Note to readers with disabilities: EHP strives to ensure that all journal content is accessible to all readers. However, some figures and Supplemental Material published in EHP articles may not conform to 508 standards due to the complexity of the information being presented. If you need assistance accessing journal content, please contact ehp508@niehs.nih.gov. Our staff will work with you to assess and meet your accessibility needs within 3 working days.

Supplemental Material

A Time-Stratified Case-Crossover Study of Ambient Ozone Exposure and Emergency Department Visits for Specific Respiratory Diagnoses in California (2005-2008)

Brian J. Malig, Dharshani L. Pearson, Yun Brenda Chang, Rachel Broadwin, Rupa Basu, Rochelle S. Green, and Bart Ostro

Table of Contents

Table S1. Geographic indicators and exposure variable means by climate zone for eligible respiratory EDVs in California, 2005-2008.

Table S2. Demographics by climate zone for eligible respiratory EDVs in California, 2005-2008.

Table S3. Demographic comparisons of eligible respiratory EDVs for those with ozone exposures assigned compared to those missing available co-pollutant exposure data with 20km in California, 2005-2008. NH = non-Hispanic; k = km;

Table S4. Excess risks (95% CI) per 10ppb ozone for respiratory outcomes in one- and two-pollutant analyses restricted to the population where another pollutant metric was available for full year and warm season (May-October). Reported risks [(OR-1)*100] are pooled estimates using random effects meta-analysis from climate zone-specific estimates obtained using conditional logistic regression comparing exposures on visit days with others of the same day of
the week within the same month, adjusting for apparent temperature (lag_0 and lag_{1-3}) and county influenza visits.

**Table S5.** Climate zone-level effect estimates and standard errors for warm season (May-October) respiratory EDV types in California, 2005-2008, using the best fitting lag.

**Table S6.** Meta-regression coefficients for warm season (May-October) respiratory EDV types and climate zone-level variables in California, 2005-2008.

**Figure S1.** Excess risks (95% CI) per 10ppb ozone (lag 03) for COPD limited to persons 50 years of age and above, in one- and two-pollutant analyses restricted to the population where another pollutant metric was available for (A) full year, (B) warm season (May-October). O_3=no subset; O_3 (subset w/NO_2) = models restricted to population with nitrogen dioxide exposures available; O_3 (adj. for NO_2) = models with same restricted population but also adjusted for nitrogen dioxide. O_3 (subset w/CO) = models restricted to population with carbon monoxide exposures available; O_3 (adj. for CO) = models with same restricted population but also adjusted for nitrogen dioxide. O_3 (subset w/SO_2) = models restricted to population with carbon monoxide exposures available; O_3 (adj. for SO_2) = models with same restricted population but also adjusted for sulfur dioxide. Reported risks [(OR-1)*100] are pooled estimates using random effects meta-analysis from climate zone-specific estimates obtained using conditional logistic regression comparing exposures on visit days with others of the same day of the week within the same month, adjusting for apparent temperature (lag_0 and lag_{1-3}) and county influenza visits.
