular outcomes, and local conditions that could affect the strength of association (e.g. presence of early warning systems); (2) detecting and attributing changing disease patterns to climate change; (3) taking a systems-based approach to develop models to project how health burdens could change under different climate and socio-ecosystem futures; (4) evaluating the effectiveness of health adaptation interventions to identify best practices and lessons learned; (5) estimating the possible health impacts of adaptation and mitigation policies and programs implemented in other sectors; and (6) developing storylines to explore the possible magnitude and extent of health impacts from low probability, high consequence climate change (e.g. migration from significant reductions in crop yields in Sub-Saharan Africa).

Methods

A panel discussion will explore these research needs in the context of the Mediterranean region. Planned speakers include: Bettina Menne, Tony McMichael, Daniela Ippoliti or Paola Michelozzi, AntonisAnalistis, or KleaKatsouyanni, Tanja Wolf, Guy Hutton, and TuomoKarljanen

IMPACT OF CLIMATE CHANGE ON HEAT-RELATED MORTALITY IN PORTUGAL: CURRENT AND FUTURE RISKS

Sofia Pinto de Almeida, *Climate Change Impacts, Adaptation and Mitigation Research Group (CC-IAM), Faculty of Sciences, University of Lisbon, Portugal*

Elsa Casimiro,*Climate Change Impacts, Adaptation and Mitigation Research Group (CC-IAM), Faculty of Sciences, University of Lisbon, Portugal - NFOTOX – Environmental Health Consultants, Lisbon, Portugal.*

Pedro Lopes,*Climate Change Impacts, Adaptation and Mitigation Research Group (CC-IAM), Faculty of Sciences, University of Lisbon, Portugal*

The observation that major causes of ill health exhibit distinct seasonal patterns suggests *a priori* that weather and/or climate influence their distribution and incidence. However, the inter-linkages between climate change and human health are complex and location specific. In this study we investigated the temperature-mortality health-related effects at local level in Portugal. We also explored possible future changes in attributable heat deaths under different climate scenarios.

The health impact assessment was done for the summer season (April – September), for Lisbon and Oporto. For each city, generalized estimating equations approach was applied to model the relationship between maximum temperature and daily mortality for all-causes, cardiovascular and respiratory diseases by age group, in the summer season. The possible future trends in heatstress were explored based on future climate scenarios.

For 1°C increase in maximum temperature above the city-specific threshold, all-cause mortality increased by 5.6% (95% CI: 4.6; 6.6) in Lisbon and 3.0% (95% CI: 2.0, 3.9) in Oporto respectively. In both cities, stronger associations were found for respiratory diseases and the elderly group was the most vulnerable. All the future climate scenarios used indicate significant increases in days with maximum temperatures above the city-specific threshold, suggesting that the risk of dying from heatstress will very likely increase in the future.

Heatstress exposure health effects area and will remain important determinants of health in Portugal under climate change. Current and future climate change adaptation measures need to consider how effective they are/will be to reduce climate-related health risks at local level.

AIR POLLUTION AND DEPRESSIVE SYMPTOMS IN THE ELDERLY: THE KOREAN ELDERLY ENVIRONMENTAL PANEL STUDY (KEEPS)

Youn-Hee Lim, *Department of Epidemiology and Biostatistics, Graduate School of Public Health, Seoul National University, Republic of Korea*
Ho Kim, *Department of Epidemiology and Biostatistics, Graudate School of Public Health, Seoul National University, Republic of Korea*
Jin Hee Kim, *Institute of Environmental Medicine, Seoul National University Medical Research Center, Republic of Korea*
Sang-Hyuk Bae, *Environmental Health Center, Seoul National University College of Medicine, Republic of Korea*
Yun-Chul Hong, *Institute of Environmental Medicine, Seoul National University Medical Research Center; Department of Preventive Medicine, Seoul National University College of Medicine, Republic of Korea*

Background and Aims: Although the effects of air pollution on various diseases were well studied, few studies examined its effects on depression. This study investigated the effect of air pollution on the depression symptoms.
Methods: Authors used 569 participants who regularly joined a community elderly care center located in Seoul. The Korean version of the Geriatric Depression Scale-Short Form (SGDS-K) was used to evaluate depression symptomatology during 3-year follow-up study from 2008. Five ambient air pollutants were analyzed using Generalized Estimating Equations (GEE) to associate with SGDS-K. A factor analysis was conducted to determine which items of the SGDS-K were combined to generate a given factor.
Results: Increases of interquartile range of a 3-day moving average of PM_{10}, a 5-day moving average of NO_2, and 3 weeks moving average of O_3 were associated with increases 0.16% (95% CI, 0.04-0.30), 0.24% (95% CI, 0.07-0.44), and 0.83% (95% CI, 0.26-1.65), respectively, of SGDS-K scores. For these three pollutants, factor analysis showed that air pollution worsened emotion such as happiness and satisfaction, and increased physical discomfort such as problems with memory and less energy. However, air pollution was not strongly associated with inferiority feeling or loss of interest. Air pollution effects on depression symptoms were exerted more for female and in warm temperature.
Conclusions: This study showed increasing particulate matter, nitrogen dioxide, and ozone may deteriorate depression symptoms among the elderly. Emotion and physical discomfort were most affected by ambient air pollution.

ENVIRONMENTAL HEALTH INDICATORS RELEVANT FOR MAORI IN NEW ZEALAND

Frances Graham, *Ministry of Health, New Zealand*
Dr Nicholas Jones, *Hawkes Bay District Health Board, New Zealand*
Jenny Mauger, *Hawkes bay District Health Board, New Zealand*
Dr Amber Pearson, *University of Canterbury, New Zealand*

Background and Aims: M• ori, the indigenous peoples (tangata whenua) of New Zealand, comprise 15% (565,329 people - 2006 census) of the total New Zealand population. M• ori are heavily over-represented in low socio-economic groups but evidence exists which shows that M• ori suffer worse health compared to non-M• ori of similar socio-economic status. Robust M• ori environmental health indicators that are relevant and meaningful are a fundamental foundation for effective planning, policy development, service delivery and monitoring for improved M• ori health outcomes. The aim of this study was to assess the feasibility for developing a set of indicators to gauge factors of M• ori environmental health in M• ori terms.
Methods: The primary method for developing environmental health indicators was extensive consultation with M• ori to ensure that indicators aligned with M• ori concepts of health and environment. The Hawkes' Bay region was chosen as a pilot study to obtain feedback from stakeholders on both the process and specific environmental health issues that should be covered by a set of indicators with an initial focus on water quality.
We also conducted a literature review which included recognised M• ori health models to ensure that the sets of indicators reflected M• ori understandings of environmental health and provided an empirical base for jurisdictional environmental health agencies to identify areas of greatest risk.
Data from government and non-government agencies (including longitudinal data sets) were identified and assessed for completeness, usability, accuracy and applicability at the regional level and match M• ori health priorities.
Results: We present a set of proposed M• ori environmental health indicators for stakeholders to inform local planning and decision-making.
Conclusions: A review of the current M• ori health indicator sets showed that they are essentially Government driven measures that are intended to assess progress towards State-defined objectives for M• ori health. The development of a specific set of M• ori environmental health indicators in consultation with M• ori will assist towards addressing M• ori needs for healthy M• ori futures.

IS THE EFFECT OF MEAN TEMPERATURE ON EMERGENCY HOSPITAL ADMISSIONS FOR CARDIOVASCULAR DISEASES MODIFIED BY DIURNAL TEMPERATURE RANGE?

Xiaofang Ye, *Queensland University of Technology, Australia*
Kerrie Mengersen, *Queensland University of Technology, Australia*
Xiaochuan Pan, *Peking University, China*
Shilu Tong, *Queensland University of Technology, Australia*

Background and Aims: Both ambient mean temperature and diurnal temperature range are associated with human health. However, it is unknown whether the effect of mean temperature is influenced by diurnal temperature range. This study explored whether the relationship between mean temperature and emergency hospital admissions for cardiovascular diseases is modified by diurnal temperature range.
Methods: We estimated the effects of mean temperature and diurnal temperature range on the daily cardiovascular emergency hospital admissions during 1996–2005 in Brisbane, Australia. Poisson regression models accounting for overdispersion were used after adjusting for population size, long-term trend, holidays, day of the week, ozone, PM_{10} and humidity. Diurnal temperature range was divided into five groups for every 20 percentage of its distribution. We also evaluated the effects of two temperature exposures among several age groups (all age, 15–64, 65–74 and 75+).
Results: Diurnal temperature range was positively related to emergency hospital admissions for cardiovascular diseases in all age groups except for people aged 15–64 years old. When the diurnal temperature range was above 14.8 ^{o}C, the risk of cardiovascular diseases admissions increased by 11.5% ($p<0.05$) compared to the baseline diurnal temperature range (<8.6 ^{o}C) after controlling for mean temperature. Higher effect estimates were found for every unit degree (standard deviation of temperature) increase in mean temperature than that of diurnal temperature range. No modification effect of diurnal temperature range was found in the association between mean temperature and emergency hospital admissions for cardiovascular diseases.
Conclusion: Diurnal temperature range does not modify the effect of mean temperature on cardiovascular morbidity. Mean temperature contributes more in the temperature-morbidity relationship than diurnal temperature range. However, the elderly are more susceptible to diurnal temperature change than people aged between 15–64 years old.

DO MORE ACCURATE EXPOSURE PREDICTIONS ALWAYS IMPROVE HEALTH EFFECT ESTIMATES?

Adam A. Szpiro, *University of Washington, USA*
Christopher J. Paciorek, *UC Berkeley, Harvard University, USA*
Lianne Sheppard, *University of Washington, USA*

Background and Aims: Air pollution concentrations are typically not measured at subject locations, so monitoring data are used to predict exposures by land-use regression (LUR) or related methods. It is often assumed that minimizing prediction error improves health effect estimation. We show this is not always correct..
Methods: We simulate exposures at subject and monitor locations by a LUR model with three geographic covariates, assuming only monitoring data are observed. We simulate health outcomes from a linear disease model. We fit a LUR model to the monitoring data and use predicted subject exposures to estimate the health effect. We calculate average out-of-sample R^2 as a measure of prediction accuracy and the bias and standard deviation of effect estimates. We compare the correctly specified LUR model to a misspecified version that omits the third geographic covariate. We vary the numbers of subjects and distribution of monitor locations.
Results: In all scenarios, the average out-of-sample R^2 at subject locations for the correctly specified LUR model is 0.70, apparently better than the corresponding value of 0.50 for the misspecified model. Health effect estimates are nearly unbiased, but their standard deviations vary between scenarios. With 10,000 subjects and uniformly high variability of geographic covariates in monitoring data, the standard deviation of health effect estimates is 0.12 for the correctly specified model and 0.21 for the misspecified model. If the third geographic covariate is less variable across monitor locations, the standard deviation is 0.23 for the correctly specified model and 0.16 for the misspecified model; i.e., the “better” exposure model leads to less certain effect estimates.
Conclusions: Improved air pollution exposure predictions do not necessarily lead to better estimation of health effects. Exposure models should be evaluated based on utility for estimating health effect parameters, in contrast to the current practice of optimizing prediction accuracy.

ESTIMATING ACUTE AIR POLLUTION HEALTH EFFECTS IN THE MULTI-ETHNIC STUDY OF ATHEROSCLEROSIS (MESA)

Adam A. Szpiro, *University of Washington, USA*
Lianne Sheppard, *University of Washington, USA*
Sara D. Adar, *University of Michigan, USA*
Joel D. Kaufman, *University of Washington, USA*

Background and Aims: There is growing interest in exploiting cohort data to estimate acute health effects of air pollution. Since exposure and outcome have seasonal trends, we need to control for temporal confounding. A methodology developed for time series studies is to include semiparametric spline terms in the regression. Methods have been proposed for selecting degrees of freedom (df), but existing literature does not address the implications for cohort data.
Methods: Our first objective is to adapt semiparametric regression methods to cohort studies, accounting for the possibility of multiple or no health observations on some days. We derive methods for choosing df and for computing standard errors. Our second objective is a more efficient alternative to semiparametric regression based on preadjusting the exposure, exploiting exposure data on days with no health observations. The health model can be fit by ordinary least squares (OLS) or by generalized least squares (GLS) using weights derived from a mixed model. We report simulation results and apply our methods to a previously published study of fine particulate matter and retinal arterial diameter in MESA, a population-based cohort of men and women aged 45-84 from 6 sites, funded by NHLBI.
Results: Sufficient df to account for temporal structure in the outcome consistently results in unconfounded effect estimates. This is not always the case if df are only sufficient to account for the trend in the exposure. Preadjusting the exposure and using GLS is more efficient than semiparametric regression for datasets with limited health observations compared to the required df.
Conclusions: Semiparametric regression methods from time series studies can be adapted for cohort data, as long as the data structure is considered in determining the number of df and in calculating standard errors. Efficiency can be improved by preadjusting the exposure and fitting the health model with GLS.

SOCIAL INEQUALITY IN PERCEIVED AIR QUALITY USING COMBINATION OF INDIVIDUAL- BASED AND AREA- BASED SOCIOECONOMIC CHRACTERISTICS IN SEOUL, KOREA

Myounghee Kim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, Republic of Korea*
Okhee Yi, *Department of Preventive Medicine, Dankook University College of Medicine, Republic of Korea*
Ho Kim, *Department of Epidemiology and Biostatistics, School of Public Health, Seoul National University, South Korea*

Background and Aims: The majority of urban air quality studies focused on scientifically measured air quality. Scant attention has so far been paid to the perceived air quality. perceived air quality is another important component for health and quality of lif e. In this paper, we offer a current picture of urban air quality in which residents think about air pollution. This study investigated t hat the relation between measured air quality and perceived air quality and the determinants of perceived local air quality focusi ng on the both individual and area characteristics.
Methods: we used representative survey (Seoul Citizen's Health Indicators Survey (SCHIS)) and integrated measured air qualit y (TAQ). The total study population was 15,856. We extracted individual-level sociodemographic and socioeconomic variables fr om SCHIS: age, sex, marital status, self-rated health, educational attainment and household income. We also considered comm unity variables which may affect perceived air quality, such as percentage of college educated aged 20 over, satisfaction of publi c transportation and percentage of below poverty line. Multilevel analysis techniques were applied for parameter estimates.
Results: Mean distributions of air quality perception by community level was opposite against the total air quality patterns using simple linear statistics by plotting. There are area variances in perceived air quality and socioeconomic status across 25 KUs. W e found that the degree of perceived air pollution was younger age (20-34 aged, odds ratio:1.397), higher educational attainmen t(graduate, odds ratio:1.667), lower household income. For area level, Communities more economically deprived and higher per centage of college educated aged 20 over were associated with poor perceived air quality.
Conclusions: This paper sought to show how the perception of air quality may be affected by individual SES and area level SE S. Education was a stronger predictor of perceived air quality than economical measurement such as income and poverty line of this study

AIR QUALITY CHANGES AFTER COMMISSIONING OF AN URBAN ROAD TUNNEL

Christine T. Cowie, *Woolcock Institute of Medical Research (WIMR), Australia*
Nectarios Rose, *NSW Health Department & WIMR, Australia*
Robert Gillett, *CSIRO, Australia*
Guy B. Marks, *Woolcock Institute of Medical Research, Australia*

Background & Aims: The commissioning of a new road tunnel in Sydney, Australia, in March 2007 provided an opportunity to assess the effect of this intervention on air pollutant concentrations in the affected area. Dispersion model-based predictions were that pollutant concentrations would decrease around the main bypassed road where traffic flow was halved and would increase along feeder roads to the tunnel.
Methods: PM_{10}, $PM_{2.5}$ and NO_2 data from six continuous monitoring stations erected in the study area were used and compared with regional changes in air quality. We also collected data on NO_2, as a marker of traffic related air pollution, using a network of passive samplers. Spatial variability was assessed by land use regression. The study period was Jan 2006 to Dec 2008.
Results: Data from the continuous monitors showed that, after adjusting for regional changes in air quality, the opening of the tunnel did not lead to consistent reductions in either PM or NO_2 in the study area as a whole. However, the passive sampler data showed that, while NO_2 levels were not significantly reduced in the first post-tunnel year (-2.1%, 95% CI -5.9% to +1.8%), they were significantly reduced in the second post-tunnel year (-16.1%, 95% CI -19.2% to -12.7%). Further, passive sampler NO_2 concentrations were reduced in both post-tunnel years along the major by-passed road. The LUR model also demonstrated reductions of NO_2 (up to 10 ppb) along the by-passed road and an increase in NO_2 of up to 5 ppb along the feeder roads.
Conclusion: This study highlights the need to study fine scale spatial variability when assessing the impact of traffic interventions and supports the effectiveness of traffic interventions in reducing exposures for people living close to main traffic routes.

LOW DOSE MIXTURE EFFECTS OF BISPHENOL A AND ISOBUTYLPARABEN FOR THE MALE REPRODUCTIVE SYSTEM

Yun-jung Yang[1,3], Mun-seo Park[1,3], Sang-yon Kim[1], Lee-so Maeng[3], Soon-chul Myoung[2], Yeon-pyo Hong[1]

1) Department of Preventive Medicine and 2) Department of Urology, College of Medicine, Chung-Ang University, Seoul 156-756, Korea
3) Institute of Catholic Integrative Medicine, E-W Translational Medicine Division, Incheon St. Mary's hospital, Incheon, Korea

Background and Aims: Exposure to individual estrogenic endocrine disruptors at relatively high doses could induce male reproductive abnormality. Recently, the concerns were increased on how estrogenic endocrine disruptors can generate reproductive adverse effects in a mixture at a concentration that does not individually induce observable effects. This study was performed to determine the effect of mixture exposure on male reproductivity at low level of bisphenol A (BPA) and isobutylparaben (IBP).
Methods: Corn oil, BPA (0.05 mg/kg/day), IBP (2.5 mg/kg/day) and mixture (BPA 0.05 mg/kg/day and IBP 2.5 mg/kg/day) were administered once daily by oral gavage to dam from gestation day 6 to lactation day 21 for 8 weeks to pregnant Sprague-Dawley rats. After lactation, treatment groups were divided into three vehicles - BPA, IBP and mixture treated groups. Male pups were sacrificed by isophorone at postnatal day 70. Male pups were examined for developmental characteristics, body and organ weight (testis, epididymis and prostate), serum sex hormones, thyroid hormones, sperm toxicity, and histological change of testis and epididymis.
Results: The IBP-treated group showed decreased estradiol levels in the early life stage. Life long period exposed groups showed increased body weight and decreased testosterone levels in IBP- and mixture-treated groups; increased relative epididymis weight in BPA-treated group compared to control; and decreased testosterone and triiodothyronine levels in the mixture-treated group. Epididymal sperm count and motility was significantly decreased in all treated groups. The histological findings using hematoxylin and eosin stain of the testis and epididymis did not change between control and treatment groups.
Conclusions: Early life exposure to low dose BPA and IBP in male rats showed adverse synergistic effects to the male reproductive system in adulthood.

CHILDHOOD EXPOSURE TO DEPLETED URANIUM: CONSEQUENCES OF THE 2003 ARMED CONFLICT IN IRAQ

Robert A. Eick, Boonshoft School of Medicine, U.S.A.
Naila Khalil, Boonshoft School of Medicine, U.S.A.
Paul Blair, Boonshoft School of Medicine, U.S.A.

Background and Aims: Ravages of war include widespread environmental and human health consequences, some becoming apparent years or decades after the conflict. Radioactive depleted uranium (DU) is used as armour-piercing munitions in current warfare. This analysis describes the exposure of Iraqi children to DU during the 2003 armed conflict.
Methods: Children are exposed to radioactivity while playing in and around abandoned military vehicles struck by DU munitions. Due to the paucity of data for 2003, analysis of DU ammunitions use during the 1991 Iraq war, as presented by Marshall (2005), was extrapolated to estimate the degree of exposure and the resulting health risks for Iraqi children during the 2003 war.
Results: Greatest exposure to DU was secondary to children playing inside discarded military vehicles. Inhalation of airborne particulate in this setting accounted for a maximum cumulative exposure of 2.077 grams, while gastrointestinal ingestion resulted in a cumulative exposure of 43.269 grams, resulting in equivalent doses of radiation to the lungs, bone surface, and colon of 0.039, 0.033, and 0.003 Sieverts, respectively. Effects of such exposure include an incremental birth defect risk of 0.052% for progeny of the exposed, with an increased incremental fatal cancer risk of 2.388%.
Conclusions: The outcomes of DU exposure are not insignificant and include increased risk of fatal malignancies and birth defects in offspring. In order to prevent such exposures, production and use of radioactive weapons should be stopped and their contamination ceased.

ACUTE EFFECTS STUDY OF EXPOSURE TO ROAD TUNNEL VENTILATION STACK EMISSIONS

Christine T. Cowie, *Woolcock Institute of Medical Research (WIMR), Australia*
Wafaa Ezz, *Woolcock Institute of Medical Research (WIMR), Australia*
Wei Xuan, *Woolcock Institute of Medical Research (WIMR), Australia*
Bill Lilley, *CSIRO, Australia*
Nectarios Rose, *NSW Health Department & WIMR, Australia*
Michael Rae, *CSIRO, Australia*
Guy B. Marks, *Woolcock Institute of Medical Research, Australia*

Background & Aims: To study the association between exposure to emissions from a road tunnel ventilation stack and short term respiratory and irritant effects in a group of volunteers.
Methods: We recruited 36 volunteers in Sydney, Australia, to a randomised cross-over study over three years. 2006 represented the baseline year where the tunnel was not operational, and 2007 and 2008 post-intervention years when the tunnel was active (58,318 vpd, November 2008). Each group underwent three types of exposures each year: downwind of the road tunnel ventilation stack; upwind of the stack; and at a positive control site (remote, heavily trafficked site). Each exposure consisted of two consecutive mornings of two hours exposure each. Three repeated measurements for spirometry, exhaled nitric oxide (FeNO) and irritant and respiratory symptom scores were collected each morning. We collected data on PM_{10}, $PM_{2.5}$ & PM_1, NO_2 and VOCs during each of the exposure sessions. Data were analysed by mixed effects regression.
Results: 25% of subjects reported a diagnosis of asthma and 72% were atopic at baseline. 26 (72%) subjects participated in 2007 and 20 (56%) in 2008. Exposure downwind of the ventilation stack was associated with some increase in "dry nose" scores, but there was no effect on FEV_1, FVC, FeNO or other symptoms. Over the three year period as a whole, exposure at the heavily trafficked control site was associated with higher FeNO (ratio=1.09; $p<0.001$), higher scores for eye symptoms ($p=0.03$), chest symptoms ($p<0.001$), and throat symptoms ($p=0.06$).
Conclusion: There was little evidence of any short-term adverse effect of exposure downwind of the road tunnel ventilation stack. The findings of increased symptoms and inflammation at the control site overall validates the study design for detecting effects of short-term traffic exposures.

INFLUENZA EPIDEMIC AND METEOROLOGICAL FACTORS IN 47 PREFECTURES IN JAPAN

Yasushi Honda, Kazutoshi Sugimoto, *University of Tsukuba, Japan*
Kayo Ueda, Masaji Ono, *UInstitute for Environmental Studies, Japan*

Background and Aims: In evaluating the impact of climate change on human health, it is important to evaluate not only the heat effects, but also the cold effects. It is, however, not straight-forward to evaluate cold effects; unlike heat effect, cold effect is not a direct (non-linear) function of temperature. We thought that influenza epidemic is one of the reasons for this, because influenza epidemic occurs in winter, but is not necessarily larger during colder winter. Here, we explored the relation between influenza incidence and meteorological factors to obtain some clue to model the influenza effect in evaluating cold effects.
Methods: Meteorological factors in each of the 47 Prefectures in Japan were related to the corresponding government-provided number of patients per sentinel medical facility per week. The relation was regressed using smoothing spline. Absolute humidity was calculated using the formula, 217 * (vapor pressure) / (temperature in Celsius + 273.15).
Results: Among the factors, absolute humidity showed one of the most consistent relations, with only one exception, i.e., Okinawa Prefecture. Down to a certain level, no patients were observed, and beyond the level, the incidence became higher monotonously along with the absolute humidity. The "highest no patient limit" level appeared higher in Southern Prefectures. As the only exception, Okinawa Prefecture, where the climate is subtropical, showed that epidemics occurred even on days with high absolute humidity. Unlike absolute humidity, relative humidity showed inconsistent relation.
Conclusions: To relate the influenza incidence, it is better to use absolute humidity, rather than relative humidity. We speculate that the "highest no patient limit" level was higher for Southern Prefectures, because the winter is warmer for Southern Prefectures during the influenza epidemic season. This may lead to the modelling of influenza effect as one of the cold effects.

TIME WINDOW OF EXPOSURE IN THE RELATION TO PRETERM BIRTH FROM AMBIENT AIR POLLUTION

Yu-Ting Lin, *China Medical University, Taiwan*

Huey-Hong Hsieh, *Taiwan Shoufu Univerity , Taiwan*

Yung-Ling Lee, *National Taiwan University, Taiwan*

Bing-Fang Hwang, *China Medical University, Taiwan*

Background and Aims: Whether air pollution contributed to preterm birth is as yet unanswered with the previous evidence pointing in different directions, but none of the previous epidemiological studies has elaborated the susceptible embryologic period of preterm birth. The study was to assess the time window of exposure and its role in the relation between ambient air pollution and the risk of preterm birth.

Methods: We conducted a nation-wide cross-sectional study of 1,490,247 singleton Taiwanese births in 2001-2007 using information from the Birth Registry. The outcome of interests was preterm delivery (gestational age < 37 weeks). The exposure assessment was based on residential address during pregnancy, and applied geographic information system (GIS) to integrate monthly air pollutant data from 72 EPA monitoring stations which was interpolated to pollutant surfaces using inverse distance weighting method (IDW). The effect estimates were presented as odds ratios per 10 ppb changes for O_3, NO_2, 10 $\mu g/m^3$ changes for PM_{10}, 1 ppb changes for SO_2 and 100 ppb changes for CO.

Results: In the logistic regression adjusting for confounding, the risk of preterm birth was increased in relation to the first (adjusted OR=1.031, 95% CI: 1.026, 1.037), second (adjusted OR=1.015, 95% CI: 1.010, 1.021), and third (adjusted OR=1.025, 95% CI: 1.019, 1.031) trimester O_3. The effect estimates for preterm birth were significantly elevated during the third (adjusted OR=1.010, 95% CI: 1.006, 1.014) trimester PM_{10} exposure.

Conclusions: The study provides evidence that exposure to outdoor air O_3 and PM_{10} may increase the risk of preterm birth and the most susceptible time periods are during the whole pregnancy for O3 and third trimester of gestation for PM_{10}.

ASSOCIATIONS BETWEEN SMALL AREA LEVELS OF AIR POLLUTION AND SOCIO-ECONOMIC CHARACTERISTICS IN THE NETHERLANDS AND ENGLAND

Paul Fischer, *National Institute for Public Health and the Environment (RIVM), Centre for Environmental Health (MGO) , P.O. Box 1, 3720 BA Bilthoven, Netherlands, Email: paul.fischer@rivm.nl*

David Briggs, *Imperial College London, Department of Epidemiology and Biostatistics, London, United Kingdom*

Background and aims: Several studies have shown that elevated levels of air pollution are concentrated among social deprivated neighbourhoods and areas. As inhabitants of these areas may be especially vulnerable to the negative health effects of air pollution, insight in local associations between population characteristics and air pollution levels is of public health interest. We assessed the relation between long term exposure to (traffic-related) air pollution and several population characteristics.
Methods: Detailed 100m maps of air pollution levels of PM10 and NO_2 were developed using land use regression. Population characteristics were collected from Statistics Netherlands and the Office of National Statistics (UK). We linked the socio-economic population characteristics at the lowest possible aggregation level, which was the 6-digit postal code level in the Netherlands (appr. 20 addresses) and the Census Super Output Area in the England, with modelled air pollution averaged at the same level of aggregation. We then assessed the association between area air pollution levels and population characteristics by descriptive statistics.
Results: In a national analysis in the Netherlands, pollution levels increased with higher degree of urbanization, percentage non-western immigrants, lower house price , while average monthly person income was unrelated to air pollution levels. We found that city results could deviate between cities and from the national results. For England associations with income, education, employment, ethnicity and urbanisation will be analysed.
Conclusion: This study on small area differences in air pollution and population characteristics shows that in the Netherlands postal code areas with lower social economic status (and probably the highest traffic density) encounter the highest air pollution levels. The use of small area information based on land use regression techniques can be helpful to elucidate such information for local (environmental) policy.

INTERNATIONAL COORDINATION IN BIRTH COHORTS

Eisaku Toda, *Ministry of the Environment, Japan*
